  The feature creates shared memory and shared memory message queues during data load. These are used to send external data from the back end to the parallel workers, and for error notifications.

Information

If the value of shared_buffers in postgresql.conf is small, the system will often have to wait for write exclusive locks to the same data page (as described in "Database server memory" in "12.1.1 Deciding whether to Install"). Since input data cannot be loaded from the shared memory message queues during such waits, they will often be full. In these cases, it will not be possible to write to the shared memory message queues, resulting in degraded data load performance.

See

Refer to "High-Speed Data Load Memory Requirements" in the Installation and Setup Guide for Server for information on the formula for estimating memory requirements.

12.1.3 Setup

This section describes how to set up high-speed data load.

Setup flow

1. Setting Parameters
2. Installing the Extension

12.1.3.1 Setting Parameters

Set the parameters required for high-speed data load in postgresql.conf. After that, start or restart the instance.

The table below lists the postgresql.conf parameters that must be changed, and the values that must be added to their current values. After editing postgresql.conf, start or restart the instance.

Parameter	Setting	Required
max_prepared_transactions	Add the number of transactions that can be prepared by parallel workers during data load to the parameter's current value. The resulting value must be equal to or greater than the maximum number of parallel workers used with this feature.	Mandatory
max_worker_processes	Number of parallel workers to perform data load.	Mandatory
max_parallel_workers	Add the maximum number of parallel workers to be used in a parallel query by this feature to the parameter's current value. The resulting value must be equal to or greater than the number of parallel workers used with this feature.	Mandatory

As shown in the following example, set the value of max_prepared_transactions, max_worker_processes and max_parallel_workers multiplied by the number of instances of this feature executed simultaneously.

Example

The example below shows how to configure 2 instances of high-speed data load being executed simultaneously using a degree of parallelism of 4.

```
max_prepared_transactions = 13  #Example if the initial value was 5: 5 + 2 x 4 = 13
max_worker_processes = 16        #Example if the initial value was 8: 8 + 2 x 4 = 16
max_parallel_workers = 12        #Example if the initial value was 4: 4 + 2 x 4 = 12
```

The table below lists the postgresql.conf parameters that must also be checked.

Parameter	Setting	Required
dynamic_shared_memory_type	Implementation of dynamic shared memory to be used by the instance. The default value is recommended.	Mandatory

See

Refer to "Resource Consumption" in the PostgreSQL Documentation for information on the parameters.

12.1.3.2 Installing the Extension

Execute CREATE EXTENSION to install the high-speed data load extension. The extension needs to be installed on each database. Also, extensions can only be installed on the public schema by a superuser.

Example

The example below installs the extension on the "postgres" database.

```
postgres=# CREATE EXTENSION pgx_loader;
CREATE EXTENSION
```

12.2 Using High-Speed Data Load

This section describes how to use high-speed data load.

12.2.1 Loading Data

To load data from a file into a Fujitsu Enterprise Postgres table, execute the pgx_loader command in load mode. The data inserted using this feature is dumped as a COPY command by the pg_dump command and the pg_dumpall command.

Example

The example below loads the file E:\path\to\data.csv (2000 records) into table tbl using a degree of parallelism of 3.

```
> pgx_loader load -j 3 -c "COPY tbl FROM 'E:\path\to\data.csv' WITH CSV"
LOAD 2000
```

Point

If an external file contains data that violates the format or constraints, the data load may fail partway through, resulting in delays for routine tasks such as nightly batch processing. Therefore, it is recommended to remove the invalid data before executing the data load.

See

- Refer to "pgx_loader" in the Reference for information on the command.
- Refer to "COPY" in the PostgreSQL Documentation for information on the deployment destination and access privileges for external files.

12.2.2 Checking Progress

If you are performing a data load with a large external file as input, you can verify that the process is continuing by getting progress information during the load. Progress information can be obtained from the pgx_stat_progress_loader view. This view displays the sum of the progress information of the back-end process and the number of parallel worker processes. Search the pgx_stat_progress_loader view, for example, with a SELECT statement, to locate the appropriate row. After running the pgx_loader command, look in the pg_stat_activity view and locate a row in the pgx_stat_progress_loader view with the PID obtained.

Example

1. See the pg_stat_activity view. (9311 for back-end processes, 9312, 9313, 9314 for worker processes)

```
postgres=# select pid, application_name, backend_type from pg_stat_activity
pid  | application_name |         backend_type
-----+------------------+------------------------------
6216 |                  | autovacuum launcher
6218 |                  | logical replication launcher
6271 | psql             | client backend
9311 | pgx_loader       | client backend
9312 |                  | parallel loader for PID 9311
9313 |                  | parallel loader for PID 9311
9314 |                  | parallel loader for PID 9311
6214 |                  | background writer
6213 |                  | checkpointer
6215 |                  | walwriter
```

2. Check the information in the pgx_stat_progress_loader view.

```
postgres=# SELECT * FROM pgx_stat_progress_loader
pid  | datid | datname | relid | command  | type | bytes_processed | bytes_total |
tuples_processed | tuples_excluded
-----+-------+---------+-------+----------+------+-----------------+-------------
+------------------+----------------
9311 |  222  | testdb  | 333   |COPY FROM | FILE |        192000   |    450000   |        189000
|           3000
```

Refer to "D.7 pgx_stat_progress_loader" for information on the pgx_stat_progress_loader view.

Point

When you run the pgx_loader command, the PostgreSQL pg_stat_progress_copy view prints the progress of the back-end process and the number of parallel worker processes on each line. The backend process progress information tuples_processed, tuples_excluded is 0. Also, bytes_processed and bytes_total for worker processes are 0.

```
postgres=# SELECT * FROM pg_stat_progress_copy
pid  | datid | datname | relid | command  | type | bytes_processed | bytes_total | tuples_processed |
tuples_excluded
-----+-------+---------+-------+----------+------+-----------------+-------------+------------------
+----------------
9311 |  222  | testdb  | 333   |COPY FROM | FILE |         192000  |    450000   |                0
|              0
9312 |  222  | testdb  | 333   |COPY FROM | FILE |              0  |         0   |          63000
```

```
|           1000
9313 |   222  | testdb   | 333    |COPY FROM | FILE |              0  |         0    |          63000
|           1000
9314 |   222  | testdb   | 333    |COPY FROM | FILE |              0  |         0    |          63000
|           1000
```

Refer to "pg_stat_progress_copy View" in the PostgreSQL Documentation for information on the pg_stat_progress_copy view.

12.2.3 Recovering from a Data Load that Ended Abnormally

If a system interruption such as a server failure occurs while high-speed data load is being performed, transactions prepared using this feature may be changed to the in-doubt state. At that point, resources occupied by the transaction will be locked, and access to the relevant resources from other transactions will be blocked, rendering them unusable.

In such cases, check transactions that are in an in-doubt state, and resolve them.

Checking for in-doubt transactions

This section describes how to check for in-doubt transactions.

1. Refer to the pgx_loader_state table in the pgx_loader schema.

   Retrieve the global transaction identifier (gid column) of in-doubt transactions. In-doubt transactions will contain "rollback" in the column "state".

   Example

   The example below retrieves the global transaction identifier (gid) of in-doubt transactions performed by the database role myrole and that used table tbl. The retrieved global transaction identifiers pgx_loader:9589 and pgx_loader:9590 identify in-doubt transactions.

```
postgres=# SELECT gid, state FROM pgx_loader.pgx_loader_state WHERE
postgres-# role_oid IN (SELECT oid FROM pg_roles WHERE rolname = 'myrole') AND
postgres-# relation_oid IN (SELECT relid FROM pg_stat_all_tables WHERE
postgres-# relname = 'tbl');
       gid       | state
-----------------+-------------
 pgx_loader:9590 | rollback
 pgx_loader:9591 | commit
 pgx_loader:9589 | rollback
(3 rows)
```

2. Refer to the pg_prepared_xacts system view.

   Check if the in-doubt transactions retrieved above exist.

   Example

   The example below checks if in-doubt transactions with the global transaction identifiers pgx_loader:9589 and pgx_loader:9590 exist.

```
postgres=# SELECT gid FROM pg_prepared_xacts WHERE gid IN ('pgx_loader:9589','pgx_loader:9590');
       gid
------------------
 pgx_loader:9590
 pgx_loader:9589
(2 rows)
```

See

Refer to "G.1 pgx_loader_state" for information on the pgx_loader_state table.

Resolving in-doubt transactions

Execute the pgx_loader command in recovery mode to resolve in-doubt transactions.

After executing the pgx_loader command in recovery mode, perform the procedure described in "Checking for in-doubt transactions" to check if the in-doubt transactions have been resolved.

Example

The example below completes the in-doubt transactions prepared for table tbl.

```
$ pgx_loader recovery -t tbl
```

Point

The recovery mode of the pgx_loader command only resolves transactions prepared by high-speed data load. For transactions prepared by an application using distributed transactions other than this feature, follow the procedure described in "16.13 Actions in Response to Error in a Distributed Transaction".

12.3 Removing High-Speed Data Load

This section describes how to remove high-speed data load.

12.3.1 Removing the Extension

Execute DROP EXTENSION to remove the high-speed data load extension. The information required for operation of high-speed data load is stored in the pgx_loader_state table of the pgx_loader schema. Do not remove the high-speed data load extension if the pgx_loader_state table is not empty.

The extension needs to be removed on each database. Also, extensions can only be removed on the public schema by a superuser.

Example

The example below removes the extension on the "postgres" database.

```
postgres=# DROP EXTENSION pgx_loader;
DROP EXTENSION
```

Chapter 13 Global Meta Cache

The Global Meta Cache (GMC) feature loads a meta cache into shared memory using the pgx_global_metacache parameter. This reduces the amount of memory required throughout the system.

This feature can only be used in Advanced Edition.

13.1 Usage

Describes how to use the Global Meta Cache feature.

13.1.1 Deciding Whether to Enable the Global Meta Cache Feature

Global Meta Cache is a mechanism for sharing meta caches between processes, so it works well on systems with a high number of resources accessed and SQL connections. The number of resources is primarily the number of tables accessed by a process, the number of indexes, or the total number of all columns in all tables accessed.

In particular, consider using Global Meta Cache if the total size of the meta cache for each process exceeds the amount of installed memory, or takes up a large portion of that memory, thereby squeezing memory allocations to the database cache or the Operating system file cache. Using Global Meta Cache may increase the time it takes to execute a single SQL to reference a meta cache on shared memory, but you can expect a greater benefit from being able to allocate more memory, such as for the database cache.

If performance degradation using Global Meta Cache is not acceptable, you may want to limit the number of tables accessed by a process.

13.1.2 Estimating Memory for Global Meta Cache

To enable the Global Meta Cache feature, the pgx_global_metacache parameter must specify an upper limit on the size of the shared memory (Hereinafter, the GMC area) dedicated to Global Meta Cahche. Ideally, this upper limit should be the size estimated in “Appendix A Parameters”. Values lower than this can still work, but refer to "13.1.3 How the GMC Memory Area Is Used" on using the GMC area to understand the disadvantages.

13.1.3 How the GMC Memory Area Is Used

At startup, the memory for the GMC area is not used much, but the GMC area grows as new meta caches are placed in the GMC area. If it does, it discards any meta caches that the system determines are not heavily used and places a new one in the GMC area.

Therefore, the GMC area will work even if it is smaller than the estimate, but the meta cache will be regenerated if the discarded meta cache needs to be reused. Note that if this happens frequently, it will degrade overall performance.

With this in mind, it may not be a problem if, for example, the tables to be accessed are different depending on the time zone, and the degradation of the time zone immediately after the change is acceptable.

In any case, be sure to test and tune the system thoroughly before running it.

13.1.4 Enabling the Global Meta Cache Feature

To Enable the Global Meta Cache feature edit the postgresql.conf file and set the pgx_global_metacahe parameter. Restarting the instance after editing the postgresql.conf file is required. Refer to "Appendix A Parameters" for information on the parameters.

Parameter Name	Description
pgx_global_metacache	Specify the maximum amount of memory for the GMC area on shared memory. When it’s set to 0 (default value), the Global Meta Cache feature is disabled. When enabled, the minimum value allowed is 10MB.

When the cache is created, if the total amount of meta caches on shared memory exceeds the value specified by pgx_global_metacache, the inactive, unreferenced meta caches are removed from the GMC area. Note that if all GMC are in use and the cache cannot be created in the GMC area, the cache is temporarily created in the local memory of the backend process.

Example

Here is an example postgresql.conf configuration:

```
pgx_global_metacache = 800 MB
```

Wait Events

The Global Meta Cache feature may cause wait events. Wait events are identified in the wait_event column of the pg_stat_activity view. GMC specific wait events are described below.

[GMC Feature Wait Events]

Wait Event Type	Wait Event Name	Description
LWLock	GlobalCatcache	Waiting to find, add, and remove meta caches in the GMC area.
IPC	GMCSweep	Waiting to select a meta cache that can be deleted when GMC space is low. If the GMC is fully referencing and there is no deletable meta cache, it is waiting for the reference to be removed and a deletable meta cache to be selected.

Point

If GMCSweep is happened frequently, increase the pgx_global_metacache setting.

See

Refer to "Viewing Statistics" in the PostgreSQL Documentation for information on the pg_stat_activity view.

13.1.5 Estimating Resources

Refer to "Global Meta Cache Memory Requirements" in the Installation and Setup Guide for Server for formulas to estimate the amount of memory used by the Global Meta Cache feature.

13.2 Statistics

Describes the statistics for the Global Meta Cache feature.

13.2.1 System View

You can check the cache hit ratio and size of the GMC area in the system view pgx_stat_gmc. Refer to "D.6 pgx_stat_gmc" for information on the columns.

If the cache hit ratio is low and the current memory usage is close to pgx_global_metacache, increase the pgx_global_metacache setting because performance may be degraded.

Refer to "8.6 Monitoring Database Activity" in the Operations Guide for information on the statistics.

Chapter 14 Local Meta Cache Limit

Local Meta Cache Limit feature limits the size of a Local Meta Cache by removing it if it has not been accessed for a long time.

This feature is available only in the Advanced Edition.

14.1 Usage

Describes how to use the Local Meta Cache Limit feature.

14.1.1 Deciding Whether to Enable the Local Meta Cache Limit Feature

Refer to "Appendix A Parameters", after estimating the total amount of memory to be used as the catalog cache and relation cache, when the total amount of memory exceeds the amount of installed memory or occupies a large amount of installed memory, consider using this feature.

This feature adds the action of discarding the meta cache that has been held permanently. If you attempt to refer to a destroyed meta cache again, the meta cache is recreated, so using this feature will result in poor performance compared to not using it.

Therefore, read the following to understand how to discard a meta cache.

- 14.1.3 Cache Removal when Local Meta Cache Limit is Enabled
- 14.1.4 Performance Impact and Parameter Tuning of the Local Meta Cache Limit Feature
- Parameters for the Local Meta Cache Limit feature

How to set the upper limit with these considerations is described in detail in the estimation formula in "Appendix A Parameters".

14.1.2 How to Set Parameters for the Local Meta Cache Limit Feature

To enable the Local Meta Cache Limit feature, set the pgx_catalog_cache_max_size and pgx_relation_cache_max_size parameters.

Parameter Name	Description
pgx_catalog_cache_max_size	Specify the maximum amount of memory that the backend process should use as the catalog cache. You can enable catalog cache removal by setting it to 8 KB or more. When it is set to 0 (default value), the catalog cache removal is disabled.
pgx_relation_cache_max_size	Specify the maximum amount of memory that the backend process should use as the relation cache. You can enable relation cache removal by setting it to 8 KB or more. When it is set to 0 (default value), the relation cache removal is disabled.

Example

Here is an example postgresql.conf configuration:

```
pgx_catalog_cache_max_size = 1MB
pgx_relation_cache_max_size = 1MB
```

14.1.3 Cache Removal when Local Meta Cache Limit is Enabled

When this feature is enabled, the caching strategy is to keep the cache as long as possible within the specified upper limit. If holding a new cache exceeds the limit, consider locality of reference and remove the cache from the one with the longest unreferenced time.

However, because the cache used by active transactions cannot be removed, if a transaction uses a large number of caches, the cache may be held above the limit. In this case, remove the all caches at the end of the transaction. This is necessary to free up memory.

In PostgreSQL, in order to acquire memory at high speed, a memory block of a certain size is acquired from the OS, and a small memory is cut out from the block and used. The memory for the metacache is cut out in the same way. Therefore, it is possible to return the memory block to the OS by destroying all the meta caches scattered throughout the memory block. When this happens, the next SQL execution will

be slowed down due to the re-creation of the meta cache. Therefore, upper limit of feature should be set to a value larger than the size of the meta cache used by at least one transaction.

When the size of the meta cache exceeds the upper limit, the following message is output:

```
WARNING: could not reduce Cat/RelCacheMemoryContext size to AA kilobytes, reduced to BB kilobytes
HINT: consider increasing the configuration parameter pgx_catalog/relation_cache_max_size
```

(***AA***: Upper limit, ***BB***: Amount of memory actually used)

CatCacheMemoryContext and RelCacheMemoryContext are memory areas for storing the catalog cache and relation cache, respectively. If this message is output, consider increasing the upper limit.

If the memory consumption by the backend process exceeds the allowable value by increasing the upper limit, reconsider the SQL to be executed, such as reducing the number of tables accessed in one transaction, or add memory adjust to the amount of memory used.

14.1.4 Performance Impact and Parameter Tuning of the Local Meta Cache Limit Feature

By observing how much meta cache regeneration is taking place, you can determine if the low upper limit is the cause of the failure to achieve the desired performance.

From the message below, calculate the cache hit ratio as follows:

```
Cache hit ratio = Number of cache hits ÷ Number of times the cache was searched
```

If the cache hit ratio is 80% or higher, this feature will not be the main factor that impedes performance. If not, raise the upper limit and see if performance can reach the goal. In doing so, first try to shift the focus of allocation to the relations cache. This is because when executing SQL, the relation cache generated based on the catalog cache is mainly referenced, so it is advantageous to leave a large amount of relation cache.

```
Catalog cache:catalog cache hit stats: search XX, hits YY
Relation cache:relation cache hit stats: search XX, hits YY
```

(***XX***: Number of times the cache was searched, ***YY***: Number of cache hits)

This message is printed when the transaction ends. However, if you output the message frequently, the performance will be degraded by itself, so you can adjust the output interval with the following parameters.

Parameter Name	Description
pgx_cache_hit_log_interval	When the transaction ends, if the time set in this parameter has elapsed since the previous message was output, the message is output. If set to 0, a message will be output each time the transaction ends. Setting -1 disables the output. The default value is 10min. Even if pgx_catalog_cache_max_size and pgx_relation_cache_max_size are disabled, the message output of the corresponding cache will be invalid. Immediately after connecting to the server, a small transaction occurs before the request from the user application, such as for user authentication. Since it is meaningless to know the hit ratio for these, a message is output at the end of the transaction that started after the time set in this parameter has elapsed after connecting to the server. For the same reason, setting a small value such as 0 may result in a message being printed at the end of such a small transaction. You can check which transaction the message corresponds to from the information output at the beginning. This information depends on the setting of the parameter log_line_prefix.

Example

Here is an example postgresql.conf configuration:

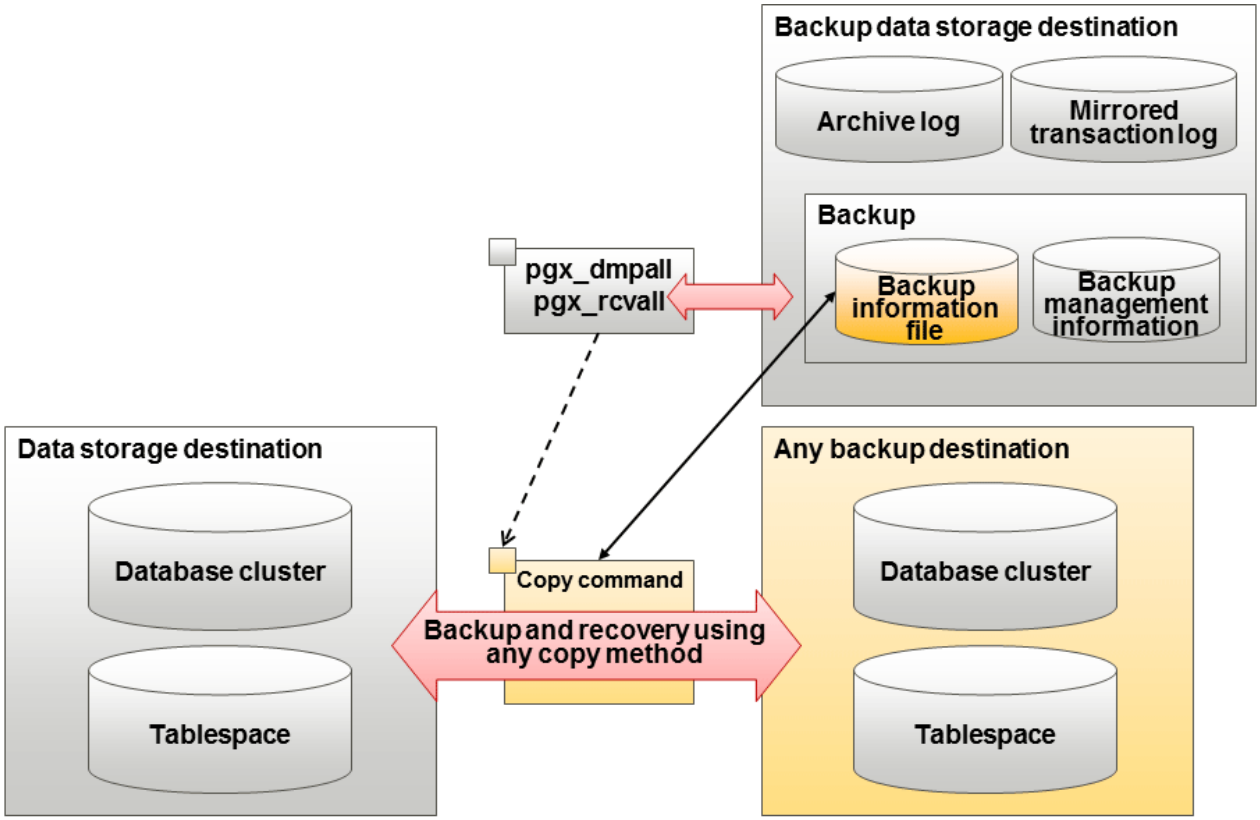
```
pgx_cache_hit_log_interval= 30min
```

Chapter 15 Backup/Recovery Using the Copy Command

By using a copy command created by the user, the pgx_dmpall command and the pgx_rcvall command can perform backup to any destination and can perform recovery from any destination using any copy method.

Copy commands must be created in advance as executable scripts for the user to implement the copy process on database clusters and tablespaces, and are called when executing the pgx_dmpall and pgx_rcvall commands.

This appendix describes backup/recovery using the copy command.



Point

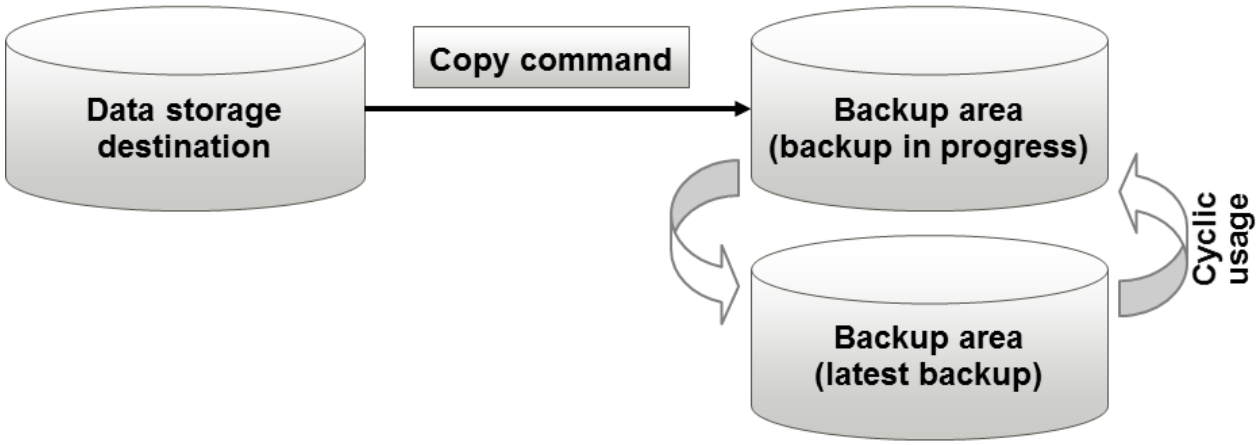
- It is also possible to back up only some tablespaces using the copy command. However, database resources not backed up using the copy command are still backed up to the backup data storage destination.
- Both the backup data storage destination and the optional backup destination are necessary for recovery - if they are located in secondary media, combined management of these is necessary.

15.1 Configuration of the Copy Command

This section describes the configuration of the copy command for backup and recovery.

Cyclic usage of the backup area

Prepare two backup areas for the copy command in case an issue affects the data storage destination during backup. The copy command performs backup while cyclically using these backup areas.

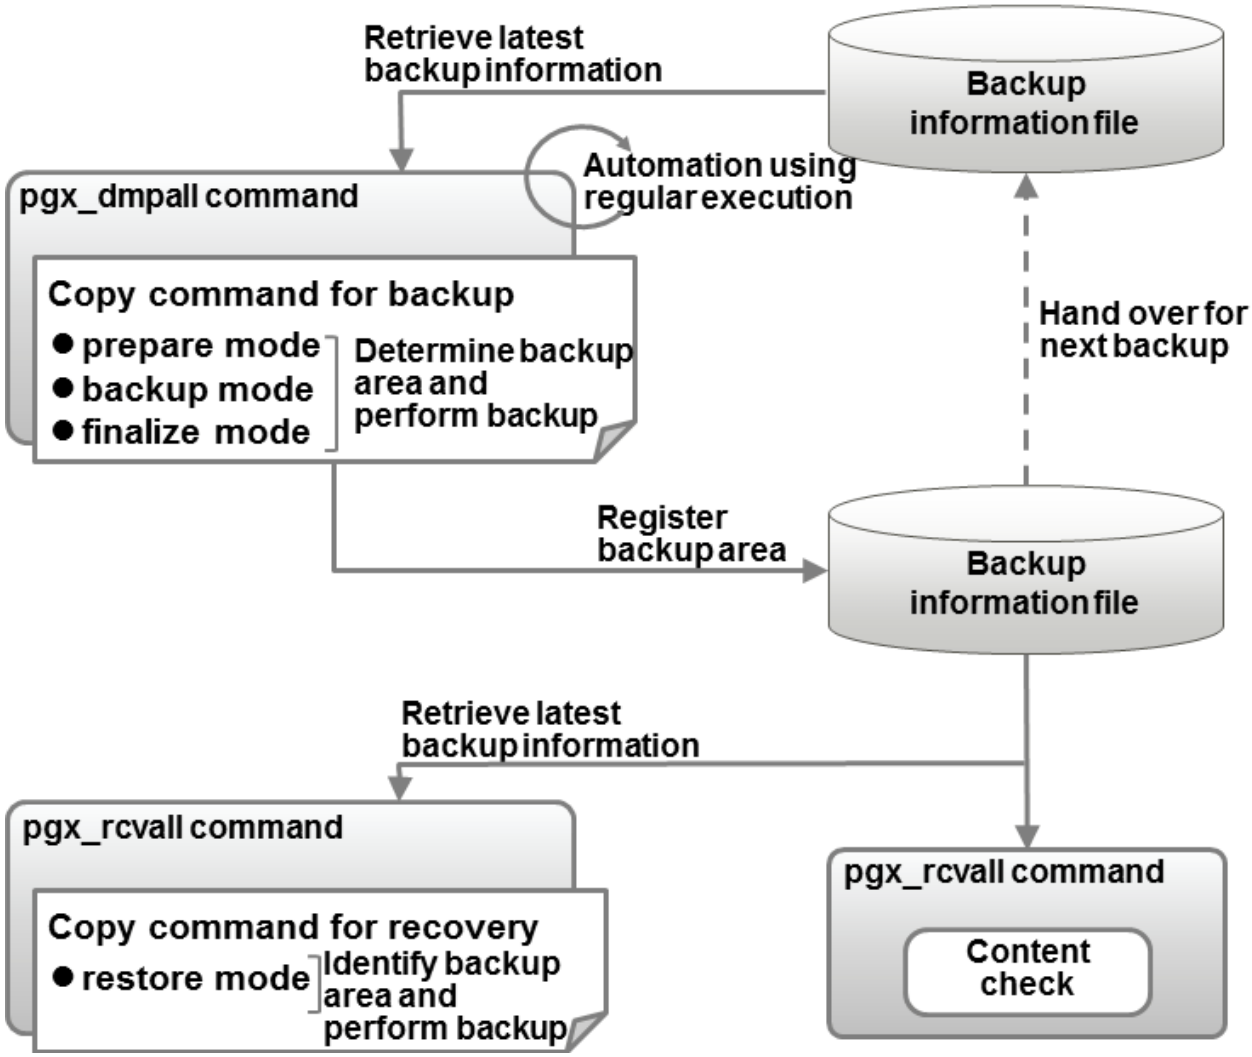


Information

The backup data storage destination cannot be used as these backup areas used by the copy command.

Backup using the backup information file

The copy command must determine the backup destination on each backup, as it is necessary to cycle through the backup areas. Backup can be automated by using the backup information file, which contains information about the backup destination.



Information

The backup information file is prepared in the backup data storage destination by the pgx_dmpall command, and contains information that can be read or updated by the copy command. This file is managed by associating it with the latest backup successfully completed by the pgx_dmpall command, so the latest backup information relating to the copy command registered by the user can be retrieved. Additionally, the content of the backup information file can be displayed using the pgx_rcvall command.

Configuration of the copy command for backup

The pgx_dmpall command calls the copy command for backup after execution for the three modes below. It is therefore necessary for the copy command for backup to implement the required processing for each of the modes. The user can use any method to hand over backup information between modes within the copy command, such as creating temporary files.

- prepare mode

  Determines which of the two backup areas will be used for the current backup.

  The backup area to be used for the current backup is determined by reading the information relating to the latest backup destination where the backup information file was written to during the previous backup.

- backup mode

  Performs backup on the backup area determined by prepare mode, using any copy method.

- finalize mode

  Writes information relating to the destination of the current backup to the backup information file.

  This enables the prepare mode to check the destination of the previous backup during the next backup.

Configuration of the copy command for recovery

The pgx_rcvall command calls the copy command for recovery for the mode below. It is therefore necessary for the copy command for recovery to implement the required processing for the mode.

- restore mode

  Any copy method can be used to implement restore from the backup destination retrieved using the copy command for backup.

Point

By referring to the mode assigned to the copy command as an argument, backup and recovery can be implemented using a single copy command.

Example

Using a batch file

```
if "%1" == "prepare"  goto prepare
if "%1" == "backup"   goto backup
if "%1" == "finalize" goto finalize
if "%1" == "restore"  goto restore
:prepare
    processingRequiredForPrepareMode
    exit /b
:backup
    processingRequiredForBackupMode
    exit /b
:finalize
    processingRequiredForFinalizeMode
    exit /b
```

```
:restore
    processingRequiredForRestoreMode
    exit /b
```

Point

A sample batch file that backs up the database cluster and tablespace directory to a specific directory is supplied to demonstrate how to write a copy command.

The sample is stored in the directory below:

```
installDir\share\copy_command.bat.sample
```

15.2 Backup Using the Copy Command

To perform backup using the copy command, in addition to performing the standard backup procedure, it is also necessary to create a copy command, and then execute the pgx_dmpall command specifying it. This section describes the procedure specific to using the copy command.

Preparing for backup

You must prepare for backup before actually starting the backup process.

Perform the following procedure:

1. Determine the database resources to be backed up

   Determine the database resources to be backed up using the copy command. The copy command can back up the following resources:

   - Database cluster
   - Tablespace

   To back up only some tablespaces, create a file listing them. This file is not necessary to back up all tablespaces.

   Example

   To back up only tablespaces tblspc1 and tblspc2

   ```
   tblspc1
   tblspc2
   ```

2. Prepare a backup area

   Prepare a backup area to save the database resources to be backed up, as determined in step 1.

3. Create the copy command

   Create the copy commands for backup and recovery. Refer to "15.4 Copy Command Interface" for details.

Performing backup

Execute the pgx_dmpall command with the -Y option specifying the full path of the copy command for backup created in step 3 of preparation for backup.

The example below backs up only some tablespaces, but not the database cluster, using the copy command.

Example

```
> pgx_dmpall -D D:\database\inst1 -Y D:\database\command\backup.bat
  --exclude-copy-cluster -P D:\database\command\tablespace_list.txt
```

Point

- To exclude up the database cluster from backup using the copy command, specify the --exclude-copy-cluster option.
- To back up only some tablespaces using the copy command, use the -P option specifying the full path of the file created in step 1 of preparation for backup.

See

- Refer to "pgx_dmpall" in the Reference for information on the command.

Checking backup status

Use the pgx_rcvall command to check the backup status.

Execute the pgx_rcvall command with the -l option specified to output backup data information. If backup was performed using the copy command, the resources backed up using the copy command will also be output.

Example

```
> pgx_rcvall -l -D D:\database\inst1
Date                Status   Dir                                 Resources backed up by the copy command
2022-03-01 13:30:40 COMPLETE E:/backup/inst1/2022-03-01_13-30-40 pg_data,dbspace,indexspace
```

15.3 Recovery Using the Copy Command

To perform recovery using the copy command, in addition to performing the standard recovery procedure, it is also necessary to create a copy command, and then execute the pgx_rcvall command specifying it. This section describes the procedure specific to using the copy command.

Determining the backup area of the latest backup

Check the backup information file to determine the backup area used for the latest backup, and confirm that it is in a recoverable state.

Execute the pgx_rcvall command with the --view-results-of-copying option to output the content of the backup information file.

Example

```
> pgx_rcvall -D D:\database\inst1 --view-results-of-copying
```

Perform recovery

Execute the pgx_rcvall command with the -Y option specifying the full path of the copy command for recovery created in step 3 of the preparation for backup described in "15.2 Backup Using the Copy Command".

The example below recover only some tablespaces, but not the database cluster, using the copy command.

Example

```
> pgx_rcvall -D D:\database\inst1 -B E:\backup\inst1 -Y D:\database\command\recovery.bat
```

Point

If the latest backup was performed using the copy command, the pgx_rcvall command automatically recognizes which database resources were backed up using the copy command, or whether resources were backed up to the backup data storage destination. Therefore, recovery can be performed by simply executing the pgx_rcvall command specifying the copy command for recovery.

See

Refer to "pgx_rcvall" in the Reference for information on the command.

15.4 Copy Command Interface

The following types of copy command are available:

- Copy command for backup
- Copy command for recovery

This appendix describes the interface of each copy command.

15.4.1 Copy Command for Backup

Feature

User exit (for the copy command) called from the pgx_dmpall command.

Format

The syntax for calling the copy command from the pgx_dmpall command is described below.

If the operation mode is "prepare"

```
copyCommandName prepare "pathOfBackupInfoFile" "pathOfBackupTargetListFile"
```

If the operation mode is "backup"

```
copyCommandName backup
```

If the operation mode is "finalize"

```
copyCommandName finalize "pathOfBackupInfoFile"
```

Argument

- Operation mode

Mode	Description
prepare	Implements the preparation process for backing up using the copy command. Called before the PostgreSQL backup mode is started.
backup	Implements the backup process. Called during the PostgreSQL backup mode.
finalize	Implements the backup completion process. Called after the PostgreSQL backup mode is completed.

- Full path of the backup information file

  Full path of the backup information file of the latest backup, enclosed in double quotation marks. If a backup has not been performed, specify '-'.

- Full path of the backup target list file

  Full path of the file containing the resources to be backed up using the copy command, enclosed in double quotation marks. One of the following is described in each resource name.

Resource	Description
Database cluster	pg_data
Tablespace	Tablespace name

Example

To back up the database cluster and the tablespaces dbspace and indexspace using the copy command, the file should contain the following:

```
pg_data
dbspace
indexspace
```

Information

The encoding of resource names output to the backup target list file by the pgx_dmpall command is the encoding used when this command connects to the database with auto specified for the client_encoding parameter, and is dependent on the locale at the time of command execution.

The number of arguments vary depending on operation mode. The argument of each operation mode is as follows.

Operation mode	First argument	Second argument	Third argument
prepare	Operation mode	Backup information file path name	Backup target list file path name
backup		None	None
finalize		Backup information file path name	

Additionally, the access permissions for the backup information file and backup target list file are different depending on the operation mode. The access permissions of each operation mode are as follows:

Operation mode	Backup information file	Backup target list file
prepare	Can be viewed	Can be viewed
backup	-	-
finalize	Can be viewed and updated	-

Return value

Return value	Description
0	Normal end The pgx_dmpall command continues processing.
Other than 0	Abnormal end The pgx_dmpall command terminates in error.

Description

- The copy command operates with the privileges of the operating system user who executed the pgx_dmpall command. Therefore, grant copy command execution privileges to users who will execute the pgx_dmpall command. Additionally, have the copy command change users as necessary.
- To write to the backup information file, use a method such as redirection from the copy command.
- Because the copy command is called for each mode, implement all processing for each one.
- To copy multiple resources simultaneously, have the copy command copy them in parallel.
- The backup information file and backup target list file cannot be deleted. Additionally, the privileges cannot be changed.
- Standard output and standard error output of the copy command are output to the terminal where the pgx_dmpall command was executed.
- If the copy command becomes unresponsive, the pgx_dmpall command will also become unresponsive. If the copy command is deemed to be unresponsive by the operating system, use an operating system command to forcibly stop it.
- Output the copy command execution trace and the result to a temporary file, so that if it terminates in error, the cause can be investigated at a later time.
- For prepare mode only, it is possible to use the PostgreSQL client application to access the database using the copy command. For all other modes, do not execute Fujitsu Enterprise Postgres commands or PostgreSQL applications.
- Enable the fsync parameter in postgresql.conf, because data on the shared memory buffer needs to have been already written to disk when backup starts.

15.4.2 Copy Command for Recovery

Feature

User exit (for the copy command) called from the pgx_rcvall command.

Format

The syntax for calling the copy command from the pgx_rcvall command is described below.

```
copyCommandName restore "pathOfBackupInfoFile" "pathOfBackupTargetListFile"
```

Argument

- Operation mode

Mode	Description
restore	Performs restore.

- Full path of the backup information file

  Full path of the backup information file, enclosed in double quotation marks.

- Full path of the backup target list file

  Full path of the file containing the resources to be restored using the copy command, enclosed in double quotation marks.

The access permissions for the backup information file and backup target list file are as below.

Backup information file	Backup target list file
Can be viewed	Can be viewed

Return value

Return value	Description
0	Normal end The pgx_rcvall command continues processing.
Other than 0	Abnormal end The pgx_rcvall command terminates in error.

Description

- The copy command operates with the privileges of the operating system user who executed the pgx_rcvall command. Therefore, grant copy command execution privileges to users who will execute the pgx_rcvall command. Additionally, have the copy command change users as necessary.
- The copy command is called once only in restore mode.
- To copy multiple resources simultaneously, have the copy command copy them in parallel.
- The backup information file and backup target list file cannot be deleted. Additionally, the privileges cannot be changed.
- Standard output and standard error output of the copy command are output to the terminal where the pgx_rcvall command was executed.
- If the copy command becomes unresponsive, the pgx_rcvall command will also become unresponsive. If the status of the copy command is deemed to be unresponsive by the operating system, use an operating system command to forcibly stop it.
- Output the copy command execution trace and the result to a temporary file, so that if it terminates in error, the cause can be investigated at a later time.
- Do not execute Fujitsu Enterprise Postgres commands or PostgreSQL applications in the copy command.
- There may be files and directories not required for recovery using the archive log included in the backup, such as postmaster.pid, pg_wal/*subdirectory* and pg_replslot in the database cluster. If such unnecessary files and directories exist, have the copy command delete them after the restore.

Chapter 16 Actions when an Error Occurs

This chapter describes the actions to take when an error occurs in the database or an application, while Fujitsu Enterprise Postgres is operating.

Depending on the type of error, it may be necessary to recover the database cluster. The recovery process recovers the following resources:

- Data storage destination
- Transaction log storage destination (if the transaction log is stored in a separate disk from the data storage destination)
- Backup data storage destination

Even if a disk is not defective, the same input-output error messages, as those generated when the disk is defective, may be output. The recovery actions differ for these error messages.

Check the status of the disk, and select one of the following actions:

- If the disk is defective

  Refer to "16.1 Recovering from Disk Failure (Hardware)", and take actions accordingly.

- If the disk is not defective

  Refer to "16.14 I/O Errors Other than Disk Failure", and take actions accordingly.

  A few examples of errors generated even if the disk is not defective include:

  - Network error with an external disk
  - Errors caused by power failure or mounting issues

Determining the cause of an error

If an error occurs, refer to the WebAdmin message and the event log, and determine the cause of the error.

See

Refer to "Configuring Parameters" in the Installation and Setup Guide for Server for information on server logs.

Approximate recovery time

The formulas for deriving the approximate recovery time of resources in each directory are given below.

If using the copy command with the pgx_rcvall command, the recovery time will depend on the implementation of the copy command.

- Data storage destination or transaction log storage destination

```
Recovery time = (usageByTheDataStorageDestination + usageByTheTransactionLogStorageDestination) /
diskWritePerformance x 1.5
```

  - *usageByTheDataStorageDestination*: Disk space used by the database cluster
  - *usageByTheTransactionLogStorageDestination*: Disk space used by the transaction log stored outside the database cluster
  - *diskWritePerformance*: Measured maximum data volume (bytes/second) that can be written per second in the system environment where the operation is performed
  - 1.5: Coefficient assuming the time excluding disk write, which is the most time-consuming step

- Backup data storage destination

```
Recovery time = usageByTheBackupDataStorageDestination / diskWritePerformance x 1.5
```

  - *usageByTheBackupDataStorageDestination*: Disk space used by the backup data

- *diskWritePerformance*: Measured maximum data volume (bytes/second) that can be written per second in the system environment where the operation is performed
- 1.5: Coefficient assuming the time excluding disk write, which is the most time-consuming step

16.1 Recovering from Disk Failure (Hardware)

This section describes how to recover database clusters to a point immediately before failure, if a hardware failure occurs in the data storage disk or the backup data storage disk.

There are two methods of recovery:

- 16.1.1 Using WebAdmin
- 16.1.2 Using Server Command

Point

Back up the database cluster after recovering it. Backup deletes obsolete archive logs (transaction logs copied to the backup data storage destination), freeing up disk space and reducing the recovery time.

16.1.1 Using WebAdmin

Recover a failed disk using WebAdmin.

In a streaming replication configuration, the master instance can be recovered, but the standby instance cannot. If disk failure occurs on a standby instance, it may be necessary to delete and re-create the instance. Also, recovering the master instance stops streaming replication to and from all standby instances. In such an event, the standby instances can be promoted to standalone instances or can be deleted and re-created

Recover the database cluster by following the appropriate recovery procedure below for the disk where the failure occurred.

If failure occurred in the data storage disk or the transaction log storage disk

Follow the procedure below to recover the data storage disk or the transaction log storage disk.

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance. Refer to "2.1.1 Using WebAdmin" for information on how to stop an instance. WebAdmin automatically stops instances if recovery of the database cluster is performed without stopping the instance.

3. Recover the failed disk

   Replace the disk, and then recover the volume configuration information.

4. Create a tablespace directory

   If a tablespace was defined after backup, create a directory for it.

5. Recover the keystore, and enable automatic opening of the keystore

   Do the following if the data in the database has been encrypted:

   - Restore the keystore to its state at the time of the database backup.
   - Enable automatic opening of the keystore.

6. Recover the database cluster

   Log in to WebAdmin, and in the [Instances] tab, click [Solution] for the error message in the lower-right corner.

7. Run recovery

   In the [Restore Instance] dialog box, click [Yes].

Instance restore is performed. An instance is automatically started when recovery is successful.

8. Resume applications

   Resume applications that are using the database.

Point

WebAdmin may be unable to detect disk errors, depending on how the error occurred.

If this happens, refer to "16.10.3 Other Errors" to perform recovery.

If failure occurred on the backup data storage disk

Follow the procedure below to recover the backup data storage disk.

1. Recover the failed disk

   Replace the disk, and then recover the volume configuration information.

2. Recover the backup data

   Log in to WebAdmin, and in the [Instances] tab, click [Solution] for the error message.

3. Run backup

   Perform backup to enable recovery of the backup data. In the [Backup] dialog box, click [Yes]. The backup is performed. An instance is automatically started when backup is performed.

Point

If you click [Recheck the status], the resources in the data storage destination and the backup data storage destination are reconfirmed. As a result, the following occurs:

- If an error is not detected

  The status of the data storage destination and the backup data storage destination returns to normal, and it is possible to perform operations as usual.

- If an error is detected

  An error message is displayed in the message list again. Click [Solution], and resolve the problem by following the resolution for the cause of the error displayed in the dialog box.

16.1.2 Using Server Command

Recover the database cluster by following the appropriate recovery procedure below for the disk where the failure occurred.

If failure occurred on the data storage disk or the transaction log storage directory

Follow the procedure below to recover the data storage disk or the transaction log storage directory.

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance, refer to "2.1.2 Using Commands" for details.

   If the instance fails to stop, refer to "16.11 Actions in Response to Failure to Stop an Instance".

3. Recover the failed disk

   Replace the disk, and then recover the volume configuration information.

4. Create a storage destination directory

   - If failure occurred on the data storage disk
     Create a data storage destination directory. If a tablespace was defined, also create a directory for it.
   - If failure occurred on the translation log storage disk
     Create a transaction log storage destination directory.

   In [Properties] in Windows(R) Explorer, set appropriate permissions so that only the instance administrator can access the storage destination directory. (Refer to [Help and Support] in Windows(R) for information on [Properties].)

   See

   Refer to "Preparing Directories to Deploy Resources" under "Setup" in the Installation and Setup Guide for Server for information on how to create a storage directory.

5. Recover the keystore, and enable automatic opening of the keystore

   When the data in the database has been encrypted, restore the keystore to its state at the time of the database backup. Configure automatic opening of the keystore as necessary.

6. Recover the database cluster

   Recover the database cluster using the backup data.

   Specify the following in the pgx_rcvall command:

   - Specify the data storage location in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
   - Specify the backup data storage location in the -B option.

   Example

   ```
   > pgx_rcvall -D D:\database\inst1 -B E:\backup\inst1
   ```

   If recovery fails

   If recovery fails, remove the cause of the error in accordance with the displayed error message and then re-execute the pgx_rcvall command.

   If the message "pgx_rcvall: an error occurred during recovery" is displayed, then the log recorded when recovery was executed is output after this message. The cause of the error is output in around the last fifteen lines of the log, so remove the cause of the error in accordance with the message and then re-execute the pgx_rcvall command.

   Information

   The following message displayed during recovery is output as part of normal operation of pgx_rcvall command (therefore the user does not need not be concerned).

   ```
   FATAL: the database system is starting up
   ```

7. Start the instance

   Refer to "2.1.2 Using Commands" for information on how to start an instance.

8. Resume applications

   Resume applications that are using the database.

If failure occurred on the backup data storage disk

The procedure for recovering the backup data storage disk is described below.

There are two methods of taking action:

- Performing recovery while the instance is active
- Stopping the instance before performing recovery

The following table shows the different steps to be performed depending on whether you stop the instance.

No	Step	Instance stopped	
		No	Yes
1	Confirm that transaction log mirroring has stopped	Y	N
2	Stop output of archive logs	Y	N
3	Stop applications	N	Y
4	Stop the instance	N	Y
5	Recover the failed disk	Y	Y
6	Create a backup data storage destination directory	Y	Y
7	Resume output of archive logs	Y	N
8	Resume transaction log mirroring	Y	N
9	Start the instance	N	Y
10	Run backup	Y	Y
11	Resume applications	N	Y

Y: Required
N: Not required

The procedure is as follows:

If an instance has not been stopped

1. Confirm that transaction log mirroring has stopped

   Use the following SQL function to confirm that transaction log mirroring has stopped.

```
 postgres=# SELECT pgx_is_wal_multiplexing_paused();
 pgx_is_wal_multiplexing_paused
-------------------
 t
(1 row)
```

   If transaction log mirroring has not stopped, then stop it using the following SQL function.

```
postgres=# SELECT pgx_pause_wal_multiplexing();
LOG:  multiplexing of transaction log files has been stopped
pgx_pause_wal_multiplexing
---------------------------

(1 row)
```

2. Stop output of archive logs

   Transaction logs may accumulate during replacement of backup storage disk, and if the data storage disk or the transaction log storage disk becomes full, there is a risk that operations may not be able to continue.

   To prevent this, use the following methods to stop output of archive logs.

   - Changing archive_command

     Specify a command that will surely complete normally, so that archive logs will be regarded as having been output.

If you specify echo, a message is output to the server log, so it may be used as a reference when you conduct investigations.

- Reload the configuration file

  Execute the pg_ctl reload command or the pg_reload_conf SQL function to reload the configuration file.

If you simply want to stop output of errors without the risk that operations will not be able to continue, specify an empty string ('') in archive_command and reload the configuration file.

3. Recover the failed disk

   Replace the disk, and then recover the volume configuration information.

4. Create a backup data storage destination

   Create a backup data storage destination.

   In [Properties] in Windows(R) Explorer, set appropriate permissions so that only the instance administrator can access the backup data storage destination directory. (Refer to [Help and Support] in Windows(R) for information on [Properties].)

   Refer to "3.2.2 Using Server Commands" for information on how to create a backup data storage destination.

5. Resume output of archive logs

   Return the archive_command setting to its original value, and reload the configuration file.

6. Resume transaction log mirroring

   Execute the pgx_resume_wal_multiplexing SQL function.

   Example

   ```
   SELECT pgx_resume_wal_multiplexing()
   ```

7. Run backup

   Use the pgx_dmpall command to back up the database cluster.

   Specify the following value in the pgx_dmpall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

   Example

   ```
   > pgx_dmpall -D D:\database\inst1
   ```

If an instance has been stopped

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance. Refer to "2.1.2 Using Commands" for details.

   If the instance fails to stop, refer to "16.11 Actions in Response to Failure to Stop an Instance".

3. Recover the failed disk

   Replace the disk, and then recover the volume configuration information.

4. Create a backup data storage destination

   Create a backup data storage destination.

   In [Properties] in Windows(R) Explorer, set appropriate permissions so that only the instance administrator can access the backup data storage destination directory. (Refer to [Help and Support] in Windows(R) for information on [Properties].)

   Refer to "3.2.2 Using Server Commands" for details.

5. Start the instance

   Start the instance. Refer to "2.1.2 Using Commands" for information on how to start an instance.

6. Run backup

   Use the pgx_dmpall command to back up the database cluster.

   Specify the following value in the pgx_dmpall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

   Example

```
> pgx_dmpall -D D:\database\inst1
```

7. Resume applications

   Resume applications that are using the database.

See

- Refer to "pgx_rcvall" and "pgx_dmpall" in the Reference for information on the pgx_rcvall command and pgx_dmpall command.
- Refer to "Write Ahead Log" under "Server Administration" in the PostgreSQL Documentation for information on archive_command.
- Refer to "B.1 WAL Mirroring Control Functions" for information on pgx_resume_wal_multiplexing.

16.2 Recovering from Data Corruption

If data in a disk is logically corrupted and the database does not operate properly, you can recover the database cluster to its state at the time of backup.

There are two methods of recovery:

- 16.2.1 Using WebAdmin
- 16.2.2 Using the pgx_rcvall Command

Point

- Back up the database cluster after recovering it. Backup deletes obsolete archive logs (transaction logs copied to the backup data storage destination), freeing up disk space and reducing the recovery time.
- If you recover data to a point in the past, a new time series (database update history) will start from that recovery point. When recovery is complete, the recovery point is the latest point in the new time series. When you subsequently recover data to the latest state, the database update is re-executed on the new time series.

16.2.1 Using WebAdmin

If using WebAdmin, recover the data to the point immediately prior to data corruption by using the backup data.

Refer to "16.1.1 Using WebAdmin" for details.

16.2.2 Using the pgx_rcvall Command

Recover the database cluster by specifying in the pgx_rcvall command the date and time of the backup you want to read from. Then re-execute the transaction as required to recover the data.

Follow the procedure below to recover the data storage disk.

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance. Refer to "2.1.2 Using Commands" for information on how to stop an instance.

   If the instance fails to stop, refer to "16.11 Actions in Response to Failure to Stop an Instance".

3. Confirm the backup date and time

   Pinpoint a date and time prior to the data corruption based on the content of the job log or event log.

4. Recover the keystore, and enable automatic opening of the keystore

   When the data in the database has been encrypted, restore the keystore to its state at the time of the database backup. Configure automatic opening of the keystore as necessary.

5. Recover the database cluster

   Use the pgx_rcvall command to recover the database cluster.

   Specify the following values in the pgx_rcvall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
   - Specify the backup storage directory in the -B option.
   - Specify the recovery date and time in the -e option.

   Example

   In the following examples, "March 20, 2022 10:00:00" is specified as the recovery time.

   ```
   > pgx_rcvall -D D:\database\inst1 -B E:\backup\inst1 -e "2022-03-20 10:00:00"
   ```

   If recovery fails

   If recovery fails, remove the cause of the error in accordance with the displayed error message and then re-execute the pgx_rcvall command.

   If the message "pgx_rcvall: an error occurred during recovery" is displayed, then the log recorded when recovery was executed is output after this message. The cause of the error is output in around the last fifteen lines of the log, so remove the cause of the error in accordance with the message and then re-execute the pgx_rcvall command.

Information

The following message displayed during recovery is output as part of normal operation of pgx_rcvall command (therefore the user does not need not be concerned).

```
FATAL:  the database system is starting up
```

6. Start the instance

   Start the instance. Refer to "2.1.2 Using Commands" for information on how to start an instance.

   If necessary, re-execute transaction processing from the specified recovery time, and then resume database operations.

7. Resume applications

   Resume applications that are using the database.

See

Refer to "pgx_rcvall" in the Reference for information on the pgx_rcvall command.

16.3 Recovering from an Incorrect User Operation

This section describes how to recover database clusters when data has been corrupted due to erroneous user operations.

There are two methods of recovery:

- 16.3.1 Using WebAdmin
- 16.3.2 Using the pgx_rcvall Command

Point

- Back up the database cluster after recovering it. Backup deletes obsolete archive logs (transaction logs copied to the backup data storage destination), freeing up disk space and reducing the recovery time.
- If you recover data to a point in the past, a new time series (database update history) will start from that recovery point. When recovery is complete, the recovery point is the latest point in the new time series. When you subsequently recover data to the latest state, the database update is re-executed on the new time series.
- An effective restore point is one created on a time series for which you have made a backup. That is, if you recover data to a point in the past, you cannot use any restore points set after that recovery point. Therefore, once you manage to recover your target past data, make a backup.

16.3.1 Using WebAdmin

Recover data to a backup point using WebAdmin.

In a streaming replication configuration, the master instance can be recovered, but the standby instance cannot. If disk failure occurs on a standby instance, it may be necessary to delete and re-create the instance. Also, recovering the master instance stops streaming replication to and from all standby instances. In such an event, the standby instances can be promoted to standalone instances or can be deleted and re-created

Follow the procedure below to recover the data in the data storage disk.

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance. Refer to "2.1.1 Using WebAdmin" for information on how to stop an instance.

3. Recover the keystore, and enable automatic opening of the keystore

   Do the following if the data in the database has been encrypted:

   - Restore the keystore to its state at the time of the database backup.
   - Enable automatic opening of the keystore.

4. Recover the database cluster

   Log in to WebAdmin, and in the [Instances] tab, select the instance to be recovered and click .

5. Recover to the backup point

   In the [Restore Instance] dialog box, click [Yes].

   Recovery is performed. An instance is automatically started when recovery is successful.

6. Resume database operations

   If necessary, re-execute transaction processing from the backup point to when an erroneous operation was performed, and then resume database operations.

16.3.2 Using the pgx_rcvall Command

The pgx_rcvall command recovers database clusters to the restore point created with the server command. Refer to "Setting a restore point" in "3.2.2 Using Server Commands" for information on how to create a restore point.

Follow the procedure below to recover the data in the data storage disk.

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance. Refer to "2.1.2 Using Commands" for information on how to stop an instance.

   If the instance fails to stop, refer to "16.11 Actions in Response to Failure to Stop an Instance".

3. Confirm the restore point

   Use a restore point recorded in an arbitrary file, as explained in ""3.2.2 Using Server Commands", to determine a restore point prior to the erroneous operation.

4. Recover the keystore, and enable automatic opening of the keystore

   When the data in the database has been encrypted, restore the keystore to its state at the time of the database backup. Configure automatic opening of the keystore as necessary.

5. Recover the database cluster

   Use the pgx_rcvall command to recover the database cluster.

   Specify the following values in the pgx_rcvall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
   - Specify the backup data storage destination in the -B option.
   - The -n option recovers the data to the specified restore point.

   Example

   The following example executes the pgx_rcvall command with the restore point "batch_20220303_1".

   ```
   > pgx_rcvall -D D:\database\inst1 -B E:\backup\inst1 -n batch_20220303_1
   ```

   If recovery fails

   If recovery fails, remove the cause of the error in accordance with the displayed error message and then re-execute the pgx_rcvall command.

   If the message "pgx_rcvall: an error occurred during recovery" is displayed, then the log recorded when recovery was executed is output after this message. The cause of the error is output in around the last fifteen lines of the log, so remove the cause of the error in accordance with the message and then re-execute the pgx_rcvall command.

   Information

   The following message displayed during recovery is output as part of normal operation of pgx_rcvall command (therefore the user does not need not be concerned).

   ```
   FATAL:  the database system is starting up
   ```

6. Start the instance

   Start the instance.

   Refer to "2.1.2 Using Commands" for information on how to start an instance.

7. Restart operation of the database

   If necessary, re-execute transaction processing from the specified recovery time to the point when an erroneous operation was performed, and then resume database operations.

See

Refer to "pgx_rcvall" in the Reference for information on the pgx_rcvall command.

16.4 Actions in Response to an Application Error

If there is a connection from a client that has been in the waiting state for an extended period, you can minimize performance degradation of the database by closing the problematic connection.

The following methods are available for identifying a connection to be closed:

- view(pg_stat_activity) (refer to "16.4.1 When using the view (pg_stat_activity)")
- pgAdmin (refer to "16.4.2 Using pgAdmin")

Use the system management function (pg_terminate_backend) to disconnect connections.

16.4.1 When using the view (pg_stat_activity)

When using the view (pg_stat_activity), follow the procedure below to close a connection.

1. Use psql command to connect to the postgres database.

```
> psql postgres
psql (<x>) (*1)
Type "help" for help.
```

   *1: *<x>* indicates the PostgreSQL version on which this product is based.

2. Close connections from clients that have been in the waiting state for an extended period.

   Use pg_terminate_backend() to close connections that have been trying to connect for an extended period.

   However, when considering continued compatibility of applications, do not reference or use system catalogs and functions directly in SQL statements. Refer to " Notes on Application Compatibility" in the Application Development Guide for details.

   Example

   The following example closes connections where the client has been in the waiting state for at least 60 minutes.

```
select pid,usename,application_name,client_addr,pg_terminate_backend(pid) from pg_stat_activity
where backend_type = 'client backend' and state='idle in transaction' and current_timestamp >
cast(query_start + interval '60 minutes' as timestamp);
-[ RECORD 1 ]--------+--------------
pid                  | 4684
username             | fsepuser
application_name     | apl1
client_addr          | 192.11.11.1
pg_terminate_backend | t
```

See

- Refer to "System Administration Functions" under "The SQL Language" in the PostgreSQL Documentation for information on pg_terminate_backend.

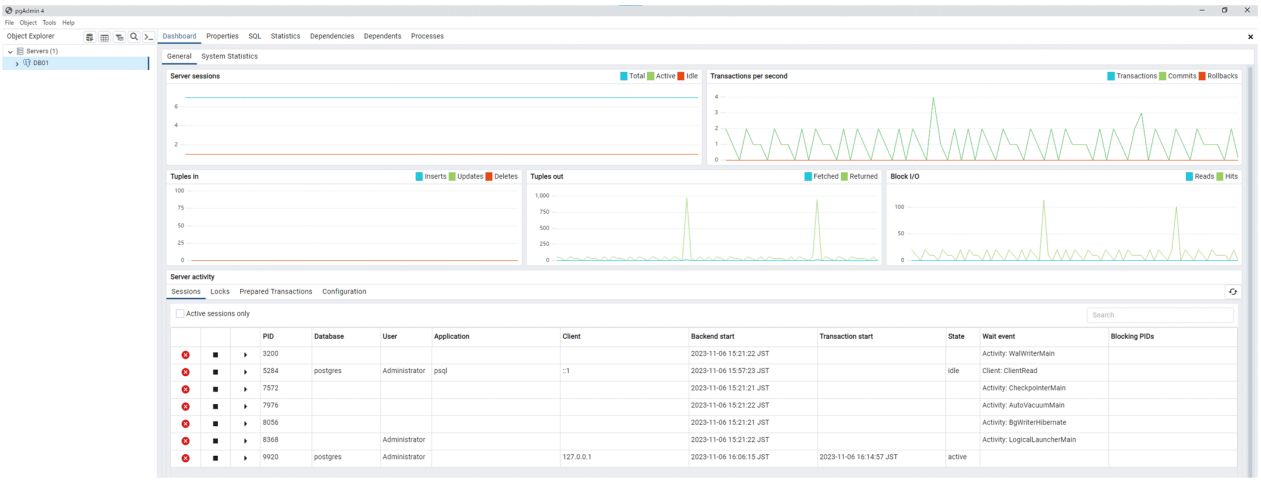
- Refer to "Notes on Application Compatibility" in the Application Development Guide for information on how to maintain application compatibility.

16.4.2 Using pgAdmin

If using pgAdmin, follow the procedure below to close connections.

1. In the [Browser] pane, click the relevant database server.
2. Close the client connections that have been in a wait state for an extended period.

   Click the [Dashboard] tab. In the [Server activity] section, select the connections that have been in an "idle" or "idle in transaction" state for an extended period. For each of these connections, click to close the session.



16.5 Actions in Response to an Access Error

If access is denied, grant privileges allowing the instance administrator to operate the following directories, and then re-execute the operation. Also, refer to the event log and the server log, and confirm that the file system has not been mounted as read-only due to a disk error. If the file system has been mounted as read-only, mount it properly and then re-execute the operation.

- Data storage destination
- Tablespace storage destination
- Transaction log storage destination
- Backup data storage destination

See

Refer to "Preparing Directories to Deploy Resources" under "Setup" in the Installation and Setup Guide for Server for information on the privileges required for the directory.

16.6 Actions in Response to Insufficient Space on the Data Storage Destination

If the data storage destination runs out of space, check if the disk contains any unnecessary files and delete them so that operations can continue.

If deleting unnecessary files does not solve the problem, you must migrate data to a disk with larger capacity.

There are two methods of migrating data:

- 16.6.1 Using a Tablespace
- 16.6.2 Replacing the Disk with a Larger Capacity Disk

16.6.1 Using a Tablespace

Fujitsu Enterprise Postgres enables you to use a tablespace to change the storage destination of database objects, such as tables and indexes, to a different disk.

The procedure is as follows:

1. Create a tablespace

   Use the CREATE TABLESPACE command to create a new tablespace in the prepared disk.

2. Modify the tablespace

   Use the ALTER TABLE command to modify tables for the newly defined tablespace.

See

Refer to "SQL Commands" under "Reference" in the PostgreSQL Documentation for information on the CREATE TABLESPACE command and ALTER TABLE command.

16.6.2 Replacing the Disk with a Larger Capacity Disk

Before replacing the disk with a larger capacity disk, migrate resources at the data storage destination using the backup and recovery features.

There are two methods of performing backup and recovery:

- 16.6.2.1 Using WebAdmin
- 16.6.2.2 Using Server Commands

The following sections describe procedures that use each of these methods to replace the disk and migrate resources at the data storage destination.

Point

It is recommended that you back up the database cluster following recovery. Backup deletes obsolete archive logs (transaction logs copied to the backup data storage destination), freeing up disk space and reducing the recovery time.

16.6.2.1 Using WebAdmin

Follow the procedure below to replace the disk and migrate resources at the data storage destination by using WebAdmin.

1. Back up files

   If the disk at the data storage destination contains any required files, back up the files. It is not necessary to back up the data storage destination.

2. Stop applications

   Stop applications that are using the database.

3. Back up the database cluster

   Back up the latest resources at the data storage destination. Refer to "3.2.1 Using WebAdmin" for details.

4. Stop the instance

   Stop the instance. Refer to "2.1.1 Using WebAdmin" for information on how to stop an instance.

5. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

6. Recover the database cluster

   Log in to WebAdmin, and perform recovery operations. Refer to steps 4 ("Create a tablespace directory ") to 7 ("Run recovery") under "If failure occurred in the data storage disk or the transaction log storage disk" in "16.1.1 Using WebAdmin" for information on the procedure. An instance is automatically started when recovery is successful.

7. Resume applications

   Resume applications that are using the database.

8. Restore the files

   Restore the files backed up in step 1.

16.6.2.2 Using Server Commands

Follow the procedure below to replace the disk and migrate resources at the data storage destination by using server commands.

1. Back up files

   If the disk at the data storage destination contains any required files, back up the files. It is not necessary to back up the data storage destination.

2. Stop applications

   Stop applications that are using the database.

3. Back up the database cluster

   Back up the latest resources at the data storage destination. Refer to "3.2.2 Using Server Commands" for details.

4. Stop the instance

   After backup is complete, stop the instance. Refer to "2.1.2 Using Commands" for information on how to stop an instance.

   If the instance fails to stop, refer to "16.11 Actions in Response to Failure to Stop an Instance".

5. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

6. Create a data storage destination

   Create a data storage destination. If a tablespace was defined, also create a directory for it.

   In [Properties] in Windows(R) Explorer, set appropriate permissions so that only the instance administrator can access the data storage destination directory. (Refer to [Help and Support] in Windows(R) for information on [Properties].)

7. Recover the keystore, and enable automatic opening of the keystore

   When the data in the database has been encrypted, restore the keystore to its state at the time of the database backup. Configure automatic opening of the keystore as necessary.

8. Recover the database cluster

   Use the pgx_rcvall command to recover the database cluster.

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
   - Specify the backup storage directory in the -B option.

   Example

```
> pgx_rcvall -D D:\database\inst1 -B E:\backup\inst1
```

If recovery fails

If recovery fails, remove the cause of the error in accordance with the displayed error message and then re-execute the pgx_rcvall command.

If the message "pgx_rcvall: an error occurred during recovery" is displayed, then the log recorded when recovery was executed is output after this message. The cause of the error is output in around the last fifteen lines of the log, so remove the cause of the error in accordance with the message and then re-execute the pgx_rcvall command.

Information

The following message displayed during recovery is output as part of normal operation of pgx_rcvall command (therefore the user does not need not be concerned).

```
FATAL:  the database system is starting up
```

See

Refer to "pgx_rcvall" in the Reference for information on the pgx_rcvall command.

9. Start the instance

   Start the instance.

   Refer to "2.1.2 Using Commands" for information on how to start an instance.

10. Resume applications

    Resume applications that are using the database.

11. Restore files

    Restore the files backed up in step 1.

16.7 Actions in Response to Insufficient Space on the Backup Data Storage Destination

If space runs out on the backup data storage destination, check if the disk contains any unnecessary files and delete them, and then make a backup as required.

If deleting unnecessary files does not solve the problem, take the following action:

- 16.7.1 Temporarily Saving Backup Data
- 16.7.2 Replacing the Disk with a Larger Capacity Disk

16.7.1 Temporarily Saving Backup Data

This method involves temporarily moving backup data to a different directory, saving it there, and securing disk space on the backup data storage destination so that a backup can be made normally.

Use this method if you need time to prepare a larger capacity disk.

If space runs out on the backup data storage destination, archive logs can no longer be stored in the backup data storage destination. As a result, transaction logs continue to accumulate in the data storage destination or the transaction log storage destination.

If action is not taken soon, the transaction log storage destination will become full, and operations may not be able to continue.

To prevent this, secure space in the backup data storage destination, so that archive logs can be stored.

There are two methods of taking action:

- 16.7.1.1 Using WebAdmin

- 16.7.1.2 Using Server Commands

16.7.1.1 Using WebAdmin

Follow the procedure below to recover the backup data storage disk.

1. Temporarily save backup data

   Move backup data to a different directory and temporarily save it, and secure space in the backup data storage destination directory.

   The reason for saving the backup data is so that the data in the data storage destination can be recovered even if it is corrupted before you perform recovery. If there is no disk at the save destination and you consider that there is no risk of corruption at the data storage destination, delete the backup data.

   The following example saves backup data from the backup data storage destination directory (E:\backup\inst1) under F:\mnt\usb\backup.

   Example

   ```
   > mkdir F:\mnt\usb\backup
   > move E:\backup\inst1\* F:\mnt\usb\backup
   ```

   Note: Place the temporary backup destination directory in a location where it will not impact on operating system resources or Fujitsu Enterprise Postgres resources.

2. Back up the database cluster

   Back up the latest resources at the data storage destination. Refer to "3.2.1 Using WebAdmin" for details.

3. Delete temporarily saved backup data

   If backup completes normally, the temporarily saved backup data becomes unnecessary and is deleted.

   The following example deletes backup data that was temporarily saved in F:\mnt\usb.

   Example

   ```
   > rmdir /S /Q F:\mnt\usb\backup
   ```

16.7.1.2 Using Server Commands

The following describes the procedure for recovering the backup storage disk.

There are two methods of taking action:

- Performing recovery while the instance is active
- Stopping the instance before performing recovery

The following table shows the different steps to be performed depending on whether you stop the instance.

No	Step	Instance stopped	
		No	Yes
1	Stop transaction log mirroring	Y	N
2	Stop output of archive logs	Y	N
3	Stop applications	N	Y
4	Stop the instance	N	Y
5	Temporarily save backup data	Y	Y
6	Resume output of archive logs	Y	N
7	Resume transaction log mirroring	Y	N
8	Start an instance	N	Y

No	Step	Instance stopped	
		No	Yes
9	Run backup	Y	Y
10	Resume applications	N	Y
11	Delete temporarily saved backup data	Y	Y

Y: Required
N: Not required

The procedure is as follows:

Performing recovery while the instance is active

1. Stop transaction log mirroring

   Stop transaction log mirroring.

```
postgres=# SELECT pgx_pause_wal_multiplexing();
LOG:  multiplexing of transaction log files has been stopped
pgx_pause_wal_multiplexing
---------------------------

(1 row)
```

2. Stop output of archive logs

   Transaction logs may accumulate during replacement of backup storage disk, and if the data storage disk or the transaction log storage disk becomes full, there is a risk that operations may not be able to continue.

   To prevent this, use the following methods to stop output of archive logs.

   - Changing the archive_command parameter

     Specify a command that will surely complete normally, so that archive logs will be regarded as having been output.

     If you specify echo, a message is output to the server log, so it may be used as a reference when you conduct investigations.

   - Reloading the configuration file

     Run the pg_ctl reload command or the pg_reload_conf SQL function.

   If you simply want to stop output of errors without the risk that operations will not be able to continue, specify an empty string ('') in archive_command and reload the configuration file.

3. Temporarily save backup data

   Move backup data to a different directory and temporarily save it, and secure space in the backup data storage destination directory.

   The reason for saving the backup data is so that the data in the data storage destination can be recovered even if it is corrupted before you perform the next step. If there is no disk at the save destination and you consider that there is no risk of corruption at the data storage destination, delete the backup data.

   The following example saves backup data from the backup data storage destination directory (E:\backup\inst1) under F:\mnt\usb \backup.

   Example

```
> mkdir F:\mnt\usb\backup
> move E:\backup\inst1\* F:\mnt\usb\backup
```

   Note: Place the temporary backup destination directory in a location where it will not impact on operating system resources or Fujitsu Enterprise Postgres resources.

4. Resume output of archive logs

   Return the archive_command setting to its original value, and reload the configuration file.

5. Resume transaction log mirroring

   Execute the pgx_resume_wal_multiplexing SQL function.

   Example

   ```
   SELECT pgx_resume_wal_multiplexing()
   ```

6. Run backup

   Use the pgx_dmpall command to back up the database cluster.

   Specify the following option in the pgx_dmpall command:

   - Specify the directory of the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

     Example

     ```
     > pgx_dmpall -D D:\database\inst1
     ```

7. Delete temporarily saved backup data

   If backup completes normally, the temporarily saved backup data becomes unnecessary and is deleted.

   The following example deletes backup data that was temporarily saved in F:\mnt\usb.

   Example

   ```
   > rmdir /S /Q F:\mnt\usb\backup
   ```

If an instance has been stopped

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance. Refer to "2.1.2 Using Commands" for details.

   If the instance fails to stop, refer to "16.11 Actions in Response to Failure to Stop an Instance".

3. Temporarily save backup data

   Move backup data to a different directory and temporarily save it, and secure space in the backup data storage destination directory.

   The reason for saving the backup data is so that the data in the data storage destination can be recovered even if it is corrupted before you perform recovery. If there is no disk at the save destination and you consider that there is no risk of corruption at the data storage destination, delete the backup data.

   The following example saves backup data from the backup data storage destination directory (E:\backup\inst1) under F:\mnt\usb \backup.

   Example

   ```
   > mkdir F:\mnt\usb\backup
   > move E:\backup\inst1\* F:\mnt\usb\backup
   ```

   Note: Place the temporary backup destination directory in a location where it will not impact on operating system resources or Fujitsu Enterprise Postgres resources.

4. Start the instance

   Start the instance. Refer to "2.1.2 Using Commands" for information on how to start an instance.

5. Run backup

   Use the pgx_dmpall command to back up the database cluster.

   Specify the following value in the pgx_dmpall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

     Example

     ```
     > pgx_dmpall -D D:\database\inst1
     ```

6. Resume applications

   Resume applications that are using the database.

7. Delete temporarily saved backup data

   If backup completes normally, the temporarily saved backup data becomes unnecessary and is deleted.

   The following example deletes backup data that was temporarily saved in F:\mnt\usb.

   Example

   ```
   > rmdir /S /Q F:\mnt\usb\backup
   ```

See

- Refer to "pgx_rcvall" and "pgx_dmpall" in the Reference for information on the pgx_rcvall command and pgx_dmpall command.
- Refer to "Write Ahead Log" under "Server Administration" in the PostgreSQL Documentation for information on archive_command.
- Refer to "B.1 WAL Mirroring Control Functions" for information on the pgx_is_wal_multiplexing_paused and pgx_resume_wal_multiplexing.

16.7.2 Replacing the Disk with a Larger Capacity Disk

This method involves replacing the disk at the backup data storage destination with a larger capacity disk, so that it does not run out of free space again. After replacing the disk, back up data to obtain a proper backup.

There are two methods of performing backup:

- 16.7.2.1 Using WebAdmin
- 16.7.2.2 Using Server Commands

16.7.2.1 Using WebAdmin

Follow the procedure below to recover the backup storage disk.

1. Back up files

   If the disk at the backup data storage destination contains any required files, back up the files. It is not necessary to back up the backup data storage destination.

2. Temporarily save backup data

   Save the backup data to a different directory.

   The reason for saving the backup data is so that the data in the data storage destination can be recovered even if it is corrupted before you perform the next step. If there is no disk at the save destination and you consider that there is no risk of corruption at the data storage destination, delete the backup data.

   The following example saves backup data from the backup data storage destination directory (E:\backup\inst1) under F:\mnt\usb\backup.

Example

```
> mkdir F:\mnt\usb\backup
> move E:\backup\inst1\* F:\mnt\usb\backup
```

Note: Place the temporary backup destination directory in a location where it will not impact on operating system resources or Fujitsu Enterprise Postgres resources.

3. Stop applications

   Stop applications that are using the database.

4. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

5. Run backup

   Log in to WebAdmin, and perform recovery operations. Refer to steps 2 ("Recover the backup data") and 3 ("Run backup") under "If failure occurred on the backup storage disk" in "16.1.1 Using WebAdmin".

6. Restore files

   Restore the files backed up in step 1.

7. Delete temporarily saved backup data

   If backup completes normally, the temporarily saved backup data becomes unnecessary and is deleted.

   The following example deletes backup data that was temporarily saved in F:\mnt\usb.

   Example

```
> rmdir /S /Q F:\mnt\usb\backup
```

16.7.2.2 Using Server Commands

The procedure for recovering the backup data storage disk is described below.

There are two methods of taking action:

- Performing recovery while the instance is active
- Stopping the instance before performing recovery

The following table shows the different steps to be performed depending on whether you stop the instance.

No	Step	Instance stopped	
		No	Yes
1	Back up files	Y	Y
2	Temporarily save backup data	Y	Y
3	Confirm that transaction log mirroring has stopped	Y	N
4	Stop output of archive logs	Y	N
5	Stop applications	N	Y
6	Stop the instance	N	Y
7	Replace with a larger capacity disk	Y	Y
8	Create a backup storage directory	Y	Y
9	Resume output of archive logs	Y	N
10	Resume transaction log mirroring	Y	N
11	Start the instance	N	Y
12	Run backup	Y	Y

No	Step	Instance stopped	
		No	Yes
13	Resume applications	N	Y
14	Restore files	Y	Y
15	Delete temporarily saved backup data	Y	Y

Y: Required
N: Not required

The procedure is as follows:

If an instance has not been stopped

1. Back up files

   If the disk at the backup data storage destination contains any required files, back up the files. It is not necessary to back up the backup data storage destination.

2. Temporarily save backup data

   Save the backup data to a different directory.

   The reason for saving the backup data is so that the data in the data storage destination can be recovered even if it is corrupted before you perform the next step. If there is no disk at the save destination and you consider that there is no risk of corruption at the data storage destination, delete the backup data.

   The following example saves backup data from the backup data storage destination directory (E:\backup\inst1) under F:\mnt\usb\backup.

   Example

   ```
   > mkdir F:\mnt\usb\backup
   > move E:\backup\inst1\* F:\mnt\usb\backup
   ```

3. Confirm that transaction log mirroring has stopped

   Use the following SQL function to confirm that transaction log mirroring has stopped.

   ```
    postgres=# SELECT pgx_is_wal_multiplexing_paused();
    pgx_is_wal_multiplexing_paused
   -------------------
    t
   (1 row)
   ```

   If transaction log mirroring has not stopped, then stop it using the following SQL function.

   ```
   postgres=# SELECT pgx_pause_wal_multiplexing();
   LOG:  multiplexing of transaction log files has been stopped
   pgx_pause_wal_multiplexing
   ---------------------------

   (1 row)
   ```

4. Stop output of archive logs

   Transaction logs may accumulate during replacement of backup storage disk, and if the data storage destination disk or the transaction log storage destination disk becomes full, there is a risk that operations may not be able to continue.

   To prevent this, use the following methods to stop output of archive logs.

   - Changing the archive_command parameter

     Specify a command that will surely complete normally, so that archive logs will be regarded as having been output.

If you specify echo, a message is output to the server log, so it may be used as a reference when you conduct investigations.

- Reloading the configuration file

  Run the pg_ctl reload command or the pg_reload_conf SQL function.

If you simply want to stop output of errors without the risk that operations will not be able to continue, specify an empty string ('') in archive_command and reload the configuration file.

5. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

6. Create a backup data storage destination

   Create a backup data storage destination.

   In [Properties] in Windows(R) Explorer, set appropriate permissions so that only the instance administrator can access the backup data storage destination directory. (Refer to [Help and Support] in Windows(R) for information on [Properties].)

   Refer to "3.2.2 Using Server Commands" for details.

7. Resume output of archive logs

   Return the archive_command setting to its original value, and reload the configuration file.

8. Resume transaction log mirroring

   Execute the pgx_resume_wal_multiplexing SQL function.

   Example

   ```
   SELECT pgx_resume_wal_multiplexing()
   ```

9. Run backup

   Use the pgx_dmpall command to back up the database cluster.

   Specify the following value in the pgx_dmpall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

   Example

   ```
   > pgx_dmpall -D D:\database\inst1
   ```

10. Restore files

    Restore the files backed up in step 1.

11. Delete temporarily saved backup data

    If backup completes normally, the temporarily saved backup data becomes unnecessary and is deleted.

    The following example deletes backup data that was temporarily saved in F:\mnt\usb.

    Example

    ```
    > rmdir /S /Q F:\mnt\usb\backup
    ```

If an instance has been stopped

1. Back up files

   If the disk at the backup data storage destination contains any required files, back up the files. It is not necessary to back up the backup data storage destination.

2. Temporarily save backup data

   Save the backup data to a different directory.

The reason for saving the backup data is so that the data in the data storage destination can be recovered even if it is corrupted before you perform the next step. If there is no disk at the save destination and you consider that there is no risk of corruption at the data storage destination, delete the backup data.

The following example saves backup data from the backup data storage destination directory (E:\backup\inst1) under F:\mnt\usb\backup.

Example

```
> mkdir F:\mnt\usb\backup
> move E:\backup\inst1\* F:\mnt\usb\backup
```

Note: Place the temporary backup destination directory in a location where it will not impact on operating system resources or Fujitsu Enterprise Postgres resources.

3. Stop applications

   Stop applications that are using the database.

4. Stop the instance

   Stop the instance. Refer to "2.1.2 Using Commands" for information on how to stop an instance.

   If the instance fails to stop, refer to "16.11 Actions in Response to Failure to Stop an Instance".

5. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

6. Create a backup data storage destination

   Create a backup data storage destination.

   In [Properties] in Windows(R) Explorer, set appropriate permissions so that only the instance administrator can access the backup data storage destination directory. (Refer to [Help and Support] in Windows(R) for information on [Properties].)

   Refer to "3.2.2 Using Server Commands" for details.

7. Start the instance

   Start the instance. Refer to "2.1.2 Using Commands" for information on how to start an instance.

8. Run backup

   Use the pgx_dmpall command to back up the database cluster.

   Specify the following value in the pgx_dmpall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

   Example

   ```
   > pgx_dmpall -D D:\database\inst1
   ```

9. Resume applications

   Resume applications that are using the database.

10. Restore files

    Restore the files backed up in step 1.

11. Delete temporarily saved backup data

    If backup completes normally, the temporarily saved backup data becomes unnecessary and is deleted.

    The following example deletes backup data that was temporarily saved in F:\mnt\usb.

    Example

    ```
    > rmdir /S /Q F:\mnt\usb\backup
    ```

See

- Refer to "pgx_rcvall" and "pgx_dmpall" in the Reference for information on the pgx_rcvall command and pgx_dmpall command.
- Refer to "Write Ahead Log" under "Server Administration" in the PostgreSQL Documentation for information on archive_command.
- Refer to "B.1 WAL Mirroring Control Functions" for information on the pgx_is_wal_multiplexing_paused and pgx_resume_wal_multiplexing.

16.8 Actions in Response to Insufficient Space on the Transaction Log Storage Destination

If the transaction log storage destination runs out of space, check if the disk contains any unnecessary files and delete them so that operations can continue.

If deleting unnecessary files does not solve the problem, you must migrate data to a disk with larger capacity.

16.8.1 Replacing the Disk with a Larger Capacity Disk

Before replacing the disk with a larger capacity disk, migrate resources at the transaction log storage destination using the backup and recovery features.

There are two methods of performing backup and recovery:

- 16.8.1.1 Using WebAdmin
- 16.8.1.2 Using Server Commands

The following sections describe procedures that use each of these methods to replace the disk and migrate resources at the transaction log storage destination.

Point

It is recommended that you back up the database cluster following recovery. Backup deletes obsolete archive logs (transaction logs copied to the backup data storage destination), freeing up disk space and reducing the recovery time.

16.8.1.1 Using WebAdmin

Follow the procedure below to replace the disk and migrate resources at the transaction log storage destination by using WebAdmin.

1. Back up files

   If the disk at the transaction log storage destination contains any required files, back up the files. It is not necessary to back up the transaction log storage destination.

2. Back up the database cluster

   Back up the latest data storage destination resources and transaction log storage destination resources (refer to "3.2.1 Using WebAdmin" for details).

3. Stop applications

   Stop applications that are using the database.

4. Stop the instance

   Stop the instance. Refer to "2.1.1 Using WebAdmin" for information on how to stop an instance. WebAdmin automatically stops instances if recovery of the database cluster is performed without stopping the instance.

5. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

6. Create a tablespace directory

   If a tablespace was defined after backing up, create a directory for it.

7. Recover the keystore, and enable automatic opening of the keystore

   Do the following if the data in the database has been encrypted:

   - Restore the keystore to its state at the time of the database backup.
   - Enable automatic opening of the keystore.

8. Recover the database cluster

   Log in to WebAdmin, and perform recovery operations. Refer to steps 4 ("Create a tablespace directory ") to 7 ("Run Recovery") under " If failure occurred in the data storage disk or the transaction log storage disk " in "16.1.1 Using WebAdmin" for information on the procedure. An instance is automatically started when recovery is successful.

9. Resume applications

   Resume applications that are using the database.

10. Restore files

    Restore the files backed up in step 1.

16.8.1.2 Using Server Commands

Follow the procedure below to replace the disk and migrate resources at the transaction log storage destination by using server commands.

1. Back up files

   If the disk at the transaction log storage destination contains any required files, back up the files. It is not necessary to back up the transaction log storage destination.

2. Back up the database cluster

   Use server commands to back up the latest data storage destination resources and transaction log storage destination resources. Refer to "3.2.2 Using Server Commands" for information on how to perform backup.

3. Stop applications

   Stop applications that are using the database.

4. Stop the instance

   After backup is complete, stop the instance. Refer to "2.1.2 Using Commands" for information on how to stop an instance.

   If the instance fails to stop, refer to "16.11 Actions in Response to Failure to Stop an Instance".

5. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

6. Create a transaction log storage destination

   Create a transaction log storage destination. If a tablespace was defined, also create a directory for it.

   In [Properties] in Windows(R) Explorer, set appropriate permissions so that only the instance administrator can access the transaction log destination directory. (Refer to [Help and Support] in Windows(R) for information on [Properties].)

7. Recover the keystore, and enable automatic opening of the keystore

   When the data in the database has been encrypted, restore the keystore to its state at the time of the database backup. Configure automatic opening of the keystore as necessary.

8. Recover the database cluster

   Use the pgx_rcvall command to recover the database cluster.

- Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
- Specify the backup storage directory in the -B option.

Example

```
> pgx_rcvall -D D:\database\inst1 -B E:\backup\inst1
```

If recovery fails

If recovery fails, remove the cause of the error in accordance with the displayed error message and then re-execute the pgx_rcvall command.

If the message "pgx_rcvall: an error occurred during recovery" is displayed, then the log recorded when recovery was executed is output after this message. The cause of the error is output in around the last fifteen lines of the log, so remove the cause of the error in accordance with the message and then re-execute the pgx_rcvall command.

Information

The following message displayed during recovery is output as part of normal operation of pgx_rcvall command (therefore the user does not need not be concerned).

```
FATAL:  the database system is starting up
```

See

Refer to "pgx_rcvall" in the Reference for information on the pgx_rcvall command.

9. Start the instance

   Start the instance.

   Refer to "2.1.2 Using Commands" for information on how to start an instance.

10. Resume applications

    Resume applications that are using the database.

11. Restore files

    Restore the files backed up in step 1.

16.9 Errors in More Than One Storage Disk

If an error occurs in the storage destination disks or resources are corrupted, determine the cause of the error from event logs and server logs and remove the cause.

If errors occur in either of the following combinations, you cannot recover the database.

Recreate the instance, and rebuild the runtime environment.

Data storage disk	Transaction log storage disk	Backup data storage disk
Error	-	Error
-	Error	Error

See

Refer to "Setup" in the Installation and Setup Guide for Server for information on how to create an instance and build the runtime environment.

16.10 Actions in Response to Instance Startup Failure

If an instance fails to start, refer to the event log and the server log, and determine the cause of the failure.

If using WebAdmin, remove the cause of the error. Then, click [Solution] and [Recheck the status] and confirm that the instance is in the normal state.

The following sections describe common causes of errors and the actions to take.

16.10.1 Errors in the Configuration File

If you have directly edited the configuration file using a text editor or changed the settings using WebAdmin, refer to the event log and the server log, confirm that no messages relating to the files below have been output.

- postgresql.conf
- pg_hba.conf

See

Refer to the following for information on the parameters in the configuration file:

- "Configuring Parameters" in the Installation and Setup Guide for Server
- "Appendix A Parameters"
- "Server Configuration" and "Client Authentication" under "Server Administration" in the PostgreSQL Documentation

16.10.2 Errors Caused by Power Failure or Mounting Issues

If mounting is cancelled after restarting the server, for example, because the disk device for each storage destination disk was not turned on, or because automatic mounting has not been set, then starting an instance will fail.

Refer to "16.14.2 Errors Caused by Power Failure or Mounting Issues", and take actions accordingly.

16.10.3 Other Errors

This section describes the recovery procedure to be used if you cannot take any action or the instance cannot start even after you have referred to the event log and the server log.

There are two methods of recovery:

- 16.10.3.1 Using WebAdmin
- 16.10.3.2 Using Server Commands

Note that recovery will not be possible if there is an error at the backup data storage destination. If the problem cannot be resolved, contact Fujitsu technical support.

16.10.3.1 Using WebAdmin

Follow the procedure below to perform recovery.

1. Delete the data storage destination directory and the transaction log storage destination directory

   Back up the data storage destination directory and the transaction log storage destination directory before deleting them.

2. Reconfirm the status

   Log in to WebAdmin, and in the [Instances] tab, click [Solution] for the error message.

   Click [Recheck the status] to reconfirm the storage destination resources.

3. Run recovery

   Restore the database cluster after WebAdmin detects an error.

   Refer to "16.2.1 Using WebAdmin" for details.

16.10.3.2 Using Server Commands

Follow the procedure below to recover the database.

1. Delete the data storage destination directory and the transaction log storage destination directory

   Save the data storage destination directory and the transaction log storage destination directory, and then delete them.

2. Execute recovery

   Use the pgx_rcvall command to recover the database cluster.

   Refer to "16.2.2 Using the pgx_rcvall Command" for details.

16.11 Actions in Response to Failure to Stop an Instance

If an instance fails to stop, refer to the event log and the server log, and determine the cause of the failure.

If the instance cannot stop despite taking action, perform the following operation to stop the instance.

There are two methods of recovery:

- 16.11.1 Using WebAdmin
- 16.11.2 Using Server Commands

16.11.1 Using WebAdmin

In the [Instances] tab, click and select the Fast stop mode or the Immediate stop mode to stop the instance. Forcibly terminate the server process from WebAdmin if the instance cannot be stopped.

Refer to "2.1.1 Using WebAdmin" for information on the stop modes.

16.11.2 Using Server Commands

There are three methods:

- Stopping the Instance Using the Fast Mode

  If backup is in progress, then terminate it, roll back all executing transactions, forcibly close client connections, and then stop the instance.

- Stopping the Instance Using the Immediate Mode

  Forcibly terminate the instance immediately. A crash recovery is run when the instance is restarted.

- Forcibly Stopping the Server Process

  Reliably stops the server process when the other methods are unsuccessful.

16.11.2.1 Stopping the Instance Using the Fast Mode

Specify "-m fast" in the pg_ctl command to stop the instance.

If the instance fails to stop when you use this method, stop the instance as described in "16.11.2.2 Stopping the Instance Using the Immediate Mode" or "16.11.2.3 Forcibly Stopping the Server Process".

Example

```
> pg_ctl stop -D D:\database\inst1 -m fast
```

16.11.2.2 Stopping the Instance Using the Immediate Mode

Specify "-m immediate " in the pg_ctl command to stop the instance.

If the instance fails to stop when you use this method, stop the instance as described in "16.11.2.3 Forcibly Stopping the Server Process".

Example

```
> pg_ctl stop -D D:\database\inst1 -m immediate
```

16.11.2.3 Forcibly Stopping the Server Process

If both the Fast mode and the Immediate mode fail to stop the instance, use the kill parameter of the pg_ctl command to forcibly stop the server process.

The procedure is as follows:

1. Execute the wmic command to identify the process ID of the server process.

   ```
   c:\>wmic
   wmic:root\cli>process where "name = \"postgres.exe\"" get CommandLine,Name,ProcessId
   CommandLine                                                                    Name
   ProcessId
   :
   "C:\Program Files\Fujitsu\fsepv<x>server64\bin\postgres.exe" -D "D:\database\inst1"
   postgres.exe  896
   :
   ```

   The postgres.exe process ID(896) that indicates the data storage destination directory of the applicable instance in the -D option becomes the server process.

2. Forcibly stop the server process

   As instance manager, forcibly stop the server process using the pg_ctl command.

   ```
   c:\>pg_ctl kill QUIT 896
   ```

16.12 Actions in Response to Failure to Create a Streaming Replication Standby Instance

When creating a streaming replication standby instance using WebAdmin, if the instance creation fails, refer to the event log and the server log, and determine the cause of the failure.

When an error occurs in the creation of the standby instance using WebAdmin, it is unlikely that the partially created standby instance can be resumed to complete the operation.

In such a scenario, fix the cause of the error, delete the partially created standby instance, and then create a new standby instance. This recommendation is based on the following assumptions:

- As the instance is yet to be created completely, there are no applications connecting to the database.
- The standby instance is in error state and is not running.
- There are no backups for the standby instance and as a result, it cannot be recovered.

See

Refer to "Deleting Instances" in the Installation and Setup Guide for details on how to delete an instance.

16.13 Actions in Response to Error in a Distributed Transaction

If a system failure (such as server failure) occurs in an application that uses distributed transactions (such as .NET TransactionScope), then transactions may be changed to the in-doubt state.

At that point, resources accessed by the transaction will be locked, and rendered unusable by other transactions.

The following describes how to check for in-doubt transactions, and how to resolve them.

How to check for in-doubt transactions

The following shows how to check for them:

If the server fails

1. An in-doubt transaction will have occurred if a message similar to the one below is output to the log when the server is restarted.

   Example

   ```
   LOG: Restoring prepared transaction 2103.
   ```

2. Refer to system view pg_prepared_xacts to obtain information about the prepared transaction.

   If the transaction identifier of the prepared transaction in the list (in the transaction column of pg_prepared_xacts) is the same as the identifier of the in-doubt transaction obtained from the log output when the server was restarted, then that row is the information about the in-doubt transaction.

   Example

   ```
   postgres=# select * from pg_prepared_xacts;
    transaction |   gid     |   prepared |  owner   | database
   -------------+-----------+------------+----------+----------
   2103 | 374cc221-f6dc-4b73-9d62-d4fec9b430cd | 2022-03-06 16:28:48.471+08 | postgres |
   postgres (1 row)
   ```

   Information about the in-doubt transaction is output to the row with the transaction ID 2103 in the transaction column.

If the client fails

If there are no clients connected and there is a prepared transaction in pg_prepared_xacts, then you can determine that the transaction is in the in-doubt state.

If at least one client is connected and there is a prepared transaction in pg_prepared_xacts, you cannot determine whether there is a transaction in the in-doubt state. In this case, use the following query to determine the in-doubt transaction from the acquired database name, user name, the time PREPARE TRANSACTION was executed, and the information about the table name accessed.

```
select gid,x.database,owner,prepared,l.relation::regclass as relation from pg_prepared_xacts x
left join pg_locks l on l.virtualtransaction = '-1/'||x.transaction and l.locktype='relation';
```

If it still cannot be determined from this information, wait a few moments and then check pg_prepared_xacts again.

If there is a transaction that has continued since the last time you checked, then it is likely that it is the one in the in-doubt state.

Point

As you can see from the explanations in this section, there is no one way to definitively determine in-doubt transactions.

Consider collecting other supplementary information (for example, logging on the client) or performing other operations (for example, allocating database users per job).

How to resolve in-doubt transactions

From the system view pg_prepared_xacts mentioned above, obtain the global transaction identifier (in the gid column of pg_prepared_xacts) for the in-doubt transaction, and issue either a ROLLBACK PREPARED statement or COMMIT PREPARED statement to resolve the in-doubt transaction.

- Rolling back in-doubt transactions

```
postgres=# rollback prepared '374cc221-f6dc-4b73-9d62-d4fec9b430cd';
ROLLBACK PREPARED
```

- Committing in-doubt transactions

```
postgres=# commit prepared '374cc221-f6dc-4b73-9d62-d4fec9b430cd';
COMMIT PREPARED
```

16.14 I/O Errors Other than Disk Failure

Even if a disk is not defective, the same input-output error messages, as those generated when the disk is defective, may be output.

A few examples of such errors are given below. The appropriate action for each error is explained respectively.

- 16.14.1 Network Error with an External Disk
- 16.14.2 Errors Caused by Power Failure or Mounting Issues

16.14.1 Network Error with an External Disk

This is an error that occurs in the network path to/from an external disk.

Determine the cause of the error by checking the information in the event log and the server log, the disk access LED, network wiring, and network card status. Take appropriate action to remove the cause of the error, for example, replace problematic devices.

16.14.2 Errors Caused by Power Failure or Mounting Issues

These are errors that occur when the disk device is not turned on, automatic mounting of the disk was not set, or mounting was accidentally cancelled.

In this case, check the information in the event log and the server log, the disk access LED, and whether the disk is mounted correctly. If problems are detected, take appropriate action.

If mounting has been cancelled, it is possible that mounting was accidentally cancelled, or the existing setting (automatic mounting at the time of starting the operating system) has been changed so that mounting is not performed automatically. In this case, set the mounting to be performed automatically.

16.15 Anomaly Detection and Resolution

The following operations performed via the command line interface will result in an anomaly in WebAdmin:

- Changes to the port and backup_destination parameters in postgresql.conf
- Changes to Mirroring Controller configuration of cluster replication added via WebAdmin

This section describes when WebAdmin checks for such anomalies, and what takes place when an anomaly is detected.

16.15.1 Port Number and Backup Storage Path Anomalies

An anomaly occurs when the value of [Port number] and/or [Backup storage path] in WebAdmin is different from the value of its corresponding parameter in postgresql.conf - port and backup_destination, respectively.

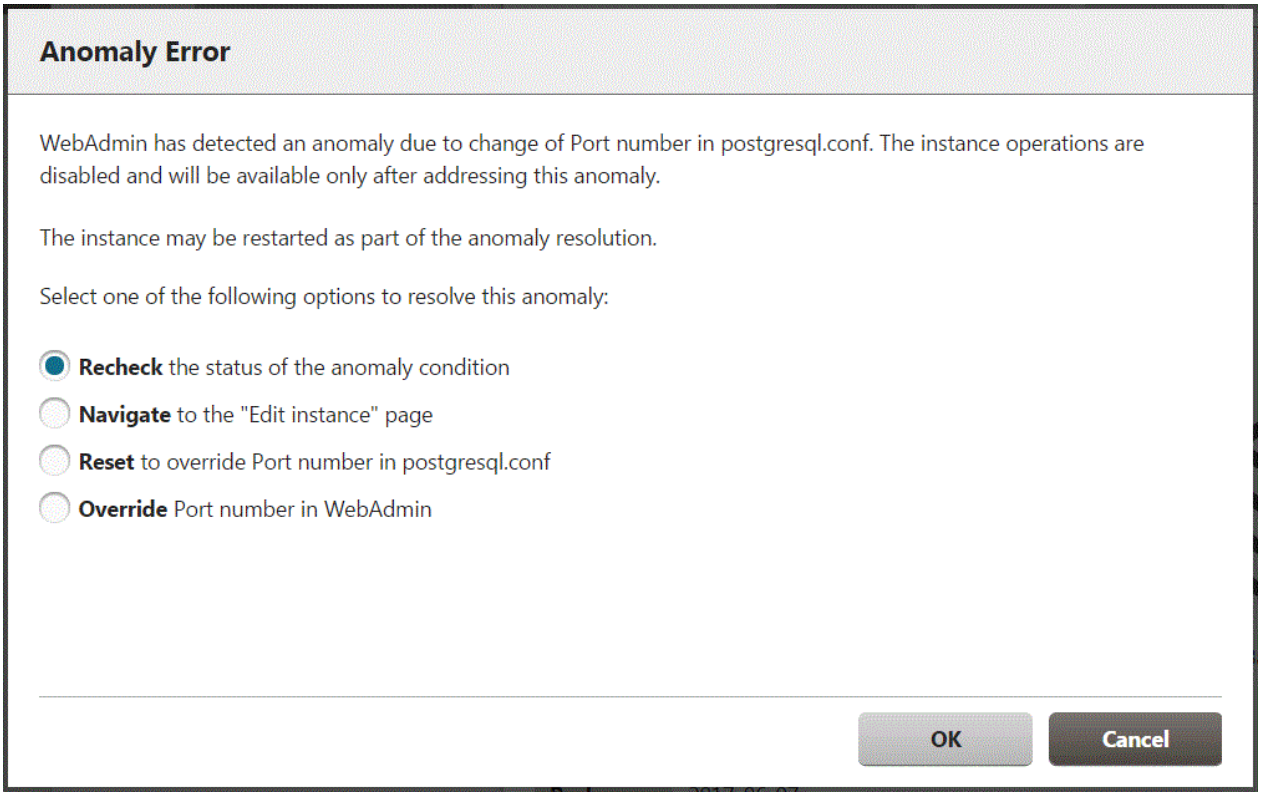
WebAdmin checks for anomalies when an instance is selected for viewing or any instance operation is performed. Anomalies will be identified for the selected instance only.

The following occurs when an anomaly is detected in port number and/or backup storage path:

- All instance operation buttons are disabled, except for "Edit instance", "Refresh instance", and "Delete Mirroring Controller"
- A red error status indicator is displayed on the instance icon
- For an anomaly specific to backup storage path, a red error status indicator is displayed on the [Backup storage] disk icon, and [Backup storage status] is set to "Error"
- The message, "WebAdmin has detected an anomaly with...", is displayed in the [Message] section along with an associated [Solution] button

Critical errors encountered during anomaly resolution will be displayed, however, rollback of the instance to its previous state is not supported.

Click [Solution]. The [Anomaly Error] dialog box is displayed.



Select the required option, click [OK], and then resolve the anomaly error.

Refer to "Editing instance information" in the Installation and Setup Guide for Server for information on the [Edit instance] page.

16.15.2 Mirroring Controller Anomalies

The following conditions will cause a Mirroring Controller anomaly:

- The Mirroring Controller management folder or configuration files have been deleted
- The permissions to the Mirroring Controller management folder or configuration files have been changed such that:
  - The instance administrator's access to Mirroring Controller configuration is denied

- Users other than an instance administrator have access privileges to Mirroring Controller configuration files

WebAdmin checks for anomalies when Mirroring Controller status check is performed.

The following occurs when a Mirroring Controller anomaly is detected:

- All Mirroring Controller functionality is disabled for the replication cluster, except for "Delete Mirroring Controller"
- [Mirroring Controller status] is set to "Error"
- Either of the following messages is displayed in the [Message] section

  "Failed to access the Mirroring Controller management folder or configuration files '*path*'. Mirroring Controller functionality has been disabled. Consider deleting Mirroring Controller and adding it again."

  "Failed to find the Mirroring Controller management folder or configuration files '*path*'. Mirroring Controller functionality has been disabled. Consider deleting Mirroring Controller and adding it again."

Appendix A Parameters

This appendix describes the parameters to be set in the postgresql.conf file of Fujitsu Enterprise Postgres.

The postgresql.conf file is located in the data storage destination.

Information

The maximum value that can be expressed as a 4-byte signed integer changes according to the operating system. Follow the definition of the operating system in use.

Specify Path

Note the following when specifying the path:

- Specify \\ as the path delimiter.
- Enclose the path in double quotes (") if it contains spaces.

- core_directory (string)

  This parameter specifies the directory where the corefile is to be output. If this parameter is omitted, the data storage destination is used by default. This parameter can only be set when specified on starting an instance. It cannot be changed dynamically, while an instance is active.

- core_contents (string)

  This parameter specifies the contents to be included in the corefile.

  - full: Outputs all contents of the server process memory to the corefile.
  - none: Does not output a corefile.
  - minimum: Outputs only non-shared memory server processes to the corefile. This reduces the size of the corefile. However, in some cases, this file may not contain sufficient information for examining the factor that caused the corefile to be output.

  If this parameter is omitted, "minimum" is used by default. This parameter can only be set when specified on starting an instance. It cannot be changed dynamically, while an instance is active.

- keystore_location (string)

  This parameter specifies the directory that stores the keystore file. Specify a different location from other database clusters. This parameter can only be set when specified on starting an instance. It cannot be changed dynamically, while an instance is active.

- tablespace_encryption_algorithm (string)

  This parameter specifies the encryption algorithm for tablespaces that will be created. Valid values are "AES128", "AES256", and "none". If you specify "none", encryption is not performed. The default value is "none". To perform encryption, it is recommended that you specify "AES256". Only superusers can change this setting.

- backup_destination (string)

  This parameter specifies the absolute path of the directory where pgx_dmpall will store the backup data. Specify a different location from other database clusters. This parameter can only be set when specified on starting an instance. It cannot be changed dynamically, while an instance is active.

  Place this directory on a different disk from the data directory to be backed up and the tablespace directory. Ensure that users do not store arbitrary files in this directory, because the contents of this directory are managed by the database system.

- search_path (string)

  When using the SUBSTR function compatible with Oracle databases, set "oracle" and "pg_catalog" in the search_path parameter. You must specify "oracle" before "pg_catalog".

Example

```
search_path = '"$user", public, oracle, pg_catalog'
```

Information

- The search_path feature specifies the priority of the schema search path. The SUBSTR function in Oracle database is defined in the oracle schema.
- Refer to "Statement Behavior" under "Server Administration" in the PostgreSQL Documentation for information on search_path.

- track_waits (string)

  This parameter enables collection of statistics for pgx_stat_lwlock and pgx_stat_latch.

  - on: Enables collection of statistics.
  - off: Disables collection of statistics.

  If this parameter is omitted, "on" is assumed.

  Only superusers can change this setting.

- track_sql (string)

  This parameter enables collection of statistics for pgx_stat_sql.

  - on: Enables collection of statistics.
  - off: Disables collection of statistics.

  If this parameter is omitted, "on" is assumed.

  Only superusers can change this setting.

Parameters for the in-memory feature

- reserve_buffer_ratio (numerical value)

  This parameter specifies the proportion of shared memory to be used for a stable buffer table.

  - Minimum value: 0
  - Maximum value: 80

  If this parameter is omitted, 0 will be used.

- vci.cost_threshold (numerical value)

  This parameter specifies the lowest cost that selects an execution plan that uses a VCI. If the cost of the best execution plan that does not use a VCI is lower than this value, that execution plan will be selected.

  - Minimum value: 0
  - Maximum value: Maximum value that can be expressed as a 4-byte signed integer

  If this parameter is omitted or a value outside this range is specified, 18000 will be used.

- vci.control_max_workers (numerical value)

  This parameter specifies the number of background workers that manage VCI. The number of workers for the entire instance is limited by max_worker_processes, so add the value specified here to max_worker_processes.

  - Minimum value: 1
  - Maximum value: 8388607

  If this parameter is omitted or a value outside this range is specified, 8 will be used.

- vci.enable (string)

  This parameter enables or disables VCI.

  - on: Enables VCI.
  - off: Disables VCI.

  If this parameter is omitted, "on" will be used.

- vci.log_query (string)

  This parameter enables or disables log output when VCI is not used due to insufficient memory specified by vci.max_local_ros.

  - on: Enables log output.
  - off: Disables log output.

  If this parameter is omitted, "off" will be used.

- vci.maintenance_work_mem (numerical value)

  This parameter specifies the maximum memory size used for maintenance of VCI (when executing CREATE INDEX, for example).

  - Minimum value: 1 MB
  - Maximum value: Maximum value that can be expressed as a 4-byte signed integer / 1024

  If this parameter is omitted or a value outside this range is specified, 256 MB will be used.

- vci.max_local_ros (numerical value)

  This parameter specifies the maximum memory size used for VCI scan.

  - Minimum value: 64 MB
  - Maximum value: Maximum value that can be expressed as a 4-byte signed integer

  If this parameter is omitted or a value outside this range is specified, 64 MB will be used.

- vci.max_parallel_degree (numerical value)

  This parameter specifies the maximum number of background workers used for parallel scan. The number of workers for the entire instance is limited by max_worker_processes, so add the value specified here to max_worker_processes.

  A value from -8388607 to 8388607 can be specified.

  - Integer (1 or greater): Parallel scan is performed using the specified degree of parallelism.
  - 0: Stops the parallel scan process.
  - Negative number: The specified value minus the maximum number of CPUs obtained from the environment is used as the degree of parallelism and parallel scan is performed.

  If this parameter is omitted or a value outside this range is specified, 0 will be used.

- vci.shared_work_mem (numerical value)

  This parameter specifies the maximum memory size used for VCI parallel scan.

  - Minimum value: 32 MB
  - Maximum value: Maximum value that can be expressed as a 4-byte signed integer

  If this parameter is omitted or a value outside this range is specified, 1 GB will be used.

- vci.smc_directory (string)

  This parameter specifies a directory name in which a temporary file is created as the dynamic shared memory during a scan using a VCI.

  If this parameter is omitted, a directory (*dataStorageDir*\\base\\pgsql_tmp) under the data storage directory will be used.

Parameters for the Global Meta Cache feature

- pgx_global_metacache (numerical value)

  Specifies the memory size of the GMC area.

  Specify a value calculated by the formula below.

  A value lower than the calculated value will still work, but the meta cache may not be able to fit into the GMC area.

  In this case, the system will discard the meta cache it thinks it is no longer needed, but if it is needed again, the meta cache will need to be expanded and will not perform well.

  If the value is less than 10 MB and is set to a nonzero value that disables the feature, the database startup fails because the Global Meta Cache feature cannot operate.

  A setting of 0 disables the Global Meta Cache feature. The default is 0.

  Changing this setting requires restarting the database.

```
Size of GMC area
 = Max(10MB,
     (All user table x 0.4 KB
      + All user Indexes x 0.3 KB
      + All user columns x 0.8 KB) x 1.5 (*1) )

*1) Safety Factor (1.5)
This value takes into account the case where both GMC before and after the change temporarily exist
at the same time in shared memory when the table definition is changed or the row of the system
catalog is changed.
```

- track_gmc (string)

  This parameter enables collection of statistics for pgx_stat_gmc.

  - on: Enables collection of statistics.
  - off: Disables collection of statistics.

  If this parameter is omitted, "on" is used.

  Only superusers can change this setting.

Parameters for the Local Meta Cache Limit feature

- pgx_catalog_cache_max_size(numerical value)

  Specifies the maximum amount of memory that the backend process should use as the catalog cache.

  You can enable catalog cache deletion by setting it to 8 KB or more.

  A setting of 0 disables the catalog cache removal. The default is 0.

  If no units are specified, they are treated as KB.

  - Minimum value: 8KB
  - Maximum value: Maximum value that can be expressed as a 4-byte signed integer

  When calculating the parameter settings, the factors that determine the cache size are calculated as the number of tables, the number of indexes, and the number of columns. What is kept as a catalog cache or relation cache also includes objects such as databases, roles, or procedures, but these are small compared to the above factors and do not need to be factored into them. It also includes a calculation method for pgx_relacion_cache_max_size because the given memory is distributed between the catalog cache and the relation cache.

  The calculation method here assumes that all backends have similar access and that the transaction also has access to a similar number of resources. If you have a small number of singular backends or transactions, consider excluding them as errors.

  1. Determine how much memory a backend process can use. Decide by subtracting the memory size required by the entire system such as the database cache from the installed memory and dividing the rest by the number of connections.
  2. For best performance, use the following formula to calculate the total memory size of the catalog cache when the backend holds the catalog cache for all resources accessed during its lifetime.

The amount of memory varies depending on whether Global Meta Cache is enabled or disabled. Enabling Global Meta Cache reduces the amount of memory required because most of the cache is located on shared memory.

```
When Global Meta Cache is enabled:
  (Number of tables to access + Number of indexes to access + Number of columns to access)
      × 0.1KB × 1.5 (*1)
When Global Meta Cache is disabled:
  { Number of tables to access × 0.5KB(pg_class tuple size)
      + Number of indexes to access × 0.5KB(pg_index tuple size)
      + Number of columns to access × 1.0KB(pg_statistic tuple size)} × 1.5 (*1)

*1) Safety Factor (1.5)
The system catalog contains columns with variable-length types. For example, the tuple size in
pg_class is a constant value multiplied by the number of tables, while relname in pg_class is
variable length data.
It is not practical to calculate every definition in detail, so we added 50% to the above
formula.
```

3. In the same way as in 2., calculate the relation cache using the following formula.

   ```
   (1.4KB × Number of tables to access + 2.4KB × Number of indexes to access) × 1.5 (*1)

   *1) Safety Factor (1.5)
   The relation cache is structured to facilitate the use of table and index definitions, holds
   pointers to various objects, and is sized to include them. It is variable length because the
   type of object allocated by the table definition and its size change. Since it is not
   realistic to calculate for all definitions, 50% is added.
   ```

4. If the value of 1. ≥ the value of 2. + the value of 3., the backend process can keep all caches to the extent allowed, so there is no need to limit the caches. If you want to cap for safety, set the value of 2. to pgx_catalog_cache_max_size and the value of 3. to pgx_relation_cache_max_size.
5. If the value of 1. < the value of 2. + the value of 3. then you need to limit the cache. However, this parameter does not limit the size of the cache used by a transaction. Therefore, take the following steps.
6. Calculate the catalog cache used by a transaction using the formula in 2.
7. Calculate the relation cache used by a transaction using the formula in 3.
8. If the value of 1. < the value of 6. + the value of 7., then the value of 1. needs to be increased. In other words, in some cases, it may be necessary to increase the installed memory or reduce the number of connections.
9. If the value of 1. ≥ the value of 6. + the value of 7., the condition of 1. can be satisfied by limiting the cache with this parameter. Divide the value of 1. by the ratio of 2. and 3. and set it as a parameter. Set the value distributed to 2. to pgx_catalog_cache_max_size and the value distributed to 3. to pgx_relation_cache_max_size.
10. The value calculated in 9. is a provisional value. If you cannot meet your target performance, first try to shift the focus of allocation to the relation cache. This is because when executing SQL, the relation cache generated based on the catalog cache is mainly referenced, so it is advantageous to leave a large amount of relation cache. If the performance is still not satisfied, adjust the parameters by referring to "14.1.4 Performance Impact and Parameter Tuning of the Local Meta Cache Limit Feature".

For Partitioning

Be careful when partitioning the table.

The cached definition changes depending on whether the parent table is specified in the SQL statement or the child table is specified. In particular, note that if you specify a parent table, the definitions of all child tables are cached. This is because when you specify a parent table in an SQL statement, you need to know the definitions of all the child tables in order to determine which child table will contain the desired data. Note that the column information of the parent table is not cached.

When specifying the parent table:

```
Number of tables to access = Number of parent tables to access + Number of defined child tables
Number of columns = Number of defined columns x number of defined child tables
```

When specifying the child table directly:

```
Number of tables to access = Number of child tables actually accessed
Number of columns = Number of defined columns x number of child tables actually accessed
```

Example)

Suppose the parent table T (1 index, 3 columns) is split from child tables T1 to T5 (1 index, 3 columns, respectively). If the parent table T is specified in SQL, when the child tables that contain the data to be queried are limited to T1 and T2, and when accessing the data using the indexes defined by T1 and T2, calculate as follows.

```
Number of tables = 1(parent table) + 5(child table) = 6
Number of indexes = 2 (index to access)
Number of columns = 3 (number of columns) x 5 (child table) = 15
```

If you specify child tables T1 and T2 in SQL and use the indexes defined on T1 and T2 when accessing data, the calculation is as follows.

```
Number of tables = 2(child table)
Number of indexes = 2 (index to access)
Number of columns = 3 (number of columns) x 2 (child table) = 6
```

- pgx_relation_cache_max_size(numerical value)

  Specifies the maximum amount of memory that the backend process should use as the relation cache.

  You can enable catalog cache deletion by setting it to 8 KB or more.

  A setting of 0 disables the relation cache removal. The default is 0.

  If no units are specified, they are treated as KB.

  - Minimum value: 8KB
  - Maximum value: Maximum value that can be expressed as a 4-byte signed integer

  For the calculation method for parameter setting, refer to the calculation method of pgx_catalog_cache_max_size.

- pgx_cache_hit_log_interval(numerical value)

  Specifies the time interval to output a message indicating the cache reference status for each backend process.

  When the transaction ends, if the time set in this parameter has elapsed since the previous message was output, the message is output.

  If set to 0, a message will be output each time the transaction ends.

  Setting -1 disables the output. The default value is 10min.

  If no units are specified, they are treated as ms.

  Even if pgx_catalog_cache_max_size and pgx_relation_cache_max_size are disabled, the message output of the corresponding cache will be invalid.

  Immediately after connecting to the server, a small transaction occurs before the request from the user application, such as for user authentication. Since it is meaningless to know the hit rate for these, a message will be output at the end of the transaction that started after the time set in this parameter has elapsed after connecting to the server.

  For the same reason, setting a small value such as 0 may result in a message being printed at the end of such a small transaction.

  You can check which transaction the message corresponds to from the information output at the beginning.

  This information depends on the setting of the parameter log_line_prefix.

  - Minimum value: 0
  - Maximum value: 2147483647ms

See

Refer to "Server Configuration" under "Server Administration" in the PostgreSQL Documentation for information on other postgresql.conf parameters.

Parameters for the Policy-based Login Security

- userprofile_database(string)

  Specifies the name of the database to which the background worker process connects. This parameter must specify a connectable database name. If you omit this parameter, then it is assumed to be "postgres".

  The pseudo database "replication" cannot be specified for streaming replication.

  If you change this parameter, reload the configuration file.

Parameters for using OpenSSL legacy algorithms

- openssl_conf(string)

  Specifies the OpenSSL configuration file. Specifying a valid configuration file makes legacy algorithms available. Use the example below to prepare the configuration file in any directory.

  If this parameter is not specified, the empty string is assumed.

  This parameter can only be set by specifying the parameter at instance startup.

  You cannot make dynamic changes during instance startup.

  ## Example

  openssl_conf = 'openssl.conf'

  [OpenSSL Configuration File (openssl.conf) Example]

  ```
  ====================
  openssl_conf = openssl_init

  [openssl_init]
  providers = provider_sect

  [provider_sect]
  default = default_sect
  legacy = legacy_sect

  [default_sect]
  activate = 1

  [legacy_sect]
  activate = 1
  ====================
  ```

- openssl_modules(string)

  Specifies the directory that contains additional OpenSSL modules.

  Legacy algorithms are available by specifying 'server installation directory\lib\ossl-modules'.

  If this parameter is not specified, the empty string is assumed.

  This parameter can only be set by specifying the parameter at instance startup.

  You cannot make dynamic changes during instance startup.

This parameter sets the OPENSSL_MODULES environment variable to be applied to the server process. Do not set the OPENSSL_MODULES environment variable in any way other than setting this parameter, as this may cause abnormal behavior.

Example

openssl_modules = 'c:\Program Files\Fujitsu\fsepv<*x*>server64\lib\ossl-modules'

Note that "<*x*>" indicates the product version.

Information

Legacy algorithms include the following encryption algorithms:

- BF
- CAST5
- DES-ECB
- DES-CBC
- MD4
- Whirlpool

Parameters for scheduling aggressive freeze for tuples

- pgx_stat_vacuum_freeze.track_freeze_info (boolean)

  Collects and maintains information about aggressive freeze for tuples. The default is on.

  - on: Enables information collection.
  - off: Disables information collection.

- pgx_stat_vacuum_freeze.monitoring_interval (numerical value)

  Aggregate statistics for aggressive freeze for tuples in this interval, so that statistics for each interval can be obtained in the pgx_stat_freeze_results table. Note that an aggressive freeze for tuples across this interval will still account for the overall tuple freeze at completion time. The default is 1hour.

  Set the aggressive freeze for tuples script to run at weekly intervals of days, daily intervals of hours, and hourly intervals of minutes.

  - Minimum value: 1min
  - Maximum value: 1d

  If a value out of range is specified, 1h is set.

  If this parameter is omitted, 1h is assumed.

- pgx_stat_vacuum_freeze.log_retention_period (numerical value)

  Specify how long statistics are kept. The default is 90 days.

  Set the period according to the work cycle. For example, if a monthly batch is to be processed every 1 month, set it to 90 days, which is approximately 3 times that period. to capture changes in the aggressive freeze for tuples over the duration of the cycle.

  - Minimum value: 1d
  - Maximum value: 180d

  If an out-of-range value is specified, 90d is set.

  If this parameter is omitted, 90d is assumed.

Appendix B System Administration Functions

This appendix describes the system administration functions of Fujitsu Enterprise Postgres.

See

Refer to "System Administration Functions" under "The SQL Language" in the PostgreSQL Documentation for information on other system administration functions.

B.1 WAL Mirroring Control Functions

The following table lists the functions that can be used for backup and recovery based on WAL mirroring.

Table B.1 WAL mirroring control functions

Name	Return type	Description
pgx_pause_wal_multiplexing()	void	Stops WAL multiplexing
pgx_resume_wal_multiplexing()	void	Resumes WAL multiplexing
pgx_is_wal_multiplexing_paused()	boolean	Returns true if WAL multiplexing has stopped

If WAL multiplexing has not been configured, these functions return an error. Setting the backup_destination parameter in postgresql.conf configures WAL multiplexing.

Only superusers can execute these functions.

B.2 Transparent Data Encryption Control Functions

The following table lists the functions that can be used for transparent data encryption.

Table B.2 Transparent data encryption control functions

Name	Return type	Description
pgx_open_keystore(*passphrase*)	void	Opens the keystore
pgx_set_master_key(*passphrase*)	void	Sets the master encryption key
pgx_set_keystore_passphrase(*oldPassphrase*, *newPassphrase*)	void	Changes the keystore passphrase

B.2.1 pgx_open_keystore

The pgx_open_keystore function uses the specified passphrase to open the keystore. When the keystore is opened, the master encryption key is loaded into the database server memory. In this way, you can access the encrypted data and create encrypted tablespaces. If the keystore is already open, this function returns an error.

Only superusers can execute this function. Also, this function cannot be executed within a transaction block.

B.2.2 pgx_set_master_key

The pgx_set_master_key function generates a master encryption key and stores it in keystore.

If the keystore does not exist, this function creates a keystore. If the keystore already exists, this function modifies the master encryption key. If the keystore has not been opened, this function opens it.

The passphrase is a string of 8 to 200 bytes.

Only superusers can execute this function. Also, this function cannot be executed within a transaction block. Processing is not affected by whether the keystore is open.

B.2.3 pgx_set_keystore_passphrase

The pgx_set_keystore_passphrase function changes the keystore passphrase.

Specify the current passphrase in *oldPassphrase*, and a new passphrase in *newPassphrase*.

The passphrase is a string of 8 to 200 bytes.

Only superusers can execute this function. Also, this function cannot be executed within a transaction block. Processing is not affected by whether the keystore is open.

B.3 Profile Management Functions and User Management Functions

The table below lists the profile management functions and user management functions used in policy-based login security.

B.3.1 Profile Management Functions

Name	Return type	Description

pgx_create_profile(profile_name name, password_parameter json)	void	Create a new profile.
		For profile_name, specify the profile name. An error will occur if an existing profile name is specified.
		For password_parameter, specify parameters and values in key-value format as follows.
		`'{`
		`"INACTIVE_USER_TIME": 15,`
		`"PASSWORD_LIFE_TIME": 30,`
		`"PASSWORD_GRACE_TIME": "UNLIMITED",`
		`"PASSWORD_REUSE_TIME": 10,`
		`"PASSWORD_REUSE_MAX": 5,`
		`"PASSWORD_LOCK_TIME": 0.5,`
		`"FAILED_LOGIN_ATTEMPTS": "DEFAULT",`
		`"PASSWORD_ALLOW_HASHED": true,`
		`"PASSWORD_ROLLOVER_TIME": 0.125`
		`}');`
		The json value accepts integer, numeric, boolean depending on the parameter, but only accepts strings "DEFAULT" and "UNLIMITED" as special values.
		For parameters that are omitted in json or that specify null for value, they follow the values in the default profile.Also, password_parameter can be omitted, and if omitted, a profile with all parameters conforming to the default profile will be created.

pgx_alter_profile(profile_name name, alter_parameter json)	void	Update the contents of an existing profile. For profile_name, specify the name of the profile to update. If you specify a profile name that does not exist, an error will occur. In alter_parameter, specify the variable name and value you want to change in key-value format as follows. Does not change the profile contents for parameters that are omitted or for which value is null.

Name	Return type	Description
		'{ "name": "new_name", "PASSWORD_LIFE_TIME": 50, "PASSWORD_GRACE_TIME": 10 }'); name: Specify the modified profile name. null cannot be specified. If the default profile is specified in profile_name, the following changes cannot be made. - Change name - Change each password_parameter to "DEFAULT"
pgx_drop_profile(profile_name name, if_exists boolean, cascade boolean)	void	Delete an existing profile. Specify the profile name to be deleted in profile_name. Specifying the default profile will result in an error. if_exists specifies whether an error occurs when a nonexistent profile name is specified in profile_name. If true, no error. if_exists is optional. Default value is false. cascade specifies whether an error occurs when a profile assigned to a user is specified in profile_name. If false, an error will occur. If true, unassign all of the profiles before deleting them, and any unassigned users will be assigned the default profile instead. cascade is optional. Default value is false. [Example when specifying true] Specify arguments explicitly. (Example of named notation) SELECT pgx_drop_profile('test_profile', cascade => true);

B.3.2 User Management Functions

Name	Return type	Description
pgx_assign_profile_to_user(user_name name, profile_name name)	void	Assigns an existing profile to a user. Specify the assignee user in user_name. If you specify a user name that does not exist, an error will occur. Specify the profile name to be assigned in profile_name. If you specify a profile name that does not exist, an error will occur.
pgx_lock_user(user_name name)	void	Lock the user explicitly. Specify the user name in user_name. If you specify a user name that does not exist, an error will occur. If locked by this function, the lock period is indefinite. If you want to unlock it, you need to unlock it with the pgx_unlock_user function. If you lock a user that is already locked, the lock state is overwritten and becomes an indefinite lock even if it was previously a finite lock.
pgx_unlock_user(user_name name)	void	Explicitly unlock the user. The type of lock (profile reference lock or permanent lock) does not matter. Specify the user name in user_name. If you specify a user name that does not exist, an error will occur.

Name	Return type	Description
		Specifying an unlocked user does not result in an error.
pgx_make_password_expire(user_name name, expireat timestamptz)	void	Expires the specified user's password immediately. Alternatively, specify the time to expire. Specify the user name in user_name. If you specify a user name that does not exist, an error will occur. expireat can be a time that expires.expireat is optional. If omitted, execution time is specified.
pgx_make_password_rollover_expire(user_name name)	void	Expires immediately the period during which the specified user's old and new passwords can be used together so that the user cannot log in with the old password. Specify the user name in user_name. If you specify a user name that does not exist, an error will occur. If this command is executed outside the period for using the old and new passwords, it is ignored.

B.4 Data Masking Control Functions

The table below lists the functions that can be used for data masking.

Table B.3 Data masking control functions

Name	Return type	Description
pgx_alter_confidential_policy	boolean	Changes masking policies
pgx_create_confidential_policy	boolean	Creates masking policies
pgx_drop_confidential_policy	boolean	Deletes masking policies
pgx_enable_confidential_policy	boolean	Enables or disables masking policies
pgx_update_confidential_values	boolean	Changes replacement characters when full masking is specified for masking type

B.4.1 pgx_alter_confidential_policy

Description

Changes masking policies

Format

The format varies depending on the content to be changed. The format is shown below.

- Common format

```
common_arg:
[schema_name    := 'schemaName',]
table_name    := 'tableName',
policy_name     := 'policyName'
```

- Add a masking target to a masking policy

```
pgx_alter_confidential_policy(
commonArg,
[action        := 'ADD_COLUMN', ]
column_name    := 'colName'
```

```
[, function_type    := 'FULL'] |
[, function_type    := 'PARTIAL', partialOpt] |
[, function_type    := 'REGEXP', regexpOpt]
)

partialOpt:
function_parameters    := 'maskingFmt'

regexpOpt:
regexp_pattern        := 'regexpPattern',
regexp_replacement    := 'regexpReplacementChar',
[, regexp_flags        := 'regexpFlags']
```

- Delete a masking target from a masking policy

```
pgx_alter_confidential_policy(
commonArg,
action        := 'DROP_COLUMN',
column_name    := 'colName'
)
```

- Change the masking condition

```
pgx_alter_confidential_policy(
commonArg,
action        := 'MODIFY_EXPRESSION',
expression    := 'expr'
)
```

- Change the content of a masking policy set for a masking target

```
pgx_alter_confidential_policy(
commonArg,
action        := 'MODIFY_COLUMN',
column_name    := 'colName'
[, function_type    := 'FULL'] |
[, function_type    := 'PARTIAL', partialOpt] |
[, function_type    := 'REGEXP', regexpOpt]
)

partialOpt:
function_parameters    := 'maskingFmt'

regexpOpt:
regexp_pattern        := 'regexpPattern',
regexp_replacement        := 'regexpReplacementChar',
[, regexp_flags        := 'regexpFlags']
```

- Change the masking policy description

```
pgx_alter_confidential_policy(
commonArg,
action        := 'SET_POLICY_DESCRIPTION',
policy_description    := 'policyDesc'
)
```

- Change the masking target description

```
pgx_alter_confidential_policy(
commonArg,
action        := 'SET_COLUMN_DESCRIPTION',
```

```
column_name    := 'colName',
column_description    := 'colDesc'
)
```

Argument

The argument varies depending on the content to be changed. Details are as follows.

- Common arguments

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	schema_name	varchar(63)	Schema name of table for which a masking policy is applied	'public'
	table_name	varchar(63)	Name of table for which a masking policy is applied	Mandatory
	policy_name	varchar(63)	Masking policy name	Mandatory

- Add a masking target to a masking policy

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	action	varchar(63)	'ADD_COLUMN'	'ADD_COLUMN'
	column_name	varchar(63)	Masking target name	Mandatory
	function_type	varchar(63)	Masking type - 'FULL': Full masking - 'PARTIAL': Partial masking - 'REGEXP': Regular expression masking	'FULL'
Partial masking	function_parameters	varchar(1024)	Masking format for partial masking	Mandatory
Regular expression masking	regexp_pattern	varchar(1024)	Search pattern for regular expression masking	Mandatory
	regexp_replacement	varchar(1024)	Replacement character/string for regular expression masking	Mandatory
	regexp_flags	varchar(20)	Regular expression flags	NULL

- Delete a masking target from a masking policy

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	action	varchar(63)	'DROP_COLUMN'	Mandatory
	column_name	varchar(63)	Masking target name	Mandatory

- Change the masking condition

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	action	varchar(63)	'MODIFY_EXPRESSION'	Mandatory
	expression	varchar(1024)	Masking condition to be changed	Mandatory

- Change the content of a masking policy set for a masking target

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	action	varchar(63)	'MODIFY_COLUMN'	Mandatory
	column_name	varchar(63)	Masking target name	Mandatory
	function_type	varchar(63)	Masking type - 'FULL': Full masking - 'PARTIAL': Partial masking - 'REGEXP': Regular expression masking	'FULL'
Partial masking	function_parameters	varchar(1024)	Masking format for partial masking	Mandatory
Regular expression masking	regexp_pattern	varchar(1024)	Search pattern for regular expression masking	Mandatory
	regexp_replacement	varchar(1024)	Replacement character/string for regular expression masking	Mandatory
	regexp_flags	varchar(20)	Regular expression flags	NULL

- Change the masking policy description

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	action	varchar(63)	'SET_POLICY_DESCRIPTION'	Mandatory
	policy_description	varchar(1024)	Masking policy description	Mandatory

- Change the masking target description

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	action	varchar(63)	'SET_COLUMN_DESCRIPTION'	Mandatory
	column_name	varchar(63)	Masking target name	Mandatory
	column_description	varchar(1024)	Masking target description	Mandatory

Details about whether arguments can be omitted are as follows.

Argument	Mandatory or optional									
	ADD_COLUMN			DROP_COLUMN	MODIFY_EXPRESSION	MODIFY_COLUMN			SET_POLICY_DESCRIPTION	SET_COLUMN_DESCRIPTION
	Full masking	Partial masking	Regular expression masking			Full masking	Partial masking	Regular expression masking		
schema_name	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
table_name	N	N	N	N	N	N	N	N	N	N
policy_name	N	N	N	N	N	N	N	N	N	N
action	Y	Y	Y	N	N	N	N	N	N	N
column_name	N	N	N	N	-	N	N	N	-	N
function_type	Y	N	N	-	-	Y	N	N	-	-
expression	-	-	-	-	N	-	-	-	-	-
policy_description	-	-	-	-	-	-	-	-	N	-
column_description	-	-	-	-	-	-	-	-	-	N
function_parameters	-	N	-	-	-	-	N	-	-	-
regexp_pattern	-	-	N	-	-	-	-	N	-	-
regexp_replacement	-	-	N	-	-	-	-	N	-	-
regexp_flags	-	-	Y	-	-	-	-	Y	-	-

Y: Can be omitted; N: Cannot be omitted; -: Ignored when specified

Return value

Return value	Description
TRUE	Ended normally
FALSE	Ended abnormally

Execution example 1

Adding masking policy p1 to masking target c2

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1', action :=
'ADD_COLUMN', column_name := 'c2', function_type := 'PARTIAL', function_parameters := 'VVVFVVVVFVVVV,
VVV-VVVV-VVVV, *, 4, 11');
 pgx_alter_confidential_policy
-------------------------------
 t
(1 row)
```

Execution example 2

Deleting masking target c1 from masking policy p1

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1', action :=
'DROP_COLUMN', column_name := 'c1');
 pgx_alter_confidential_policy
-------------------------------
```

```
 t
(1 row)
```

Execution example 3

Changing the masking condition for masking policy p1

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1', action :=
'MODIFY_EXPRESSION', expression := 'false');
 pgx_alter_confidential_policy
-------------------------------
 t
(1 row)
```

Execution example 4

Changing the content of masking policy p1 set for masking target c2

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1', action :=
'MODIFY_COLUMN', column_name := 'c2', function_type := 'FULL');
 pgx_alter_confidential_policy
-------------------------------
 t
(1 row)
```

Execution example 5

Changing the description of masking policy p1

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1', action :=
'SET_POLICY_DESCRIPTION', policy_description := 'this policy is an example.');
 pgx_alter_confidential_policy
-------------------------------
 t
(1 row)
```

Execution example 6

Changing the description of masking target c2

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1', action :=
'SET_COLUMN_DESCRIPTION', column_name := 'c2', column_description := 'c2 column is FULL.');
 pgx_alter_confidential_policy
-------------------------------
 t
(1 row)
```

Description

- The arguments for the pgx_alter_confidential_policy system management function can be specified in any order.
- The action parameters below can be specified. When action parameters are omitted, ADD_COLUMN is applied.

Parameter	Description
ADD_COLUMN	Adds a masking target to a masking policy.
DROP_COLUMN	Deletes a masking target from a masking policy.
MODIFY_EXPRESSION	Changes expression.
MODIFY_COLUMN	Changes the content of a masking policy set for a masking target.
SET_POLICY_DESCRIPTION	Changes policy_description.

Parameter	Description
SET_COLUMN_DESCRIPTION	Changes column_description.

- The function_parameters argument is enabled when the function_type is PARTIAL. If the function_type is other than PARTIAL, it will be ignored.
- The arguments below are enabled when the function_type is REGEXP. If the function_type is other than REGEXP, these arguments will be ignored.
  - regexp_pattern
  - regexp_replacement
  - regexp_flags

- Refer to "String Constants" in the PostgreSQL Documentation for information on the strings to specify for arguments.
- Refer to "POSIX Regular Expressions" in the PostgreSQL Documentation and check pattern, replacement, and flags for information on the values that can be specified for regexp_pattern, regexp_replacement, and regexp_flags.

B.4.2 pgx_create_confidential_policy

Description

Creates masking policies

Format

The format varies depending on the masking type. The format is shown below.

```
pgx_create_confidential_policy(
[schema_name        := 'schemaName',]
table_name        := 'tableName',
policy_name         := 'policyName',
expression        := 'expr'
[, enable            := 'policyStatus']
[, policy_description    := 'policyDesc']
[, column_name        := 'colName'
     [, function_type    := 'FULL'] |
     [, function_type    := 'PARTIAL', partialOpt] |
     [, function_type    := 'REGEXP', regexpOpt]
     [, column_description    := 'colDesc']
])

partialOpt:
function_parameters    := 'maskingFmt'

regexpOpt:
regexp_pattern        := 'regexpPattern',
regexp_replacement        := 'regexpReplacementChar',
[, regexp_flags        := 'regexpFlags']
```

Argument

Details are as follows.

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	schema_name	varchar(63)	Schema name of table for which the masking policy is created	'public'
	table_name	varchar(63)	Name of table for which the masking policy is created	Mandatory
	policy_name	varchar(63)	Masking policy name	Mandatory
	expression	varchar(1024)	Masking condition	Mandatory
	enable	boolean	Masking policy status - 't': Enabled - 'f': Disabled	't'
	policy_description	varchar(1024)	Masking policy description	NULL
	column_name	varchar(63)	Masking target name	NULL
	function_type	varchar(63)	Masking type - 'FULL': Full masking - 'PARTIAL': Partial masking - 'REGEXP': Regular expression masking	'FULL'
	column_description	varchar(1024)	Masking target description	NULL
Partial masking	function_parameters	varchar(1024)	Masking format for partial masking	Mandatory
Regular expression masking	regexp_pattern	varchar(1024)	Search pattern for regular expression masking	Mandatory
	regexp_replacement	varchar(1024)	Replacement character/string for regular expression masking	Mandatory
	regexp_flags	varchar(20)	Regular expression flags	NULL

Details about whether arguments can be omitted are as follows.

Argument	Mandatory or optional		
	Full masking	Partial masking	Regular expression masking
schema_name	Y	Y	Y
table_name	N	N	N
policy_name	N	N	N
expression	N	N	N
enable	Y	Y	Y
policy_description	Y	Y	Y
column_name	Y	Y	Y
function_type	Y	Y	Y
column_description	Y	Y	Y
function_parameters	-	N	-
regexp_pattern	-	-	N
regexp_replacement	-	-	N

Argument	Mandatory or optional		
	Full masking	Partial masking	Regular expression masking
regexp_flags	-	-	Y

Y: Can be omitted; N: Cannot be omitted; -: Ignored when specified

Return value

Return value	Description
TRUE	Ended normally
FALSE	Ended abnormally

Execution example 1

Creating masking policy p1 that does not contain a masking target

```
postgres=# select pgx_create_confidential_policy(table_name := 't1', policy_name := 'p1',
expression := '1=1');
 pgx_create_confidential_policy
--------------------------------
 t
(1 row)
```

Execution example 2

Creating masking policy p1 that contains masking target c1 of which the masking type is full masking

```
postgres=# select pgx_create_confidential_policy(schema_name := 'public', table_name := 't1',
policy_name := 'p1', expression := '1=1', enable := 't', policy_description := 'this policy is an
example.', column_name := 'c1', function_type := 'FULL', column_description := 'c1 column is FULL.');
 pgx_create_confidential_policy
--------------------------------
 t
(1 row)
```

Execution example 3

Creating masking policy p1 that contains masking target c2 of which the masking type is partial masking

```
postgres=# select pgx_create_confidential_policy( table_name := 't1', policy_name := 'p1',
expression := '1=1', column_name := 'c2', function_type := 'PARTIAL', function_parameters :=
'VVVFVVVVFVVVV, VVV-VVVV-VVVV, *, 4, 11');
 pgx_create_confidential_policy
--------------------------------
 t
(1 row)
```

Execution example 4

Creating masking policy p1 that contains masking target c3 of which the masking type is regular expression masking

```
postgres=# select pgx_create_confidential_policy( table_name := 't1', policy_name := 'p1',
expression := '1=1', column_name := 'c3', function_type := 'REGEXP', regexp_pattern := '(.*)(@.*)',
regexp_replacement := 'xxx\2', regexp_flags := 'g');
 pgx_create_confidential_policy
--------------------------------
 t
(1 row)
```

Description

- The arguments for the pgx_create_confidential_policy system management function can be specified in any order.
- If column_name is omitted, only masking policies that do not contain masking target will be created.
- One masking policy can be created for each table. Use the pgx_alter_confidential_policy system management function to add a masking target to a masking policy.
- The function_parameters argument is enabled when the function_type is PARTIAL. If the function_type is other than PARTIAL, it will be ignored.
- The arguments below are enabled when the function_type is REGEXP. If the function_type is other than REGEXP, these arguments will be ignored.
  - regexp_pattern
  - regexp_replacement
  - regexp_flags
- If a table for which a masking policy is to be applied is deleted, delete the masking policy as well.

See

- Refer to "String Constants" in the PostgreSQL Documentation for information on the strings to specify for arguments.
- Refer to "POSIX Regular Expressions" in the PostgreSQL Documentation and check pattern, replacement, and flags for information on the values that can be specified for regexp_pattern, regexp_replacement, and regexp_flags.

B.4.3 pgx_drop_confidential_policy

Description

Deletes masking policies

Format

```
pgx_drop_confidential_policy(
[schema_name    := 'schemaName', ]
table_name     := 'tableName',
policy_name    := 'policyName'
)
```

Argument

Details are as follows.

Argument	Data type	Description	Default value
schema_name	varchar(63)	Schema name of table for which a masking policy is deleted	'public'
table_name	varchar(63)	Name of table for which a masking policy is deleted	Mandatory
policy_name	varchar(63)	Masking policy name	Mandatory

Details about whether arguments can be omitted are as follows.

Argument	Mandatory or optional
schema_name	Y
table_name	N
policy_name	N

Y: Can be omitted; N: Cannot be omitted

Return value

Return value	Description
TRUE	Ended normally
FALSE	Ended abnormally

Execution example

Deleting masking policy p1

```
postgres=# select pgx_drop_confidential_policy(table_name := 't1', policy_name := 'p1');
 pgx_drop_confidential_policy
------------------------------
 t
(1 row)
```

Description

- The arguments for the pgx_drop_confidential_policy system management function can be specified in any order.
- If a table for which a masking policy is to be applied is deleted, delete the masking policy as well.

See

Refer to "String Constants" in the PostgreSQL Documentation for information on the strings to specify for arguments.

B.4.4 pgx_enable_confidential_policy

Description

Enables or disables masking policies

Format

```
pgx_enable_confidential_policy(
[schema_name    := 'schemaName', ]
table_name     := 'tableName',
policy_name    := 'policyName',
enable        := 'policyStatus'
)
```

Argument

Details are as follows.

Argument	Data type	Description	Default value
schema_name	varchar(63)	Schema name of table for which a masking policy is enabled or disabled	'public'
table_name	varchar(63)	Name of table for which a masking policy is enabled or disabled	Mandatory
policy_name	varchar(63)	Masking policy name	Mandatory
enable	boolean	Masking policy status - 't': Enabled - 'f': Disabled	Mandatory

Details about whether arguments can be omitted are as follows.

Argument	Mandatory or optional
schema_name	Y
table_name	N
policy_name	N
enable	N

Y: Can be omitted; N: Cannot be omitted

Return value

Return value	Description
TRUE	Ended normally
FALSE	Ended abnormally

Execution example

Enabling masking policy p1

```
postgres=# select pgx_enable_confidential_policy(table_name := 't1', policy_name := 'p1', enable :=
't');
 pgx_enable_confidential_policy
--------------------------------
 t
(1 row)
```

Description

The arguments for the pgx_enable_confidential_policy system management function can be specified in any order.

Refer to "String Constants" in the PostgreSQL Documentation for information on the strings to specify for arguments.

B.4.5 pgx_update_confidential_values

Description

Changes replacement characters when full masking is specified for masking type

Format

```
pgx_update_confidential_values(
[number_value    := 'numberValue']
[, char_value    := 'charValue']
[, varchar_value    := 'varcharValue']
[, date_value    := 'dateValue']
[, ts_value    := 'tsValue']
)
```

Argument

Details are as follows.

Argument	Data type	Description
number_value	integer	Replacement character in numeric type
char_value	varchar(1)	Replacement character in char type
varchar_value	varchar(1)	Replacement character in varchar type
date_value	date	Replacement character in date type
ts_value	timestamp	Replacement character in timestamp type

Return value

Return value	Description
TRUE	Ended normally
FALSE	Ended abnormally

Execution example

Using '*' as a replacement character in char type and varchar type

```
postgres=# select pgx_update_confidential_values(char_value := '*', varchar_value := '*');
 pgx_update_confidential_values
--------------------------------
 t
(1 row)
```

Description

- The arguments for the pgx_update_confidential_values system management function can be specified in any order.
- Specify one or more arguments for the pgx_update_confidential_values system management function. A replacement character is not changed for an omitted argument.

Refer to "String Constants" in the PostgreSQL Documentation for information on the strings to specify for arguments.

B.5 VCI Data Load Control Function

The table below lists the function that loads VCI data to buffer cache.

Table B.4 VCI data load control function

Name	Return type	Description
pgx_prewarm_vci(vci_index regclass)	int8	Loads the VCI data to buffer cache.

pgx_prewarm_vci loads the specified VCI data to buffer cache and returns the number of blocks of the loaded VCI data.

The aggregation process using VCI may take time immediately after an instance is started, because the VCI data has not been loaded to buffer cache. Therefore, the first aggregation process can be sped up by executing pgx_prewarm_vci after an instance is started.

The amount of memory required for preloading is the number of blocks returned by pgx_prewarm_vci multiplied by the size of one block.

This function can only be executed if the user has reference privilege to the VCI index and execution privilege to the pg_prewarm function.

B.6 High-Speed Data Load Control Functions

The table below lists the functions that can be used for high-speed data load.

Table B.5 High-speed data load control functions

Name	Return type	Description
pgx_loader	bigint	Creates dynamic shared memory, starts parallel workers and loads data
pgx_loader_recovery	smallint	Resolves in-doubt transactions

The pgx_loader command executes the above functions internally.

Appendix C System Catalogs

Describes the system catalog of Fujitsu Enterprise Postgres.

See

Refer to "System Catalogs" under "Internals" in the PostgreSQL Documentation for information on other system catalogs.

C.1 pgx_profile

A system catalog for managing profile information. -1 is stored if DEFAULT is specified for each parameter in the profile, and -2 is stored if UNLIMITED is specified.

Column	Type	Description
oid	oid	Profile identifier (Primary key constraint)
prfname	name	Profile name (Unique constraint, NOT NULL constraint)
prfpasswordlifetime	integer	Value of PASSWORD_LIFE_TIME (seconds) (NOT NULL constraint)
prfpasswordgracetime	integer	Value of PASSWORD_GRACE_TIME (seconds) (NOT NULL constraint)
prfpasswordreusetime	integer	Value of PASSWORD_REUSE_TIME (seconds) (NOT NULL constraint)
prfpasswordreusemax	integer	Value of PASSWORD_REUSE_MAX (seconds) (NOT NULL constraint)
prfpasswordlocktime	integer	Value of PASSWORD_LOCK_TIME (seconds) (NOT NULL constraint)
prffailedloginattempts	integer	Value of FAILED_LOGIN_ATTEMPTS (seconds) (NOT NULL constraint)
prfpasswordallowhashed	integer	Value of PASSWORD_ALLOW_HASHED (NOT NULL constraint)
prfinactiveusertime	integer	Value of INACTIVE_USER_TIME (seconds) (NOT NULL constraint)
prfpasswordrollovertime	integer	Value of PASSWORD_ROLLOVER_TIME (seconds) (NOT NULL constraint)

C.2 pgx_user_profile

A system catalog that manages profile-related information associated with users. When DROP ROLE, the corresponding row is automatically deleted.

Column	Type	References	Description
userprfroleid	oid	pg_authid.oid	User's identifier (Primary key constraint)
userprfprfid	oid	pgx_profile.oid	Identifier of the profile assigned to the user
userprfaccountlock	smallint		User lock state (NOT NULL constraint) 0: Not locked

Column	Type	References	Description
			1: Lock (Refer to PASSWORD_LOCK_TIME in profile for duration) 2: Lock (Unlimited)
userprfpasswordstatus	char		Password status Updated if there are any changes at login (NOT NULL constraint) o: Current valid password g: In grace period e: Expired
userprflockdate	timestamp with time zone		Time the user was locked
userprfpasswordsetat	timestamp with time zone		Time you updated your current password
userprfpasswordexpire	timestamp with time zone		Password expiration time
userprflastactivetime	timestamp with time zone		Time the user's session was last checked
userprfpasswordrolloverexpire	timestamp with time zone		Time at which the period in which old and new passwords can be used ends

C.3 pgx_auth_password

The system catalog for storing user-associated password information. Used for password rollover.

Since this catalog contains passwords, it must not be readable by third parties.

Column	Type	References	Description
authpwdroleid	oid	pg_authid.oid	User's identifier (Primary key constraint)
authpwdoldpassword	text		Hashed password Used for authentication when password rollover is enabled.
authpwdoldpasswordsetat	timestamp with time zone		Time at which authpwdoldpassword was set
authpwdnewpassword	text		Hashed password Used for authentication when password rollover is enabled.
authpwdnewpasswordsetat	timestamp with time zone		Time at which authpwdnewpassword was set

C.4 pgx_password_history

A system catalog for managing password history. Used for password reuse confirmation and password rollover. When DROP ROLE is executed, the corresponding row is automatically deleted.

Since this catalog contains passwords, it must not be readable by third parties.

This system catalog is updated when the password is updated, and if the password reuse limit is finite, unnecessary history deletion is also performed. Old passwords that have been removed from the catalog are treated as having never been used.

passhistpassword is saved in the format specified by the password_encryption parameter.

Column	Type	Description
passhistroleid	oid	Identifier of the user whose password was set Set unique constraint with (passhistroleid, passhistpassword).
passhistpassword	text	Encrypted password Save rolpassword value in pg_authid as history (NOT NULL constraint)
passhistpasswordsetat	timestamp with time zone	Time when the password was updated (NOT NULL constraint)

Appendix D System Views

This appendix describes how to use the system views in Fujitsu Enterprise Postgres.

See

Refer to "System Views" under "Internals" in the PostgreSQL Documentation for information on other system views.

D.1 pgx_tablespaces

The pgx_tablespaces view provides information related to the encryption of tablespaces.

Table D.1 pgx_tablespaces view

Column	Type	References	Description
spctablespace	oid	pg_tablespace.oid	Tablespace OID
spcencalgo	text		Tablespace encryption algorithm

The spcencalgo string displays one of the following values:

- none: Tablespace is not encrypted
- AES128: AES with key length of 128 bits
- AES256: AES with key length of 256 bits

D.2 pgx_stat_lwlock

The pgx_stat_lwlock view displays statistics related to lightweight locks, with each type of content displayed on a separate line.

Table D.2 pgx_stat_lwlock view

Column	Type	Description
lwlock_name	name	Name of the lightweight lock
total_waits	bigint	Number of waits caused by the lightweight lock
total_wait_time	double precision	Number of milliseconds spent in waits caused by the lightweight lock
stats_reset	timestamp with timezone	Last time at which this statistics was reset

D.3 pgx_stat_latch

The pgx_stat_latch view displays statistics related to latches, with each type of wait information within Fujitsu Enterprise Postgres displayed on a separate line.

Table D.3 pgx_stat_latch view

Column	Type	Description
latch_name	name	Name of the latch
total_waits	bigint	Number of waits caused a wait
total_wait_time	double precision	Number of milliseconds spent in waits caused by the latch
stats_reset	timestamp with timezone	Last time at which this statistic was reset

D.4 pgx_stat_walwriter

The pgx_stat_walwriter view displays statistics related to WAL writing, in a single line.

Table D.4 pgx_stat_walwriter view

Column	Type	Description
dirty_writes	bigint	Number of times old WAL buffers were written to the disk because the WAL buffer was full when WAL records were added
writes	bigint	Number of WAL writes
write_blocks	bigint	Number of WAL write blocks
total_write_time	double precision	Number of milliseconds spent on WAL writing
stats_reset	timestamp with timezone	Last time at which this statistic was reset

D.5 pgx_stat_sql

The pgx_stat_sql view displays statistics related to SQL statement executions, with each type of SQL statement displayed on a separate line.

Table D.5 pgx_stat_sql view

Column	Type	Description
selects	bigint	Number of SELECT statements executed In database multiplexing mode, this number includes the SELECT statements executed in Mirroring Controller. Mirroring Controller executes the SELECT statement using the interval specified for the heartbeat_interval of the server definition file (milliseconds).
inserts	bigint	Number of INSERT statements executed
deletes	bigint	Number of DELETE statements executed
updates	bigint	Number of UPDATE statements executed
selects_with_parallelism	bigint	Number of times parallel scan was used in SELECT statements
inserts_with_parallelism	bigint	Not used
deletes_with_parallelism	bigint	Not used
updates_with_parallelism	bigint	Not used
copies_with_parallelism	bigint	Not used
declares	bigint	Number of DECLARE statements executed (number of cursor OPENs)
fetches	bigint	Number of FETCH statements executed
checkpoints	bigint	Number of CHECKPOINT statements executed
clusters	bigint	Number of CLUSTER statements executed
copies	bigint	Number of COPY statements executed
reindexes	bigint	Number of REINDEX statements executed
truncates	bigint	Number of TRUNCATE statements executed
locks	bigint	Number of times a lock occurred
stats_reset	timestamp with timezone	Last time at which this statistic was reset

D.6 pgx_stat_gmc

The pgx_stat_gmc view provides information about the GMC areas.

Table D.6 pgx_stat_gmc view

Column	Type	Description
searches	bigint	Number of times the cache table is searched.
hits	bigint	Number of times the cache table is hit.
size	bigint	The current amount of memory (bytes) used in the GMC area.
stats_reset	timestamp with timezone	Last time these statistics were reset.

D.7 pgx_stat_progress_loader

The pgx_stat_progress_loader view provides overall progress information for pgx_loader command.

The pgx_stat_progress_loader view displays the sum of the progress information of the back-end processes and the number of parallel worker processes when pgx_loader runs.

Table D.7 pgx_stat_progress_loader view

Column	Type	Description
pid	integer	Process ID of the backend.
datid	Oid	Oid of the database to connect to.
datname	name	Name of the database to connect to.
relid	Oid	Oid of the table to load.
command	text	Command executes the load process. (Always "COPY FROM"for pgx_loader)
type	text	Type of data source for the load operation.
bytes_processed	bigint	Size of the data at the end of the load. (Backend and worker totals)
bytes_total	bigint	Size of the data to load. (Backend and worker totals)
tuples_processed	bigint	Number of rows that have completed loading. (Backend and worker totals)
tuples_excluded	bigint	Number of rows skipped during the load process. (Backend and worker totals)

Appendix E Tables Used by Data Masking

This appendix explains tables used by the data masking feature.

Information

These tables are updated by the data masking control function, so do not use SQL statements to directly update these tables.

E.1 pgx_confidential_columns

This table provides information on masking target for which masking policies are set.

Column	Type	Description
schema_name	varchar(63)	Schema name of table for which a masking policy is applied
table_name	varchar(63)	Name of table for which a masking policy is applied
policy_name	varchar(63)	Masking policy name
column_name	varchar(63)	Masking target name
function_type	varchar(63)	Masking type - 'FULL': Full masking - 'PARTIAL': Partial masking - 'REGEXP': Regular expression masking
function_parameters	varchar(1024)	Masking format for partial masking
regexp_pattern	varchar(1024)	Search pattern for regular expression masking
regexp_replacement	varchar(1024)	Replacement character/string for regular expression masking
regexp_flags	varchar(20)	Regular expression flags
column_description	varchar(1024)	Masking target description

Execution example

```
postgres=# select * from pgx_confidential_columns;
 schema_name | table_name | policy_name | column_name | function_type |
function_parameters           | regexp_pattern | regexp_replacement | regexp_flags |
column_description
-------------+------------+-------------+-------------+---------------
+---------------------------------------+----------------+--------------------+-------------
+--------------------
 public      | t1         | p1          | c1          | FULL          |
|                |                     |             |
 public      | t1         | p1          | c2          | PARTIAL       | VVVFVVVVFVVVV, VVV-VVVV-VVVV,
*, 4, 11 |                |                     |             |
(2  row)
```

E.2 pgx_confidential_policies

This table provides information on masking policies.

Column	Type	Description
schema_name	varchar(63)	Schema name of table for which a masking policy is applied

Column	Type	Description
table_name	varchar(63)	Name of table for which a masking policy is applied
policy_name	varchar(63)	Masking policy name
expression	varchar(1024)	Masking condition
enable	boolean	Masking policy status - 't': Enabled - 'f': Disabled
policy_description	varchar(1024)	Masking policy description

Execution example

```
postgres=# select * from pgx_confidential_policies;
 schema_name | table_name | policy_name | expression | enable | policy_description
-------------+------------+-------------+------------+--------+--------------------
 public      | t1         | p1          | 1=1        | t      |
(1 row)
```

E.3 pgx_confidential_values

This table provides information on replacement characters when full masking is specified for masking type.

Column	Data type	Description	Default value
number_value	integer	Numeric	0
char_value	varchar(1)	char type	Spaces
varchar_value	varchar(1)	varchar type	Spaces
date_value	date	date type	'1970-01-01'
timestamp_value	timestamp	timestamp type	'1970-01-01 00:00:00'

Execution example

```
postgres=# select * from pgx_confidential_values;
 number_value | char_value | varchar_value | date_value |      ts_value
--------------+------------+---------------+------------+---------------------
            0 |            |               | 1970-01-01 | 1970-01-01 00:00:00
(1 row)
```

Appendix F Tables Used by Aggressive Freeze for Tuples

This appendix explains tables used by the aggressive freeze for tuples feature.

F.1 pgx_stat_freeze_results

The table pgx_stat_freeze_results logs statistics about aggressive freeze for tuples. If an aggressive freeze for tuples is performed, that information will be added as an accumulation. The cumulative information is summarized for the time period specified by the pgx_stat_vacuum_freeze.monitoring_interval parameter, and the information for the time period specified by the pgx_stat_vacuum_freeze.log_retention_period parameter is kept. For the information about the pgx_stat_vacuum_freeze.monitoring_interval and pgx_stat_vacuum_freeze.log_retention_period parameters, refer to "Parameters for scheduling aggressive freeze for tuples".

You can gather information to determine how long the aggressive freeze for tuples process is taking, and help estimate the aggressive freeze for tuples schedule.

Column	Type	Description
measurement_start_time	timestamp with time zone	Start time of the measurement
measurement_end_time	timestamp with time zone	End time of the measurement
vacuum_count	bigint	Number of times the freeze operation was performed
autovacuum	boolean	true for autovacuum driven vacuum
scan_pages	bigint	Accumulation of pages scanned during freezing
frozen_pages	bigint	Accumulation of frozen pages
frozen_tuples	bigint	Accumulation of frozen tuples
total_frozen_wal_records	bigint	Accumulation of the number of WAL records produced by freezing
frozen_full_page_image_wal_records	bigint	Accumulation of the number of WAL full-page images produced by freezing
wal_total_bytes	numeric	Accumulation, in bytes, of WAL generated by freezing
total_elapsed_time	double precision	Accumulation of freezing time. Units are milliseconds
sleep_times	double precision	Accumulation of time spent sleeping during freezing. Units are milliseconds

Appendix G Tables Used by High-Speed Data Load

This appendix describes the tables used by high-speed data load.

G.1 pgx_loader_state

The pgx_loader_state table provides information about transactions prepared by high-speed data load.

Column	Type	Description
id	serial	Unique identifier. This value is assigned from the pgx_loader_state_id_seq sequence.
gid	text	Global transaction identifier assigned to a transaction.
state	text	State of the transaction. The value can be one of the following: - commit: The prepared transaction has been committed. - rollback: The prepared transaction is in in-doubt state.
leader_pid	integer	Process ID of the backend process (leader process) that executed the pgx_loader control function.
role_oid	integer	Role identifier (OID). A prepared transaction can only be completed by the same user who executed the original transaction or by a superuser.
relation_oid	integer	Object identifier (OID).

Information

The pgx_loader_state table and pgx_loader_state_id_seq sequence are updated by high-speed data load. Do not update these database objects directly using SQL.

Appendix H Starting and Stopping the Web Server Feature of WebAdmin

To use WebAdmin for creating and managing a Fujitsu Enterprise Postgres instance on a server where Fujitsu Enterprise Postgres is installed, you must first start the Web server feature of WebAdmin.

- Using WebAdmin in a single-server configuration

  You must start the Web server on the server on which Fujitsu Enterprise Postgres and WebAdmin are installed.

- Using WebAdmin in a multiserver configuration

  You must start the Web server on all servers on which WebAdmin has been installed.

This appendix describes how to start and stop the Web server feature of WebAdmin.

See

Refer to "Installing WebAdmin in a Multiserver Configuration" in the Installation and Setup Guide for Server for information on multiserver installation.

H.1 Starting the Web Server Feature of WebAdmin

Follow the procedure below to start the Web server feature of WebAdmin:

1. Display the [Services] window

   In the [Administrative Tools], click [Services].

2. Start a service

   Select the displayed name "Fujitsu Enterprise Postgres WebAdmin *version*", and then click [Start Service].

You can also start a service by specifying the service name of the Web server feature of WebAdmin in the net start command or sc start command.

H.2 Stopping the Web Server Feature of WebAdmin

This section describes how to stop the Web server feature of WebAdmin.

Follow the procedure below to stop the Web server feature of WebAdmin:

1. Display the [Services] window

   In the [Administrative Tools], click [Services].

2. Stop a service

   Select the displayed name "Fujitsu Enterprise Postgres WebAdmin *version*", and then click [Stop Service].

You can also stop a service by specifying the service name of the Web server feature of WebAdmin in the net stop command or sc stop command.

Appendix I WebAdmin Wallet

This appendix describes how to use the Wallet feature of WebAdmin.

When a remote instance or a standby instance is created, it is necessary to provide user name and password for authentication with the remote machine or the database instance.

The Wallet feature in WebAdmin is a convenient way to create and store these credentials.

Once created, these credentials can be repeatedly used in one or more instances.

I.1 Creating a Credential

1. In the [My Wallet] tab, click . The [New credential] page will be displayed.
2. Enter the information for the credentials.

   Credential name, User name and Password should not contain hazardous characters. Refer to "Appendix J WebAdmin Disallow User Inputs Containing Hazardous Characters".

   - [Credential name]: Name of the credential

     The name must meet the conditions below:

     - Maximum of 16 characters
     - The first character must be an ASCII alphabetic character
     - The other characters must be ASCII alphanumeric characters
   - [User name]: The operating system user name or database instance user name that will be used later
   - [Password]: Password for the user
   - [Confirm password]: Reenter the password.
3. Click to store the credential.

I.2 Using a Credential

Once a credential is created in the Wallet, it can be used during remote instance creation or standby instance creation.

If you select the credential saved in "I.1 Creating a Credential" in [Operating system credential], the user name and password will be automatically populated.

Appendix J WebAdmin Disallow User Inputs Containing Hazardous Characters

WebAdmin considers the following as hazardous characters, which are not allowed in user inputs.

```
| (pipe sign)

& (ampersand sign)

; (semicolon sign)

$ (dollar sign)

% (percent sign)

@ (at sign)

' (single apostrophe)

" (quotation mark)

\' (backslash-escaped apostrophe)

\" (backslash-escaped quotation mark)

<> (triangular parenthesis)

() (parenthesis)

+ (plus sign)

CR (Carriage return, ASCII 0x0d)

LF (Line feed, ASCII 0x0a)

, (comma sign)

\ (backslash)
```

Appendix K Collecting Failure Investigation Data

For information on collecting failure investigation data, refer to "Collecting Failure Investigation Data" in the Installation and Setup Guide for Server.

Security Operation Guide

Windows/Linux

J2UL-3058-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document describes security when building and operating a Fujitsu Software Enterprise Postgres database system.

Intended readers

This document is intended for those who are:

- Considering installing Fujitsu Enterprise Postgres
- Designing, building, and operating the security operating environment in Fujitsu Enterprise Postgres
- Accessing Fujitsu Enterprise Postgres database systems

Readers of this document are assumed to have general knowledge of:

- Business operations
- Fujitsu Enterprise Postgres
- Linux

Structure of this document

This document is structured as follows:

Chapter 1 Overview of Security

Provides an overview of the security system, and explains the security features provided by Fujitsu Enterprise Postgres.

Chapter 2 Overview of Security Operation

Provides an overview of security operation.

Chapter 3 Tasks of the Manager

Explains the tasks for security measures to be implemented by the manager.

Chapter 4 Tasks of Administrators

Explains the tasks for security measures to be implemented by administrators.

Chapter 5 Tasks of Users

Explains the tasks for security measures to be implemented by users.

Chapter 6 Audit Log Feature

Explains the audit log feature provided by Fujitsu Enterprise Postgres.

Chapter 7 Confidentiality Management

Explains the confidentiality management feature provided by Fujitsu Enterprise Postgres.

Appendix A Tables Used by Confidentiality Management Feature

Explains the tables used by the confidentiality management feature.

Appendix B System Management Functions Used by Confidentiality Management Feature

Explains the functions used by the confidentiality management feature.

References

This document contains abstracts from the following document:

- Database Security Guideline Version 2.0
  (Database Security Consortium (DBSC))

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

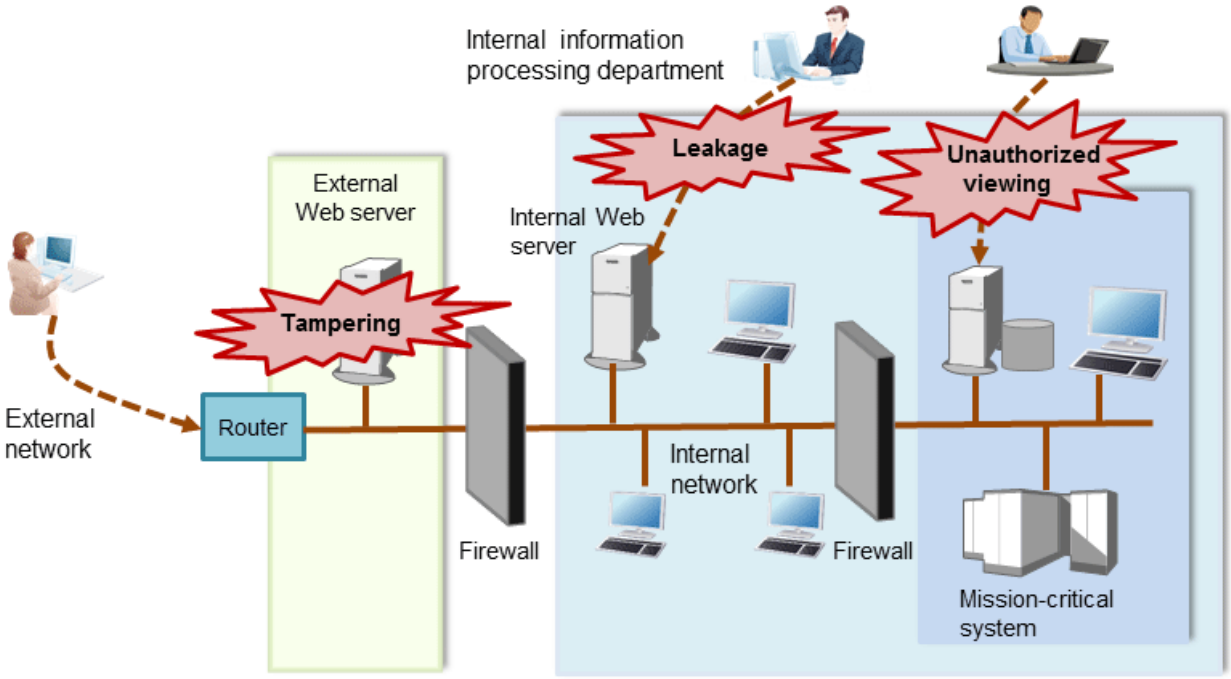
Chapter 1 Overview of Security

1.1 What is Security?

Computer security is the protection of information systems and data from risks such as leakage or tampering of information, attacks, intrusions, eavesdropping from external sources, and interference with information services. Security measures are essential for the advance prevention of security threats in order for information systems to gain trust as social infrastructure.

Figure 1.1 Security threats



The security measures in information systems can be classified as follows:

- Network
- Web
- Application
- Database
- PC

This document focuses on database security measures when using Fujitsu Enterprise Postgres.

1.2 Security Requirements

Below are the necessary security requirements for information systems.

Maintenance of security policies

A security policy clarifies the approach the company should take in relation to information assets, and the actions employees should take.

It is necessary to undertake security of information systems while maintaining security policies.

Integrated security management

Security has the aspects below. It is necessary to manage information in an integrated manner based on these aspects.

Confidentiality

Access to the information is restricted to prevent leakage of information outside of the company

Example measures: Prevention of information leakage or setup of access privileges

Integrity

Integrity is guaranteed, ensuring information does not become corrupted or tampered with

Example measures: Prevention or detection of tampering

Availability

Failure is prevented and normal operation is maintained so that information can be used when needed

Example measures: Power supply measures, system mirroring

1.3 Security Threats

A security threat is defined as something that threatens the confidentiality, integrity, and availability indicated in "1.2 Security Requirements" in respect to information assets. This includes technical threats such as accessing a database, but does not include physical destruction.

Threats are considered to be a combination of type of user who is the source of the threat, information assets that need to be protected, techniques, and unauthorized actions. For example, a threat might be a general user exploiting a database vulnerability to obtain database management information, and then tampering with that information.

When considering security measures, it is firstly necessary to clarify what kind of threats there are. A list of possible threats is shown in the table below. Refer to "Types of user" and "Information assets" for details on the definition of each type of user and information assets that should be protected.

Possible threats

Type of user	Information asset	Technique	Unauthorized action
General user Internal user System manager System developer System administrator System operator	Database management information	Eavesdropping of packets	Unauthorized acquisition (viewing) of information Unauthorized tampering or destruction (updating) of information
		Dictionary attack of passwords	
		Unauthorized acquisition of IDs/passwords through social engineering	
		Unauthorized acquisition of information through misuse of settings	
		Unauthorized acquisition of information through exploiting a database vulnerability	
		Acquisition by an unauthorized route	
General user Internal user	General database information	Acquisition by a normal route	Misuse of information that can be acquired normally (taking data outside of the company)
		SQL issued with the aim of obstructing a job	Obstructing a job (resource depletion)

Type of user	Information asset	Technique	Unauthorized action
General user Internal user	General database information	Eavesdropping of packets	Unauthorized tampering or destruction (updating) of information
		Dictionary attack of passwords	
		Unauthorized acquisition of IDs/passwords through social engineering	
		Unauthorized acquisition of information through exploiting configuration errors	
		Unauthorized acquisition of information through exploiting a database vulnerability	
		Acquisition by an unauthorized route	
System manager System developer System administrator System operator	General database information	Eavesdropping of packets	Unauthorized acquisition (viewing) of information Unauthorized tampering or destruction (updating) of information
		Dictionary attack of passwords	
		Unauthorized acquisition of IDs/passwords through social engineering	
		Unauthorized acquisition of information through exploiting configuration errors	
		Unauthorized acquisition of information through exploiting a database vulnerability	
		Acquisition by an unauthorized route	
System developer	Database management information	Creation of a backdoor	Unauthorized acquisition (viewing) of information Unauthorized tampering or destruction (updating) of information
	General database information		
System manager System administrator	Database management information	Unauthorized acquisition of information by creating an unauthorized database administrator account	Unauthorized acquisition (viewing) of information Unauthorized tampering or destruction (updating) of information
	General database information		
System manager System operator	Database management information	Unauthorized acquisition of information by tampering with database-related files	Unauthorized acquisition (viewing) of information

Type of user	Information asset	Technique	Unauthorized action
	General database information	(definition file, physical file, and so on)	Unauthorized tampering or destruction (updating) of information
Database administrator	Database management information	Misuse of information (taking information outside of the company) after obtaining it through the normal route	Misuse of information that can be acquired normally (taking information outside of the company)
		Unauthorized use of IDs/ passwords from the management information	Tampering with or destroying information that can be acquired
		Unauthorized acquisition of information by tampering with management information	
		SQL issued with the aim of obstructing a job	Obstructing a job (resource depletion)
	General database information	Eavesdropping of packets	Unauthorized acquisition (viewing) of information Unauthorized tampering or destruction (updating) of information
		Misuse of information (taking information outside of the company) after obtaining it through an unauthorized route	
Database operator	Database management information	Eavesdropping of packets	Unauthorized acquisition (viewing) of information Unauthorized tampering or destruction (updating) of information
		Dictionary attack of passwords	
		Unauthorized acquisition of IDs/passwords through social engineering	
		Unauthorized acquisition of information by exploiting configuration errors	
		Unauthorized acquisition of information through exploiting a database vulnerability	
		Acquisition by an unauthorized route	
	General database information	Acquisition by a normal route	Misuse of information that can be acquired normally (taking data outside of the company)
		SQL issued with the aim of obstructing a job	Obstructing a job (resource depletion)

Types of user

In database security, the persons involved with databases and their roles are defined below.

Type of user	Role
System manager	Manages developers, administrators, and operators
System developer	Builds the network around the database server Builds the database server
System administrator	Operates devices of the surrounding database network Operates the database server
System operator	Operates the surrounding database network
Database administrator	Builds the database system Operates the database system
Database operator	Performs business operations
Internal user	End user inside the company
General user	End user outside the company

Information assets

In database security, it is necessary to protect the information assets to be stored on the database server.

Such assets are defined below.

Database management information

- Database configuration information (system catalog, user ID/password, and so on)
- Database logs (such as access logs)

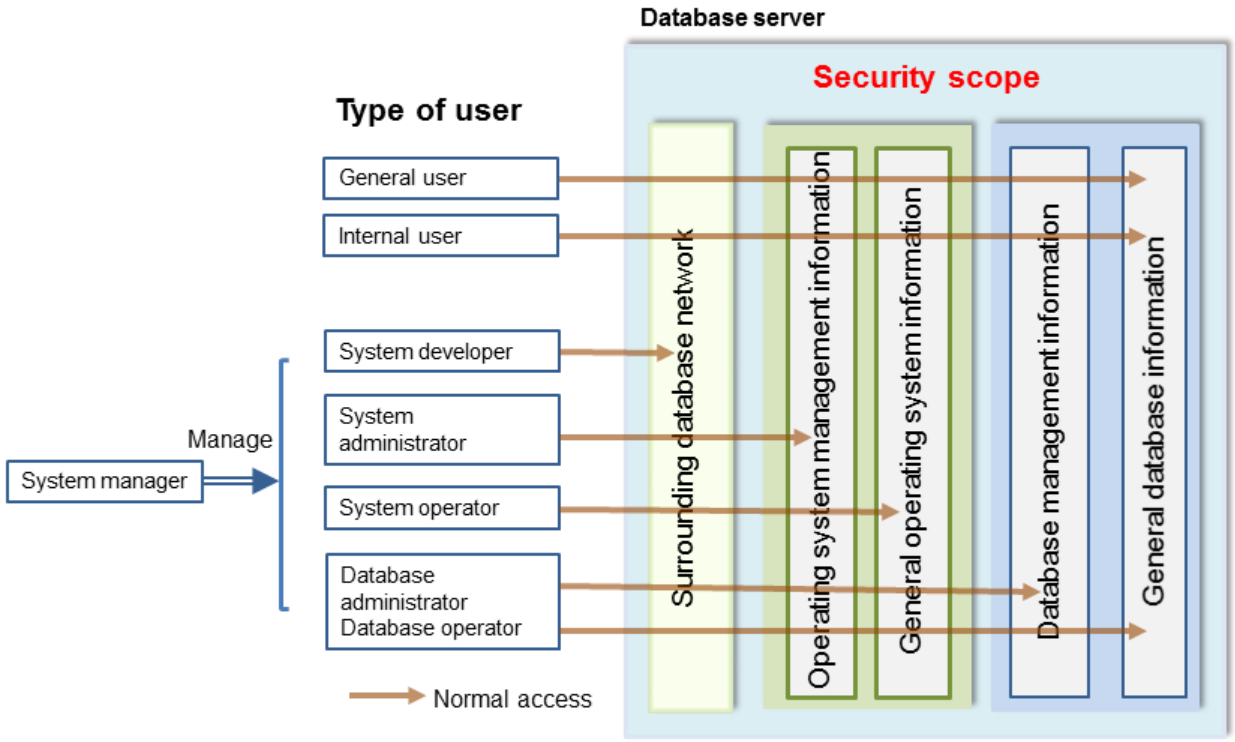
General database information

- Job data
- Applications

1.4 Security Scope

In database systems, both the database server and the surrounding database network are part of the security scope. It is necessary to clarify the extent of the security scope that each type of user is involved with, and consider security measures for the same.

The relationship of the security scope and the types of user is shown below.



1.5 Security Provided by Fujitsu Enterprise Postgres

Fujitsu Enterprise Postgres provides security features that satisfy the security requirements indicated in "1.2 Security Requirements".

This section describes security provided by Fujitsu Enterprise Postgres.

1.5.1 Roles Targeted For Security

In Fujitsu Enterprise Postgres database systems, the roles targeted in relation to security are "Manager", "Administrator", and "User". In order to build a robust security system, it is necessary to put security measures in place for each role.

The roles targeted for security and the mapping of Types of user indicated in "1.3 Security Threats" are shown in the table below.

Role targeted for security	Type of user
Manager	System manager
Administrator	System developer
	System administrator
	System operator
	Database administrator
	Database operator
User	General user
	Internal user

Manager

The manager establishes a security policy and decides on an operations policy for the organization as a whole.

Refer to "Chapter 3 Tasks of the Manager" for details.

Administrator

Administrators design, build and operate a system. While doing this, the administrators must implement the security measures in accordance with the security policy established by the manager.

Refer to "Chapter 4 Tasks of Administrators" for details.

User

A user is a person other than the manager or an administrator who accesses a database. There may be any number of users. It is necessary for users to be registered in the database system, and that access to the database is restricted according to the access privileges.

Refer to "Chapter 5 Tasks of Users" for details.

1.5.2 Security Features

Fujitsu Enterprise Postgres provides the following security features:

- Authentication
- Access control
- Encryption
- Audit log
- Data masking

This section describes each of these features.

Authentication

The databases that can be accessed can be restricted by authenticating the database users who access the database. Additionally, authentication of the server can be performed to prevent spoofing of the database server.

Refer to "Client Authentication" in "Server Administration" in the PostgreSQL Documentation for details on authentication.

Refer to "Secure TCP/IP Connections with SSL" in "Server Setup and Operation" in the PostgreSQL Documentation for details on server authentication.

In Fujitsu Enterprise Postgres, when password authentication is used as client authentication to connect to a database, the database administrator can force database users to use passwords based on predefined security policies. For more information, refer to "Policy-based Login Security" in the Operations Guide.

Access control

Database objects can only be used by the object creator or database user who was specified as the owner when the object was created (both persons are hereinafter referred to as "owner"), or superuser, when objects are in their initial state. By having the object owner or superuser control access privileges for database users, it is possible to control what kind of tables the database users who connect to the database can access, and what kind of operations they can perform.

Fujitsu Enterprise Postgres provides security management support features that support the design and operation of access control. For details, refer to "Chapter 7 Confidentiality Management".

Refer to "Privileges" in "The SQL Language" in the PostgreSQL Documentation for details on object access control.

Encryption

Fujitsu Enterprise Postgres provides a transparent data encryption feature that satisfies the requirements below.

- Confidential information can be changed into an unidentifiable state.
- The encryption key and data are managed separately.
- The encryption key is replaced at regular intervals.

Also, confidential data should not be operated without encryption. Fujitsu Enterprise Postgres provides security management support features to help prevent this. For details, refer to "Security Management Support".

PostgreSQL provides an encryption feature called "pgcrypto" that can also be used in Fujitsu Enterprise Postgres, however, it is recommended to use the transparent data encryption features because it will otherwise be necessary to modify the applications that consider encryption. Refer to "Protecting Storage Data Using Transparent Data Encryption" in the Operation Guide for details.

Additionally, if communication data transferred between a client and a server contains confidential information, it is necessary to encrypt the communication data to protect it against threats, such as eavesdropping on the network.

Refer to "Configuring Secure Communication Using Secure Sockets Layer" in the Operation Guide for details on encryption of communication data.

Audit log

A feature that addresses threats such as misuse of administrator privileges, unauthorized access to a database by a user, and other such threats. Information for tracing the processing of administrators and users is retrieved and stored as an audit log.

By periodically viewing and monitoring audit logs, the administrators can detect events that are impacting on the system in some way, or are depleting system resources as a result of incorrect operations by users, and can take appropriate measures to prevent information leakages or system failures in advance.

Refer to "Chapter 6 Audit Log Feature" for details.

Data masking

A feature that changes part of the data to make it available for reference in response to queries issued by an application.

For example, for a query of employee data, digits except the last four digits of an eight-digit employee number can be changed to "*" so that it can be used for reference without exposing the actual data.

Specifically, the data changed by the data masking feature can be transferred to a test database so that users who perform testing or development can reference the data. During testing, it is desirable to use the data that will be used on a production environment database. However, actual production data should not be used as is for testing because of the risk of leakage of confidential data. This feature enables data that is similar to actual production data to be safely used in test and development environments.

Refer to "Data Masking" in the Operation Guide for details on data masking.

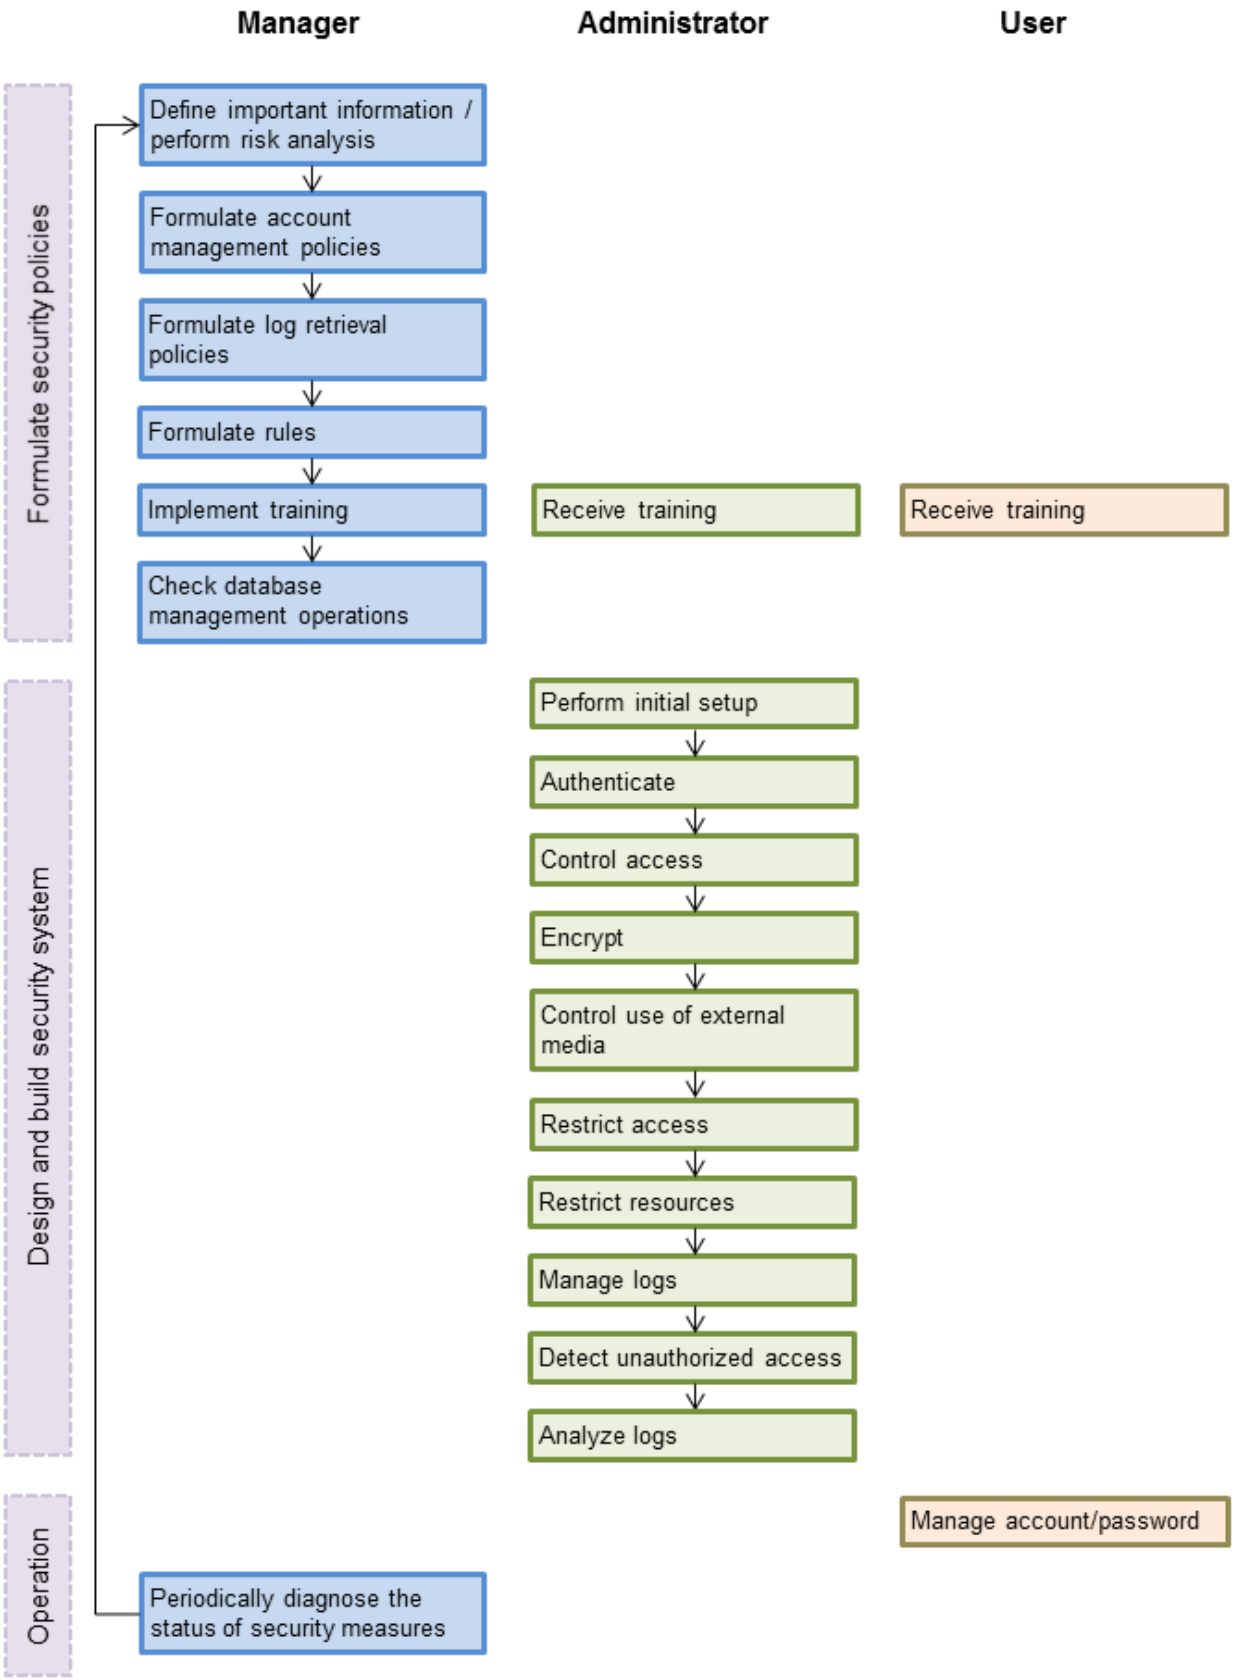
Chapter 2 Overview of Security Operation

2.1 Security Operation Flow

This section shows the flow of work when building a security environment and performing security operation in Fujitsu Enterprise Postgres.

When performing security operation, there are technical measures to be implemented to address security threats by equipping the system with security features, and manual work, such as the implementation of security guidelines, a training system, and the establishment of usage rules.

Figure 2.1 Security operation flow



Chapter 3 Tasks of the Manager

The manager formulates security policies, which become guidelines for security measures.

3.1 Defining Important Information and Risk Analysis

Before formulating security policies, define important information and perform risk analysis. Based on the importance of the information and the result of risk analysis, decide what kind of security measures to put in place.

In defining the important information, identify what should be protected and classify it by importance in order to effectively implement the security measures. Information that should be protected includes "database management information" and "general database information", as indicated in "Information assets". Examples of information classifications are "personal information" and "confidential information".

In the risk analysis, refer to "Possible threats" to identify threats that may arise, and analyze the risks in respect to such threats.

Additionally, by performing a risk analysis once annually as a guide, it is possible to identify threats that may adversely impact the business and related vulnerabilities.

3.2 Formulating Account Management Policies

In formulating an account management policy, implement the following and document the formulated policy.

Organize system users and roles

Identify the necessary roles of the relevant system based on "Types of user". Additionally, organize personnel for each role.

Organize accounts

Organize accounts with the appropriate privileges for each role, and decide on account policies.

- Database administrator account
  - Organize separate accounts for database administrators and database operators
  - Ensure that the database administrator account can only be used by specific persons
  - Perform tasks that do not require database administrator privileges using a separate account without database administrator privileges
- General account

  Create an account for general users by application usage.

Review account management policy

Review the accounts in order to effectively implement security measures.

- Regularly check the accounts mentioned above and their privileges, and determine if they are still appropriate
- If there have been system or operational changes, review the accounts and privileges
- If unsuitable accounts and privileges are discovered, modify them as required

3.3 Formulating Log Retrieval Policies

In formulating a log retrieval policy, implement the following and document the formulated policy.

Organize the purpose of log retrieval

To clarify what logs will be retrieved for, define their reason for retrieval.

Examples of the purpose might include, "To use for investigation in the event of unauthorized access", and "To submit to investigating authorities as evidence if any issues arise".

Decide on the types of logs to be retrieved

In order to retrieve appropriate logs, organize the types of logs that can be retrieved in the target system, and decide on the logs to be retrieved.

Examples of log types are "operating system logs", "application run logs", and "database audit logs".

Organize log retrieval target access

In order to decide on access for log retrieval targets, organize what kind of access will take place.

For example, the following access is possible:

- Access related to important information
  - Access to personal information, confidential information, and database management information
  - Access outside of business hours
  - Login
  - Specific SQL
- Access suspected to be unauthorized
  - Large amount of search access
  - Access from different locations
  - Access outside of business hours

Decide on the log retrieval content

In order to effectively use retrieved logs, organize the required content as a log, and decide on the retrieval content.

For example, the following output content is possible:

- When (time)
- Who (database account, application user)
- What (object ID, table name)
- Where from (machine name, IP address)
- How (SQL type, SQL statement)
- Execution result (success/fail)

Formulate log maintenance policy

In order to use the logs as purposed, formulate the log maintenance policy.

For each log, define its location, storage medium, retention period, access control, and so on.

3.4 Formulating Rules

Formulate the rules that will become the standard for security measures of the target system. Additionally, prescribe penalties for security violations. For example, formulate rules and penalties as below:

- Rules
  - Applying security patches and update programs
  - Prohibiting unauthorized acquisition of information from the database
  - Prohibiting the saving of acquired information to media that is not permitted for use
- Penalties
  - Prescribe penalties in the company's employment policies and procedures

- Set fines

3.5 Implementing Training

In order to have administrators and users recognize the importance and necessity of information security, and to prevent unauthorized access due to operational omissions and mistakes, implement and promote security-related training for administrators and users.

For example, implement promotion of security policies, formulation of training schedules, and formulation of training materials.

3.6 Checking the Database Management Operations

In order to prevent operational errors and unauthorized actions by administrators, implement the measures below:

- Always collect the latest information on security incidents and vulnerabilities related to databases
- Implement management operations only after providing advance notice
- Retain records of management operations

3.7 Periodic Diagnosis of the Status of Security Measures

In order to check if the security measures are effective, periodically diagnose if the security measures have been put in place appropriately based on the security threats.

Additionally, evaluate if the current security measures and policies are effective for the threats and vulnerabilities, and if there are any issues, review the security policies and security measures.

Chapter 4 Tasks of Administrators

Administrators perform the actions below as security measures when designing, building, and operating the system in accordance with the security policies formulated by the manager.

Preparation

- Implement training

Measures to protect against unauthorized behavior

- Perform initial setup
- Authenticate
- Control access
- Encrypt
- Control use of external media
- Restrict access
- Restrict resources

Measures to detect and trace unauthorized behavior

- Manage logs
- Detect unauthorized access
- Analyze logs

4.1 Receiving Training

Administrators receive security-related training in accordance with the training schedule formulated by the manager. Additionally, administrators instruct users to receive training.

4.2 Initial Setup

To minimize database vulnerabilities and the possibility of unauthorized access, implement the security measures below in the initial stage of system building. Additionally, configure the database server so that it primarily operates the database system only.

Making the server more robust

Configure the operating system and network to prevent intrusion into or destruction of a database server, so that the system operates on a secure server.

- Remove unnecessary features or services on the operating system
- Enable only the necessary protocols
- Implement the security features for services, protocols, and daemons considered to have a relatively low security level, such as file sharing and FTP

Installing the latest version

Always download and apply the latest patches in order to reflect the latest security measures.

Installing the minimum necessary features

Install only the necessary features in order to prevent unauthorized use of the system.

Additionally, delete or disable features and services that will not be used.

Changing the port

To prevent unauthorized use of the system, change the default port that is set during installation.

Point

Specify the port during setup of Fujitsu Enterprise Postgres. Refer to the Installation and Setup Guide for Server for details.

Access restrictions for communication features

To prevent unauthorized use of the system using the communication features, implement access restrictions for communication features.

Settings for prohibiting the access path to database configuration files

To prevent database destruction, implement the measures below:

- Restrict users who are permitted to access database configuration files, and periodically review the permissions
- Allow only administrators to access table or definition scripts

Restrictions on the access path to the database

To prevent unauthorized use or operating errors for the database, restrict the distribution range of applications used to access the database only to devices used by users who are permitted access.

Dealing with unauthorized programs

To prevent unauthorized intrusions into a system through a backdoor, such as by tampering with the program source code of an application, document the author of the program to be run and perform checking and testing so that the program will not be tampered with. Additionally, employ safe coding techniques so that issues with general coding vulnerabilities can be addressed.

System security settings

In cases where it is clear that the system security settings will impact security, set reliable security settings in the initial setup stage, such as setting appropriate security parameters.

4.3 Authentication

When accessing a database, authentication must always be performed in order to prevent tampering or information leakage from spoofing by a malicious user.

Password authentication is used when logging on to a database, and the account and password used for authentication are to be strictly managed by administrators.

Additionally, authentication must also be implemented reliably for connections to a database from clients, so that only permitted users can access the database.

4.3.1 Managing Accounts

For account management, perform the actions below.

Create the required accounts

To prevent unauthorized use of accounts, such as spoofing, implement the measures below when creating an account:

- Select the required account
- Specify the user privileges
- Create database administrator accounts and general user accounts separately according to the privileges

Point

Accounts are created using the CREATE ROLE statement. Refer to "CREATE ROLE" in the PostgreSQL Documentation for details.

Delete unnecessary accounts

Remove accounts not used on a daily basis, such as unused accounts and accounts not needed for operations that are created by default during product installation.

Point

Accounts are deleted using the DROP ROLE statement. Refer to "DROP ROLE" in the PostgreSQL Documentation for details.

Set up account lockout

The usage frequency of accounts is to be checked periodically, and if there are any accounts that have not been used for a long period, lock those accounts. Set a limit for failed login attempts, and if this limit is exceeded, lock the account. Additionally, set the period until a locked account is reenabled.

Point

Account locking can be performed by using LDAP authentication. Refer to "LDAP Authentication" in the PostgreSQL Documentation for details.

Manage database administrator accounts

Manage database administrator accounts in accordance with the account management policy formulated by the manager.

Manage development environment and production environment accounts

To prevent unauthorized use of accounts used in a development environment, delete accounts used in the development environment before operation starts in the production environment. In cases where it is unavoidable to use an account used in the development environment in the production environment, use different passwords in each environment.

Set up a temporary use account

If a temporary user will use the system, either provide a shared account with a temporary password for each use, or create a temporary account.

4.3.2 Managing Passwords

Manage passwords as below.

Make strong passwords

The use of account passwords that can easily be guessed by others, such as a password that matches the ID, or the default password provided during installation, is prohibited. Set a complex and strong password.

Change passwords regularly

Change passwords regularly to prevent others from accessing the account in case the password is obtained by unauthorized means. Additionally, configure the settings to force a password change when prompted after the first use.

Set the password expiry period

To encourage regular changing of passwords, set a password expiry period.

In addition, by setting a password authentication policy called a profile, if a database user's password status deviates from the predefined policy, connection to the database server can be refused or the user can be forced to change their password. For information on setting password operation policies using profiles, refer to "Policy-based Login Security" in the Operation Guide.

Point

Password setting and changing is specified using the CERATE ROLE statement or ALTER ROLE statement. Refer to "CREATE ROLE" and "ALTER ROLE" in the PostgreSQL Documentation for details.

Additionally, by using passwordcheck and LDAP authentication, the actions below can be performed:

- The default password set during installation can be changed
- The password expiry period can be set
- The number and types of characters used for the password can be checked

Refer to "passwordcheck" and "LDAP Authentication" in the PostgreSQL Documentation for details.

4.3.3 Configuring Connections and Authentication

Configure connections and authentication so that the database can only be accessed by permitted users.

Point

Client authentication is configured in pg_hba.conf. Refer to "Client Authentication" in the PostgreSQL Documentation for details.

4.4 Access Control

If appropriate access privileges are not set for administrators and users, security incidents may occur, such as information leakage resulting from access to information by an unauthorized person. To minimize such incidents, it is necessary to implement the security measures below for the access privileges and perform rule-based access control.

Point

Notes when setting access privileges

- The creation of a special account that allows granting of privileges to all users is prohibited
- The creation of a general account that allows access to general information such as operations data is prohibited

Identifying the database access requirements

To set the appropriate access privileges for each usage purpose for the database, follow the procedure below to identify the access requirements:

1. Classify the usage purpose of the account, such as "For database management", "For object management", and "For data access".
2. Classify the required privileges for each usage purpose, such as "By feature" and "By object".
3. Categorize the accounts based on each privilege.
4. Identify the minimum necessary range of data and minimum necessary access content (view, update, create, delete) to be accessed for each categorized account, and decide on the database access requirements.

Setting the access privileges

Assign the minimum necessary privileges based on the database access requirements for each categorized account. Additionally, restrict accounts when assigning administrator privileges.

Reviewing access privileges

To reflect changes in access requirements in the system, periodically review the access privileges and check if there are any access privileges that are no longer needed. If any unnecessary access privileges have been set, promptly modify the access privileges.

Point

Access privileges are set using the GRANT statement or REVOKE statement. Refer to "GRANT" and "REVOKE" in the PostgreSQL Documentation for details.

4.5 Encryption

To prevent unauthorized usage of data in the event information leakage occurs due to data theft, eavesdropping of communication, and other such activities, implement the encryption measures below.

Encrypt communication

To protect data from eavesdropping over the network between a database server and clients, use the encryption feature to encrypt communications.

Refer to "Configuring Secure Communication Using Secure Sockets Layer" in the Operation Guide for details.

Encrypt data

To protect data from theft, use the encryption feature to encrypt the data. The data below is targeted for encryption:

- Data to be stored on the database
- Backup data
- Data files

Refer to "Protecting Storage Data Using Transparent Data Encryption" in the Operation Guide for details.

Manage encryption keys

Restrict the persons who can access the encryption key to a minimum number of database administrators.

Additionally, to ensure the encrypted information will not be easily decrypted, create a mechanism for appropriately managing the encryption key for the entire life cycle (generation, distribution, saving, and disposal), and strictly manage the encryption key.

Refer to "Configuring Secure Communication Using Secure Sockets Layer" and "Protecting Storage Data Using Transparent Data Encryption" in the Operation Guide for details.

4.6 Controlling Use of External Media

Information leakage can be prevented by controlling use of external media (such as CD/DVD, USB drive, and external hard disk) and PCs that are connected to the database, and restricting the removal of data from the database.

Restricting connection of external media

Remove external media and printers that will not be used in operations, and restrict connection of external media to which information may be written.

Restricting use of external media

Restrict connections for external media and printers to control the writing of information to these devices.

Controlling use of connected PCs

Prevent leakage of information from PCs connected to the database:

- Limit connections of external media to PCs
- Implement security measures to make the PC robust
- Implement individual authentication for access from the PC
- Manage the installed software and monitor the software usage status
- Limit connections to printers

4.7 Security Measures for Servers/Applications

An even more robust security system can be achieved by strengthening security for servers and applications in addition to the security measures for databases. Implement the security measures below for servers and applications:

Restrict access

Implement the measures below and restrict access to the database server:

- Install the database server inside the firewall to prevent direct access to the database server from many unspecified PCs.
- In the local network, implement measures such as using the router to restrict IP addresses, and restrict PCs and segments that can directly access the database server.

Restrict resources

Restrict excessive use of CPU resources by general users to prevent the disruption of service and extraction of large amounts of data.

4.8 Log Management

Logs are a feature that addresses threats such as misuse of administrator privileges, and unauthorized access to a database by a user. Information for investigating/tracing processes and operations performed for the database is retrieved and managed as logs for identifying the cause in the event information leakage or unauthorized access occurs.

Fujitsu Enterprise Postgres provides the audit log feature for retrieving and managing logs. Refer to "Chapter 6 Audit Log Feature" for details.

This section describes the information that should be obtained as logs and how to maintain logs, as a measure for managing information leakage and unauthorized access.

4.8.1 Retrieving Logs

The audit logs below are retrieved in accordance with the log retrieval policy formulated by the manager.

Login information

Retrieves logs during login and logout.

Database access information (view/update)

Retrieves all access relating to the information below:

- General database information (such as personal information and confidential information used in the business)
- Database management information (system catalog, user ID/password, and so on)

Changed information of database objects

Retrieves logs related to creating, changing, and deleting database objects such as database accounts and tables.

Operation logs for audit logs

To prevent suppression of retrieved audit logs, operations such as initialization of audit logs, and stoppage of the audit log feature are retrieved as logs.

4.8.2 Maintaining Logs

Logs are maintained in accordance with the log retrieval policy formulated by the manager.

Storing logs

Perform the actions below and store logs securely so that the retrieved logs will not be updated by others:

- Save logs to external media, and store the external media in a secure location, such as lockable storage
- Restrict the viewing of logs to administrators only, and set access restrictions for logs, such as not assigning update rights

- Decide on the log retention period, with consideration to cases where investigation tracing back to the time of discovery of an issue is required

Preventing tampering of logs

Implement measures to prevent tampering of logs, such as retaining multiple copies of logs and using storage that cannot be rewritten.

Encrypting logs

Encrypt logs so that logs are not easily viewed.

4.9 Detecting Unauthorized Access

To address unauthorized access, it is necessary to establish a mechanism for detecting unauthorized access to databases and monitor access.

Communicating unauthorized access

Create a mechanism that notifies of detected unauthorized access, such as notifying the manager and the administrator, if an account lock occurs due to the limit for failed login attempts being exceeded.

Checking access times

Create a mechanism that can check for suspicious access to the information below outside of normal access hours, together with implementing measures to address such access.

Detecting access to database management information

- Monitor logs and detect access during timeframes that have not been applied for
- In the event a request for access permission outside of normal access hours is made, the log is checked for any discrepancies in the requested content and work result

Detecting access to general database information

- Decide on the timeframes during which access to the database is permitted for each general account
- Detect access outside of normal access hours from session information logs

Checking the connection source where access is not permitted

To detect access from connection sources that are not permitted, define the sources from where access is permitted, and detect access from connection sources that are not permitted.

Define the access patterns (connection source, operating system user and account) of database administrator accounts and general accounts, and check for access outside of these patterns.

4.10 Analyzing Logs

Create a mechanism that analyzes logs to detect unauthorized behavior in cases where information leakage, unauthorized access, or other such activity, is suspected. Analyses should include those shown below.

Periodic analysis of session information

Analyze session information of logs from the perspectives below to detect unauthorized logins:

- Trend of sessions with a large number of failed login attempts
- Trend of sessions with accounts that are logged in for long periods of time
- Trend of sessions in which a large amount of resources are used

Periodic analysis of database access information

Analyze SQL statements from the perspectives below to detect unauthorized access to the database:

- Trend of SQL being executed over a long period of time
- Trend of SQL using a large amount of resources

Chapter 5 Tasks of Users

The user performs the actions below as security measures when using the system.

5.1 Receiving Training

The user must receive security-related training as instructed by the manager or the administrator to learn about security. By having users with a common awareness relating to security, an even more stable security system can be established.

5.2 Managing Accounts/Passwords

Users can use the database system by using the account and password provided by the administrator. At such times, the user is to implement the measures below so that the account and password are not misused by others:

- Be responsible for managing the ID and password in a manner that ensures the account does not become locked during login
- Change the password regularly
- Comply with the expiry period set for the password by promptly changing the password when it is about to expire

Chapter 6 Audit Log Feature

In PostgreSQL, logs output as server logs can be used as audit logs by using the log output feature. There are, however, logs that cannot be analyzed properly, such as SQL runtime logs, which do not output the schema name. Additionally, because the output conditions cannot be specified in detail, log volumes can be large, which may lead to deterioration in performance.

The audit log feature of Fujitsu Enterprise Postgres enables retrieval of details relating to database access as an audit log by extending the feature to pgaudit. Additionally, audit logs can be output to a dedicated log file or server log. This enables efficient and accurate log monitoring.

The scalable audit log feature enables multiple output mechanisms to capture audit logs without performance degradation, even for systems with high application multiplicity and high output volumes.

If you want to take advantage of the scalable audit log feature, refer to "6.2 Setup" and "6.3 Setting Up the Scalable Audit Log Feature.

Note

The audit log feature cannot be used if PostgreSQL is running in single-user mode.

6.1 Audit Log Output Modes

In pgaudit, the two types of audit log below can be output.

Session Audit Logging

Session Audit Logging outputs information related to SQL executed in backend processes (processes generated when connection requests are received from clients), information related to starting and connecting databases, and information related to errors, as a log. In Session Audit Logging, by specifying the log output conditions and filtering the logs to be output, performance degradation due to outputting large volumes of logs can be prevented.

Refer to "6.5 Session Audit Logging" for details.

Object Audit Logging

When SELECT, INSERT, UPDATE, and DELETE are executed for specific objects (tables, columns), Object Audit Logging outputs these as a log. TRUNCATE is not supported. Object Audit Logging outputs object operations for which privileges have been assigned to specified roles, as a log. Object Audit Logging can control log output at an even finer level of granularity than Session Audit Logging.

Refer to "6.6 Object Audit Logging" for details.

Information

Depending on the application or command, Fujitsu Enterprise Postgres may execute SQL internally and the audit logs may be retrieved.

Also, the audit logs of multiple SQLs with the same statement ID may be retrieved. This is because before the user executes the SQL, another SQL is executed internally by Fujitsu Enterprise Postgres.

6.2 Setup

This section describes the setup method of pgaudit.

1. Copy the pgaudit files

   As superuser, run the following command. Note that "<*x*>" in paths indicates the product version.

```
$ su -
Password:******
# cp -r /opt/fsepv<x>server64/OSS/pgaudit/* /opt/fsepv<x>server64
```

W

Open a command prompt as administrator privileges, run the following command. Note that "<*x*>" in paths indicates the product version.

```
> xcopy /E "c:\Program Files\Fujitsu\fsepv<x>server64\OSS\pgaudit\*"  "c:\Program
Files\Fujitsu\fsepv<x>server64"
```

2. Create the pgaudit configuration file

   Create the pgaudit configuration file, which describes the information required for pgaudit actions. Create the file using the same encoding as used for the database.

   In addition, set write permissions for the database administrator only in the pgaudit configuration file so that policies related to the audit log are not viewed by unintended users.

   Refer to "6.4 pgaudit Configuration File" for details.

   Note

   Do not define the rule section in the pgaudit configuration file at this point.

   Example of a pgaudit configuration file

   ```
   [output]
   logger = 'auditlog'
   ```

3. Configure postgresql.conf

   Configure the parameters below in postgresql.conf to use audit logs:

   shared_preload_libraries

   Specify "pgaudit".

   pgaudit.config_file

   Specify the deployment destination path of the pgaudit configuration file.

   If a relative path is specified, the path will be relative to the data storage directory.

   log_replication_commands

   Specify "on".

   log_min_messages

   Check if "ERROR" or higher has been specified.

   If outputting an audit log to a server log ("serverlog" is specified in the logger parameter of the pgaudit configuration file), check the parameters below relating to server logs.

   logging_collector

   Check if "on" has been specified.

   log_destination

   Check if "stderr" has been specified.

L

log_file_mode

Check if the server log permissions are appropriate, so that only the permitted persons can access it.

Information

The default for the log_file_mode parameter is 0600, which only allows the database administrator to have access.

For example, to permit other members of the group to which the database administrator belongs to view the audit logs, specify 0640 for log_file_mode.

Example

```
log_file_mode = 0640
```

The database administrator can also be prevented from viewing audit logs by specifying 0000. However, write privileges are assigned for outputting logs.

If outputting an audit log to a dedicated log file ("auditlog" is specified in the logger parameter of the pgaudit configuration file), check the parameter below.

max_worker_processes

If the max_worker_processes parameter has been set, add 1 to the specified value.

If you want to take advantage of the scalable audit log feature, refer to "6.3 Setting Up the Scalable Audit Log Feature".

See

Refer to "Error Reporting and Logging" in the PostgreSQL Documentation for details on server logs.

If using database multiplexing, refer to "6.7 Database Multiplexing" for details.

Example of postgresql.conf

In the example below, only the parameters that need to be configured when using the audit log feature are described.

```
shared_preload_libraries = 'pgaudit'
pgaudit.config_file = 'pgaudit.conf'
log_replication_commands = on
log_min_messages = WARNING
```

4. Start the instance

   Start the instance and check if the message below is output.

```
LOG: pgaudit extension initialized
```

5. Create the pgaudit extension

   Execute CREATE EXTENSION to create the pgaudit extension.

```
$ psql
=# CREATE EXTENSION pgaudit;
=# \dx
                  List of installed extensions
Name    | Version |   Schema   |     Description
--------+---------+------------+---------------------------------
pgaudit | 1.0     | public     | provides auditing functionality
plpgsql | 1.0     | pg_catalog | PL/pgSQL procedural language
(2 rows)
```

6. Configure the parameters in the pgaudit configuration file

   Add or change the parameters in the pgaudit configuration file as required.

   Refer to "6.4 pgaudit Configuration File" for details.

7. Restart the instance

   Restart the instance to apply the changes to the pgaudit configuration file. After restarting, check if the changes have been reflected correctly.

Linux

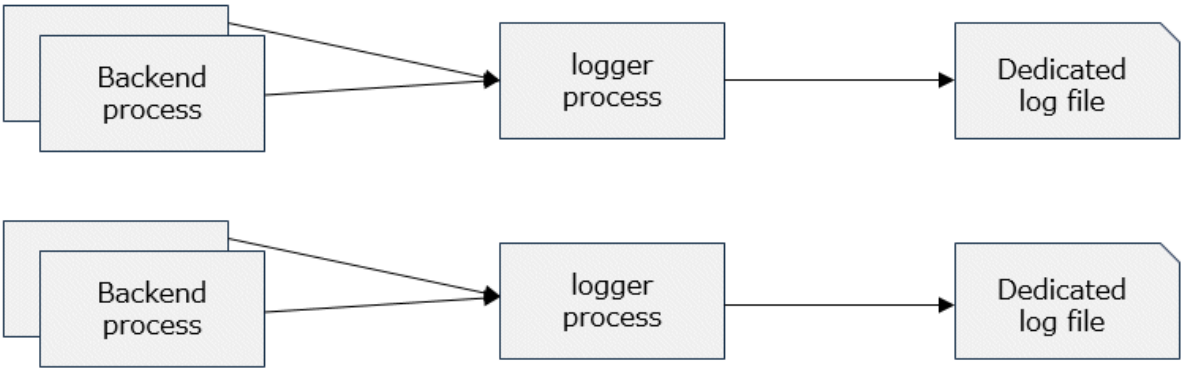
```
LOG:  log_catalog = 1
LOG:  log_level_string =
LOG:  log_level = 15
LOG:  log_parameter = 0
LOG:  log_statement_once = 0
LOG:  role =
LOG:  logger = auditlog
LOG:  log_directory = pgaudit_log
LOG:  log_filename = pgaudit-%Y-%m-%d_%H%M%S.log
LOG:  log_file_mode = 0600
LOG:  log_rotation_age = 1440
LOG:  log_rotation_size = 10240
LOG:  log_truncate_on_rotation = 0
LOG:  fifo_directory = /tmp
LOG:  Rule 0
LOG:  pgaudit extension initialized
```

Windows

```
LOG:  log_catalog = 1
LOG:  log_level_string =
LOG:  log_level = 15
LOG:  log_parameter = 0
LOG:  log_statement_once = 0
LOG:  role =
LOG:  logger = auditlog
LOG:  log_directory = pgaudit_log
LOG:  log_filename = pgaudit-%Y-%m-%d_%H%M%S.log
LOG:  log_file_mode = 0600
LOG:  log_rotation_age = 1440
LOG:  log_rotation_size = 10240
LOG:  log_truncate_on_rotation = 0
LOG:  Rule 0
LOG:  pgaudit extension initialized
```

6.3 Setting Up the Scalable Audit Log Feature

With normal audit log feature, there is only one logger process and only one dedicated log file.
Therefore, the load of audit logs, including logs output by all backend processes, in the instance concentrates to the logger process and dedicated log file.
The scalable audit log feature distributes multiple dedicated log files, as shown below, and executes multiple output processes (logger processes) in a one-to-one relationship with those files. The number of distributions can be changed by parameter settings.



Information

Because there is a one-to-one relationship between the dedicated log file and the logger process, the logger process also operates as many dedicated log files as there are. A number is appended to the end of the its command title as reported by ps or Process Explorer, as follows. Use this information as a reference when monitoring the process status.

Example

```
pgaudit logger 0
pgaudit logger 1
pgaudit logger 2
```

Parameters in the pgaudit configuration file

Set the following parameters to the "output section":
Refer to the "6.4 pgaudit Configuration File" for details on the parameters.

enable_parallel_logger

Set "on". The default is "off".
If the logger parameter in the pgaudit configuration file is not "auditlog" (the default), it is ignored even if set to "on"

parallel_loggers

Sets the number of logger processes. Specify a value greater than or equal to "2."
Refer to "6.4 pgaudit Configuration File" for an estimate of the values to set.

log_rotation_age

We strongly recommend that you set this parameter. Although the scalable audit log feature works without configuration, it is easier to avoid incorrect analysis when analyzing the output audit logs. Refer to "Considerations when Using the Scalable Audit Log Feature".

Example

```
[output]
enable_parallel_logger = on
parallel_loggers = 5
log_rotation_age = 1h
```

postgresql.conf Parameters

max_worker_processes

Adds the value set for parallel_loggers to the value set for the max_worker_processes parameter. This is because the logger process acts as a background worker.

Example

If max_worker_processes is set to 8 and you want to set parallel_loggers to 3, do the following:

```
max_worker_processes = 11
```

Storage location of the dedicated log file

A dedicated log file is output with the following path and name:
For more information about the log_directory and log_filename parameters, refer to "6.4 pgaudit Configuration File".

```
log_directory parameter setting/number/number-log_filename parameter setting
```

The number is a number between 0 and the number specified by parallel_loggers. If parallel_loggers is 3, it can be 0 or greater and 2 or less. For more information about how to analyze these multiple files, refer to "6.9 Analyzing Audit Logs in SQL".

Example

If you set parallel_loggers=3, a dedicated log file is generated as follows:

```
pgaudit_log/0/0-pgaudit-2024-02-02_153000.log
pgaudit_log/1/1-pgaudit-2024-02-02_153000.log
pgaudit_log/2/2-pgaudit-2024-02-02_153000.log
```

If you can use multiple disks, you can also distribute the disk I/O load by setting the dedicated log file storage directory as a symbolic link to another disk, as shown below.
For Windows, use junction instead of symbolic links.

Example

Place pgaudit_log/2 on a different disk:

L

```
ln -s /other_disk/2  pgaudit_log/2
```

W

```
mklink /J pgaudit_log\2 E:\other_disk\2
```

Depending on the situation, create a symbolic link as follows. If the directory (or symbolic link) specified as the log output destination for the scalable audit log feature does not exist, the directory is automatically created. If the directory already exists, it is used as the log output destination.

- If you are using the scalable audit log feature for the first time, there is no dedicated log file directory. In this case, create a symbolic link after stopping the instance.
- If you are already using the scalable audit log feature, you already have a dedicated log file directory. After stopping the instance, move the stored dedicated log file to another location, and then delete the storage directory. Then, create a symbolic link with the same name as the deleted directory.

6.4 pgaudit Configuration File

In the pgaudit configuration file, specify the information required for pgaudit actions. The pgaudit configuration file comprises three sections: "output section", "option section", and "rule section".

output section

The output section is specified using the format below:

- *paramName* = '*value*'

The valid parameters in the output section are shown in the table below.

L

Linux

Parameter name	Description	Remarks
logger	Dedicated log file (auditlog)/*serverLog* (serverlog) that will be the output destination of the audit log The default is "auditlog" (dedicated log file).	The dedicated log file is output using the same encoding as used for the database.
log_directory	Directory where the audit log is to be created Specify the full path or the relative path from the data storage directory. The default is "pgaudit_log". However, make sure that audit log files are not output under the data storage directory. This is because if you are a backup target, such as pg_basebackup, and recover using that backup data, the audit log from the current time to the backup time will disappear. This is fine if the audit log file is located at the end of the symbolic link. This is because backups such as pg_basebackup do not track such symbolic links. If you specify "on" for the enable_parallel_logger parameter, an audit log is created for "log_directory parameter setting/number". Refer to "6.3 Setting Up the Scalable Audit Log Feature" for more information.	Enabled only if "auditlog" is specified for the logger parameter
log_filename	File name of the audit log Specify a file name that varies according to the time, in the same manner as for log_filename in the postgresql.conf file. The default is "pgaudit-%Y-%m-%d_%H%M%S.log". If you specify "on" for the enable_parallel_logger parameter, the audit log filename is "number-log _filename parameter setting". Refer to "6.3 Setting Up the Scalable Audit Log Feature" for more information.	Enabled only if "auditlog" is specified for the logger parameter
log_file_mode	Specify the permissions of the audit log so that only permitted persons can access it. The parameter value is the numeric mode specified in the format permitted in chmod and umask system calls. The default is "0600". Refer to "log_file_mode" in "6.2 Setup" for information on audit log file permissions.	Enabled only if "auditlog" is specified for the logger parameter
log_rotation_age	Maximum age of the audit log file A new audit log file is generated when the time (minute units) specified here elapses. To disable generation of new log files based on time, specify "0". The valid units are "min" (minutes), "h" (hours), and "d" (days). If the unit is omitted, "min" will be used. The default is "1d" (1 day). We strongly recommend that you set this parameter if you want to take advantage of the scalable audit log feature. This is because all logger processes rotate their dedicated log files at the same time, making it easier to	Enabled only if "auditlog" is specified for the logger parameter

Parameter name	Description	Remarks
	avoid incorrect analysis. For more information, refer to "Considerations when Using the Scalable Audit Log Feature".	
log_rotation_size	Maximum size of the audit log file A new log file will be generated after logs of the size specified here are output to a log file. To disable generation of new log files based on size, specify "0". The valid units are "kB" (kilobytes), "MB" (megabytes), and "GB" (gigabytes). If the unit is omitted, "kB" will be used. The default is "10MB".	Enabled only if "auditlog" is specified for the logger parameter
log_truncate_on_rotation	If rotating audit log files based on time, this parameter is used to specify whether to overwrite (on)/not overwrite (off) existing audit log files of the same name. For example, if "on" is specified, and "pgaudit-%H.log" is specified for log_filename, 24 separate log files will be generated based on time, and those files will be cyclically overwritten. The default is "off". If "off" is specified, the logs will be written to the existing audit log files.	Enabled only if "auditlog" is specified for the logger parameter
fifo_directory	FIFO (named pipe) directory to be used between the daemon process that outputs audit log files and the backend process FIFO named p.PGAUDIT.*nnnn* (*nnnn* is the postmaster PID) are created in the fifo_directories directory. The files cannot be deleted manually. The default is "/tmp". If you specify "on" for the enable_parallel_logger parameter, the name of the FIFO is "p. PGAUDIT. nnnn. number". Refer to "6.3 Setting Up the Scalable Audit Log Feature" for more information about the numbers.	Enabled only if "auditlog" is specified for the logger parameter
enable_parallel_logger	Specify whether to distribute the audit log output load (on)/not (off). The default is "off". The setting of this parameter is ignored when you specify "serverlog" for the logger parameter, because the serverlog of the database server cannot be distributed.	Enabled only if "auditlog" is specified for the logger parameter
parallel_loggers	Specifies the multiplicity at which the output load of the audit log is to be distributed. You can specify a number greater than or equal to 1, but to distribute the audit log output load, specify a number greater than or equal to 2. The default is "2". Estimate parallel_loggers as follows: parallel_loggers = number of cores / 2 This estimate assumes the highest load to output audit logs, so setting a value less than the estimated value will not significantly degrade performance in most cases. The disadvantage of increasing this value is that it consumes a little more memory. For more information about estimating memory, refer to "FUJITSU Enterprise	Enabled only if "auditlog" is specified for the logger parameter

Parameter name	Description	Remarks
	Postgres Memory Requirements" in the Installation and Setup Guide for Server. Because the logger process acts as a background worker, add the value set for this parameter to the parameter max_worker_processes in postgresql.conf that sets the maximum number of background workers. [Note] If the max_worker_processes setting is insufficient, the instance cannot be started.	

Windows

Parameter name	Description	Remarks
logger	Dedicated log file (auditlog)/*serverLog* (serverlog) that will be the output destination of the audit log The default is "auditlog" (dedicated log file).	The dedicated log file is output using the same encoding as used for the database.
log_directory	Directory where the audit log is to be created Specify the full path or the relative path from the data storage directory. The default is "pgaudit_log". However, make sure that audit log files are not output under the data storage directory. This is because if you are a backup target, such as pg_basebackup, and recover using that backup data, the audit log from the current time to the backup time will disappear. This is fine if the audit log file is located at the end of the junction. This is because backups such as pg_basebackup do not track such junction. If you specify "on" for the enable_parallel_logger parameter, an audit log is created for "log_directory parameter setting/number". Refer to "6.3 Setting Up the Scalable Audit Log Feature" for more information.	Enabled only if "auditlog" is specified for the logger parameter
log_filename	File name of the audit log Specify a file name that varies according to the time, in the same manner as for log_filename in the postgresql.conf file. The default is "pgaudit-%Y-%m-%d_%H%M%S.log". If you specify "on" for the enable_parallel_logger parameter, the audit log filename is "number-log _filename parameter setting". Refer to "6.3 Setting Up the Scalable Audit Log Feature" for more information.	Enabled only if "auditlog" is specified for the logger parameter
log_file_mode	This parameter is ignored in Windows.	
log_rotation_age	Maximum age of the audit log file A new audit log file is generated when the time (minute units) specified here elapses. To disable generation of new log files based on time, specify "0". The valid units are "min" (minutes), "h" (hours), and "d" (days). If the unit is omitted, "min" will be used.	Enabled only if "auditlog" is specified for the logger parameter

Parameter name	Description	Remarks
	The default is "1d" (1 day). We strongly recommend that you set this parameter if you want to take advantage of the scalable audit log feature. This is because all logger processes rotate their dedicated log files at the same time, making it easier to avoid incorrect analysis. For more information, refer to "Considerations when Using the Scalable Audit Log Feature".	
log_rotation_size	Maximum size of the audit log file A new log file will be generated after logs of the size specified here are output to a log file. To disable generation of new log files based on size, specify "0". The valid units are "kB" (kilobytes), "MB" (megabytes), and "GB" (gigabytes). If the unit is omitted, "kB" will be used. The default is "10MB".	Enabled only if "auditlog" is specified for the logger parameter
log_truncate_on_rotation	If rotating audit log files based on time, this parameter is used to specify whether to overwrite (on)/not overwrite (off) existing audit log files of the same name. For example, if "on" is specified, and "pgaudit-%H.log" is specified for log_filename, 24 separate log files will be generated based on time, and those files will be cyclically overwritten. The default is "off". If "off" is specified, the logs will be written to the existing audit log files.	Enabled only if "auditlog" is specified for the logger parameter
enable_parallel_logger	Specify whether to distribute the audit log output load (on)/not (off). The default is "off". The setting of this parameter is ignored when you specify "serverlog" for the logger parameter, because the serverlog of the database server cannot be distributed.	Enabled only if "auditlog" is specified for the logger parameter
parallel_loggers	Specifies the multiplicity at which the output load of the audit log is to be distributed. You can specify a number greater than or equal to 1, but to distribute the audit log output load, specify a number greater than or equal to 2. The default is "2". Estimate parallel_loggers as follows: parallel_loggers = number of cores / 2 This estimate assumes the highest load to output audit logs, so setting a value less than the estimated value will not significantly degrade performance in most cases. The disadvantage of increasing this value is that it consumes a little more memory. For more information about estimating memory, refer to "FUJITSU Enterprise Postgres Memory Requirements" in the Installation and Setup Guide for Server. Because the logger process acts as a background worker, add the value set for this parameter to the parameter max_worker_processes in postgresql.conf that sets the maximum number of background workers.	Enabled only if "auditlog" is specified for the logger parameter

Parameter name	Description	Remarks
	[Note] If the max_worker_processes setting is insufficient, the instance cannot be started.	

Information

If the logger parameter is set to "serverlog", audit logs will be output to the server log as log messages, therefore the status information and message severity level according to the log_line_prefix parameter in postgresql.conf will be output to the beginning of the audit log.

If the logger parameter is omitted or set to "auditlog", audit logs will be output to a dedicated log file as dedicated logs, therefore the status information and message severity level according to the log_line_prefix parameter in the postgresql.conf file will not be output.

Refer to "Output format" in "6.5 Session Audit Logging"or "Output format" in "6.6 Object Audit Logging" for information on the output format of audit logs.

L

Point

The pgaudit log_file_mode configuration parameter setting is separate from, and unaffected by, the log_file_mode GUC parameter setting and the -g/-allow-group-access initdb option.

When using a dedicated pgaudit log file, since the pgaudit log_directory location defaults to inside the data storage directory, it is possible for the pgaudit log_file_mode permissions to conflict with the intended file permissions specified by the -g/-allow-group-access initdb option. In this case, the pgaudit log_directory should be specified to be a directory located outside of the data storage directory.

W

Point

If the file permissions for the server log do not satisfy the security requirements of the system, specify a dedicated log file for the output destination of the audit log, and set the access permissions for the output destination directory so that the security requirements are satisfied. At that time, assign read and write permissions to the database administrator.

option section

The option section is specified using the format below:

- *paramName* = '*value*'

The valid parameters in the option section are shown in the table below.

Parameter name	Description	Remarks
role	Name of roles used in Object Audit Logging If specifying a name containing uppercase characters, key words, multibyte characters and commas, enclose the name in double quotation marks.	Parameter used in Object Audit Logging only
log_catalog	Whether to enable (on)/disable (off) log output for pg_catalog	

Parameter name	Description	Remarks
	If pgAdmin, and so on, will not be retrieving audit logs that access pg_catalog, specify "off". The default is "on" (enabled).	
log_parameter	Whether to enable (on)/disable (off) output of values passed by parameters in SQL execution The default is "off" (disabled).	
log_statement_once	Whether to control (on)/not control (off) output for the second and subsequent SQL statements if the same SQL statement is the log output target The default is "off" (do not control).	
log_level	Log level of audit logs The valid values are "DEBUG5", "DEBUG4", "DEBUG3", "DEBUG2", "DEBUG1", "INFO", "NOTICE", "WARNING", and "LOG". The default is "LOG".	Enabled only if "serverlog" is specified for the logger parameter
audit_log_disconnections	When using Mirroring Controller, specify whether to enable (on) or disable (off) the output of disconnection logs for connections other than those of Mirroring Controller. The default is "off" (disabled). This parameter is valid when log_disconnections in postgresql.conf is off.	Parameter used in Session Audit Logging only

rule section

The rule section is used in Session Audit Logging. Refer to "6.5 Session Audit Logging" for details.

Note

Do not specify the rule section if the role parameter has been specified in the option section. If you specify the rule section, the audit logs of Object Audit Logging and Session Audit Logging will be output intermingled. The CSV format of the role audit log and the CSV format of the rule audit log are different, you will be unable to view in CSV format.

6.5 Session Audit Logging

In Session Audit Logging, specify the rules for filtering logs to be output in the rule section in the pgaudit configuration file.

Rules are specified using the formats below. Multiple values can be specified, using a comma as the delimiter.

- *paramName* = '*value*'
- *paramName* != '*value*'

If [rule] is described on its own in the rule section with no parameters specified, all audit logs of Session Audit Logging will be output.

Example

```
[output]
logger = 'auditlog'
[rule]
```

If [rule] is not described as a section, audit logs of Session Audit Logging will not be output.

Example

```
[output]
logger = 'auditlog'
```

The valid parameters in the rule section are shown in the table below.

Parameter name	Description	Example
timestamp	Timestamp range Refer to "timestamp" for details on how to specify timestamps.	timestamp = '09:00:00 - 10:00:00, 18:00:00 - 18:30:00'
database	Database name To specify a blank value, specify use a pair of double quotation marks ("") instead of the *value*. When specifying a name containing uppercase characters, key words, multibyte characters and commas, enclose the name in double quotation marks.	database = 'prodcut_db'
audit_role	Role name To specify a blank value, specify use a pair of double quotation marks ("") instead of the *value*. When specifying a name containing uppercase characters, key words, multibyte characters and commas, enclose the name in double quotation marks.	audit_role = 'appuser1'
class	Operation class Select from the values below. Multiple values can be specified. Refer to "class" for details on the meaning of each class. - BACKUP - CONNECT - DDL - ERROR - FUNCTION - MISC - READ - ROLE - WRITE - SYSTEM	class = 'READ, WRITE'
object_type	Object type This parameter is enabled when the class parameter is "READ" and "WRITE". Select from the values below. Multiple values can be specified.	object_type = 'TABLE, INDEX'

Parameter name	Description	Example
	- TABLE - INDEX - SEQUENCE - TOAST_VALUE - VIEW - MATERIALIZED_VIEW - COMPOSITE_TYPE - FOREIGN_TABLE - FUNCTION	
object_name	Object name This parameter is enabled when the class parameter is "READ" and "WRITE". For objects that can be modified by a schema, such as a table, modify such objects by schema name. When specifying a name containing uppercase characters, key words, multibyte characters and commas, enclose the name in double quotation marks. When specifying the object name "*schemaName*.*tableName*", enclose the entire object name modified by schema name in double quotation marks. To specify a blank value, use a pair of double quotation marks ("") instead of the *value*.	object_name = 'myschema.tbl1' object_name = 'myschema.tbl1, "*mySchema*.TABLE"'
application_name	Application name To specify a blank value, use a pair of double quotation marks ("") instead of the *value*.	application_name = 'myapp'
remote_host	Connection source(client side) host name or IP address If "on" is specified for the log_hostname parameter in the postgresql.conf file, specify a host name. Otherwise, specify the IP address. If using a local host, specify "[local]". To specify a blank value, use a pair of double quotation marks ("") instead of the *value*.	remote_host = 'ap_server'

timestamp

Specify a timestamp range from "*startTime*" to "*endTime*" for the log output target. The timestamp format is 'hh:mm:dd-hh:mm:dd' (hh is expressed in 24-hour notation, and hh, mm, and dd are expressed in two-digit notation).

The start time must be earlier than the end time. If specifying multiple ranges, specify each start and end timestamp using a comma as the delimiter.

End timestamps consider milliseconds. For example, if '11:00:00 - 11:59:59' is specified for the timestamp, "11:00:00:000" to "11:59:59:999" will be the target range.

The timestamps used by evaluation in the rule section of pgaudit are different to the timestamps issued in the log entries. That is because log entries are output after evaluation by pgaudit, with the timestamp being generated at that time.

class

The meaning of each class specified in the class parameter is below:

- READ: SELECT, COPY FROM
- WRITE: INSERT, UPDATE, DELETE, TRUNCATE, COPY TO
- FUNCTION: Function call, DO
- ROLE: GRANT, REVOKE, CREATE ROLE, ALTER ROLE, DROP ROLE
- DDL: All DDLs (such as CREATE and ALTER) other than the DDLs of the ROLE class
- CONNECT: Events relating to connecting (request, authenticate, and disconnect)
- SYSTEM: Instance start, promotion to primary server
- BACKUP: pg_basebackup
- ERROR: Event completed by an error (PostgreSQL error codes other than 00). This class can be used if ERROR or lower level is specified for the log_min_messages parameter in postgresql.conf.
- MISC: Other commands (such as DISCARD, FETCH, CHECKPOINT, and VACUUM)

Evaluation of the rule section

- When a log event occurs, all expressions in the rule section are evaluated at once. Log entries are only output if all parameters in the rule section are evaluated as being true.

  For example, if the rule below has been set, of the operations performed by 'apserver' to 'myschema.tbl1', the operations applicable to classes other than 'WRITE" in the period from 10 a.m. to 11 a.m. will be output as audit logs.

  ```
  [rule]
  timestamp = '10:00:00-11:00:00'
  remote_host = 'apserver'
  object_name = 'myschema.tbl1'
  class != 'WRITE'
  ```

- Multiple rule sections can be defined in the pgaudit configuration file. Log events are evaluated using each rule section, and an audit log is output for each matching rule section.

  For example, if the rules below are set, duplicated audit logs will be output.

  ```
  [rule]
  object_name = 'myschema.tbl1'
  [rule]
  object_name = 'myschema.tbl1'
  ```

- If the same parameter is specified multiple times in one rule section, the last specified parameter is effective.

  For example, if the rule below has been set, "object_name = 'myschema.tbl3'" will take effect.

  ```
  [rule]
  object_name = 'myschema.tbl1'
  object_name = 'myschema.tbl2'
  object_name = 'myschema.tbl3'
  ```

Output format

In Session Audit Logging, audit logs are output in the format below:

```
AUDIT: SESSION,READ,2022-03-12 19:00:58 PDT,
   (1)         (2)     (3)
[local],19944,psql,appuser,postgres,2/8, 2, 1,SELECT,,TABLE,myschema.account, ,
  (4)    (5)   (6)   (7)      (8)   (9)(10)(11)(12)(13)(14)    (15)        (16)
SELECT * FROM myschema.account;,<not logged>
       (17)                      (18)
```

No	Content
(1)	Log header Fixed as "AUDIT: SESSION".
(2)	Class
(3)	SQL start time
(4)	Remote host name If using a local host, [local] is output.
(5)	Backend process ID
(6)	Application name If an application name is not specified, [unknown] is output.
(7)	User name
(8)	Database name
(9)	Virtual transaction ID
(10)	Statement ID
(11)	Substatement ID
(12)	Command tag
(13)	SQLSTATE
(14)	Object type
(15)	Object name
(16)	Error message
(17)	SQL If the SQL contains a password, such as for CREATE ROLE, and so on, it will be replaced with "<REDACTED>". Additionally, if "on" is specified for the log_statement_once parameter of the option section in the pgaudit configuration file, "<previously logged>" is output for the second and subsequent statements.
(18)	Depending on the log_parameter parameter value of the option section in the pgaudit configuration file, the output content will be as below. - log_parameter=on is specified If parameters are specified in the SQL, the parameters are concatenated and output, using a space as the delimiter. If parameters are not specified in the SQL, "<none>" is output. - log_parameter=off (default) is specified "<not logged>" is output.

No	Content
	Additionally, if "on" is specified for the log_statement_once parameter of the option section in the pgaudit configuration file, "<previously logged>" is output for the second and subsequent statements.

Information

If accessing resources that use the features below, the command tag (12) may be output as "???".

- INSTEAD OF trigger
- RULE
- VIEW
- Security policy per row
- Table inheritance

Example

Below is an example of retrieving audit logs in Session Audit Logging.

1. Settings

   In the pgaudit configuration file, specify the rule section below.

```
[rule]
class = 'READ, WRITE'
object_name = 'myschema.account'
```

2. Retrieving logs

   Execute the SQL below from the client.

```
CREATE TABLE myschema.account
(
    id int,
    name text,
    password text,
    description text
);
INSERT INTO myschema.account (id, name, password, description) VALUES (1, 'user1',
'HASH1', 'blah, blah');
SELECT * FROM myschema.account;
```

   The audit log below can be retrieved.

   'DDL' is not defined in the class parameter, so CREATE TABLE is not output as an audit log.

```
AUDIT: SESSION,WRITE,2022-03-12 19:00:49 PDT,[local],19944,psql,appuser,postgres,
2/7,1,1,INSERT,,TABLE,myschema.account,,"INSERT INTO myschema.account (id, name,
password, description) VALUES (1, 'user1', 'HASH1', 'blah, blah');",<not logged>
AUDIT: SESSION,READ,2022-03-12 19:00:58 PDT,[local],19944,psql,appuser,postgres,
2/8,2,1,SELECT,,TABLE,myschema.account,,SELECT * FROM myschema.account;,<not logged>
```

6.6 Object Audit Logging

In Object Audit Logging, retrieval of audit logs is achieved by using roles.

Roles are specified in the role parameter of the option section to retrieve audit logs. If there are privileges for commands executed by a role, or if privileges have been inherited from another role, those command operations are output as audit logs.

For example, after "auditor" is set for the role parameter of the option section, the SELECT and DELETE privileges for the account table are assigned to "auditor". In this case, when SELECT or DELETE is executed for the account table, audit logs are output.

Output format

In Object Audit Logging, audit logs are output in the format below:

```
AUDIT: OBJECT,1,1,READ,SELECT,TABLE,public.account,SELECT password FROM account;,<not
logged>
     (1)    (2)(3)(4)  (5)    (6)        (7)              (8)                    (9)
```

No	Content
(1)	Log header Fixed as "AUDIT: OBJECT".
(2)	Statement ID
(3)	Substatement ID
(4)	Class name
(5)	Command tag
(6)	Object type
(7)	Object name
(8)	SQL If "on" is specified for the log_statement_once parameter of the option section in the pgaudit configuration file, "<previously logged>" is output for the second and subsequent statements.
(9)	Depending on the log_parameter parameter value of the option section in the pgaudit configuration file, the output content will be as below. - When log_parameter=on If parameters are specified in the SQL, the parameters are concatenated and output, using a comma as the delimiter. If parameters are not specified in the SQL, "<none>" is output. - When log_parameter=off (default) "<not logged>" is output. Additionally, if "on" is specified for the log_statement_once parameter of the option section in the pgaudit configuration file, "<previously logged>" is output for the second and subsequent statements.

Information

If accessing resources that use the features below, the command tag (5) may be output as "???".

- INSTEAD OF trigger
- RULE
- VIEW
- Security policy per row
- Table inheritance

Example

Below is an example of retrieving logs in Object Audit Logging.

By setting the target for assigning privileges to roles in detail, log output can be controlled.

In the example below, log retrieval of the account table is controlled by the privileges assigned to the columns, however, log retrieval of the account_role_map table is controlled by the privileges assigned to the table.

1. Settings

The role parameter below is specified for the option section in the pgaudit configuration file.

```
[option]
role = 'auditor'
```

2. Defining a role

A role is defined for Object Audit Logging.

```
CREATE USER auditor NOSUPERUSER LOGIN;
```

3. Retrieving logs

Execute the SQL below from the client.

```
CREATE TABLE account
(
    id int,
    name text,
    password text,
    description text
);
GRANT SELECT (password) ON public.account TO auditor;
SELECT id, name FROM account;
SELECT password FROM account;
GRANT UPDATE (name, password) ON public.account TO auditor;
UPDATE account SET description = 'yada, yada';
UPDATE account SET password = 'HASH2';
CREATE TABLE account_role_map
(
    account_id int,
    role_id int
);
GRANT SELECT ON public.account_role_map TO auditor;
SELECT account.password, account_role_map.role_id
  FROM account
  INNER JOIN account_role_map ON account.id = account_role_map.account_id;
```

The audit log below can be retrieved.

In the account table, only the operations for columns that privileges have been assigned to are output as logs.

In the account_role_map table, privileges are assigned to the table, so operations performed for the table are output as logs.

```
AUDIT: OBJECT,4,1,READ,SELECT,TABLE,public.account,SELECT password FROM account;,<not
logged>
AUDIT: OBJECT,7,1,WRITE,UPDATE,TABLE,public.account,UPDATE account SET password =
'HASH2';,<not logged>
AUDIT: OBJECT,10,1,READ,SELECT,TABLE,public.account,"SELECT account.password,
account_role_map.role_id
```

```
        FROM account
        INNER JOIN account_role_map ON account.id = account_role_map.account_id;",<not
logged>
AUDIT: OBJECT,10,1,READ,SELECT,TABLE,public.account_role_map,"SELECT account.password,
account_role_map.role_id
        FROM account
        INNER JOIN account_role_map ON account.id = account_role_map.account_id;",<not
logged>
```

6.7 Database Multiplexing

This section describes audit log retrieval while in database multiplexing mode.

6.7.1 Setup

If setting up the audit log feature in a database multiplexing environment that has already been built, follow the procedure below.

1. Copy the pgaudit files

   Copy the pgaudit files on the primary server and standby server.

   Refer to step 1 in "6.2 Setup" for details on copying the pgaudit files.

2. Create the pgaudit configuration file

   Create the pgaudit configuration file on the primary server. Copy the pgaudit configuration file you created to the standby server.

   Refer to step 2 in "6.2 Setup" for details on creating the pgaudit configuration file.

3. Configure postgresql.conf

   In the postgresql.conf file on the primary server and standby server, configure the parameters for using audit logs. Set the same values for the parameters.

   Refer to step 3 in "6.2 Setup" and "6.7.2 Configuring Audit Log Retrieval" for details on the parameters to configure.

4. Configure the *serverIdentifier*.conf file of Mirroring Controller

   In the *serverIdentifier*.conf file on the primary server and standby server, configure the parameters for using audit logs.

   Refer to "6.7.2 Configuring Audit Log Retrieval" for details on the parameters to be set.

5. Start the instance

   Start the instance of the primary server and standby server.

6. Create the pgaudit extension

   Execute CREATE EXTENSION on the primary server to create a pgaudit extension.

   Refer to step 5 in "6.2 Setup" for details on creating pgaudit extensions.

7. Configure the parameters in the pgaudit configuration file

   Add/change the parameters of the pgaudit configuration file on the primary server. Copy the pgaudit configuration file with the added/changed parameters to the standby server.

   Refer to "6.4 pgaudit Configuration File" and "6.7.2 Configuring Audit Log Retrieval" for details on the parameters to set.

8. Restart the instance

   Restart the instance of the primary server and standby server.

6.7.2 Configuring Audit Log Retrieval

In database multiplexing mode, Mirroring Controller periodically accesses the database to check the multiplexing status and detect failure. Due to this, audit logs are also periodically retrieved, so log files become used up. Therefore, set the parameters below so that audit logs are not retrieved by Mirroring Controller.

postgresql.conf

log_connections

Omit, or specify "off".

log_disconnections

Omit, or specify "off".

serverIdentifier.conf file of Mirroring Controller

target_db

Specify "template1".

Note

If creating a new database, create it after stopping Mirroring Controller, or specify a name other than "template1" for the template database.

pgaudit configuration file

option section audit_log_disconnections

If you want to output disconnection logs for connections other than Mirroring Controller, specify audit_log_disconnections = "on".

rule section database

Specify database != 'template1'.

6.8 Failover

This section explains audit log retrieval performed by the failover feature integrated with the cluster software.

6.8.1 Configuring Audit Log Retrieval

The failover feature accesses the database periodically to check the instance status. Due to this, audit logs are also periodically retrieved, so log files become depleted. Therefore, set the parameters below so that audit logs are not retrieved.

postgresql.conf

log_connections

Omit, or specify "off".

log_disconnections

Omit, or specify "off".

pgaudit configuration file

rule section database

Specify database != 'template1'.

6.9 Analyzing Audit Logs in SQL

In general, you can quickly and easily analyze the audit log by creating a table for analysis and loading the audit log into that table.

Maybe the analysis table is not updated, so we recommend creating that table as an UNLOGGED table. This is because when loading, the write-ahead log (WAL) is not output and it is not replicated, so it can be loaded faster without interfering with other tasks.

How to Identify the Audit Log Files to Load

To analyze audit logs for a specific time period, load all files that contain audit logs for that time period.
However, do not access dedicated log files with the latest update date. This is because it contains incomplete audit log data that is being written.

Loading Method

The audit log is output in csv format, and can be loaded using the COPY FROM statement or the pgx_loader command.
The following example shows how to load Session Audit Logging output to a dedicated log file.

1. Creating Tables

   Define a table with the columns required to reference the audit log.

```
$ psql
=# CREATE UNLOGGED TABLE auditlog (
header text,
class text,
sql_start_time timestamp with time zone,
remote_host_name text,
backend_process_id integer,
application_name text,
session_user_name text,
database_name text,
virtual_transaction_id text,
statement_id integer,
substatement_id integer,
command_tag text,
sqlstate text,
object_type text,
object_name text,
error_message text,
sql text,
parameter text
);
```

2. Creating an Index

   For example, creating an index on a timestamp is useful for time-series analysis.

```
$ psql
=# CREATE INDEX auditlog_time_index ON auditlog (sql_start_time);
```

3. Loading the Audit Log

   Specify a dedicated log file in the FROM clause of COPY FROM.

```
$ psql
=# COPY auditlog FROM
'pgaudit-2024-02-02_150000.log' WITH CSV DELIMITER ',';
```

   You can also use the PROGRAM clause to load multiple dedicated log files together.
   The following example loads one day of audit logs by specifying wildcard for day part of file name:

```
$ psql
=# COPY auditlog FROM
PROGRAM 'cat pgaudit-2024-02-02_*' WITH CSV DELIMITER ',';
```

```
$ psql
=# COPY auditlog FROM
PROGRAM 'type pgaudit-2024-02-02_*' WITH CSV DELIMITER ',';
```

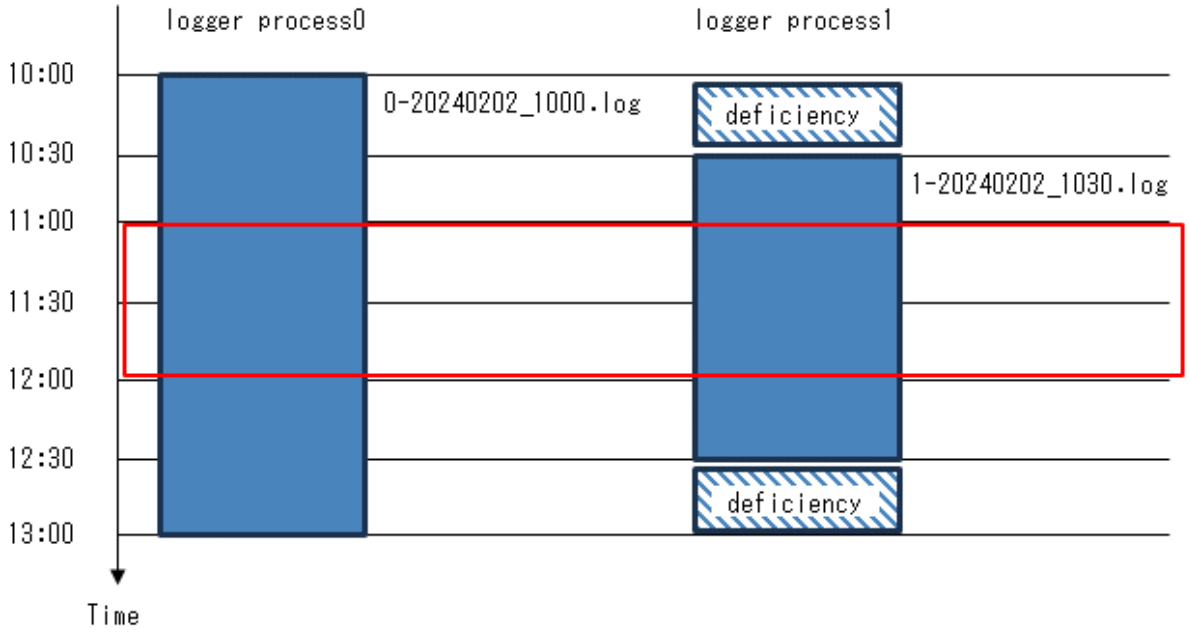
4. Audit Log Analysis

   Access the table that loaded the audit log.
   Loaded records are not in chronological order, but can be sorted by timestamp

```
$ psql
=# SELECT * FROM auditlog ORDER BY sql_start_time;
 header         |  class |        sql_start_time     | remote_host_name  |  ...
----------------+--------+---------------------------+-------------------+  ...
AUDIT: SESSION | DDL    | 2024-02-02 15:00:49+09    | ::1               |  ...
AUDIT: SESSION | SYSTEM | 2024-02-02 15:00:58+09    |                   |  ...
```

Considerations when Using the Scalable Audit Log Feature

- When you enable the scalable audit log feature, there are many dedicated log files for the target period as you specify for parallel_loggers, so make sure to load all the dedicated log files.
- When you disable log_rotation_age, do not analyze the time except target period because not all audit logs may have been loaded.
  For example, suppose that you are analyzing the audit log at 11:00-12:00, and you load the file output by logger process 0 at 10:00-13:00 and the file output by logger process 1 at 10:30-12:30, as shown in the following figure. Audit log records up to 10:00-13:00 appears in the table loaded with log files, but some audit logs (Audit log output by logger process 1 at 10:00-10:30 and 12:30-13:00) have not been loaded.
  When log_rotation_age is enabled, the timing of the dedicated log file changeover is consistent across all logger processes to prevent such erroneous analysis.



6.10 Removing Setup

This section describes how to remove the setup of pgaudit.

1. Start the instance

2. Remove the pgaudit extension

   Execute DROP EXTENSION to remove the pgaudit extension from the database.

```
$ psql -d <database name>
=# DROP EXTENSION pgaudit;
=# \q
```

3. Change postgresql.conf

   Remove the parameters below relating to pgaudit.

   - shared_preload_libraries
   - pgaudit.config_file

4. Restart the instance

5. Remove the pgaudit files

L

As superuser, run the following command. Note that "<*x*>" in paths indicates the product version.

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/pgaudit
```

W

Open a command prompt as administrator privileges, run the following command. Note that "<*x*>" in paths indicates the product version.

```
> del "c:\Program Files\Fujitsu\fsepv<x>server64\filesCopiedDuringSetup"
```

Information

The files copied during setup can be checked below.

```
> dir /b /s "c:\Program Files\Fujitsu\fsepv<x>server64\OSS\pgaudit"
```

Chapter 7 Confidentiality Management

In order to prevent unauthorized use of the various data stored in the database, it is necessary to set appropriate privileges for each database resource for database users. However, there are multiple users to whom privileges are granted, and there are also many target database resources. So it takes a lot of effort to set it up. The confidentiality management feature reduces the time and effort required to do so and supports the setting and maintenance of appropriate privileges.

This chapter describes how to install, design and use confidentiality management features. For usage examples of the feature, refer to "7.8 Usage Example of Confidentiality Management".

7.1 Setup

This feature is provided as an EXTENSION of PostgreSQL. The name is pgx_confidential_management_support. Register the extension with the database cluster using the CREATE EXTENSION statement as follows:

This must be run by superuser. Because this extension registers PostgreSQL event triggers. By registering an event trigger, when a database object such as a table is deleted, related information is deleted from the information managed by the confidentiality management feature.

This extension can be created for any schema.

```
CREATE EXTENSION pgx_confidential_management_support
```

Note

- The various definitions described below are registered in the tables included in this extension. Note that dropping this extension with the DROP EXTENSION statement will therefore drop all these definitions as well.
- If the superuser also serves as the confidentiality management role, or if you have only one confidentiality management role, setup is complete. For confidentiality management roles, refer to "7.2.2 Determining Confidentiality Management Roles". However, if multiple confidentiality management roles manage different confidentiality matrices, they must be prevented from manipulating each other's confidentiality matrices. To do so, a superuser should run the script provided by the product as follows. This script defines policies for the row level security feature on the tables provided by the confidentiality management. ${install_dir} refers to the directory where you installed the product.

  ```
  psql -f ${install_dir}/share/extension/pgx_confidential_management_support_policy.sql
  ```

- 'public' is granted SELECT on tables included by this extension when CREATE EXETENSION statement is executed. Don't revoke the privilege from 'public'. For example, event trigger of the extension confirms to update its tables when a general user drop some table. The privilege is required at the time. Also, there is no problem that users refer content of the tables like pg_catalog.

7.2 Designing Confidentiality Management

Describes the design of confidentiality management.

7.2.1 Designing a Confidentiality Matrix

A confidentiality matrix is a matrix of confidentiality levels and confidentiality groups. Elements of the confidentiality matrix are confidentiality privileges. Here we define them.

A confidentiality level is a group of data with the same degree of confidentiality, and a confidentiality group is a group of roles with the same access to confidentiality data. The details are described below.

The end result is to classify database objects into confidentiality levels and roles into confidentiality groups. But for the first step, define your confidentiality matrix abstractly without thinking about concrete tables, roles, etc. By doing so, the relationship between confidentiality levels and confidentiality groups can also be applied to databases with different sets of database objects.

You can define multiple confidentiality matrices. These confidentiality matrices are identified by a name, but the name is unique within the database (not the database cluster).

A role that manages the confidentiality matrix is called a confidentiality management role. The details are described below.

How to create multiple confidentiality matrices

There are various design methods, but an example is shown below.

- Create one confidentiality matrix for a dataset

  For example, create one confidentiality matrix for one section of your organization.

- Copy the confidentiality matrix if the two sections have the same confidentiality design
- When multiple organizations share datasets, create a single confidentiality matrix for the shared datasets

  An example of this case is shown below.

  - Create a confidentiality matrix *A* for the dataset that only section 1 has access to.
  - Create a confidentiality matrix *B* for the dataset that only section 2 has access to.
  - Create a confidentiality matrix *S* for the dataset shared by section 1 and section 2.
  - Section 1 administrator *M1* is in charge of the confidentiality management role for confidentiality matrix *A*.
  - Section 2 administrator *M2* is in charge of the confidentiality management role for confidentiality matrix *B*.
  - Role group *G* to which *M1* and *M2* belong is in charge of confidentiality management role of confidentiality matrix *S*.

7.2.1.1 Defining Confidentiality Levels

Confidentiality level is a concept that indicates degree of confidentiality. For example, determine a confidentiality level that classifies tables that contain personal information and those that do not.

A collection of data that you classify as confidentiality level is a database object, such as a table. Such objects are called confidentiality objects. Refer to "What is a confidentiality objects?" for confidentiality objects.

Attributes can be set for the confidentiality level. For example, if a confidentiality level has an attribute that requires encryption, tables belonging to that confidentiality level are required to be encrypted. The confidentiality management feature may or may not automatically change the attribute of the confidentiality object to which it belongs. Also, each attribute targets a different confidentiality object.

The table below shows the attribute description, the confidentiality object targeted, and whether to change the attribute of the confidentiality object automatically.

Confidentiality level attributes	Specifiable values	Confidentiality object type	Auto change	Description
encryption_algorithm	AES128 AES256 none	table column rowset	No	Requires confidentiality objects to be encrypted with the specified algorithm. For details, refer to "Protecting Storage Data Using Transparent Data Encryption" in the Operation Guide. If ***none*** is specified, no encryption is requested. Default is ***none***. The attribute is not changed autlmatically because encryption and decryption involve large data updates.

Confidentiality level attributes	Specifiable values	Confidentiality object type	Auto change	Description
				Instead, you cannot add a confidentiality object with an encryption strength lower than the specified encryption strength. Also, when changing to increase the encryption strength, confidentiality objects that do not meet the post-change conditions must not be included.

What is a confidentiality objects?

Confidentiality objects have the types shown in the following table. For example, some data contained in table *T* can be added to confidentiality level *L1* and other data to confidentiality level *L2*.

Confidentiality object type	Description
schema	It does not mean all the tables contained in the schema. It simply means an object that exists in the system catalogs. Means the schema itself that is the target of access control by the GRANT statement.
table	Includes views, materialized views and partitions as well as tables. Currently do not support foreign tables.
column	Means column.
rowset	A set of rows that satisfy a specified condition. Although there is no rowset object in the PostgreSQL system catalog, it is treated as a confidentiality object in the confidentiality management feature for ease of use. Access control for rowset-type confidentiality objects uses PostgreSQL's row-level security functionality internally. Therefore, how access is controlled follows the row-level security specification.

The following objects may also contain confidential information. However, the current confidentiality management feature does not support them as confidentiality objects. When managing these, it is recommended to manage them in a role different from the confidentiality management role. The details are described in "7.5 Suggestions for Monitoring Methods".

- Function
- Procedure
- Foreign server
- Foreign data wrapper
- Foreign table

7.2.1.2 Defining Confidentiality Groups

A confidentiality group is an object that indicates which confidentiality level roles in confidentiality group can acdess to. For example, decide which role groups have access to personal information and which groups do not. Confidentiality groups are actually automatically defined as PostgreSQL roles (role groups). This role is called a confidentiality group role.

What is a confidentiality group role?

Confidentiality group roles are targets of GRANT and REVOKE statements executed internally by the confidentiality management feature. And when you add a role to the confidentiality group, the added role becomes a member of the

confidentiality group role. The privileges of the added role are given by inheriting the privileges given to the confidentiality group role by the confidentiality management feature.

The following attributes can be set for the confidentiality group role via the function that creates the confidentiality group. The meaning and default value of attribute are the same as in the CREATE ROLE statement specification. These are limited to attributes that may be necessary when managing confidentiality. Therefore, use the confidentiality management feature to change it. The confidentiality management feature automatically sets the following attributes for the role added to the confidentiality group.

- SUPERUSER
- CREATEDB
- CREATEROLE
- REPLICATION
- BYPASSRLS

Other attributes follow the PostgreSQL CREATE ROLE statement defaults. Even if the attribute is changed using the ALTER ROLE statement, the operation of confidentiality management feature will not be disturbed.

The naming convention for confidentiality group roles is as follows.

```
pgx_cgroup_role_${serial_number}
```

When deleting a confidentiality group, you can choose not to delete the confidentiality group role. In such a case, it is a means to know that it was a confidentiality group role later.

Note

Do not define roles using strings that follow this naming convention. This is because the name of the new confidentiality group role will be the number next to the maximum *${serial_number}* of the role that follows this naming convention. For example, if a role named 'pgx_cgroup_role_999999999999999999' exists, you will not be able to create new confidentiality group roles.

7.2.1.3 Defining Confidentiality Privilege

Confidentiality privileges indicate how a confidentiality group can access confidentiality objects registered at a certain confidentiality level.

For example, a confidentiality group *R* can be defined to have SELECT, INSERT, UPDATE, and DELETE privileges on table-type confidentiality objects belonging to confidentiality level *L*.

Once a confidentiality object or role has been added to a confidentiality level or confidentiality group, the feature automatically uses the GRANT or CREATE POLICY statement to grant privileges to the actual database object according to the confidentiality privilege definition to the confidentiality group role.

For rowset types, confidentiality privileges are those that can be specified in the CREATE POLICY statement. In cases other than rowset, it is a privilege that can be specified in the GRANT statement. For detailed privileges, refer to the respective SQL statement reference in the PostgreSQL Documentation.

Note

Do not change the definition of POLICY that this feature creates internally. Even if you change it, the function of this feature may return to the state before the change without warning.

Point

For roles registered in the confidentiality matrix, if the privilege to a certain confidentiality object is more than the confidentiality privilege, revoke those privileges according to the confidentiality privilege.

If a role not registered in the confidentiality matrix or PUBLIC was granted privileges to a confidentiality object registered in the confidentiality matrix, functions of this feature for adding confidentiality objects or roles will fail. Because this function is not allowed to manage.

Even in a slightly more complicated situation, failing functions that add confidentiality objects and roles prevent roles added to the confidentiality matrix from deviating from confidentiality privileges:

- It is set so that a role registered in the confidentialmatrix can inherit a role not registered in the confidentiality matrix, and as a result, it has more privileges than the confidentiality privileges.
- Roles registered in the confidentiality matrix are granted privileges by a POLICY not created by this feature. In this case, the function will fail if such a POLICY exists without rigorously checking for violations of confidentiality privilege.

7.2.2 Determining Confidentiality Management Roles

The confidentiality management role performs all operations on the confidentiality matrix. As such, the confidentiality management role requires very strong privileges to either:

1. Has all of the following rights
    - Superuser privileges
    - Ownership of database objects belonging to the confidentiality level
2. Has all of the following privileges
    - CREATEROLE privilege
    - SELECT, INSERT, UPDATE, and DELETE privileges on all tables included in the extension 'public' is granted SELECT when CREATE EXTENSION statement is executed.
    - Ownership of database objects belonging to the confidentiality level

Note

Note that the previous owner may not be able to execute GRANT statements, etc. once the confidentiality management role becomes the owner. This is because ownership of database objects cannot be shared by multiple roles belonging to different role groups. This is the PostgreSQL specification.

The confidentiality management role can create and manage multiple confidentiality matrices, but it is safer to distribute the authority. For that reason, we recommend that you decide on confidentiality management rules in the following order of priority.

- Create one-to-one confidentiality matrices and confidentiality management roles.
- Create a role group with multiple confidentiality management roles as members, or manage multiple confidentiality matrices with one confidentiality management role.
- A superuser is also a confidentiality management role.

Note

- To assign attributes that only a superuser can grant to a role managed using the confidentiality management feature, the superuser must also serve as the confidentiality management role. For example, the REPLICATION attribute is such an attribute. Refer to the reference of the PostgreSQL Documentation for details.

- The CREATEROLE privilege changed in Fujitsu Enterprise Postgres 16. For this reason, if you want to use a non-superuser role as the confidentiality management role, you must first add the privilege (CREATEDB, BYPASSRLS, etc.) that you set for creating and updating confidentiality groups to the confidentiality management role. If these privileges are not set, the confidentiality group operation may fail. For information about changing the CREATEROLE privilege, refer to "Migration to Version 16" in the PostgreSQL Documentation.

7.2.3 Classify Confidentiality Objects According to the Definition of Confidentiality Level

7.2.3.1 Defining Confidentiality Objects

First, refer to list of definitions of schemata, tables in your database, etc. that you want to manage, and define confidentiality objects. As mentioned earlier, there are various types of confidentiality objects such as column type and rowset type, so you can define confidentiality objects based on their data content.

Access control for rowset-type confidentiality objects uses PostgreSQL's row-level security functionality internally. Therefore, the method of specifying a set of rows follows the specifications of the AS clause, USING clause, and WITH CHECK clause of the CREATE POLICY statement. Also, the definition of the rowset-type confidentiality object is specified in the argument of the function that registers the rowset-type confidentiality object to the confidentiality level. This feature executes the ALTER TABLE statement with the ENABLE ROW LEVEL SECURITY clause to enable POLICY when a rowset-type confidentiality object is added.

Currently it is not possible to register a foreign table as a table-type confidentiality object.

Point

Recommend that you do not grant privileges on confidentiality objects to PUBLIC. Granting privileges to PUBLIC is the same as granting privileges to all roles registered in the confidentiality matrix. This makes no sense if all roles that access confidentiality objects are managed using this feature. If PUBLIC is granted privileges to confidentiality objects, the functions included in this feature will check that the privileges granted to each role are not exceeded, and will fail if they are.

Note

- Be careful when confidentiality objects are of column type. This is because if the table-type confidentiality object is set at the same time, the table type privilege takes precedence.

  For example, if you want to revoke the SELECT privilege only from a special column *C* in some table *T*, list the columns other than column *C* and grant the SELECT privilege to them without granting the SELECT privilege to table *T*. This follows the PostgreSQL's GRANT statement specification for column.

  If you have to enumerate a large number of columns, it might be a good idea to move the special columns to a new table and present your existing application with a VIEW that JOINs both tables.

- If the confidentiality object is of rowset type, set the same privileges for the table type as those specified for the rowset type. This is because when a SQL statement accesses data, it first checks that you have privilege to access the table. After that, the rowset privileges are checked for matching rows. This follows the PostgreSQL row level security specification.

7.2.3.2 Classify Confidentiality Objects

Classify confidentiality objects according to the confidentiality level definition.

A single confidentiality object cannot be classified in multiple confidentiality levels, even if they are in different confidentiality matrices.

7.2.4 Classify Roles According to Confidentiality Group Definitions

A role can belong to multiple confidentiality groups in different confidentiality matrices at the same time. However, a single role cannot be classified into multiple confidentiality groups within a single confidentiality matrix.

Note

- We strongly recommend that you do not group confidentiality group roles into other confidentiality groups. This is because the confidentiality management feature does not prohibit such usage, but it probably only complicates security management. Also note that PostgreSQL does not allow cyclic groupings of roles.
- After adding roles to a confidentiality group, it is highly recommended that such roles not be made members of role groups not managed by the confidentiality matrix. This is because although the confidentiality management feature does not prohibit such situations, for example, unreasonably increasing the privileges of such role groups may become a way out for roles managed by the confidentiality management feature.
  Note that this feature does not allow roles with such loopholes to be added to confidentiality groups.
- As of Fujitsu Enterprise Postgres 16, the CREATEROLE privilege has been changed to require ADMIN OPTION privilege on roles added to confidentiality groups if non-superusers are to be used as confidentiality management roles. Therefore, the roles that can be added to the confidentiality group must be:
  - Roles created with confidentiality management role privileges
  - A role that previously granted the ADMIN OPTION privilege for a role to a confidentiality management role

    Example) To grant the confidentiality management role manager_role only the ADMIN OPTION privilege for role user_role1:

    ```
    GRANT user_role1 TO manager_role WITH ADMIN TRUE, INHERIT FALSE, SET FALSE;
    ```

  For information about changing the CREATEROLE privilege, refer to "Migration to Version 16" in the PostgreSQL Documentation.

7.3 How to Use Confidentiality Management Feature (Definition)

Confidentiality management feature provides functions and tables.

Some functions define, change, or drop confidentiality matrices, etc. These functions will output an audit log indicating that they were executed, so you can later confirm that an illegal operation was performed.

In addition, you can directly refer to the table provided by this feature and check the defined contents using functions that help referencing.

Also, some functions output the attributes of confidentiality objects defined in the PostgreSQL system catalog and the attributes that should be set for that confidentiality object. You can use these to compare attributes.

For details, refer to "Appendix B System Management Functions Used by Confidentiality Management Feature".

Tables included by the pgx_confidential_management_support extension

Table name	Description
pgx_confidential_matrix	A list of confidentiality matrices. You can refer to the attributes of the registered confidentiality matrix, the update time, or the time when the confidentiality level or confidentiality group was registered or deleted.
pgx_confidential_level	A list of confidentiality levels.

Table name	Description
	You can refer to the registered confidentiality level attributes, update time, or the time when a confidentiality object was registered to the confidentiality level or removed from the confidentiality level.
pgx_confidential_group	A list of confidentiality groups. You can refer to the registered confidentiality group attributes, update time, or the time when a role was registered to the confidentiality group or removed from the confidentiality group.
pgx_confidential_privilege	A list of confidentiality privileges. You can refer to confidentiality privilege set for each confidentiality object, update time, and so on.
pgx_confidential_object	A list of confidentiality objects. You can refer to object attributes or update time, and so on.
pgx_confidential_role	A list of roles registered in the confidentiality group. You can refer to role attributes or update time, and so on.
pgx_confidential_policy	This is a list of policies created to set privileges for rowset-type confidentiality objects. You can refer to the name of the policy you created and the privileges it has set. Rows in this table are inserted when you add a rowset-type confidentiality object.

Rows in each table are added, deleted, or updated when you execute functions to add, delete, or update definitions.

Also, if the target confidentiality object is deleted by a DROP TABLE statement, etc., it will also be deleted from the following tables.

- pgx_confidential_object
- pgx_confidential_policy

Functions for adding, removing or updating definitions

These functions will print an audit log indicating that they were executed.

Function name	Description
pgx_create_confidential_matrix	Create a confidentiality matrix.
pgx_alter_confidential_matrix	Change the attributes of the confidentiality matrix.
pgx_drop_confidential_matrix	Drop the confidentiality matrix.
pgx_copy_confidential_matrix	Copy the confidentiality matrix.
pgx_create_confidential_level	Create confidentiality levels and register them in the confidentiality matrix.
pgx_alter_confidential_level	Change the confidentiality level attribute.
pgx_drop_confidential_level	Remove a confidentiality level from the confidentiality matrix and drop a confidentiality level.
pgx_create_confidential_group	Create a confidentiality group and register it in the confidentiality matrix.
pgx_alter_confidential_group	Change the attributes of a confidentiality group.

Function name	Description
pgx_drop_confidential_group	Remove confidentiality groups from the confidentiality matrix and drop confidentiality group.
pgx_grant_confidential_privilege	Grant confidentiality privileges.
pgx_revoke_confidential_privilege	Revoke confidentiality privileges.
pgx_add_object_to_confidential_level	Add confidentiality objects to the confidentiality level.
pgx_remove_object_from_confidential_level	Removes confidentiality objects from the confidentiality level.
pgx_add_role_to_confidential_group	Add a role to a confidentiality group.
pgx_remove_role_from_confidential_group	Remove a role from a confidentiality group.

Functions that Support Definition Referencing and Comparison with System Catalogs

Function name	Description
pgx_get_attribute_of_objects	For all confidentiality objects registered in the specified confidentiality matrix, displays the attributes defined in the confidentiality matrix and the attributes actually set in the database.
pgx_get_attribute_of_roles	For all roles registered in the specified confidentiality matrix, displays the attributes defined in the confidentiality matrix and the attributes actually set in the system catalog.
pgx_get_privileges_on_level_and_group	Displays a list of combinations of confidentiality objects registered with the specified confidentiality level and roles registered with the specified confidentiality group, such that the following can be compared. - Privileges specified by the confidentiality privilege settings that should be granted to the specified role - Privileges granted in the actual system catalog
pgx_get_privileges_on_object	For the specified confidentiality object, display a list that allows you to compare the following: - Privileges dictated by confidentiality privilege settings that should be granted to all roles - Privileges granted in the actual system catalog
pgx_get_privileges_on_role	For all confidentiality objects, display a list that allows you to compare: - Privileges specified by the confidentiality privilege settings that should be granted to the specified role - Privileges granted in the actual system catalog
pgx_get_privileges_on_matrix	For all objects registered in the specified confidentiality matrix, display a list that allows you to compare:

Function name	Description
	- Privileges defined by confidentiality privilege settings that should be granted to all roles registered in the confidentiality matrix. - Privileges granted in the actual system catalog

Describe the definition procedure.

7.3.1 Creating a Confidentiality Management Role

Create a confidentiality management role using the CREATE ROLE statement, or use an existing role as a confidentiality management role. Set the privileges and attributes shown in "7.2.2 Determining Confidentiality Management Roles" for the confidentiality management role.

Note

- Use caution when renaming a confidentiality management role. If you want to do so, delete all confidentiality matrices managed by that confidentiality management role, rename the confidentiality management role, and then define the same confidentiality matrix again. Otherwise, you will not be able to operate the confidentiality matrix. For example, you cannot change confidentiality privileges or remove confidentiality objects from the confidentiality level. If you accidentally renamed it first, change it back to the original name and then proceed as described above. In the future, we will simply allow the changed name of the confidentiality management role to be set in the confidentiality matrix.
- If you want to delete the confidentiality management role, delete the confidentiality management role after deleting the confidentiality matrix. Otherwise, you will not be able to create a confidentiality matrix with the same name because you will not be able to delete the confidentiality matrix left behind. If you accidentally delete the confidentiality management role before deleting the confidentiality matrix, create a confidentiality management role with the same name again and delete the confidentiality matrix, or delete the confidentiality matrix with a role that has SUPERUSER privileges.

7.3.2 Creating a Confidentiality Matrix

Create a confidentiality matrix with comments describing the confidentiality matrix as follows. This comment is stored in the pgx_confidential_matrix table.

```
select pgx_create_confidential_matrix('matrix_foo', 'This matrix is defined for foo.')
```

Point

The role executing this function is considered the confidentiality management role. If this function is executed after SET ROLE, the role specified in SET ROLE will be regarded as the confidentiality management role, not the role that executed SET ROLE.

You can also create a new confidentiality matrix 'matrix_dest' by duplicating the already created confidentiality matrix 'matrix_src' as follows. If you copy the confidentiality matrix and create it, the comments will also be copied. Comments can be changed using the pgx_alter_confidential_matrix function.

```
select pgx_copy_confidential_matrix('matrix_dest', 'matrix_src')
```

You can also check the created matrix by referring to the pgx_confidential_matrix table.

Point

The source must be within the same database. If you want to copy from different databases or different database instances, choose one of the following methods. If you choose the method using COPY statement, confirm the cautions shown below.

- Define using a function in the same way as the original.
- Perform the following steps

  Execute steps other than step 6 with a role that has SUPERUSER privileges.

  1. Set up extensions in the target database.
  2. From the table below, specify the ID of the source confidentiality matrix in the WHERE clause and extract the data using the COPY TO statement.
     - pgx_confidential_matrix
     - pgx_confidential_level
     - pgx_confidential_group
     - pgx_confidential_privilege
  3. Refer to the *pg_sequences* system view and save the value of the *last_value* column of the following SEQUENCE in a file.
     - pgx_confidential_matrix_cmatid_seq
     - pgx_confidential_level_clevid_seq
     - pgx_confidential_group_cgroid_seq
     - pgx_confidential_privilege_cpriid_seq
  4. Load the data extracted in step 2 into the above table in the target database using the COPY FROM statement. This operation can be performed by any confidentiality management role in any confidentiality matrix.
  5. Use the *pg_catalog.setval* function to set the *last_value* for each SEQUENCE on the copy destination, specifying the value saved in step 3. An example is shown below.

     ```
     SELECT pg_catalog.setval('pgx_confidential_matrix_cmatid_seq', 5)
     ```

  6. Create a new confidentiality matrix using the *pgx_copy_confidential_matrix* function and specifying the confidentiality matrix loaded in step 4 as the copy source. Perform this operation in the confidentiality management role of the newly created confidentiality matrix.
  7. Use the *pgx_drop_confidential_matrix* function specifying ***false*** for *drop_role* to drop the confidentiality matrix loaded in step 4.

Note

- If you specify true for *drop_role*, you will not be able to continue to be managed by the original confidentiality matrix. The reason is as follows.

  After completing step 6, you should have:

  a) Confidentiality matrix of source database

  b) the confidentiality matrix loaded in step 4

  c) Confidentiality matrix duplicated in step 6

  The b) and c) confidentiality matrices use different confidentiality group roles. This is the effect of the *pgx_copy_confidential_matrix* function. However, the confidentiality matrices of a) and b) share the same confidentiality group role. Although this is temporary, it is a bad situation. To do so, remove the confidentiality matrix in b) in step 7. If *true* is specified for *drop_role* at this time, the confidentiality group role used in a) will be deleted. Therefore, management by the confidentiality matrix of a) cannot be continued.

- The destination must have just installed this extension with CREATE EXTENSION. This is because the table data contained in this extension contains an ID representing the confidentiality matrix and confidentiality level, and this ID is generated by the SEQUENCE included in the extension. For example, if you have created at least one

confidentiality matrix, the confidentiality matrix is numbered with an ID of 1, but that matrix is not the object numbered with an ID of 1 in the copy source.

7.3.3 Adding Confidentiality Levels to the Confidentiality Matrix

Create a confidentiality level and add it to the confidentiality matrix as follows: In the example below, the JSON format third argument requests that confidentiality objects belonging to 'level1' are encrypted. Specify *NULL* if you don't want anything. Refer to "B.2 Confidentiality Level Manipulation Functions" for the content of the request.

```
select pgx_create_confidential_level('matrix_foo', 'level1',
'{"encryption_algorithm":"AES256"}', 'The strongest encryption is required for this
level.')
```

You can also check the added confidentiality level by referring to the pgx_confidential_level table.

7.3.4 Adding Confidentiality Groups to the Confidentiality Matrix

Create a confidentiality group and add it to the confidentiality matrix as follows. Attributes are given to the confidentiality group by the third argument in JSON format. Refer to "B.3 Confidentiality Group Manipulation Functions" for the attributes that can be assigned.

In the example below, a role belonging to this confidentiality group grants the CREATEDB privilege.

```
select pgx_create_confidential_group('matrix_foo', 'group1', '{"CREATEDB":true}', 'Roles
belonging to this confidentiality role are permitted to create db.')
```

You can also check the added confidentiality group by referring to the pgx_confidential_group table.

7.3.5 Granting Confidentiality Privileges to Confidentiality Groups

In the example below, roles belonging to 'group1' are granted SELECT, INSERT and DELETE privileges for tables belonging to 'level1'. Specify privileges for each type of confidentiality object by the fourth argument in JSON format. Refer to "B.4 Confidentiality Privilege Manipulation Functions" for the privileges that can be granted.

```
select pgx_grant_confidential_privilege('matrix_foo', 'level1', 'group1',  '{"schema":
["ALL"], "table":["SELECT","INSERT","DELETE"]}')
```

If a confidentiality object of the target type is registered in the confidentiality level, when this function is executed, the confidentiality management feature internally uses the GRANT statement to grant a confidentiality group role access to confidentiality objects that are registered at a confidentiality level. The effect of the GRANT statement can be checked as follows.

```
select pgx_get_privileges_on_level_and_group('matrix_foo', 'level1', '["role1","role2"]')
```

For the format of the table returned by a function that outputs authority information, such as this function, refer to "B.7 Functions that Support Definition Referencing and Comparison with System Catalogs".

7.3.6 Adding Confidentiality Objects to Confidentiality Level

Classify the intended database object into the appropriate confidentiality level according to the confidentiality level design. In the example below, 'table1' of 'schema1' and 'table2' of 'schema1' are added to 'level1' at the same time. Specify the confidentiality object type and confidentiality object name in the third argument in JSON format. If the type is same, you can enumerate multiple confidentiality objects. You can enumerate multiple objects you want to register for each sensitive object type. In this example, only the *table* type is registered, but *schema* type can also be registered at the same time.

```
select pgx_add_object_to_confidential_level ('matrix_foo', 'level1',
'[{
    "type":"table",
```

```
    "object":[
        {
          "schema":"schema1",
          "table":["table1","table2"]
        }
     ]
}]')
```

When specifying a rowset, you must declare what kind of set of rows it is in the value of the *rowset_expression* key. For details on how to specify it, refer to "B.5 Confidentiality Object Manipulation Functions".

When this function is executed, the confidentiality management feature internally uses the GRANT statement or CREATE POLICY statement to grant privileges to the specified confidentiality objects to all confidentiality groups set in the confidentiality matrix. The effect of the GRANT statement can be checked as follows. This example checks the privileges granted on 'table1' in 'schema1' and 'table2' in 'schema1'.

```
select pgx_get_privileges_on_object('matrix_foo',
'[{
    "type":"table",
    "object":[
      "schema":"schema1",
      "table":["table1","table2"]
    ]
}]')
```

7.3.7 Adding Roles to Confidentiality Groups

Classify the intended role into the appropriate confidentiality group according to the confidentiality group design. You can add multiple roles at once. In the example below, role role1 and role role2 are added to confidentiality group 'group1'.

```
select pgx_add_role_to_confidential_group('matrix_foo', 'group1', '["role1","role2"]')
```

The confidentiality management feature adds the specified role to the members of the confidentiality group role.

The feature does not execute GRANT statements for confidentiality objects at this time. This is because we have already executed the GRANT statement between the confidentiality group role and the confidentiality object, and we will not execute the GRANT statement between the individual roles and the confidentiality object.

By using the function below, you can check the privileges that can be exercised by the specified role after inheriting the privilege of the confidentiality group role with the INHERIT attribute on the role side or changing to the confidentiality group role with the SET ROLE statement. In other words, you can check the access privileges that the actually registered roles can exercise. For details on the output format, refer to "B.7 Functions that Support Definition Referencing and Comparison with System Catalogs". The example below checks the privileges of role 'role1' and role 'role2'.

```
select pgx_get_privileges_on_role('matrix_foo',  '["role1","role2"]')
```

7.4 How to Use Confidentiality Management Feature (Change and Deletion)

7.4.1 Renaming Confidentiality Objects

The current confidentiality management feature cannot follow when confidentiality objects are renamed. Therefore, if the name is changed, remove the old name confidentiality object with the *pgx_remove_object_from_confidential_level* function specifying the old name, and register the confidentiality object with the new name using the *pgx_add_object_to_confidential_level* function specifying the new name.

7.4.2 Renaming Roles

The current confidentiality management feature cannot follow when roles are renamed. Therefore, when renaming, exclude the role with the old name with the *pgx_remove_role_from_confidential_group* function specifying the old name, and after renaming the role, register the role with the new name with the *pgx_add_role_to_confidential_group* function specifying the new name.

7.4.3 Deleting Roles

The current confidentiality management feature cannot follow when roles are dropped. Therefore, when dropping, exclude the role with *pgx_remove_role_from_confidential_group* function.

7.4.4 Changing Confidentiality Matrix

Change the name or attributes of the confidentiality matrix as follows. Specify the name and attribute value to be changed in JSON format. You can change the name and multiple attributes at once. Attributes not specified here are not changed.

```
select pgx_alter_confidential_matrix('matrix_foo', '{"name": "matrix_bar",
"comment":"This matrix is defined for bar."}')
```

7.4.5 Deleting Confidentiality Matrix

Delete the confidentiality matrix as follows.

```
select pgx_drop_confidential_matrix('matrix_foo', false, false)
```

By specifying a second or third argument, you can choose to delete all confidentiality levels and confidentiality groups added to the confidentiality matrix, or remove confidentiality group roles. Confidentiality group roles that were not deleted can be identified using the previously mentioned naming convention. No matter what you choose, the roles registered in the confidentiality group will not be deleted. The above example simply deletes the confidentiality matrix only.

7.4.6 Changing Confidentiality Level

Change the name and attributes of the confidentiality levels that were added to the confidentiality matrix 'matrix_foo' as follows. Specify the value after changing the name and attributes in JSON format. You can change the name or multiple attributes at once. Attributes not specified here are not changed.

```
select pgx_alter_confidential_level('matrix_foo', 'level1', '{"name": "levelX",
"comment":"This level required the highest confidential clearance."}')
```

If a confidentiality object was already registered with the confidentiality level, the attributes of the confidentiality object are also changed automatically. However, as mentioned in "7.2.1.1 Defining Confidentiality Levels", it may not be possible to automatically change the attributes of confidentiality objects. At that time, the function checks that the attributes of the registered confidentiality object are stricter than the attribute of the modified confidentiality level. If the check fails, this function will also fail. For example, if you try to change the encryption_algorithm from AES128 to AES256 and an AES128 encrypted table is registered as a confidentiality object, this function will fail. In such a case, please execute this function again after encrypting the table with AES256.

7.4.7 Deleting Confidentiality Level

Delete the confidentiality level as follows.

```
select pgx_drop_confidential_level('matrix_foo', 'level1', false)
```

With a third argument, you can choose to delete those that depend on the specified confidentiality level. Of course, confidentiality objects registered with the confidentiality level are not deleted.

7.4.8 Changing Confidentiality Group

Change the name and attributes of the confidentiality groups that were added to the confidentiality matrix 'matrix_foo' as follows. Specify the value after changing the name and attributes in JSON format. You can change the name or multiple attributes at once. Attributes not specified here are not changed.

```
select pgx_alter_confidential_group('matrix_foo', 'group1', '{"name": "groupX",
"comment":"Members of this group have the highest confidential clearance."}')
```

7.4.9 Deleting Confidentiality Group

Delete the confidentiality group as follows.

```
select pgx_drop_confidential_group('matrix_foo', 'group1', true, true)
```

By specifying a second or third argument, you can choose to delete dependencies on the specified confidentiality group or delete the confidentiality group role. Any choice will not delete the roles belonging to the confidentiality group.

Note

Even if you leave the confidentiality group role, this function will revoke privileges from the confidentiality group role. The privilege to revoke is the privilege defined in confidentiality privileges. Therefore, note that a role registered in a confidentiality group will be deprived of various privileges granted by inheriting the confidentiality group role.

7.4.10 Revoking Confidentiality Privileges

Revoke confidentiality privileges from confidentiality groups as follows. Specify the confidentiality object and confidentiality group and the privileges to revoke in JSON format. The following example revokes INSERT and DELETE privileges for table-type confidentiality objects belonging to 'level1' from 'group1'.

```
select pgx_revoke_confidential_privilege('matrix_foo','level1', 'group1',  '{"table":
["INSERT","DELETE"]}')
```

7.4.11 Removing Confidentiality Objects from Confidentiality Level

Remove confidentiality objects from the confidentiality level as follows. Specify the type and name of confidentiality objects to be excluded in JSON format. The following example removes table-type confidentiality objects schema1.table1 and schema1.table2 from the confidentiality level 'level1'.

```
select pgx_remove_object_from_confidential_level('matrix_foo', 'level1'
'[{
    "type":"table",
    "object":[
        {
          "schema":"schema1",
          "table":["table1","table2"]
        }
     ]
}]')
```

7.4.12 Removing Roles from Confidentiality Groups

Remove the role from the confidentiality group as follows. Specify the roles to remove in JSON format. The following example removes roles 'role1' and 'role2' from confidentiality group 'group1'.

```
select pgx_remove_role_from_confidential_group('matrix_foo', 'group1',
'["role1","role2"]')
```

7.5 Suggestions for Monitoring Methods

Confidentiality management role must ensure that the database is operating securely as intended, even after confidentiality managements are defined. If you are only using the confidentiality management feature, you do not have to worry about such things. However, the confidentiality management feature does not prohibit changing the definitions of tables and roles without using this feature.

So you have to detect when such an action has taken place.

However, even if they detect it, they may forget to deal with it. Therefore, it is necessary to periodically check the difference between the confidentiality level and confidentiality group and the actual definition of confidentiality objects and roles. Of course, even if there was a mismatch, it would not be a problem if the confidentiality object or role had stricter attributes and privilege.

The procedure presented here aims at matching.

7.5.1 How to Detect Privilege Changes without Using Confidentiality Management feature

Use the audit log to detect unauthorized modification of the attributes of confidentiality objects or roles, or modification of privileges without going through the confidentiality management feature.

The basic method for detection is to detect actions by roles other than the confidentiality management role. However, there are exceptions such as:

When performing an operation without using the confidentiality management feature for a legitimate reason

For example, when changing the authority of a function that the confidentiality management feature does not treat as a confidentiality object. In order to identify this, it is recommended to determine roles that perform changes that do not involve the confidentiality management feature. This is because when various roles do this, it becomes difficult to detect audit logs that deviate from operational rules.

When monitoring the activity of the confidentiality management role

For example, it would be a good idea to create rules that allow access only at specified times and from specified terminals, and to detect activities that violate those rules from audit logs. It is important to set rules so that violations cannot be covered up. For example application_name is not suitable as it can be easily spoofed.

7.5.2 How to Check Confidentiality Objects and Roles

This section describes how to confirm that the contents registered in the confidentiality matrix match the confidentiality objects and roles managed in the PostgreSQL system catalog. The method shown here is just an example.

Inspector

The inspector must be granted SELECT privilege on tables with the pg_confidential_management_support extension and SELECT privilege on the confidentiality object and role information added to the subject confidentiality matrix in the system tables. At a minimum, the confidentiality management role for the confidentiality matrix being reviewed and superuser certainly have such privileges.

Procedure

The confirmation procedure is divided into the following three phases. If you detect a discrepancy, use the audit log to investigate what caused the discrepancy. And fix it to match.

- Various objects may be changed (modified) in a chain reaction when returning to the correct state. Doing so may erase traces of unauthorized manipulation. Therefore, it is recommended that you investigate any design inconsistencies and ensure that you have the necessary audit logs for the investigation before fixing them.

- The *pgx_get_privileges_on_matrix* function presented here can output a very large table if the number of confidentiality objects or roles is large. If the size of this table exceeds the value of PostgreSQL's work_mem parameter, I/O will occur according to PostgreSQL's specifications, resulting in a slowdown. Therefore, it is recommended that work_mem be set as high as possible in the session in which this function is executed.

(1) Make sure the state of the confidentiality matrix is the same as the design

If you detect a mismatch, please restore the correct state by executing functions such as *pgx_alter_confidential_level* function provided by this extension.

- Attributes of the confidentiality matrix

  Check using the *pgx_confidential_matrix* table.

- Number of registered confidentiality levels and attributes of each confidentiality level

  Check the row that matches the *clevmatid* to be checked from the *pgx_confidential_level* table. To know the confidentiality matrix identifier, see *cmatid* in the *pgx_confidential_matrix* table.

- Number of registered confidentiality groups and attributes of each confidentiality group

  Check the row in the *pgx_confidential_role* table whose *ccolmatid* matches the identifier of the confidentiality matrix to be checked.

- Confidentiality group privileges set to confidentiality level

  Refer to the *pgx_confidential_privileges* table. However, in this table confidentiality levels and confidentiality groups are represented as identifiers. Join with *pgx_confidential_level table* and *pgx_confidential_role table* if you want to check by confidentiality level name or confidentiality group name.

(2) Verify correct confidentiality objects and roles registered

Confirm that the definition of the confidentiality management feature matches the definition of the confidentiality objects and roles. If you detect a mismatch, please restore the correct state by executing functions such as *pgx_alter_confidential_level* function provided by this extension.

- Is the number of confidentiality objects registered in the confidentiality level the same as designed?
- Do the attributes of each confidentiality object match the attributes of the confidentiality level to which it belongs?

  It is recommended to check these using *pgx_get_attribute_of_objects* function. Because this function gets the state of the confidentiality object from the PostgreSQL system catalog and outputs a table that can be compared with the definition. For the format of the table, refer to "B.7 Functions that Support Definition Referencing and Comparison with System Catalogs".

- Is the number of roles registered in the confidentiality group the same as designed?
- Do the attributes of each role match the attributes of the confidentiality group to which it belongs?

  It is recommended to check these using *pgx_get_attribute_of_roles* function.For the format of the table returned by a function that outputs authority information, such as this function, refer to "B.7 Functions that Support Definition Referencing and Comparison with System Catalogs".

(3) Check privilege of confidentiality objects

Verify that the roles granted access to confidentiality objects and what the privileges are are consistent with the definitions in the confidentiality matrix. A good help is to use the *pgx_get_privileges_on_matrix* function. For details on the output format, see "7.3.5 Granting Confidentiality Privileges to Confidentiality Groups".

If you want to focus on any confidentiality level or role, use the function below.

- pgx_get_privileges_on_level_and_group()
- pgx_get_privileges_on_object()
- pgx_get_privileges_on_role()

Point

It is inefficient to output a large table many times in order to analyze it with various SQL statements. You can perform efficient analysis by specifying a query that executes this function in the INSERT statement as shown below.

```
INSERT INTO temp_table_for_analysis SELECT pgx_get_privileges_on_matrix('matrix_foo')
```

7.6 Backup/Restore

There are 4 methods below.

- Use pg_basebackup
- Use pg_dumpall to back up the entire database cluster as a script file
- Use pg_dump and pg_restore to back up and restore only some databases
- Use pg_dump's pg_restore to back up and restore only some tables and schemas

Of these, if you adopt the method of using pg_basebackup, you do not need to be particularly careful. The following special precautions should be taken when adopting other methods.

Use pg_dumpall to back up the entire database cluster as a script file

Note the following.

- Do not use the -O option of the pg_dumpall command. This feature does not work properly if the confidentiality object changes ownership.
- Do not use the -x option of the pg_dumpall command. Of course, this would change tightly controlled privileges.
- Execute the backup script file as a superuser. A backup script file contains the CREATE EXTENSION statement for this extension. This is because the CREATE EXTENSION statement must be executed as a superuser.

Backup and restore only some databases using pg_dump and pg_restore

Note the following.

- Use the -r option of the pg_dumpall command to back up and restore role information as well. Of course, because roles are essential to confidentiality management.
- Do not use the -O option of the pg_dump command. This feature will not work properly if the confidentiality object changes ownership.
- Do not use the -x option of the pg_dump command. Of course, this would change tightly controlled privileges.
- Restore by a superuser for CREATE EXTENSION.

Use pg_dump's pg_restore to backup and restore only some tables and schema

Note the following.

- Use the -e option of the pg_dump command to back up and restore this extension as well. This is because the tables contained in this extension store the information required for confidentiality management.
- Use the -r option of the pg_dumpall command to back up and restore role information as well. Of course, because roles are essential to confidentiality management.
- Do not use the -O option of the pg_dump command. This feature will not work properly if the confidentiality object changes ownership.
- Do not use the -x option of the pg_dump command. Of course, this would change tightly controlled privileges.
- Restore by a superuser for CREATE EXTENSION.

7.7 Removing Setup

If you are no longer using this feature and want to continue using your database as before, we recommend simply DROP EXTENSION. This is because if you delete definitions such as confidentiality matrices and confidentiality levels created using this extension using the deletion functions provided by this extension, the roles automatically created by this extension will be deleted, the privileges of roles granted by this extension are revoked. Simply dropping this extension will only drop the tables it contains, it will not do any of these things.

7.8 Usage Example of Confidentiality Management

Here is an example of the concept of confidentiality levels and confidentiality groups.

This section assumes a simple business that handles customer purchase information.

First, create a confidentiality matrix for confidentiality management of this information.

```
SELECT pgx_create_confidential_matrix('matrix_purchase_managenet' , 'Confidentiality
management of customer purchase information');
```

The data we process may also contain personally identifiable information. Access to such data should be restricted to those who have access to it to minimize the risk of information disclosure.

Customer purchase information, including personally identifiable information, is managed in the following table.

```
CREATE TABLE purchase.customer_info(     -- Customer information
    customer_id     integer,               -- Customer ID
    name            text,
    address         text,
    phone_number    char(12),
    rank            integer                -- Customer's service rank
);

CREATE TABLE purchase.history(           -- History of a customer's purchase of goods
    customer_id         integer,            -- ID of the customer who purchased
    purchase_date       date,               -- Date the goods were purchased
    item_code           char(12),           -- Code of the goods purchased
    purchase_number     integer,            -- Quantity purchased
    purchase_amount     integer             -- Amount of purchased goods
);
```

Among customer information, name, address, and telephone number are personal information because they can identify an individual when combined. In order to properly handle such information, we have made it so that it can only be handled by employees belonging to a specific group who have received appropriate training.

Therefore, we have prepared two confidentiality levels: "level_personal_info", which means highly confidential personal information, and "level_customer_info", which means other information.

```
SELECT pgx_create_confidential_level('matrix_purchasee_management', 'level_personal_info',
                                     NULL, 'Personally identifiable information');
SELECT pgx_create_confidential_level('matrix_purchase_management', 'level_customer_info',
                                     NULL, 'Non-personally identifiable information');
```

In addition, we will prepare two confidentiality groups: "group_qualified " who have been educated about handling personal information and can handle personal information appropriately, and "group_non_qulified" who are not qualified.

```
SELECT pgx_create_confidential_group ('matrix_purchase_management', 'group_qualified',
                                   NULL, 'Qualified staff handling personal information');
SELECT pgx_create_confidential_group ('matrix_purchase_management', 'group_non_qulified',
                                     NULL, 'General employee');
```

Let's take a closer look at the data we're dealing with.

Since the customer information table contains personal information, it corresponds to personal information. However, the customer_id and rank contained in the customer information table are not personal information because they are not personally identifiable information. In addition, since this customer_id and rank are also information necessary for business analysis, it is inconvenient that only those who are qualified to handle personal information can access such information.

Therefore, the customer information table uses columns for confidentiality management. The entire customer information table is protected as personal information, and the range of access is expanded by making the columns that are not personal information general customer information.

Follow this policy to set confidentiality level privilege for confidentiality group.

```
SELECT pgx_grant_confidential_privilege('matrix_purchase_management',
                                        'level_personal_info',
                                        'group_qualified', '{"table":["ALL"]}');
SELECT pgx_grant_confidential_privilege('matrix_purchase_management',
                                        'level_customer_info',
                                        'group_qualified', '{"table":["ALL"]}');
SELECT pgx_grant_confidential_privilege('matrix_purchase_management',
                                        'level_customer_info',
                                        'group_not_qualified',
                                        '{"table":["ALL"], "column":["SELECT"]}');
```

Only "qualified personnel" can handle "personal information". "Customer information" can be handled by both "qualified personnel" and "general employees". Some columns of tables that handle "personal information" are allowed to be referred to as "customer information".

This completes the authorization settings in the confidentiality matrix.

Next, we will register the database objects that handle purchase information in the confidentiality matrix.

```
SELECT pgx_add_object_to_confidential_level('matrix_purchase_management',
'level_personal_info',
                                    '[{
                                         "type":"table",
                                         "object":[{
                                                      "schema": "purchase",
                                                      "table": ["customer_info"]
                                          }]
                                      }]');
SELECT pgx_add_object_to_confidential_level('matrix_purchase_management',
'level_customer_info',
                                    '[{
                                         "type":"column",
                                         "object":[{
                                                       "schema": "purchase",
                                                       "table": "customer_info",
                                                       "column": ["customer_id", "rank"]
                                          }]
                                      }]');
SELECT pgx_add_object_to_confidential_level('matrix_purchase_management',
'level_customer_info',
                                    '[{
                                         "type":"table",
                                         "object":[{
                                                      "schema": "purchase",
                                                      "table": ["history"]
                                      }]
                                      }]');
```

The entire customer information table is "personal information", the customer_id column and rank column of the customer information table are "customer information", and the entire purchase history table is also "customer information".

Finally, enroll the employee in the confidentiality group. "Alex" and "Bola" are "qualified persons" who have received training in personal information management. Also, "Charlie" and "Dana" are "general employees" because they have not yet received training on personal information management.

```
SELECT pgx_add_role_to_confidential_group('matrix_purchase_management',
                                          'group_qualified',
                                          '["Alex", "Bola"]');
SELECT pgx_add_role_to_confidential_group('matrix_purchase_management',
                                          'group_non_qualified',
                                          '["Charlie", "Dana"]');
```

Appendix A Tables Used by Confidentiality Management Feature

This section describes the tables used by the confidentiality management feature.

A.1 pgx_confidential_matrix

A list of confidentiality matrices.

You can refer to the attributes of the registered confidentiality matrix, the update time, or the time when the confidentiality level or confidentiality group was registered or deleted.

Column name	Type	Constraint	Description
cmatid	bigint	primary key generated always as identity	Identifier of the confidentiality matrix.
cmatname	varchar(63)	unique not null	Name of the confidentiality matrix.
cmatowner	name	not null	Owner of the confidentiality matrix. The role that created the confidentiality matrix becomes the owner.
cmatcomment	text		Comment.
cmatupdatetime	timestamp with time zone	not null	Update time of the confidentiality matrix itself.
cmatoperationtime	timestamp with time zone		The time when the confidentiality level and confidentiality group were added/deleted.

A.2 pgx_confidential_level

A list of confidentiality levels.

You can refer to the registered confidentiality level attributes, update time, or the time when a confidentiality object was registered to the confidentiality level or removed from the confidentiality level.

Column name	Type	Constraint	Description
clevid	bigint	primary key generated always as identity	Identifier of the confidentiality level.
clevname	varchar(63)	not null	Name of the confidentiality level.
clevmatid	bigint	not null references pgx_confidential_matrix(cmatid)	Identifier of the confidentiality matrix to which the confidentiality level belongs.
clevcomment	text		Comment.
clevupdatetime	timestamp with time zone	not null	Update time of the confidentiality level itself.

Column name	Type	Constraint	Description
clevoperationtime	timestamp with time zone		The time when the confidentiality object was added/deleted.
clevencalgorithm	text	not null	Encryption method. "none" for no encryption. AES128 and AES256 can be set.

A.3 pgx_confidential_group

A list of confidentiality groups.

You can refer to the registered confidentiality group attributes, update time, or the time when a role was registered to the confidentiality group or removed from the confidentiality group.

Column name	Type	Constraint	Description
cgroid	bigint	primary key generated always as identity	Identifier of the confidentiality group.
cgroname	varchar(63)	not null	Name of the confidentiality group.
cgromatid	bigint	not null references pgx_confidential_matrix(cmatid)	Identifier of the confidentiality matrix to which the confidentiality group belongs.
cgrocomment	text		Comment.
cgroupdatetime	timestamp with time zone	not null	Update time of the confidentiality group itself.
cgrooperationtime	timestamp with time zone		The time when the role was added/deleted.
cgrorolename	name	not null	Name of the confidentiality group role.
cgrosuperuser	bool	not null	true if the confidentiality group role has SUPERUSER privileges.
cgrocreatedb	bool	not null	true if the confidentiality group role has CREATEDB privileges.
cgrocreaterole	bool	not null	true if the confidentiality group role has CREATEROLE privileges.
cgroreplication	bool	not null	true if the confidentiality group role has REPLICATION privileges.
cgrobypassrls	bool	not null	true if the confidentiality group role has BYPASSRLS privileges.

A.4 pgx_confidential_privilege

A list of confidentiality privileges.

You can refer to confidentiality privilege set for each confidentiality object, update time, and so on.

Column name	Type	Constraint	Description
cpriid	bigint	primary key generated always as identity	Identifier of the privilege.

Column name	Type	Constraint	Description
cprimatid	bigint	not null references pgx_confidential_matrix(cmatid)	Identifier of the confidentiality matrix to which the privilege belongs.
cprilevid	bigint	not null references pgx_confidential_level(clevid)	Identifier of the confidentiality level for which privilege is set.
cprigroid	bigint	not null references pgx_confidential_group(cgroid)	Identifier of the confidentiality group for which privilege is set.
cpritype	text	not null	Type of the confidentiality object which privilege is set.
cpriupdatetime	timestamp with time zone	not null	Update time when privilege was set/ changed.
cpriacl	text[]	not null	Access privileges that have been set. (*1)

*1: The character string indicating authority appears in the following order in the text type array of cpriacl.

ALL, SELECT, INSERT, UPDATE, DELETE, TRUNCATE, REFERENCES, TRIGGER, CREATE, CONNECT, TEMPORARY, EXECUTE, USAGE

If the appropriate privilege is not set, the string simply does not appear. For example, {'INSERT','TRUNCATE'} if you only have INSERT and TRUNCATE privileges.

A.5 pgx_confidential_object

A list of confidentiality objects.

You can refer to object attributes or update time, and so on.

Column name	Type	Constraint	Description
cobjid	bigint	primary key generated always as identity	Identifier of the confidentiality object.
cobjmatid	bigint	not null references pgx_confidential_matrix(cmatid)	Identifier of the confidentiality matrix to which the confidentiality object belongs.
cobjlevid	bigint	not null references pgx_confidential_level(clevid)	Identifier of the confidentiality level to which the confidentiality object belongs.
cobjtype	text	not null	The type of confidentiality object.
cobjschema	name	not null	Schema name of the confidentiality object.
cobjtable	name	not null	Table name of the confidentiality object.
cobjname	text	not null	Name of the confidentiality object.

Column name	Type	Constraint	Description
cobjupdate	timestamp with time zone	not null	Registration time of the confidentiality object.
cobjpolicy	jsonb		Conditions that determine the range of rowsets when the type is rowset. It is expressed by the setting contents in POLICY.

A.6 pgx_confidential_role

A list of roles registered in the confidentiality group.

You can refer to role attributes or update time, and so on.

Column name	Type	Constraint	Description
crolid	bigint	primary key generated always as identity	Identifier of the role.
crolmatid	bigint	not null references pgx_confidential_matrix(cmatid)	Identifier of the confidentiality matrix to which the role belongs.
crolgroid	bigint	not null references pgx_confidential_group(cgroid)	Identifier of the confidentiality group to which the role belongs.
crolname	name	not null	Name of the role.
crolupdate	timestamp with time zone	not null	Registration time of the role.

A.7 pgx_confidential_policy

This is a list of policies created to set privileges for confidentiality objects of rowset type. You can refer to the name of the policy you created and the privileges it has set.

Rows in this table are inserted when you add a rowset type confidentiality object.

Column name	Type	Constraint	Description
cpolid	bigint	primary key generated always as identity	Identifier of the policy.
cpolmatid	bigint	not null references pgx_confidential_matrix(cmatid)	Identifier of the confidentiality matrix to which the policy belongs.
cpollevid	bigint	not null references pgx_confidential_level(clevid)	Identifier of the confidentiality level to which the policy belongs.
cpolgroid	bigint	not null references	Identifier of the confidentiality group to which the policy belongs.

Column name	Type	Constraint	Description
		pgx_confidential_group(cgroid)	
cpolobjid	bigint	not null references pgx_confidential_object(cobjid)	Identifier of the rowset object using this policy.
cpolprivilege	text	not null	Privilege this policy has (SELECT, INSERT, UPDATE, DELETE, ALL).
cpolname	name	not null	Name of the policy.
cpolexpression	jsonb	not null	Expression of the policy.

Appendix B System Management Functions Used by Confidentiality Management Feature

This section describes the system management functions used by the confidentiality management feature. All functions abort the transaction on failure.

Note

- Be careful when performing operations that involve deleting confidentiality groups.

  If you remove a confidentiality group along with a confidentiality group role, you simply no longer have the role that can access the confidentiality object. However, when you leave the confidentiality group role, the function revokes privileges from the confidentiality group role. The privilege to revoke is the privilege defined in confidentiality privileges.

- The *pgx_get_privileges_on_matrix* function may output a very large table if the number of confidentiality objects or roles is large. If the size of this table exceeds the value of PostgreSQL's *work_mem* parameter, I/O will occur according to PostgreSQL's specifications and will be slow. To prevent this, it is recommended that *work_mem* be set as high as possible in the session in which this function is executed.

B.1 Confidentiality Matrix Manipulation Functions

Function name	Return value	Description
pgx_create_confidential_matrix(confidential_matrix_name varchar, comment text)	void	Create the confidentiality matrix with the specified name. The created confidentiality matrix is registered in the *pgx_confidential_matrix* table along with the comment. Only roles with the required entitlements for the confidentiality management role can execute this function. The role that executes this function is the confidentiality management role for the confidentiality matrix. Functions such as executing by specifying a confidentiality matrix name require that the executed role is a confidentiality management role for the specified confidentiality matrix. For details, please refer to "7.2.2 Determining Confidentiality Management Roles". The length of *confidential_matrix_name* must be less than 64 characters. Note that the units are not bytes. There are no restrictions on the characters that can be used in the *confidential_matrix_name*. When you specify the name of the confidentiality matrix to other functions, you must specify the same string that you specified to this function. Note that unlike most CREATE statements, the name of the confidentiality matrix is case sensitive.
pgx_copy_confidential_matrix(confidential_matrix_name varchar, source_confidential_matrix_name varchar)	void	Copy the source confidentiality matrix specified by *source_confidential_matrix_name* to the confidentiality matrix named *confidential_matrix_name*. Confidentiality matrix, confidentiality levels, confidentiality groups, and confidentiality privileges details are replicated. However, the information of confidentiality objects registered in the confidentiality level and roles registered in the confidentiality group are not duplicated.

Function name	Return value	Description
		Any confidentiality management role in any confidentiality matrix can execute this function. The owner of the cloned confidentiality matrix is the role that executed this function. Restrictions on *confidential_matrix_name* as strings are the same as for the *pgx_create_confidential_matrix* function. Comments are also duplicated.

pgx_alter_confidential_matrix(confidential_matrix_name varchar, alter_object json)	void	Change the attributes of the confidentiality matrix named by *confidential_matrix_name*.
		
		Only confidentiality management role for the specified confidentiality matrix can execute this function.
		
		For *alter_object*, specify the attribute you want to change and the value after change in key-value format as follows. Attributes not specified remain unchanged.
		
		`'{`
		`  "name":"matrix_foo",`
		`  "comment":"This matrix is defined for foo.")`
		`}'`
		
		name: Specify the name of the modified confidentiality matrix. Cannot be *null*. The function will fail if you specify the name of a confidentiality matrix that already exists.
		
		comment: Specify a comment after the change. Can be *null*.

pgx_drop_confidential_matrix(confidential_matrix_name varchar, cascade bool, drop_role bool)	void	Drop the confidentiality matrix with the specified name. Only confidentiality management role for the specified confidentiality matrix can execute this function. Specify *true* for cascade to recursively check and remove objects that depend on this confidentiality matrix. For example, delete the confidentiality groups and confidentiality levels registered in this confidentiality matrix. Then remove the confidentiality privileges associated with that confidentiality level. To drop a confidentiality level, execute internally *pgx_drop_confidential_level* function with a *cascade* value. When dropping a confidentiality group, execute internally *pgx_drop_confidential_group* function with *cascade* and *drop_role* values. See also the descriptions of these functions. In particular, how the privilege of confidentiality objects are changed is important. Specify *false* for cascade simply removes the confidentiality matrix. The function will fail if there are objects that depend on this confidentiality matrix. If *true* is specified for *drop_role*, the confidentiality group role registered in this confidentiality matrix will be deleted. Naturally, it only makes sense when *cascade* is *true*.

B.2 Confidentiality Level Manipulation Functions

Function name	Return value	Description

pgx_create_confidential_level(confidential_matrix_name varchar, confidential_level_name varchar, options json, comment text)	void	Creates a confidentiality level, registers it with the specified confidentiality matrix, and adds it to the *pgx_confidential_level* table with the specified comment and attributes specified in *options*.
		
		Only confidentiality management role for the specified confidentiality matrix can execute this function.
		
		The length of *confidential_level_name* must be less than 64 characters.
		
		Note that the units are not bytes.
		
		There are no restrictions on the characters that can be used in the *confidential_level_name*.
		
		When specifying a confidentiality level name for any other function, you must specify the same string as specified for this function
		
		Note that unlike most CREATE statements, confidentiality level names are case-sensitive.
		
		Specify a comment for *comment*.
		
		For *options*, specify the attribute of the confidentiality level as follows. If you specify NULL, the default value for each attribute will be set.
		
		`'{`
		`  "encryption_algorithm":"AES256"`
		`}'`
		
		encryption_algorithm: Specify the encryption algorithm. The algorithms and default values that can be specified are the same as the *tablespace_encryption_algorithm* parameter of Transparent Data Encryption of Fujitsu Enterprise Postgres. Must not be *null*.

pgx_alter_confidential_level(confidential_matrix_name varchar, confidential_level_name varchar, alter_object json)	void	Change the confidentiality level attribute.
		
		Only confidentiality management role for the specified confidentiality matrix can execute this function.
		
		For *alter_object*, specify the attribute you want to change and the value after change in key-value format as follows.
		
		`'{`
		`  "name":"level_new",`
		`  "comment":"This level is the highest confidentiality level.",`
		`  "encryption_algorithm":"AES256"`
		`}'`
		
		name: Specify the name of the modified confidentiality level. Cannot be null.
		
		comment: Specify a comment after the change. Can be null.
		
		Other attributes are the same as options of *pgx_create_confidential_level* function. Attributes not specified are not changed.
		
		Be careful when increasing the degree of confidentiality. For example, if you increase the encryption strength and

Function name	Return value	Description
		there are confidentiality objects with a lower strength than the new strength, this function will fail.
pgx_drop_confidential_level(confidential_matrix_name varchar, confidential_level_name varchar, cascade bool)	void	Remove a confidentiality level from the confidentiality matrix and delete a confidentiality level. Only confidentiality management role for the specified confidentiality matrix can execute this function. If *true* is specified for *cascade*, the confidentiality level can be deleted even if confidentiality objects are registered in this confidentiality level. If *false* is specified for *cascade*, it is not possible to delete a confidentiality level that has confidentiality objects registered.

B.3 Confidentiality Group Manipulation Functions

Function name	Return value	Description

pgx_create_confidential_group(confidential_matrix_name varchar, confidential_group_name varchar, options json, comment text)	void	Create the confidentiality group, registers it with the specified confidentiality matrix, and adds it to the *pgx_confidential_group* table with the specified comment and attributes specified in *options*.
		
		Only confidentiality management role for the specified confidentiality matrix can execute this function. However, setting some attributes requires superuser privileges, as described below. Therefore, by necessity, the confidentiality management role must be superuser if those attributes are to be set.
		
		This function internally uses the CREATE ROLE statement to create a confidentiality group role.
		
		The length of *confidential_group_name* must be less than 64 characters. Note that the units are not bytes.
		
		There are no restrictions on the characters that can be used in the *confidential_group_name*.
		
		When you specify the name of the confidentiality group to other functions, you must specify the same string that you specified to this function.
		
		Note that unlike most CREATE statements, confidentiality group names are case-sensitive.
		
		For *options*, specify the attributes of the confidentiality group as follows. If you specify NULL, the default value for each attribute will be set.
		
		`'{`
		`  "SUPERUSER":false,`
		`  "CREATEDB":true,`
		`  "CREATEROLE":false,`
		`  "REPLICATION":false,`
		`  "BYPASSRLS":false`
		`}'`

Function name	Return value	Description
		The only attributes that can be specified are the SUPERUSER, CREATEDB, CREATEROLE, REPLICATION, and BYPASSRLS attributes that relate to access privileges to data. These attributes are some of the role attributes that can be specified in the CREATE ROLE statement. The attribute semantics and default values are the same as in the CREATE ROLE statement specification. As noted in the CREATE ROLE statement description, this function fails if a non-superuser specifies *true* for the SUPERUSER, REPLICATION, and BYPASSRLS attributes.

pgx_alter_confidential_group(confidential_matrix_name varchar, confidential_group_name varchar, alter_object json);	void	Change the attributes of a confidentiality group.
		
		Only confidentiality management role for the specified confidentiality matrix can execute this function. As described in *pgx_create_confidential_group* function, you must be superuser to set some attributes.
		
		This function internally uses the ALTER ROLE statement to change the attributes of the confidentiality group role.
		
		For *alter_object*, specify the attribute you want to change and the value after change in key-value format as follows.
		
		`'{`
		`  "name":"group_new",`
		`  "comment":"Members of this group have the highest confidential clearance.",`
		`  "CREATEDB":false`
		`}'`
		
		name: Specify the name of the confidentiality group after modification. Cannot be null.
		
		comment: Specify a comment after the change. Can be null.
		
		Other attributes are the same as options of *pgx_create_confidential_group* function. Attributes not specified are not changed.
		
		For example, if you change the attribute to a weaker one, such as changing CREATEDB to *false*, the attributes of roles registered in the confidentiality group will be similarly weakened.

pgx_drop_confidential_group(confidential_matrix_name varchar, confidential_group_name varchar, cascade bool, drop_role bool)	void	Drop the confidentiality group from the confidentiality matrix and delete a confidentiality group. Only confidentiality management role for the specified confidentiality matrix can execute this function. If *true* is specified for cascade, the confidentiality group can be deleted even if roles are registered in this confidentiality group. If *false* is specified for *cascade*, confidentiality groups that have roles registered cannot be deleted. Specify true for *drop_role* to drop the confidentiality group role. Roles registered in confidentiality groups remain. If

Function name	Return value	Description
		false is specified for *drop_role*, the confidentiality group role will not be deleted. When you leave the confidentiality group role, the function revokes privileges from the confidentiality group role. The privilege to revoke is the privilege defined in confidentiality privileges.

B.4 Confidentiality Privilege Manipulation Functions

Function name	Return value	Description

pgx_grant_confidential_privilege(confidential_matrix_name varchar, confidential_level_name varchar, confidential_group_name varchar, privilege json)	void	Grant confidentiality privileges.
		
		Only confidentiality management role for the specified confidentiality matrix can execute this function.
		
		Grants access to the confidentiality level specified by *confidential_level_name* to the confidentiality group specified by *confidential_group_name*.
		
		When you run this function repeatedly, it simply adds more privileges to grant. Granting the same privilege more than once does not result in an error.
		
		The privilege to be granted is specified in *privilege*. *privilege* specifies the type of the confidentiality object as the key and an array of privileges as the value, like this:
		
		`'{`
		`  "table":["SELECT", "INSERT", "UPDATE", "DELETE"],`
		`  "schema":["CREATE", "USAGE"],`
		`  "rowset":["ALL"]`
		`}'`
		
		The privileges that can be specified depend on the type of confidentiality object.
		
		Privilege for rowset type confidentiality object is privilege that can be specified in the FOR clause of the CREATE POLICY statement.
		
		Except for the rowset type, it is a privilege that can be granted with the GRANT statement according to the confidentiality object type.
		
		If ALL is specified, it is assumed that all privileges that can be specified for that type are listed.
		
		That is, ALL does not appear in the *cpriacl* column of the *pgx_confidential_privilege* table.
		
		The same specification as the WITH GRANT OPTION clause of the GRANT statement cannot be specified. This is because only confidentiality management roles should use this feature to change privilege to confidentiality objects.
		
		Be carefull when PUBLIC is granted to target confidentiality object. This is because granting privileges to PUBLIC is the same as granting privileges to all roles

Function name	Return value	Description
		registered in the confidentiality matrix. This function will fail if a privilege granted indirectly to each role using PUBLIC is defined in the confidentiality privileges that should not be granted to that role. Similarly, this function also checks privileges granted indirectly through group roles that are not registered in the confidentiality matrix. In doing so, it recursively checks the chain of inheritance.
pgx_revoke_confidential_privilege(confidential_matrix_name varchar, confidential_level_name varchar, confidential_group_name varchar, privilege json)	void	Revoke confidentiality privileges. Only confidentiality management role for the specified confidentiality matrix can execute this function. Revokes privilege to the confidentiality level specified by *confidential_level_name* from the confidentiality group specified by *confidential_group_name*. Revoking ungranted privileges does not fail. Privilege to be revoked is specified in *privilege*. The specification method is the same as *pgx_grant_confidential_privilege* function. Be carefull when PUBLIC is granted to target confidentiality object. This is because granting privileges to PUBLIC is the same as granting privileges to all roles registered in the confidentiality matrix. This function will fail if a privilege granted indirectly to each role using PUBLIC is defined in the confidentiality privileges that should not be granted to that role. Similarly, this function also checks privileges granted indirectly through group roles that are not registered in the confidentiality matrix. This time, it checks the chain of inheritance up to its ancestors.

B.5 Confidentiality Object Manipulation Functions

Function name	Return value	Description
pgx_add_object_to_confidential_level(confidential_matrix_name varchar, confidential_level_name varchar, object_name json)	void	Only confidentiality management role for the specified confidentiality matrix can execute this function. Adds the confidentiality object specified by *object_name* to the confidentiality level specified by *confidential_level_name*. This function internally uses the GRANT statement to grant privileges to the confidentiality group role according to the confidentiality privileges associated with this confidentiality level. However, if the confidentiality object is of type rowset, it internally uses the CREATE POLICY statement to grant privileges to the confidentiality group role according to the confidentiality privileges associated with this confidentiality level. Also, to enable POLICY, execute the ALTER TABLE statement on the target table with the ENABLE ROW LEVEL SECURITY clause.

Function name	Return value	Description

		Currently it is not possible to register a foreign table as a table type confidentiality object.
		
		Be carefull when PUBLIC is granted to target confidentiality object. This is because granting privileges to PUBLIC is the same as granting privileges to all roles registered in the confidentiality matrix. This function will fail if a privilege granted indirectly to each role using PUBLIC is defined in the confidentiality privileges that should not be granted to that role. Similarly, this function also checks privileges granted indirectly through group roles that are not registered in the confidentiality matrix. In doing so, it recursively checks the chain of inheritance.
		
		For rowset type confidentiality objects, this function will fail if the target table has a POLICY defined that was not created using this feature, regardless of what privileges are granted.
		
		These checks only apply to the confidentiality group role or to roles that are registered with the confidentiality group. If a POLICY exists that targets a role that is not, the function will not fail.
		
		Specify object_name as follows: Only the rowset is slightly different. The example below attempts to register multiple types of objects in one go.
		
		`'[{`
		`  "type":"schema",`
		`  "object":[`
		`  {"schema":"schema1"},`
		`  {"schema":"schema2"}`
		`  ]`
		`},`
		
		`{`
		`  "type":"table",`
		`  "object":[`
		`  {`
		`  "schema":"schema1",`
		`  "table":["table1","table2"]`
		`  },`
		`  {`
		`  "schema":"schema2",`
		`  "table":["table8","table9"]`
		`  }`
		`  ]`
		`},`
		
		`{`
		`  "type":"column",`
		`  "object":[`
		`  {`
		`  "schema":"schema1",`
		`  "table":"table1",`
		`  "column":["column1", "column2"]`
		`  },`
		`  {`
		`  "schema":"schema1",`
		`  "table":"table2",`

Function name	Return value	Description

		<pre>"column":["column8", "column9"]
		}
		]
		}]'</pre>
		For the rowset type, you define rowset and give it a name, as in the example below. This name is used by the *pgx_remove_object_from_confidential_level* function to identify the rowset type confidentiality object when removing it.
		
		This example shows:
		
		- In schema1.table1, represents a set of rows (rowset) for which the conditional expression (user = current_user OR manger = current_user) is true.
		
		- If manager=current_user is true, the col1 value of the record to be INSERTed or the record after UPDATE must be greater than zero.
		
		<pre>'[{
		"type":"rowset",
		"object":[
		{
		"schema":"schema1",
		"table":"table1",
		"rowset_name":"rowset1",
		"rowset_expression": [
		{
		"as":"permissive",
		"using":"user = current_user"
		},
		{
		"as":"permissive",
		"using":"manager =
		current_user",
		"with check":"col1 > 0"
		}
		]
		}
		]
		}]'</pre>
		Each key (as, *using*, *with check*) has the same meaning as the clause of the same name in the CREATE POLICY statement.
		
		As you can see from this, one element of the array specified in *rowset_expression* corresponds to one POLICY object created by the CREATE POLICY statement.
		
		In fact, this function internally executes as many CREATE POLICY statements as there are elements in the array. The name of POLICY at this time is 'pgx_cms_policy_${cpolid}'.
		
		${cpolid} is automatically numbered by this extension.
		
		<Note>

Function name	Return value	Description
		Do not create policies with names that begin with *pgx_cms_policy_*. Because this function may fail.
pgx_remove_object_from_confidential_level(confidential_matrix_name varchar, confidential_level_name varchar, object_name json)	void	Removes confidentiality objects from the confidentiality level. Only confidentiality management role for the specified confidentiality matrix can execute this function. Removes the confidentiality object specified by *object_name* from the confidentiality level specified by *confidential_level_name*. The format of *object_name* is the same as *object_name* in the *pgx_add_object_to_confidential_level* function. But the *rowset_expression* key is optional. If specified, it is simply ignored. Therefore, *object_name* in *pgx_add_object_to_confidential_level* can be specified to this function without modifying it. At this time, any privileges granted to the confidentiality group based on confidentiality privileges are revoked. If the confidentiality object is of rowset type, delete the internally created policy. At this time, if there are zero policies associated with the table, the ALTER TABLE statement with the DISABLE ROW SECURITY clause is internally executed to disable row level security.

B.6 Role Manipulation Functions

Function name	Return value	Description
pgx_add_role_to_confidential_group(confidential_matrix_name varchar, confidential_group_name varchar, role_name json)	void	Add a role to a confidentiality group. Only confidentiality management role for the specified confidentiality matrix can execute this function. Adds the role specified by *role_name* to the confidentiality group specified by *confidential_group_name*. If the role to be added has been granted broader privileges than the confidentiality privileges, revoke the privileges according to the confidentiality privileges. Be carefull when PUBLIC is granted to target confidentiality object. This is because granting privileges to PUBLIC is the same as granting privileges to all roles registered in the confidentiality matrix. This function will fail if a privilege granted indirectly to each role using PUBLIC is defined in the confidentiality privileges that should not be granted to that role. Similarly, this function also checks privileges granted indirectly through group roles that are not registered in the confidentiality matrix. In doing so, it recursively checks the chain of inheritance.

Function name	Return value	Description
		Also, if the added role has stronger attributes than the confidentiality group, change the attributes to match the confidentiality group. This function will fail if a strong attribute is indirectly assigned using a group role that is not registered in the confidentiality matrix. *role_name* is specified as follows. '{["role1","role"]}'
pgx_remove_role_from_confidential_group(confidential_matrix_name varchar, confidential_group_name varchar, role_name json)	void	Remove a role from a confidentiality group. Only confidentiality management role for the specified confidentiality matrix can execute this function. Removes the role specified by *role_name* from the confidentiality group specified by *confidential_group_name*. This function internally executes a REVOKE statement to remove the role from the confidentiality group role. It does not change the attributes of the role being removed, nor the privileges granted to that role. Simply banish it from the group so that it cannot inherit privileges. The method of specifying role_name is the same as *pgx_add_role_to_confidential_group* function.

B.7 Functions that Support Definition Referencing and Comparison with System Catalogs

Functions that Support Definition Referencing and Comparison with System Catalogs

Function name	Return value	Description
pgx_get_attribute_of_objects(confidential_matrix_name varchar)	setof record	Returns a table of attributes defined in the confidentiality matrix and attributes actually set in the database for all confidentiality objects registered in the specified confidentiality matrix. Refer to "Tables returned by pgx_get_attribute_of_objects" for the table format. Only confidentiality management role for the specified confidentiality matrix can execute this function.
pgx_get_attribute_of_roles(confidential_matrix_name varchar)	setof record	Returns a table of attributes defined in the confidentiality matrix and attributes actually set in the system catalog for all roles registered in the specified confidentiality matrix. Refer to "Table returned by pgx_get_attribute_of_roles" for the format of the table. Only confidentiality management role for the specified confidentiality matrix can execute this function.
pgx_get_privileges_on_level_and_group(confidential_matrix_name varchar, confidential_level_name	setof record	Returns a table that allows you to compare the following for combinations of confidentiality objects registered in the specified confidentiality level and roles registered in the

Function name	Return value	Description
varchar, confidential_group_name varchar)		specified confidentiality group. Refer to "Table returned by pgx_get_privileges_on_level_and_group" for the format of the table. - Privileges specified by the confidentiality privilege settings that should be granted to the specified role - Privileges granted in the actual system catalog Only confidentiality management role for the specified confidentiality matrix can execute this function.
pgx_get_privileges_on_object(confidential_matrix_name varchar, object_name json)	setof record	Returns a table that allows you to compare the following for the specified confidentiality objects. Refer to "Table returned by pgx_get_privileges_on_object" for the format of the table. - Privileges dictated by confidentiality privilege settings that should be granted to all roles - Privileges granted in the actual system catalog Only confidentiality management role for the specified confidentiality matrix can execute this function.
pgx_get_privileges_on_role(confidential_matrix_name varchar, role_name json)	setof record	Returns a table that allows you to compare the following for the all confidentiality objects. Refer to "Table returned by pgx_get_privileges_on_role" for the format of the table. - Privileges specified by the confidentiality privilege settings that should be granted to the specified role - Privileges granted in the actual system catalog Only confidentiality management role for the specified confidentiality matrix can execute this function.
pgx_get_privileges_on_matrix(confidential_matrix_name varchar)	setof record	Returns a table that allows you to compare the following for the all confidentiality objects in the specified confidentiality matrix. Refer to "Table returned by pgx_get_privileges_on_matrix" for the format of the table. - Privileges defined by confidentiality privilege settings that should be granted to all roles registered in the confidentiality matrix. - Privileges granted in the actual system catalog Only confidentiality management role for the specified confidentiality matrix can execute this function.

Tables returned by pgx_get_attribute_of_objects

Column name	Type	Description
matrix_name	varchar(63)	Confidentiality matrix name
confidential_level_name	varchar(63)	Confidentiality level name
object_type	text	Confidentiality object type
object_schema	name	Confidentiality object schema name

Column name	Type	Description
object_table	name	Confidentiality object table name
object_name	text	Confidentiality object name
rowset_expression	json	Conditional expression when the confidentiality object is a row
encrypt_on_matrix	text	Encryption method and strength specified in the confidentiality matrix
encrypt_on_object	text	Actual encryption method and strength of confidentiality objects

Tables returned by pgx_get_attribute_of_roles

Column name	Type	Description
matrix_name	varchar(63)	Confidentiality matrix name
confidential_group_name	varchar(63)	Confidentiality group name
role_name	name	Role name
confidential_group_role	bool	Indicates whether it is a confidentiality group role or not. *true* if it is a confidentiality group role
superuser_on_matrix	bool	SUPERUSER attribute specified in the confidentiality matrix
superuser_on_role	bool	Actual SUPERUSER attribute of the role
createdb_on_matrix	bool	CREATEDB attribute specified in the confidentiality matrix
createdb_on_role	bool	Actual CREATEDB attribute of the role
createrole_on_matrix	bool	CREATEROLE attribute specified in the confidentia matrix
createrole_on_role	bool	Actual CREATEROLE attribute of the role
replication_on_matrix	bool	REPLICATION attribute specified in the confidentia matrix
replication_on_role	bool	Actual REPLICATION attribute of the role
bypassrls_on_matrix	bool	BYPASSRLS attribute specified in the confidentia matrix
bypassrls_on_role	bool	Actual BYPASSRLS attribute of the role

Tables returned by pgx_get_privileges_on_level_and_group, pgx_get_privileges_on_object, pgx_get_privileges_on_role and pgx_get_privileges_on_matrix

Column name	Type	Description
matrix_name	varchar(63)	Confidentiality matrix name
confidential_level_name	varchar(63)	Confidentiality level name

Column name	Type	Description
confidential_group_name	varchar(63)	Confidentiality group name
object_type	text	Confidentiality object type
object_scheme	name	Confidentiality object schema name
object_table	name	Confidentiality object table name
object_name	text	Confidentiality object name
role_name	name	Role name
privilege_list_on_matrix	text[]	Privileges specified by the confidentiality matrix settings. Output is separated by commas
privilege_list_on_object	text[]	Privileges specified by the confidentiality matrix settings. Output is separated by commas
policy_name	name	NULL if the confidentiality object is not of type rowset In the case of rowset type, rowset name (*1)
policy_setting_on_matrix	jsonb	NULL if the confidentiality object is not of type rowset In the case of rowset type, the rowset policy information set in the confidentiality matrix (*1)
policy_setting_on_policy	jsonb	NULL if the confidentiality object is not of type rowset In case of rowset type, row policy information set in the actual policy (*1)

*1: When adding a rowset type confidentiality object, multiple privileges can be set at once, which is not represented by a single row in this table. For example, if you set SELECT and DELETE privileges, you will see a row for SELECT privileges and a row for DELETE privilege. This is because rowset type access control uses PostgreSQL's row-level security POLICY. In this specification, POLICY for SELECT privilege is different from POLICY for DELETE privilege.

Preface

Purpose of this document

This document describes the necessary items for setting up and operating a multi-master configuration system using Fujitsu Enterprise Postgres multi-master replication.

Intended readers

This document is intended for those who use the multi-master replication.

Readers of this document are also assumed to have general knowledge of:

- PostgreSQL
- SQL
- Linux

Structure of this document

This document is structured as follows:

Chapter 1 Overview of Multi-master Replication

Explains an overview of multi-master replication.

Chapter 2 Design

Explains the design of multi-master replication.

Chapter 3 Setup

Explains the setup of multi-master replication.

Chapter 4 Operation

Explains the operation of multi-master replication.

Chapter 5 Reference

Explains functions, tables, and parameters related to multi-master replication.

Appendix A Design Guidelines for Using Multi-master Replication

Explains the design guidelines for using multi-master replication.

Appendix B Using Other Features in Combination

Explain how to handle the use of this feature in combination with other features.

Appendix C Estimating Requirements

Explains the estimating requirements.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

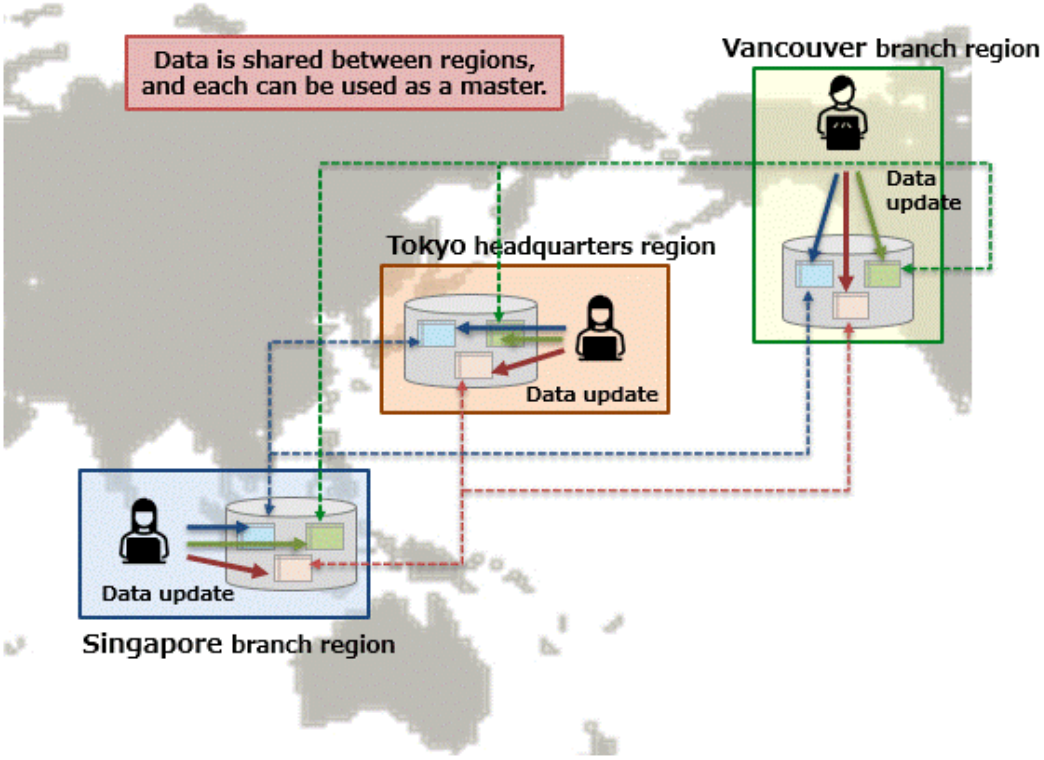
Chapter 1 Overview of Multi-master Replication

This chapter explains an overview of multi-master replication.

1.1 What is Multi-master Replication

Multi-master replication is a feature that enables bidirectional replication where database servers (nodes) located in multiple regions feature simultaneously as masters. Data can be written to each node, and those changes are automatically synchronized with all other nodes.



By utilizing multi-master replication, the following benefits can be achieved:

- Improved availability

  Even if any master node fails, other master nodes can continue reading and writing data, minimizing system-wide downtime. For example, if a disaster occurs in one region, business continuity can be quickly maintained in another operational region.

- Resource reduction

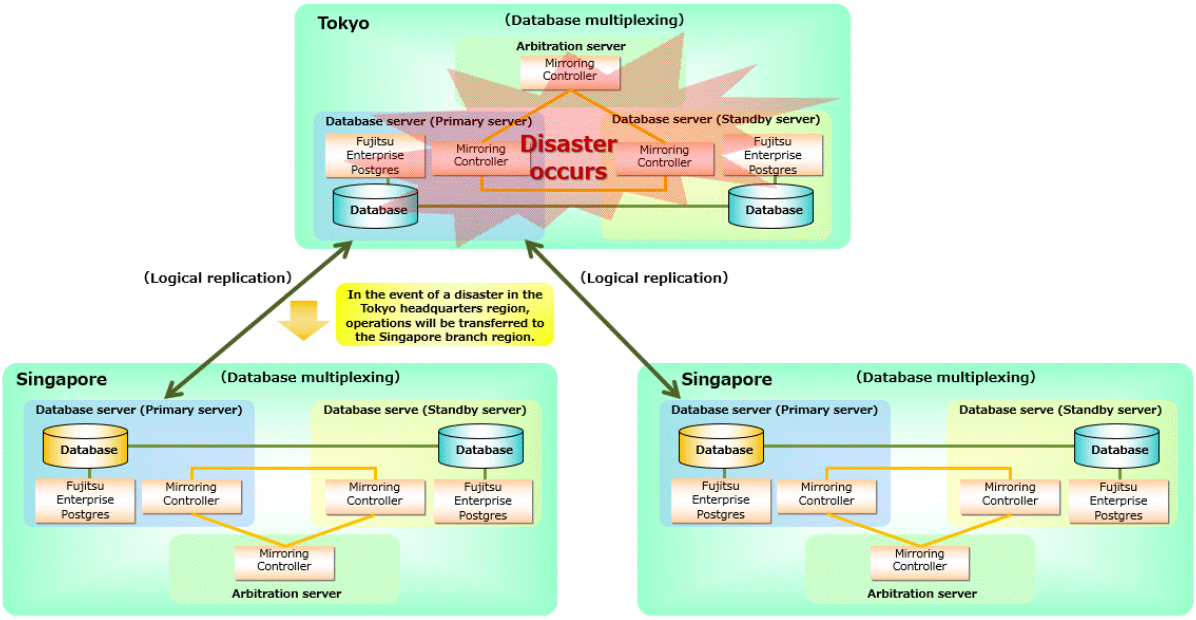
  In traditional single-master configurations, standby nodes were required to prepare for unforeseen events such as disasters. However, in a multi-master configuration, each node serves as a standby node, eliminating the need to prepare standby nodes and reducing resources.

1.2 System Configuration

Explain the system configuration of a system that uses multi-master replication.

In multi-master replication, replication within a region uses the database multiplexing feature of Fujitsu Enterprise Postgres. Additionally, between regions, bidirectional replication is achieved using PostgreSQL's logical replication.

This allows for the mutual integration of operating systems separated by regions, enabling not only high reliability within a region through the database multiplexing feature but also the duplication of databases in remote regions. This makes it possible to build a system that is prepared for a wide range of failures, from local hardware failures to large-scale disasters.

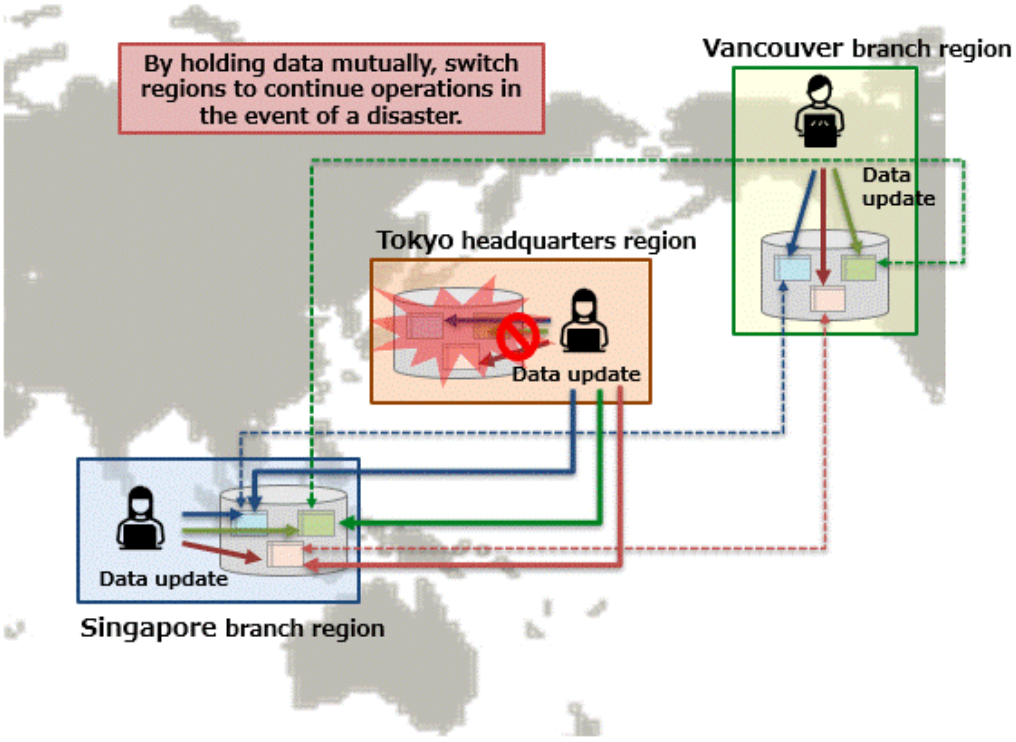


1.3 Examples of Using Multi-master Replication

Here is an example of using multi-master replication.

In the example below, systems are built in Tokyo, Singapore and Vancouver using the multi-master replication feature. Bidirectional replication synchronizes updates across regions in both directions, enabling writes from any node. This ensures each region always maintains the latest data from every other region.

For example, if the Tokyo headquarters region is affected by a disaster, the Singapore branch region can continue the operations of the Tokyo headquarters region.



Chapter 2 Design

This chapter explains the design of multi-master replication.

2.1 Considerations during Design

Multi-master replication can improve availability in the event of widespread disasters or local hardware failures in databases, as data is always active.

However, since mutual data updates occur, there is a risk of conflicts in the same data, which requires consideration in application design and operation.

Below are the considerations for design.

Table 2.1 Considerations for operation

Item	Considerations
Conflict risk	Prevention measures are necessary in design and operation
Operation during disaster switch	Only switch the application connection destination
Disaster recovery (failback)	Can resume with differential reflection (Excluding cases where complete data recovery is necessary, such as disk failure)

Table 2.2 Considerations for tables and applications

Item	Considerations
Replication target	Only data subject to DML (DDL is not allowed)
Primary key	Required for all tables, and it is essential to ensure global uniqueness, including across regions
Foreign reference key / Foreign constraint	Define so that references do not span regions to maintain referential integrity
Sequence	PostgreSQL sequences are not subject to replication, and a mechanism is needed to ensure global uniqueness and continuity after failover
Update policy	To prevent conflicts (such as updating or deleting the same row), it is necessary to partition tables
DDL reflection	Apply the same DDL on both systems (Adjustment of order and timing is necessary)
Large object	Not subject to replication (Measures such as manually copying data are necessary)

Regarding the design for using multi-master replication, refer to the "Appendix A Design Guidelines for Using Multi-master Replication" and consider whether any necessary measures are required and how to implement them.

2.2 Examples of Available Jobs and Jobs that are Difficult to Use

Examples of jobs/systems where multi-master replication can be used and where it is difficult to use are shown below.

Examples of available jobs/systems

- When databases differ between regions
- When tables and schemas are shared

  A system focused on independent operations by region, with the premise of performing reference tasks such as overall aggregation and analysis as below:

  - Independent customer management (CRM/membership management) by region
  - Independent business management and inventory management by region

- Content management system (CMS) that operates independently by region

Examples of difficult-to-use jobs/systems

- Systems that include online data sharing (such as personnel and inventory information) and debt processing, regardless of regional dependency (e-commerce, accounting systems, etc.)
- Pathology systems that store electronic medical records as large objects

2.3 Preparing for Setup

Conduct preliminary planning and design for the approach to set up the environment for using this feature.

Check the following and decide on the work plan and approach for the setup in advance.

- The operation of environment setup is performed on a database basis using the functions provided by this feature.
- When setting up a replication environment between regions, tables and data are automatically copied from one region to the other region.
  Decide in advance the source region and the destination region for the copy.
- Replication during the setup of the replication environment is only performed in one direction.
  Therefore, when setting up, define the schema and tables in the database of the source region, and prepare a database in the destination region without any definitions.
  For example, when setting up a replication environment with the Tokyo headquarters region as the source and the Singapore branch region as the destination, set up the environment as follows.

  1. Create a database for the Tokyo headquarters region and define the tables.
     At this time, please ensure that all necessary tables and data are prepared on the source side the Tokyo headquarters environment for both the source Tokyo headquarters and the destination Singapore branch office (creating an environment where both Tokyo headquarters and Singapore branch tables and data are available).
     This approach offers the advantage that when setting up the replication environment with the Singapore branch, all tables and data are also copied to the Singapore branch, making subsequent tasks easier to simplify.
  2. Define the database to be linked in the Singapore branch region. At this time, do not create any schemas or tables, and use it empty. If tables or other objects exist at the destination, the operation will fail.
  3. Define the connection information and establish a replication environment between the Tokyo headquarters region and the Singapore branch region.

- If there are tables you do not want to include in replication (for example, tables that temporarily store aggregated results within a region and do not need to be shared between regions), you can use a function to exclude them and set them as "not included in replication". If you set this before building the environment, neither the tables nor the data will be copied to the destination during the initial copy. For details on the function, refer to "5.2 Functions".
- When using this feature alongside other Fujitsu Enterprise Postgres features (such as pg_hint_plan or transparent data encryption), certain features may impose restrictions on usage. Refer to "Appendix B Using Other Features in Combination" to determine if any adjustments are necessary beforehand.

Information

Even when building using existing tables in operation, this specification requires that tables and data be integrated/aggregated into the database of the source region for replication.
For example, when constructing a replication environment with the Tokyo headquarters region as the source and the Singapore branch region as the destination, it is necessary to integrate the Singapore branch region's tables into the Tokyo headquarters region, and then either empty the Singapore branch region's database or prepare a separate empty database.

2.4 Security

It is the same as the security in database multiplexing.

For details, refer to "Security in Database Multiplexing" in the Cluster Operation Guide (Database Multiplexing).

Chapter 3 Setup

Explains the setup of multi-master replication.

3.1 Setting Up pgactive

Multi-master replication is achieved by pgactive, which is an OSS.

Perform the following on all nodes.

1. Copy of pgactive extension

   Execute the following command as a superuser.

```
$ su -
Password:******
# cp -r /opt/fsepv<x>server64/OSS/pgactive/* /opt/fsepv<x>server64
```

2. Setting parameters in the postgresql.conf file

   - Add 'pgactive' to the parameter "shared_preload_libraries".
   - Add 'on' to the parameter "track_commit_timestamp".
   - Add 'logical' to the parameter "wal_level".

3. Restart Fujitsu Enterprise Postgres.

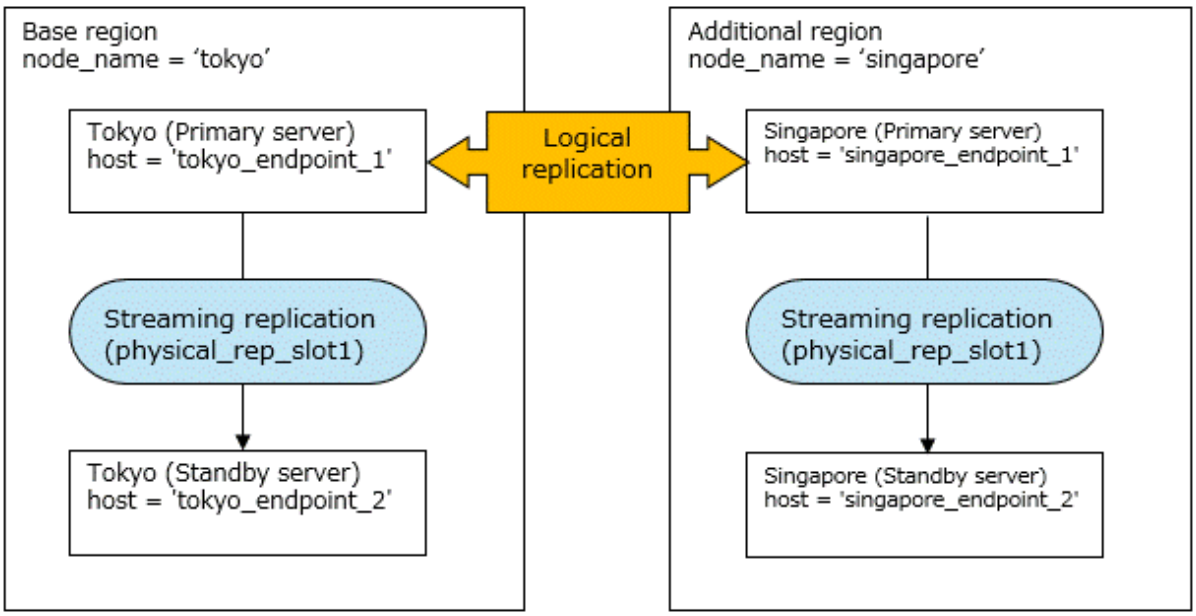
4. Enable the pgactive extension

   Execute CREATE EXTENSION for the database that uses this feature.

```
postgres=# CREATE EXTENSION pgactive;
CREATE EXTENSION
```

3.2 Setting up Multi-master Replication

Multi-master replication is built in the order of "database multiplexing within a region" and "replication between regions".



3.2.1 Database Multiplexing Within the Region

Refer to "Setting Up Database Multiplexing Mode" in the Cluster Operation Guide (Database Multiplexing) to build the primary server, standby server, and arbitration server.

Additionally, when using multi-master replication, additional tasks will occur. Refer to the following and implement them accordingly.

1. Creating a physical replication slot

Create a slot for replication (streaming replication) between the primary server and standby server created above.

The creation is performed on the primary server.

The following example creates a physical replication slot named "physical_rep_slot1".

```
SELECT pg_create_physical_replication_slot('physical_rep_slot1', true, false);
```

2. Additional settings for postgresql.conf

Configure the postgresql.conf on both the primary server and the standby server to enable physical replication slots.

- Configuration on the primary server

```
# Settings for using the pgactive extension
shared_preload_libraries = 'pgactive'
track_commit_timestamp = on
wal_level = logical

# Enabling physical replication slots
synchronized_standby_slots = 'physical_rep_slot1'
```

- Configuration on the standby server

```
# Settings for using the pgactive extension
shared_preload_libraries = 'pgactive'
track_commit_timestamp = on
wal_level = logical

# Enabling physical replication slots
sync_replication_slots = on
hot_standby_feedback = on
primary_slot_name = 'physical_rep_slot1'

# Connection string for the standby server to connect to the sending server (Note)
primary_conninfo=(dbname=’db1’ …)
```

Note: To enable primary_slot_name, ensure that dbname is specified in primary_conninfo.

3.2.2 Replication between Regions

Settings will be configured between primary servers in each region.

The setup involves performing initial configuration in one region (hereafter referred to as the "base region") and then creating the environment by connecting from another region (hereafter referred to as the "additional region").

Here, the base region is described as "tokyo" and the additional region as "singapore".

Note that these environment settings need to be created for each database. If multiple databases are used, perform the tasks for all databases.

Operation for the base region

1. Create the connection service file (pg_service.conf).
   To simplify setup and operation, specify the service name using the region name in the following format.
   To identify servers running in the HA configuration for each region, assign sequential numbers of 1 or higher to the serial number.

```
Region Name_Sequence Number
```

   The following shows an example specification for a redundant configuration with two servers—a primary server and a standby server—built in the Tokyo region.

   - This file is used as the database server information for bidirectional communication when operating as a PostgreSQL server in a multi-master environment. Therefore, it must be specified via the PGSERVICEFILE environment variable when configuring each server system or starting the PostgreSQL server.
   - Please write it in the correct format as a service file.
   - Optionally add any necessary information for the connection method (such as SSL).

```
# tokyo region Unit 1
[tokyo_1]
host=192.xx.xx.xxx
port=27500
dbname=apldb
user=dbuser1

# tokyo region Unit 2
[tokyo_2]
host=192.xx.xx.yyy
port=27500
dbname=apldb
user=dbuser1
```

2. Prepare the files required for authentication.
   For example, when setting up password authentication, create a .pgpass file.

3. Use the connection service file to verify the connection.
   The following is an example of execution when the primary server (service name=tokyo_1) and standby server (service name=tokyo_2) are specified in the connection service file for an HA configuration in the tokyo region.

```
psql service=tokyo_1 -c "select 1"
psql service=tokyo_2 -c "select 1"
```

4. Copy the connection service files required for inter-region connections and the files required for authentication to each server in each region.
   This task must be performed because all servers sharing data via multi-master replication require the same information.

5. Create a region in the replication group by specifying the initial configuration options in "pgx_pgactive_add_region.sh".
   For details, refer to "5.1.1 pgx_pgactive_add_region.sh".

```
pgx_pgactive_add_region.sh -i tokyo
```

6. Verify that the environment was created correctly.
   Verify that the region name is specified in node_name, the user specified in the connection service file is set in node_dsn's user_mapping, and the region name is specified in node_dsn's pgactive_foreign_server.
   If any of these are incorrect, check the connection service file and reconfigure it correctly.

```
psql service=tokyo_1 -c "select * from pgactive.pgactive_nodes"
```

   [Display Example]

```
-[ RECORD 1 ]------+--------------------------------------------------
node_sysid         | 7613228646898848582
node_timeline      | 0
node_dboid         | 32784
```

```
node_status        | r
node_name          | tokyo
node_dsn           | user_mapping=fsepuser pgactive_foreign_server=tokyo
node_init_from_dsn |
node_read_only     | f
node_seq_id        | 1
```

7. Upon successful completion of the script, the following files will be output to the current directory.

```
pgx_pgactive_fencing.sh
```

This file is used to automatically switch connection information during failover within a region and maintain proper connections with other regions.
Copy it to all servers monitored by the Mirroring Controller within the region, and set it as the post-switch command.
For details, refer to "Creating User Exits for Database Servers" in the "Cluster Operation Guide (Database Multiplexing)".

8. For the base region table, set the tables to be included or excluded from replication.
In this feature, all tables are basically included in replication.
If there are tables you do not want to include in replication, set exclusions here to exclude them from replication.
Use the pgx_pgactive_replication_set_exclude_table function for the settings.

Below is the setting to exclude the table "local_schema.work_sum_table" from the replication group as a table not to be replicated.
With this specification, the table "local_schema.work_sum_table" will not be created in the additional region, and the data will not be replicated.

```
SELECT pgactive.pgx_pgactive_replication_set_exclude_table('local_schema.work_sum_table');
------------------------------

(1 row)
```

The settings can be checked with the pgactive_get_table_replication_sets function.
If it is set as "exclude_rs" as shown below, the exclusion setting is enabled.

```
SELECT * FROM pgactive.pgactive_get_table_replication_sets('local_schema.work_sum_table');
     sets
---------------
{exclude_rs,all}
(1 row)
```

To remove the exclusion setting and reconfigure it to be included in the replication, execute the pgx_pgactive_replication_set_reinclude_table function.

```
SELECT pgactive. pgx_pgactive_replication_set_reinclude_table ('local_schema.work_sum_table');
------------------------------

(1 row)
```

The confirmation is done by executing the pgactive_get_table_replication_sets function.
As shown below, if there is no target, the exclusion setting is removed, and it is considered as a replication target.

```
SELECT * FROM pgactive.pgactive_get_table_replication_sets('local_schema.work_sum_table');
     sets
---------------
{default,all}
(1 row)
```

Operations for the additional regions

1. In the additional region, create connection information for bidirectional connection with the base region.
Follow steps 1 through 7 in "Operation for the base region". However, for step 5, perform the following:

Use "pgx_pgactive_add_region.sh" to add the region to the replication group.
The following is an example of adding the additional region "singapore" to the base region "tokyo".

```
pgx_pgactive_add_region.sh -c tokyo singapore
```

2. Check the configuration status.
   Execute the pgactive.pgactive_get_replication_lag_info() function and verify that the node information and each LSN column display values rather than NULL.
   If values are not displayed, it may indicate that the redundant configuration within the region has not been properly established or that the server has failed to start. Please verify this.
   Also, check if the "failover" column in pg_replication_slots is set to "t".
   If it is "f", you need to rebuild from scratch.

```
app=# select * from pgactive.pgactive_get_replication_lag_info();
-[ RECORD 1 ]--------+-------------------------------------------
node_name            | singapore
node_sysid           | 7555130268566652516

3.3 Excluding and Releasing Settings from Replication Groups After Environment Setup

After setting up this feature, the following steps are required to exclude specific tables from replication or to release the exclusion setting.

To exclude a table from replication, execute the pgx_pgactive_replication_set_exclude_table function. To release the exclusion setting and include the table in replication, execute the pgx_pgactive_replication_set_reinclude_table function.

- Settings made using this function are only effective for tables in the region where it was executed.
  If you expect the same effect in multiple regions, perform the same operation in each region.
- This function determines whether the results of DML operations after execution are excluded from replication. It does not affect data or logs before execution.
  For example, if you want to include a table that was excluded in replication, reflect the data in that table to the replication destination yourself before setting it to be included in replication.
- Immediately after a table is created, it is considered a target for replication.
  Therefore, if DML occurs before the exclusion setting is executed, replication logs will automatically be generated.
  To prevent this, when creating a table that is planned to be excluded, ensure that the table creation and the start of DML do not occur simultaneously.
  If unavoidable, since the generated logs must be received once, follow the steps below to address this.

  1. Temporarily create the same table at the replication destination.
  2. After confirming log reception at the replication destination, execute the exclusion setting.
  3. Delete the received logs at the replication destination, or delete the table from step 1.

3.4 Removing pgactive

Perform the following for all nodes.

1. Disable pgactive extension.

   Execute DROP EXTENSION on the database using this feature.

```
postgres=# DROP EXTENSION pgactive;
DROP EXTENSION
```

2. Setting parameters in the postgresql.conf file.

   Remove the parameters set during setup.

3. Deleting the pgactive extension.

   Execute the following command as a superuser.

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>server64/Files copied during setup
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/pgactive
```

Chapter 4 Operation

This chapter explains the operation of multi-master replication.

4.1 Operational Model

There are three operational models:

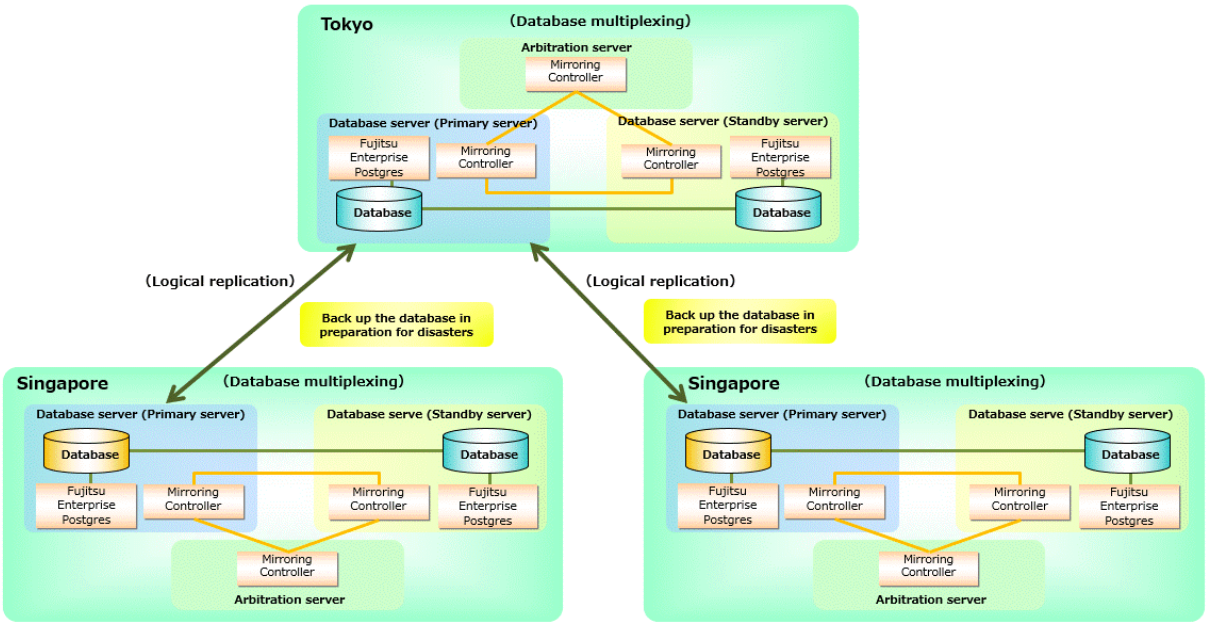
- Normal operation
- Operation during disaster
- Maintenance operation

Normal operation

This is the normal operational mode.

To prepare for disasters, data is shared through replication between remote regions.

Figure 4.1 Normal operation

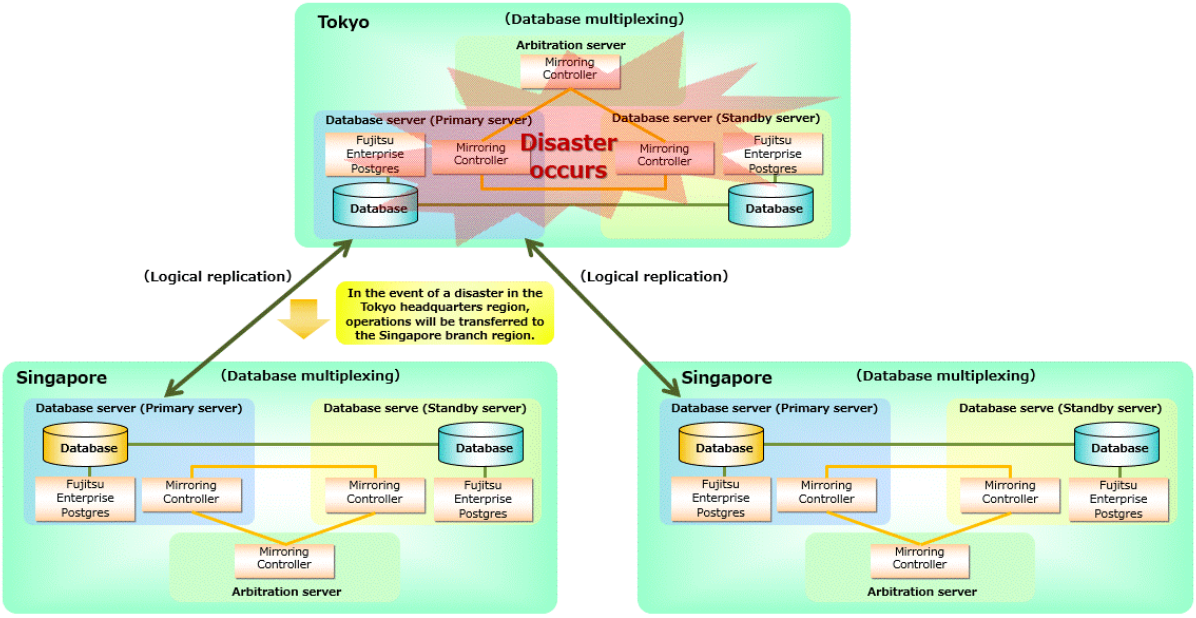


Operation during disaster

This is the operational procedure in the event either region is affected by a disaster.

If the Tokyo headquarters region is affected by a disaster, operations will continue from the Singapore branch region.

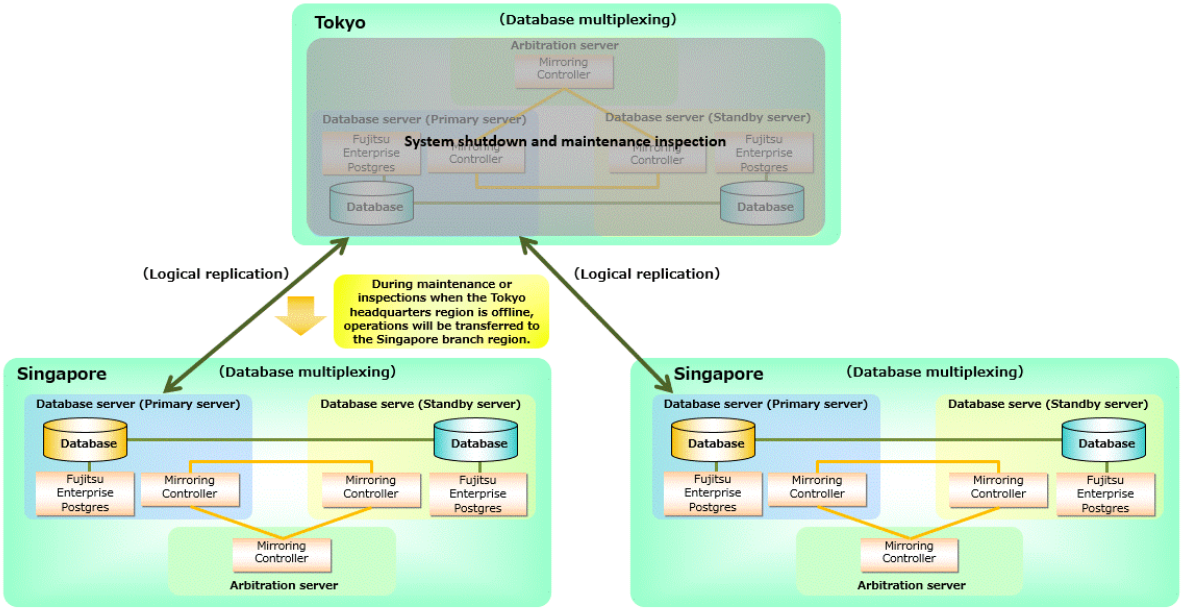
Figure 4.2 Operation during disaster



Maintenance operation

This is an operational model that involves performing planned region switches during scheduled inspections or hardware maintenance in a region to ensure business continuity.

Figure 4.3 Maintenance operation



4.2 Normal Operation Procedures

Explain the operational procedures during normal operation.

4.2.1 Starting

The startup procedure is shown below.

1. Starting the arbitration process for the Mirroring Controller

   Start using the mc_arb command. For more details, refer to "Starting and Stopping the Mirroring Controller Arbitration Process" in the Cluster Operation Guide (Database Multiplexing).

2. Starting the instance and the Mirroring Controller

   Use the mc_ctl command to simultaneously start the instance and the Mirroring Controller. For more details, refer to "Starting and Stopping the Mirroring Controller" in the Cluster Operation Guide (Database Multiplexing).

4.2.2 Checking the Operation Status

Regularly check the following to ensure that operations are running smoothly with multi-master replication.

- Status of database multiplexing within each region
- Replication status between regions
- Transmission delay of transaction logs between regions

The status of database multiplexing within each region

Execute the mc_ctl command in status mode and confirm that the "mirroring status" is switchable. Also, refer to the statistics view pg_stat_replication and confirm that the "sync_state" is "sync". For more details, refer to "Checking the Database Multiplexing Mode Status" in the Cluster Operation Guide (Database Multiplexing).

Replication status between regions

By executing the pgactive_get_replication_lag_info function on the primary server, you can check the replication status between regions.

Ensure that information for both regions is displayed.

Transmission delay of transaction logs between regions

Verify that the delay in transaction logs sent to the partner region remains within the RPO-compliant range.

For details, refer to the "4.4.2 pgactive_get_last_applied_xact_info function" and check the delay status.

4.2.3 Stopping

The procedure for stopping operation in multi-master is shown below.

In case of a disaster during the shutdown, we will synchronize the data before stopping to ensure a prompt resumption of operations.

Perform the same operation in each region.

1. Stop application.
2. Confirm that there are no unprocessed transactions left by checking the values of the pending_wal_to_apply column and the pending_wal_decoding column in the pgactive_get_replication_lag_info function.
3. Execute the mc_ctl command in stop mode to simultaneously stop the instances of the primary server and standby server, along with the Mirroring Controller.

4.2.4 Operations within the Region

If a problem occurs on one server within a region, the affected server is disconnected, and the standby server is promoted or the replication connection between regions is updated.

Automatic server switching/disconnection is basically done automatically by the Mirroring Controller.

However, in the following cases, automatic switching of the primary server will not be performed, so users need to respond accordingly.

- When automatic switching/detachment is disabled
- When heartbeat abnormality is selected for message notification in OS/server health monitoring, and OS/server downtime or non-response occurs

4.2.4.1 Manually Switching the Primary server

Below are the steps for manual switching the primary server.

1. Manually switching the connection destination by executing the mc_ctl command in switch mode on the primary server or standby server. The procedure for manually switching the primary server is the same as the manual switching of the primary server in database multiplexing operations. For details, refer to "Manually Switching the Primary Server" in the Cluster Operation Guide (Database Multiplexing).

2. Update the connection information for replication between regions.

   The work will be carried out on the promoted primary server. For updates, you can use the script provided in "5.5 Sample" to execute within the post-switch command. Edit the script according to your execution environment and then run it.

If the old primary server is normal after switching, such as during maintenance work, restart the Mirroring Controller and incorporate it as the new standby server.

Point

- In manual switching of the primary server, the Mirroring Controller changes the value of the standbycenter_mode parameter in the server identifier.conf file to primary on the new primary server and to standby on the new standby server.
- If automatic switch/disconnection is enabled, it is possible to use the method of switching the primary server at any time.

4.2.4.2 Attach of Standby Server

When operating the promoted standby server as the primary server, create a new standby server and add it to the configuration.

1. Check that the promoted standby server is functioning as the primary server. If "f" (false), the switch has been made.

```
SELECT pg_is_in_recovery();
----------------------------
 f
(1 row)
```

2. Create a new physical replication slot.

```
SELECT pg_create_physical_replication_slot('physical_rep_slot2', true, false);
```

3. Add synchronized_standby_slots to the postgresql.conf of the primary server. to match the above physical replication slot.
   Disable standby configuration values (primary_conninfo, hot_standby, sync_replication_slots, hot_standby_feedback, primary_slot_name).

```
#primary_conninfo = 'host=singapore_1 port=27501 user=fsepuser'
#hot_standby = on        # "off" disallows queries during recovery

shared_preload_libraries = 'pgactive'
track_commit_timestamp = on
wal_level = logical

#sync_replication_slots = on
#hot_standby_feedback = on
#primary_slot_name = 'physical_rep_slot1'

#Add
synchronized_standby_slots = 'physical_rep_slot2'
```

4. Execute the pgactive_apply_pause function to temporarily pause receiving replication logs.
   Note that the pause with this function is temporary, so it will be reset when the server is restarted.

```
SELECT pgactive.pgactive_apply_pause();
```

5. Reload the primary server to activate the settings from step 3.

```
pg_ctl reload -D $PGDATA
server signaled
```

6. Check if the setting is enabled.

```
SHOW synchronized_standby_slots;
 synchronized_standby_slots
----------------------------
 physical_rep_slot2
(1 row)
```

7. Set up the standby server environment.
   Separately back up the necessary information other than data (such as various settings like postgresql.conf).
   In addition, when using the pg_rewind command, also refer to the "Identify cause of error and perform recovery" in the Cluster Operation Guide (Database Multiplexing) and make adjustments to the timeline ID as well.

```
pg_basebackup -h singapore_1 -p 27501 -U fsepuser -D $PGDATA -R --dbname='application_name=stb
dbname=app' -S physical_rep_slot2
```

8. Set up the standby server and start it.
9. On the primary server, execute the pgactive_apply_resume function to resume receiving the replication log.

```
SELECT pgactive.pgactive_apply_resume();
```

10. Verify that the data is being correctly received on each server.
11. Execute the mc_ctl command in start mode on the standby server to perform the integration.

    Example)

```
$ mc_ctl start -M /mcdir/inst1
```

4.2.4.3 Fallback of Primary server

If you want to revert the primary server and standby server to their original configuration after incorporating the standby server, perform a rollback of the primary server.

The rollback procedure for the primary server is the same as the manual switch procedure for the primary server. Refer to "4.2.4.1 Manually Switching the Primary server" and execute the procedure by reading the primary server as the standby server and the standby server as the primary server.

4.2.4.4 Manually Disconnecting the Standby Server

The procedure for manually disconnecting the standby server is shown below.

In the following cases, the standby server will not be automatically disconnected.

- When automatic switching/disconnection is disabled

In the above case, manually disconnect the standby server by executing the stop mode of the mc_ctl command on the standby server.

Example)

```
$ mc_ctl stop -M /mcdir/inst1
```

Point

When setting up automatic start and stop of the Mirroring Controller using systemd, use the systemctl command instead of the mc_ctl command. For more details, refer to "Automatic Start and Stop Settings for Instances and Mirroring Controller" in the Cluster Operation Guide (Database Multiplexing).

4.2.5 Operations Between Regions

In the event that operations cannot continue in any region due to a disaster, etc., explain the procedure for continuing application operations in the active region, as well as the procedure for returning to normal operations.

4.2.5.1 When a Switch Occurs

Take over the application operations in the active region.

Additionally, due to temporary network issues or other factors, the stopped region may automatically recover before the switchover is complete. This could result in a split-brain scenario where communication between servers across regions becomes possible, potentially causing data duplication.

Therefore, ensure that transaction log reception suppression and server shutdown verification are performed reliably.

Below are the operation procedures.

1. Execute the pgactive_pause function to stop receiving transaction logs from the paused region.
   Refer to the OSS documentation for details on the function.
2. Check the startup status of each server in the stopped region and ensure that they are indeed stopped. If they are not completely stopped, take measures such as disconnecting the network after business resumes to prevent the same operations from being executed in both regions.
3. Recovery of Lost Data

   Before resuming application operations, verify the lost data from the database contents and update the database by re-executing operations if necessary.
4. Resumption of Application Operations

   Resume application operations on the primary server on the operational side.
5. Recovery of the Stopped Region

   Recover and rebuild the stopped region. Refer to "Chapter 3 Setup" procedure for reconstruction steps.

4.3 Backup

The procedure is the same as database multiplexing operation.

For details, refer to "Backup Operation" in the Cluster Operation Guide(Database Multiplexing).

4.4 Monitoring

This feature allows you to check the replication status and delay using the following two functions:

- pgactive_get_replication_lag_info function
- pgactive_get_last_applied_xact_info function

Explain the execution examples and information analysis for each function.

Refer to the OSS documentation for the function interfaces and other details.

4.4.1 pgactive_get_replication_lag_info function

You can check the replication delay between each node (WAL transmission and application status).

```
app=# SELECT * FROM pgactive.pgactive_get_replication_lag_info();
-[ RECORD 1 ]--------+-----------------------------------------------
node_name            | singapore
node_sysid           | 7558435655513626243
application_name     | pgactive:7558435655513626243:send
slot_name            | pgactive_16385_7558435655513626243_0_16389__
active               | t
```

```
active_pid           | 30583
pending_wal_decoding | 0
pending_wal_to_apply | 0
restart_lsn          | 0/3078398
confirmed_flush_lsn  | 0/30783D0
sent_lsn             | 0/30783D0
write_lsn            | 0/30783D0
flush_lsn            | 0/30783D0
replay_lsn           | 0/30783D0
-[ RECORD 2 ]--------+-------------------------------------------
node_name            | tokyo
node_sysid           | 7558435633402685045
application_name     | pgactive:7558435633402685045:send
slot_name            | pgactive_16389_7558435633402685045_0_16385__
active               | t
active_pid           | 31073
pending_wal_decoding | 0
pending_wal_to_apply | 0
restart_lsn          | 0/3069150
confirmed_flush_lsn  | 0/307FD20
sent_lsn             | 0/307FD20
write_lsn            | 0/307FD20
flush_lsn            | 0/307FD20
replay_lsn           | 0/307FD20
```

Mainly monitor the following three columns.

active

Indicates the status.

Set an alert if false ("f").

This indicates that the slot is currently not in use (the subscriber instance is disconnected from the publisher).

pending_wal_decoding

In PostgreSQL logical replication, WAL files are stored in binary format.

The publisher needs to decode these WAL changes and convert them into logical changes (such as insert, update, delete operations).

pending_wal_decoding indicates the number of WAL files waiting to be decoded on the publisher side.

This number can increase due to the following factors:

- When no subscribers are connected
- When the slot is active but the publisher cannot keep up with the volume of WAL changes, causing unprocessed WAL to accumulate

pending_wal_to_apply

Indicates the number of WAL files waiting to be applied on the subscriber side.

Due to several factors, the subscriber may become unable to apply changes, potentially leading to situations such as the disk becoming full.

- Schema differences - Even if there are changes in the WAL stream of a table named Sample, if that table does not exist on the subscriber side, etc.
- When the value of the primary key column is updated

Here is an example of when the subscriber on the Tokyo side is stopped.

active is false ("f"), and pending_wal_decoding is increasing.

```
app=# SELECT * FROM pgactive.pgactive_get_replication_lag_info();
-[ RECORD 1 ]--------+-------------------------------------------
node_name            | singapore
node_sysid           | 7558435655513626243
```

```
application_name     | pgactive:7558435655513626243:send
slot_name            | pgactive_16385_7558435655513626243_0_16389__
active               | t
active_pid           | 30583
pending_wal_decoding | 0
pending_wal_to_apply | 0
restart_lsn          | 0/3077AB0
confirmed_flush_lsn  | 0/3077AE8
sent_lsn             | 0/3077AE8
write_lsn            | 0/3077AE8
flush_lsn            | 0/3077AE8
replay_lsn           | 0/3077AE8
-[ RECORD 2 ]--------+-------------------------------------------
node_name            | tokyo
node_sysid           | 7558435633402685045
application_name     |
slot_name            | pgactive_16389_7558435633402685045_0_16385__
active               | f
active_pid           |
pending_wal_decoding | 93784
pending_wal_to_apply |
restart_lsn          | 0/3068E90
confirmed_flush_lsn  | 0/3068EC8
sent_lsn             |
write_lsn            |
flush_lsn            |
replay_lsn           |
```

4.4.2 pgactive_get_last_applied_xact_info function

Retrieve information about the last transaction applied at the specified node (source node). By executing this periodically, you can check the time committed at the source and the time committed at the destination, allowing you to confirm the magnitude of the delay.

```
app=# select pgactive.pgactive_get_last_applied_xact_info('7558435655513626243',0, 16389);
-[ RECORD 1 ]----------------------
+-------------------------------------------------------------------
pgactive_get_last_applied_xact_info | (785,"2025-10-07 20:16:18.847916+09","2025-10-07
20:16:44.840078+09")
```

In this example, it shows that the commit made around "20:16:18" at the sender side is experiencing a delay at the receiver side, and was committed around "20:16:44".

If the delay exceeds the acceptable range, use it to take actions such as raising an alert.

For function interfaces and other details, please refer to the OSS documentation for "get_last_applied_xact_info".

4.5 Tuning

It is the same as the security in database multiplexing.

For details, refer to "Tuning" in the Cluster Operation Guide (Database Multiplexing).

4.6 Maintenance Operation Procedures

When performing maintenance tasks such as applying patches to the OS or middleware, you can switch regions and transfer application operations to another region to continue operations during maintenance.

After the maintenance is completed, you can revert between regions as needed.

4.6.1 Switching Regions during Maintenance

The maintenance procedure is shown below.

1. Stop the application application operations in the region where maintenance work is performed.
2. Execute the pgactive_pause function in the region where maintenance work is performed to stop transaction log reception. Refer to the OSS documentation for details on the function.
3. Verify that no pending transactions remain in the region where maintenance by checking the pending_wal_decoding column of the pgactive_get_replication_lag_info function.
4. Stop the instance and Mirroring Controller and disable automatic start/stop

   Execute the mc_ctl command in stop mode in the region where maintenance is performed to simultaneously stop the primary server instance, standby server instance, and Mirroring Controller.

   If automatic start/stop is configured for the instance and Mirroring Controller, disable the settings.
5. Check the instance status

   Confirm that the primary server instance is normally stopped in the region where maintenance work is being performed. Execute the pg_controldata command on the primary server and confirm that the "Database cluster state" is "shut down".
6. Check the transaction log position

   Verify that the transaction log is reflected on each server in the linked region. Check the pending_wal_to_apply column of the pgactive_get_replication_lag_info function.
7. Stopping the Mirroring Controller arbitration process and disabling automatic start/stop

   Execute the mc_arb command in the region where maintenance to stop the Mirroring Controller arbitration process.
   If automatic start/stop of the Mirroring Controller arbitration process is configured, disable the setting.
8. Execution of maintenance work

   Maintenance operations will commence in the region where maintenance is being performed.
9. Resumption of application operations

   Resume application operations under maintenance on the primary server in the linked region.
10. Instance startup

    Once maintenance operations in the affected region are complete, execute the pg_ctl command on both the primary server and standby server that were performing maintenance to start the instance.

    Example)

    ```
    $ pg_ctl start -D /database/inst1
    ```
11. Initiating the Mirroring Controller arbitration process and enabling automatic start/stop

    After the maintenance work is completed, start each instance in the stopped region.

    Execute the mc_arb command in the region where maintenance to start the Mirroring Controller arbitration process.

    Example)

    ```
    $ mc_arb start -M /mcarb_dir/arbiter1
    ```

    If you have set up automatic start and stop for the Mirroring Controller arbitration process, enable the settings.
12. Starting the Mirroring Controller and enabling automatic start/stop

    Execute the mc_ctl command in the region where maintenance is being performed to start the primary server, the standby server instance, and the Mirroring Controller.

    Example)

    ```
    $ mc_ctl start -M /mcdir/inst1
    ```

    If you have set up automatic start and stop for instances and the Mirroring Controller, enable the settings.

13. Resumption of application

    Application operations will resume on the primary server in the region where maintenance work is being performed.

4.7 Change in Operations

Explain the procedure for changes in the operation of multi-master replication.

4.7.1 Change from Database Multiplexing to Multi-master Replication

The procedure for changing to multi-master operation that shares database multiplexing operations with another region for the purpose of duplicating the database in case of emergency is shown. Change the configuration of regions that are already operating database multiplexing to multi-master replication.

In order to use the multi-master configuration, a table structure and application design suitable for multi-master replication are required. Refer to "Chapter 2 Design" and consider whether any necessary actions are required and how to address them.

1. Implement the procedure for "Rolling Update" in the Cluster Operation Guide (Database Multiplexing) and make the following configuration changes on the primary server and standby server during the maintenance procedure.

   - Editing the pg_hba.conf file

     To authenticate connections from a different region, add the following entries to the pg_hba.conf files of the primary server and standby server.

```
# TYPE    DATABASE        USER        ADDRESS                                                 METHOD
  host    replication     fsep        Address of the primary server in a different region
Authentication method
  host    replication     fsep        Address of the standby server in a different region
Authentication method
```

   - Editing the postgresql.conf file

     Set the following parameters in the postgresql.conf files of the primary server and the standby server.

Table 4.1 Set parameters

Parameter	Content	Remarks
max_wal_senders	4	Specify 4 to send transaction logs bidirectionally and in preparation for executing the pg_basebackup command simultaneously on standby servers and primary servers in different region.
wal_keep_size	WAL storage size (unit: megabytes)	Specify based on the maximum transaction log volume to be accumulated according to the RPO.
archive_mode	always	Specify always to obtain archive logs on all servers.

Information

In multi-master operation, the wal_keep_size parameter is used to prevent transaction logs from being reused in preparation for wide-area network disconnection. For this reason, the capacity of accumulated transaction logs varies depending on the disconnection time of the wide-area network and the content of update transactions. For the estimation formula of the capacity of accumulated transaction logs, refer to "C.1 Estimating Transaction Log Space Requirements".

See

When operating in multi-master mode, refer to the "Parameters" in the Cluster Operation Guide (Database Multiplexing) for the parameters to set in the postgresql.conf file.

2. Define one region as the base region and the other region to be linked as the additional region. Make the region with more table definitions and data volume the base region.
3. Extract the assets of the migration target region using the pg_dump command or similar, store them in the base region database, and integrate them.
4. Prepare an empty database environment for the additional region.
5. Create a replication group for the base region.
6. Add the additional region to the above replication group and synchronize the data of both.

4.7.2 Disabling Multi-master Replication

The procedure to disable and delete this feature is shown below.

For example, it is assumed that instead of recovering the region itself during a disaster, it will be reconstructed in another region.

Note that disabling this feature will not affect user data or tables.

Perform this procedure on a database server that can connect to the base region.

1. Use the script "pgx_pgactive_delete_region.sh" to detach a region from the replication group.
   The following is an example of detaching the singapore region.

```
pgx_pgactive_delete_region.sh -c tokyo singapore
```

2. For each database, execute the following to disable pgactive.

```
SELECT pgactive.pgactive_remove();
```

If you also want to delete the pgactive extension, refer to "3.4 Removing pgactive" to execute the deletion of extension information.

4.7.3 Changing Parameter

The procedure for changing parameters is the same as the procedure for database multiplexing operation. For details, refer to "Changing Parameter" in the Cluster Operation Guide (Database Multiplexing).

4.8 Action Required when an Error Occurs in Disaster Recovery Operaion

Explains how to handle abnormal situations in multi-master operations.

The following recoveries need to be performed as countermeasures:

- Recovery for the continuation of operations

  Priority is given to recovery that enables switching to a partner region in preparation for a disaster.

- Recovery of resources where failures have occurred

  After performing recovery for the continuation of operations, resources where failures have occurred are systematically restored to normal operational status.

Resource with a malfunction	The necessity of recovery for the continuation of operations		The necessity of recovery of resources where failures have occurred	Reference
	Primary server	Standby server		
Primary server	-	N	Y	4.8.1 In Case of Primary Server Failure
Standby server	N	-	Y	4.8.2 In Case of Standby Server Failure

Resource with a malfunction	The necessity of recovery for the continuation of operations		The necessity of recovery of resources where failures have occurred	Reference
	Primary server	Standby server		
Log transfer network	N	N	Y	"Operations when the Server has Started Degrading after a Switch has Occurred" in the Cluster Operation Guide (Database Multiplexing) (*1)
Admin network	N	N	Y	"Action Required when Server Degradation Occurs" in the Cluster Operation Guide (Database Multiplexing) (*2)
Wide-area network between regions	N	N	Y	4.8.3 Operational Procedures During Wide-Area Network Disconnection

Y: Required
N: Not required

*1) If the log transfer network becomes abnormal, the standby server will be disconnected and degraded operation will be performed using the database multiplexing feature.

*2) If the management network becomes abnormal, the primary server will be switched or the standby server will be disconnected and degraded operation will be performed using the database multiplexing feature.

4.8.1 In Case of Primary Server Failure

Explain how to action errors occurring within the primary server.

Recovery for the continuation of operations

Not necessary.

Information

When automatic failover occurs via the database multiplexing feature, transaction log transmission is interrupted. However, the primary server in the linked region detects the failure and automatically switches the replication connection to the new primary server after failover, thereby resuming transaction log transmission. Therefore, even if an automatic switchover occurs in the source region due to the database multiplexing feature, there is no need to synchronize data between the primary and standby servers in the destination region or to halt operations in the destination region.

Recovery of resources where failures have occurred

It is the same as the handling method during database multiplexing operation.

See

For operational procedures in case of a primary server anomaly, refer to "Operations when the Server has Started Degrading after a Switch has Occurred" in the Cluster Operation Guide (Database Multiplexing).

Point

Due to the recovery of this procedure, the roles of servers within the region will be swapped. Therefore, if you want to revert to the configuration at the time of setup, refer to "Failback of the Primary Server" in the Cluster Operation Guide (Database Multiplexing) and perform the reversion.

4.8.2 In Case of Standby Server Failure

Explain how to action errors occurring within the standby server.

Recovery for the continuation of operations

Not necessary.

Recovery of resources where failures have occurred

It is the same as the handling method during database multiplexing operation.

See

For operational procedures in case of a standby server anomaly, refer to "Operations when the Server has Started Degrading after a Disconnection has Occurred" in the Cluster Operation Guide (Database Multiplexing).

4.8.3 Operational Procedures During Wide-Area Network Disconnection

Explain the response methods in case of a wide-area network disconnection.

Recovery for the continuation of operations

If an anomaly occurs in the wide-area line connecting regions, transaction logs between regions will not be transferred, resulting in a wide-area line disconnection. In the event of a wide-area line disconnection, application operations can continue in any region, but transaction logs will no longer be reflected.

Therefore, users will attempt to continue operations by changing the application linkage destination to one of the regions, similar to when a failure occurs within a region and business continuity within that region becomes impossible. refer to "4.2.5.1 When a Switch Occurs" for operations related to each region.

In addition, the occurrence of a wide-area circuit disconnection can be confirmed via messages output to the primary server in the partner region. When an abnormality occurs on the wide-area circuit connecting regions, a message indicating that the primary server in the originating region is disconnected will be repeatedly output to the primary server in the partner region.

An example of the message output is shown below.

```
Example)
```

```
FATAL:  connection to server at "192.0.2.100", port 5432 failed: Connection timed out
                Is the server running on that host and accepting
                TCP/IP connections?
```

Recovery of resources where failures have occurred

After identifying the cause of the anomaly from system logs, network wiring, and the status of network cards, take measures such as replacing the problematic equipment to eliminate the anomaly.

After recovery, execute the pgactive_get_replication_lag_info function on the primary server and verify that information about the primary server in the linked region is displayed. However, depending on the recovery method, transaction log transmission may not automatically resume, so if it cannot be searched from the statistical information view, try restarting the instance of the primary server.

4.9 Monitoring of Delays

Monitoring of delays within a region and between regions.

Within the region

Since it is synchronized by streaming replication, there is no need to monitor the delay.

Between regions

Refer to "4.4 Monitoring".

Chapter 5 Reference

This chapter explains the commands, functions, tables, and parameters related to multi-master replication.

5.1 Commands

To simplify environment setup, we provide a script.

5.1.1 pgx_pgactive_add_region.sh

Format (When creating a replication group)

```
pgx_pgactive_add_region.sh -i region_name
```

Format (When adding a region to an existing replication group)

```
pgx_pgactive_add_region.sh -c connect_region_name  region_name
```

Description

Add a new region to the replication group.
Execute this after establishing the environment within the region.

- Initially, you must create the replication group, so execute with the -i option.
- If you have already created a replication group, specify an existing region as the destination to connect. This handles everything from configuring the connection with the region within the group to adding the region to the group.
- All regions within the group must be operational, as the script attempts to connect to every region in the group.
- You must configure the connection information for the region you are adding in the service connection file (pg_service.conf) beforehand and copy the same file to all servers.
  The service connection file must be either a system file or specified via the PGSERVICEFILE environment variable before executing this script.
- After executing this script, the post-switch command "pgx_pgactive_fencing.sh" will be output to the current directory.
- Please run this script on a database server that can connect to the base region where Fujitsu Enterprise Postgres is installed.

Options

-i

Specify during initial creation. Creates a replication group in the specified region.

-c connect_region_name

Specify the name of the existing region to connect to.

region_name

Specify the name of the region to be added to the replication group.

Diagnostics

0: Normal exit

Other than 0: Abnormal exit

5.1.2 pgx_pgactive_delete_region.sh

Format

```
pgx_pgactive_delete_region.sh -c connect_region_name  delete_region_name
```

Description

Removes the specified node from the replication group added by pgx_pgactive_add_region.sh.
Used for node detachment or disabling prior to setup removal.

- All regions within the group must be operational, as the script attempts to connect to every region in the group.
- For connection, use the service connection file (pg_service.conf) as with pgx_pgactive_add_region.sh.
  Specify the service connection file either as a system file or via the PGSERVICEFILE environment variable before executing this script.
- Please run this script on a database server that can connect to the base region where Fujitsu Enterprise Postgres is installed.

Options

--c connect_region_name

Specifies the name of the region for which deletion is requested.

delete_region_name

Specifies the name of the region to be deleted.
Cannot specify the same region name as -c.

Diagnostics

0: Normal exit

Other than 0: Abnormal exit

5.2 Functions

Of the functions provided by OSS, do not use the following functions. Instead, use the functions provided by Fujitsu Enterprise Postgres.

Table 5.1 Functions provided by OSS that are unavailable for use

Function	Summary	Description
pgactive_include_table_replication_set	Include specific tables in the replication.	Do not use. Instead, use the functions provided by Fujitsu Enterprise Postgres.
pgactive_exclude_table_replication_set	Exclude specific tables from replication.	Do not use. Instead, use the functions provided by Fujitsu Enterprise Postgres.

Table 5.2 Functions provided by Fujitsu Enterprise Postgres

Function	Summary	Description
pgx_pgactive_connections_changed	Reflect the update of connection information.	It is used for failover.
pgx_pgactive_replication_set_exclude_table	Set the table not to be included in replication.	Use it instead of pgactive_exclude_table_replication_set function.
pgx_pgactive_replication_set_reinclude_table	Return the table to the state where it is included in replication.	The pgx_pgactive_replication_set_exclude_table function re-includes tables excluded from the replication group into the replication target.

5.2.1 pgx_pgactive_connections_changed Function

Reflecting the update of connection information.

Argument

None

Return type

void

Precautions for Use

This function is solely for reloading connection information during failover. Do not use it for anything else.

5.2.2 pgx_pgactive_replication_set_exclude_table Function

Exclude the specified table from replication processing and prevent it from being included in replication processing.

Argument

p_relation (regclass)

Return type

void

Precautions for Use

- It can only be executed after the replication group has been created.
- The target table must exist.
- It cannot be set for tables that have already been excluded.

5.2.3 pgx_pgactive_replication_set_reinclude_table Function

Remove the exclusion setting for the specified table, add it to the replication group, and include it in the replication processing.

Note that when creating a table, it is added to the replication group by default, so this operation is not necessary.

Argument

p_relation (regclass)

Return type

void

Precautions for Use

- The target table must exist.
- Cannot be executed on tables that are not excluded.

5.3 Table

Refer to the OSS documentation.

5.4 Parameters

Below are the parameters in postgresql.conf that need to be set to use this feature.

Parameter	Target server	Description
max_worker_processes	All	Add the following values. 3 + *number of connection regions* × 2
shared_preload_libraries	All	Specify "pgactive" additionally.
track_commit_timestamp	All	Specify "on".

Parameter	Target server	Description
wal_level	All	Specify "logical".
synchronized_standby_slots	Primary server	Set it to the server that is started as the primary server within the region. Specify the slot name created with the pg_create_physical_replication_slot function.
sync_replication_slots	Standby server	Specify "on".
hot_standby_feedback	Standby server	Specify.
primary_slot_name	Standby server	Specify the same value as the specified value of synchronized_standby_slots.
wal_max_size	All	Change as appropriate.

Do not use the following parameters of the pgactive extension.

Parameter	Summary	Description
pgactive.skip_ddl_replication	Automatic reflection of DDL presence or absence	Do not use it. If set, some DDLs (such as ALTER TABLE statements and CREATE POLICY statements) may not be executable. Execute the same DDL in each region.

5.5 Sample

Provide samples that can be used for construction and operation.

Here, explain how to use and modify the samples.

Usage target	Usage	Need for modification and summary of modifications
Post-switch command	When the primary server in the region stops, switch the replication environment to another region.	Modify the connection information between nodes according to the environment. Also, it is necessary to set it up so that psql can log in remotely.
Cloudwatch	This is a sample script for latency monitoring used in Cloudwatch integration.	None.
Policy setting function for preventing misoperation	This is a sample function for setting a policy to prevent data manipulation in different regions. It is also used for automatic activation with CREATE TRIGGER.	- Ownership of the table is required for execution. - Modifications are needed for parts related to column names and naming conventions.
Policy deletion function for preventing misoperation	When dropping a table, delete the policy set by the policy setting function to prevent incorrect operations.	- Ownership of the table is required for execution. - Modifications are needed for the parts related to naming conventions.
Automatic setting trigger for policy preventing misoperation	This is a sample of an event trigger that automatically executes a policy setting function to prevent	Change the name of the policy function for preventing incorrect operations.

Usage target	Usage	Need for modification and summary of modifications
	misoperations when a CREATE TABLE is performed.	

Post-switch command

```
#!/bin/sh

    ON ddl_command_end
WHEN TAG IN ('CREATE TABLE')
    EXECUTE FUNCTION set_rls_on_new_table();
```

Appendix A Design Guidelines for Using Multi-master Replication

Multi-master replication aims to integrate and manage business data that was previously separated by regions, such as the Tokyo headquarters and the Singapore branch, within a single environment.

However, it also introduces risks that were not possible in regionally isolated environments, such as the destruction of data from other regions due to operational errors and unintended data access.

By being mindful of regions from the application design and data structure stages, safer operations can be achieved.

This guideline provides specific design examples for that purpose.

A.1 Primary Key Setting

Tables included in replication require a primary key.

For tables without a primary key set, add a column that can be set as the default primary key using the pgactive_snowflake_id_nextval function or by obtaining a UUID.

When performing multi-master replication, be sure to set a primary key.

A.2 Sequence Management

The sequence provided by PostgreSQL only guarantees uniqueness within the database and is defined as an item that is not replicated in logical replication.

Therefore, for columns using sequences, use UUID or the pgactive_snowflake_id_nextval function.

For the pgactive_snowflake_id_nextval function, refer to the OSS documentation.

The sequence generated by this function has the following differences from the sequence provided by PostgreSQL, so consider addressing them accordingly.

- Only BIGINT type is supported.
  If you are using a column with INT type, a type change is necessary.
- Default values cannot be set.
  Remove any processes that set or expect default values.
- Like the sequence provided by PostgreSQL, sequential numbers are not guaranteed.
- Whether using UUID or the pgactive_snowflake_id_nextval function, sequence values guaranteed to be in ascending order based on the server's time can be obtained. However, if the server's time changes or the time settings between replicated machines differ, the order cannot be guaranteed, so ensure the server time does not regress during operation.

When performing multi-master replication, always manage sequences.

Below is an example using the pgactive_snowflake_id_nextval function.

Example of schema correspondence

```
CREATE SEQUENCE seq_1;

CREATE TABLE orders (
    order_id BIGINT PRIMARY KEY DEFAULT pgactive.pgactive_snowflake_id_nextval('seq_1'),
    customer_id BIGINT NOT NULL,
    amount NUMERIC(12,2),
    updated_at TIMESTAMP DEFAULT now()
);
```

Example of application correspondence

```
CREATE SEQUENCE seq_2;

insert into orders (order_id, customer_id,amount)
values (pgactive.pgactive_snowflake_id_nextval('seq_2'), 1, 1.11);
```

A.3 Separation of Update Targets

To ensure that update and delete records do not overlap between operations in each region, it is necessary to implement measures such as separating writable tables, partitions, and rows by region.

Since the separation of update targets is also essential for designing update rules in the application, it is necessary to consider schema design and application design together.

Basic policy

Clarify data ownership and prevent conflicts of the same record in a multi-master configuration.

1. Clearly divide the writable range by region.
2. Set "region ownership" at the partition or row level.
3. Prohibit data updates outside the region on the application side.

Schema design

The design varies depending on how the data is separated into units.

Consider which approach to take, taking into account the current data model and application.

Separation	Summary	Merits	Demerits
Database/ Schema/ Table partitioning	Create schemas and tables for each region	- No conflicts occur because data is physically separated. - Triggers and foreign keys can also be completed within the region.	- The more tables and schemas need to be integrated for aggregation and reference, the more effort is required for integration, leading to decreased throughput - Switching between regions is necessary on the application side
Partitioning	Partition with logical table + region ID (*1)	- General usage of partitioning - Manageable with a single logical table - Triggers and foreign keys can be completed within the region - Aggregation and queries can be performed on a unified table	- A column for the region is required - Region management on the application side is required - It is necessary to strictly adhere to the partition key rules between nodes - It is necessary to either provide means to prevent operational errors in the application or ensure thorough operation
Row level control	Application control with 1 table + region ID (*1) column	- Simple table structure - Easy to add regions in the future	- A column indicating the region is required

Separation	Summary	Merits	Demerits
			- Very strict control is essential in applications and policies - Complete constraints do not work on the database side - It is necessary to prepare measures to prevent incorrect operations in the application or ensure thorough operation

*1) It can be used when it is designed in a configuration where there is no possibility of duplication between regions, such as with store IDs, or when roles are determined on a regional basis.

The following are examples of attaching region IDs for each region.

- Region division by schema/table unit
  Since there is no conflict, it is possible to update on both sides and operate.
- Region division by partition unit
  Partitioning is done by region.

```
CREATE TABLE orders (
    order_id BIGINT,
    region_id TEXT,
    customer_id BIGINT,
    amount NUMERIC,
    PRIMARY KEY(order_id, region_id)
) PARTITION BY LIST(region_id);

-- Partition by region
CREATE TABLE orders_region_tokyo PARTITION OF orders FOR VALUES IN ('Tokyo');
CREATE TABLE orders_region_singapore PARTITION OF orders FOR VALUES IN ('Singapore');
```

- Region ownership at the row level (region_id column and application control)
  Instead of creating partitions, include region_id in a single table and rely on application control.
  Before INSERT/UPDATE/DELETE, check region_id=self-region in the application.

By setting the current settings to default as below, it is possible to reduce region management in the application.

```
CREATE TABLE orders (
    order_id BIGINT,
    region_id TEXT default current_setting('my.region'),
    customer_id BIGINT,
    amount NUMERIC,
    PRIMARY KEY(order_id, region_id)
) ;
```

Application design

To avoid conflicts between regions, assume the following design principles:

- Clarification of data ownership

  Design so that "which region can write" can be clearly indicated for each row and table.

- Fixation of connection information to a region
  - Applications use "connection users dedicated to their own region".
  - For those users, set permissions on the database side to prohibit data updates from other regions.
- Branching of update logic
  - Always assign the own region ID when INSERT/UPDATE.
  - Prohibit specifying the region_id of other regions at the application layer.

Here is an example based on the above.

Note that the table has been created in a format compatible with any example in this section.

Connection and Region Fixation

When connecting, set the region information where the session operates as an environment variable or application.

The following example sets the operating region in the environment variable "my.region".

```
{
  ....

        String url = "jdbc:postgresql://hostxxxxxx:27500/my_db";
        String user = "postgres";
        String password = "passwd_dummy2025";

        try (Connection conn = DriverManager.getConnection(url, user, password)) {

            // Connection Verification
            if (conn == null) {
                System.err.println("Connection failed: null connection");
                System.exit(1);
            }

            // Set environment variables using the result of getCurrentRegion()
            String region = getCurrentRegion();
            String sql = String.format("SET my.region_id = '%s'", region);

            try (Statement stmt = conn.createStatement()) {
                stmt.execute(sql);
                System.out.println("SET my.region_id executed: " + region);
            }

  ....
```

Note) By adding it as an option to the connection information, control is possible with just the connection string, and it can also be obtained from GUC.
However, if a failover occurs and business continuity is maintained within a different region, there is a possibility of trouble where only the region information changes from the original region. Therefore, it is recommended that connection and region settings be independent.

INSERT/UPDATE/DELETE of data

Make it a mechanism to always assign a region ID, so that values from other regions cannot be directly specified. In the following example, the region set in the environment variable "my.region" is set during INSERT or UPDATE execution.

```
  ....

    // === INSERT ===
    /* INSERT: Specify current_setting directly in the column */
    String insertSql =
        "INSERT INTO orders (region_id, customer_id, order_id, amount) " +
        "VALUES (current_setting('my.region_id'), 1, 666, 999)";
```

```
    try (Statement stmt = conn.createStatement()) {
        int inserted = stmt.executeUpdate(insertSql);
        if (inserted > 0) {
            System.out.println("INSERT OK with current_setting in column");
        } else {
            System.err.println("INSERT failed (no rows inserted)");
        }
    } catch (SQLException e) {
        System.err.println("INSERT failed: " + e.getMessage());
    }

    // === UPDATE ===
    /* UPDATE: Change your region's row */
    String updateSql =
        "UPDATE orders " +
        "SET amount = 9999 " +
        "WHERE region_id = current_setting('my.region_id')";

    try (Statement stmt = conn.createStatement()) {
        int updated = stmt.executeUpdate(updateSql);
        if (updated > 0) {
            System.out.println("UPDATE OK using current_setting in WHERE clause");
        } else {
            System.err.println("UPDATE failed (no matching rows)");
        }
    } catch (SQLException e) {
        System.err.println("UPDATE failed: " + e.getMessage());
    }

....
```

A.4 Detection and Prevention of Misoperation

When implementing "A.3 Separation of Update Targets", it is necessary to enforce operational rules, but especially during failover or other non-standard operational phases, there is a higher risk of incorrect operations. Therefore, it is recommended to design a mechanism to detect and prevent incorrect updates to data from different regions. The main policy is as follows. Confirm in conjunction with "A.3 Separation of Update Targets".

- Updates are possible as long as the original region is declared in session variables, even if the connected node changes.
- Data from regions other than the original region cannot be updated.
- No inconsistencies occur during failback.
- Implement update limitations and check processes using policies.

Here are specific examples based on these points.

Refer to "A.3 Separation of Update Targets" for tables and applications.

RLS (Row Level Security) Settings

To prevent updates in the wrong region, set a row-level security policy based on the region for the table.

Policies need to be set for each table, and since table ownership is required and the same operations are needed in each region, it is recommended to set a trigger to automatically execute when CREATE TABLE is executed.

Provide the following sample for policy settings. Set the same for each region.

- Policy setting function for preventing misoperation

  This is a sample function for setting a policy to prevent data manipulation in different regions.

- Automatic setting trigger for policy preventing misoperation

  This is a sample of an event trigger that automatically executes a policy setting function to prevent misoperations when a CREATE TABLE is performed.

For details about the sample, refer to "5.5 Sample".

A.5 Operation of Comprehensive Data for all Nodes

In a multi-master configuration, data is updated in each region, which can cause temporary discrepancies in data freshness between regions. If the system aggregates data while these discrepancies exist, the results may become inaccurate or duplicated. Therefore, consider the following measures:

- Aggregate only your own data in each region, and perform the overall aggregation based on those results.
- Designate a dedicated node to integrate data from multiple regions, and perform the overall aggregation only on that node.
  To reduce load, it is recommended to use standby servers.

A.6 Consideration of Delay

Design that does not require strong consistency, assuming discrepancies in data freshness between regions, and the need to add check processing and idempotent processing.

This is equivalent to foreign key constraints, and data consistency that occurs in different regions cannot always be expected.

Therefore, if there is a possibility of using data from another region, consider options such as allowing the use of slightly outdated data or retrying as a temporary error without abnormal termination even if the data is inconsistent (insufficient).

In addition, by using it in conjunction with replication delay monitoring, it is possible to determine whether the cause of data anomalies is due to delay or not.

A.7 Schema Change Method

In this feature, the results of DDL commands are not reflected on other nodes.

Therefore, it is necessary to execute the same DDL statement on all nodes that are linked with this feature.

- Before executing SQL statements that correspond to DDL additions or changes on the node, execute the DDL statement on the linked nodes first.
- Until the DDL changes are made on the linked nodes, the reflection of logs generated by DDL changes will be on hold.
  It won't result in an error immediately, but it may cause replication delays, so ensure prompt reflection.

Note that the following feature is not available.

`pgactive.skip_ddl_replication`

A.8 Failover

Design for configuration and reconnection within and between regions is required.

For more details, refer to "4.2.4 Operations within the Region" aind "4.2.5 Operations Between Regions".

A.9 Monitoring of Delays

Refer to "4.4 Monitoring" and design monitoring methods and alerts based on changes in log volume due to delays.

A.10 Addressing Mixed Locations

This feature assumes that during failover, applications that would normally run in different regions may end up running on the same server.

For your application, please verify whether it requires setting locale, time zone, etc., per session when running in different regions, or whether it needs to unify locale, timestamps, etc., to be location-independent.

A.11 Correspondence List

Explain the design items below.

Design item	Corresponding content	Table	Application	Operation
Primary Key Setting	Always set the primary key.	Y	-	-
Sequence Management	Snowflake ID, Region ID embedding sequence, use of UUID (change from PostgreSQL sequence)	Y	Y	-
Separation of Update Targets	To prevent duplication or conflict of update and delete records between regions, measures such as dividing writable tables, partitions, or rows by region will be implemented.	Y	Y	-
Detection and Prevention of Misoperation	Add a mechanism using policies and the CHECK function to prevent mistakenly updating data in a different region.	Y	Y	Y
Operation of Comprehensive Data for all Nodes	Aggregate separately cluster, or create a system that prevents duplicate updates between regions, such as managing views for the entire dataset aggregated by each region.	Y	Y	-
Consideration of Delay	Design that does not require strong consistency, assuming discrepancies between regions, and the addition of check processing and idempotent processing.	-	Y	Y
Schema Change Method	Design and regulate simultaneous changes to all nodes and phased synchronization.	Y	-	Y
Failover	Failover: Reconnection rules and settings, application design during switching.	-	Y	Y
Monitoring of Delays	Design of integration methods such as LSN monitoring and CloudWatch	-	Y	Y
Addressing Mixed Locations	Consider whether conflicts in locale or time zone may occur when the application runs in different regions.	-	Y	-

Y: Related design is required

Appendix B Using Other Features in Combination

Explain how to handle the use of this feature in combination with other features.

Affected features

Features that provide dedicated DDL for tables and SQL functions may require careful attention to usage or may not be available due to usage constraints on logical replication, such as primary keys and sequences.

In addition, if you want to use PostgreSQL features other than those provided by this product, check if they meet these conditions and consider the usage by referring to the correspondence in the text below.

Status of support for the features provided by this product

Among the features provided by this product, those with usage constraints are listed below.

When using the following features, consider corresponding to the constraints or operating in a way that does not use them in conjunction with this feature.

OSS name/Feature name	Usage constraint
pg_hint_plan	There are constraints on construction and operation
pg_dbms_stats	There are constraints on construction and operation
pgvector	Cannot be used together
pgvectorscale	Cannot be used together
Apache AGE	Cannot be used together
pgai	Cannot be used together
pg_cron	There are constraints on construction and operation
PostGIS	Cannot be used together
Data masking	Cannot be used together
Confidentiality management	Cannot be used together

The response methods according to the constraints are shown below.

When there are constraints on construction and operation

The following features have their own DDL definitions, and there are features that cannot be replicated with this feature.

- pg_hint_plan
- pg_dbms_stats
- pg_cron

Accommodate these features as follows.

Accommodate during construction

Apply according to the following procedure.

Work should be done in each region.

1. Set up the environment for using this feature in each region.
   Implement up to "Chapter 3 Setup".
2. From then on, perform the same tasks on the primary server in each region.
   Add the extension name to be used to shared_preload_libraries in postgresql.conf and restart the instance.
3. Execute the CREATE EXTENSION statement to register the extension.

4. Execute the pgx_pgactive_replication_set_exclude_table function to configure the settings so that tables created by the extension are not included in replication.

   - pg_hint_plan

```
SELECT pgactive.pgx_pgactive_replication_set_exclude_table('hint_plan.hints');
```

   - pg_dbms_stats

```
SELECT
pgactive.pgx_pgactive_replication_set_exclude_table('dbms_stats.relation_stats_locked')
SELECT
pgactive.pgx_pgactive_replication_set_exclude_table('dbms_stats.column_stats_locked');
SELECT pgactive.pgx_pgactive_replication_set_exclude_table('dbms_stats.backup_history');
SELECT
pgactive.pgx_pgactive_replication_set_exclude_table('dbms_stats.relation_stats_backup');
SELECT
pgactive.pgx_pgactive_replication_set_exclude_table('dbms_stats.column_stats_backup');
```

   - pg_cron

```
SELECT pgactive.pgx_pgactive_replication_set_exclude_table('cron.job');
SELECT pgactive.pgx_pgactive_replication_set_exclude_table('cron.job_run_details');
```

Accommodate during operation

Registration and configuration information for extensions in each region (for example, registration in the hint_plan.hints table or schedule settings for pg_cron) are not included in replication between regions. Therefore, perform the same operations in each region.

When the features cannot be used together

This feature cannot be used in conjunction.

Do not use it directly in the environment of this feature.

Appendix C Estimating Requirements

This appendix describes how to estimate requirements.

C.1 Estimating Transaction Log Space Requirements

In preparation for situations where transaction logs are not transferred between regions, such as during maintenance work or wide-area line disconnection, it is necessary to estimate the space of transaction logs according to the following requirements to ensure that transaction logs are not reused.

- RPO (Recovery Point Objective)
- Maintenance time

The space of transaction logs varies depending on the log amount of update transactions per unit time, line performance, and the time during which transaction logs are not transferred to the counterpart center.

Therefore, simulate database updates during maintenance time and allowable line disconnection time in a test environment, and measure the actual space of transaction logs.

Point

You can determine the transmission delay amount by statistically collecting the differences between the pending_wal_decoding and pending_wal_to_apply columns in the pgactive_get_replication_lag_info function.

Refer to "4.4.1 pgactive_get_replication_lag_info function".

Database Multiplexing

Linux

J2UL-3059-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document describes the tasks required for using the database multiplexing feature of Fujitsu Enterprise Postgres.

Intended readers

This document is intended for those who set up and use the database multiplexing feature.

Readers of this document are also assumed to have general knowledge of:

- PostgreSQL
- SQL
- Linux

Structure of this document

This document is structured as follows:

Chapter 1 Overview of Database Multiplexing Mode

Provides an overview of database multiplexing mode.

Chapter 2 Setting Up Database Multiplexing Mode

Describes how to set up database multiplexing mode.

Chapter 3 Operations in Database Multiplexing Mode

Explains periodic database multiplexing mode.

Chapter 4 Action Required when an Error Occurs in Database Multiplexing Mode

Explains the action required when an error occurs during a database multiplexing mode.

Chapter 5 Managing Mirroring Controller Using WebAdmin

Explains how to set up and manage Mirroring Controller in a streaming replication cluster using WebAdmin.

Appendix A Parameters

Explains the configuration files and parameters required for database multiplexing mode.

Appendix B Supplementary Information on Building the Primary Server and Standby Server on the Same Server

Explains supplementary information on building the primary server and standby server on the same server.

Appendix C User Commands

Explains the user commands.

Appendix D Notes on Performing Automatic Degradation Immediately after a Heartbeat Abnormality

Provides notes when performing automatic degradation unconditionally after a heartbeat abnormality is detected during heartbeat monitoring of an operating system or server.

Appendix E Supplementary Procedure on Configuring for Operation in Database Multiplexing Mode

Explains supplementary procedure on the configuration required for operation in database multiplexing mode.

Appendix F WebAdmin Disallow User Inputs Containing Hazardous Characters

Explains characters not allowed in WebAdmin.

Appendix G Collecting Failure Investigation Data

Explains how to collect data for initial investigation.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Chapter 1 Overview of Database Multiplexing Mode

This chapter provides an overview of database multiplexing mode.

Point

In this and subsequent chapters, the word "Mirroring Controller" may be used in the process or management directory name or explanation.

1.1 What is Database Multiplexing Mode

Database multiplexing mode is an operation mode (log shipping mode) based on PostgreSQL streaming replication. Other software such as cluster software is not required.

This mode replicates the database on all servers that comprise the cluster system. It achieves this by transferring the updated transaction logs of the database from the server that receives the updates (primary server) to another server (standby server), and then reflecting them on the standby server. The client driver automatically distinguishes between the primary and standby servers, so applications can be connected transparently regardless of the physical server.

It consists of a feature that detects faults in the elements that are essential for the continuity of the database operation (such as the database process, disk, and network), as well as simplified switchover and standby server disconnection features. Furthermore, referencing can be performed on the standby server. The database will be copied in synchronous mode.

Information

If using WebAdmin or Mirroring Controller, Fujitsu Enterprise Postgres supports cluster systems comprising one primary server and one standby server.

- Although it is possible to connect an asynchronous standby server to the cluster system as an additional server, the standby server is not targeted for monitoring by Mirroring Controller.
- A synchronous standby server cannot be connected to the cluster system as an additional server.

See

The streaming replication feature is not described in this manual.

Refer to "High Availability, Load Balancing, and Replication" in the PostgreSQL Documentation for information on the streaming replication feature.

Figure 1.1 Failover from the primary server to the standby server

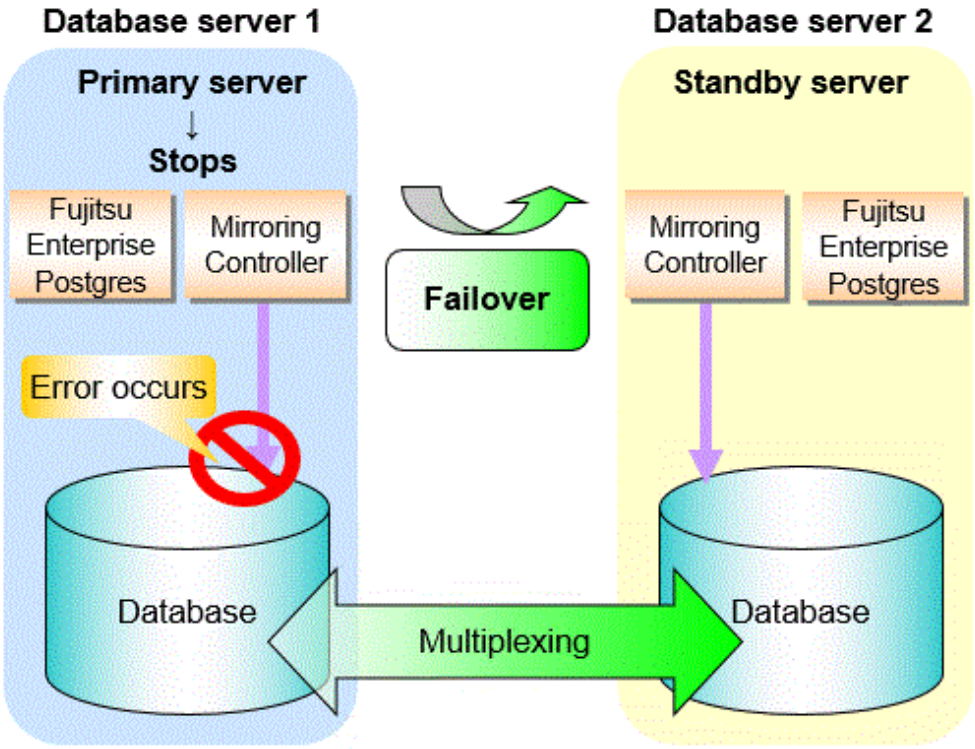

Figure 1.2 Standby server disconnection

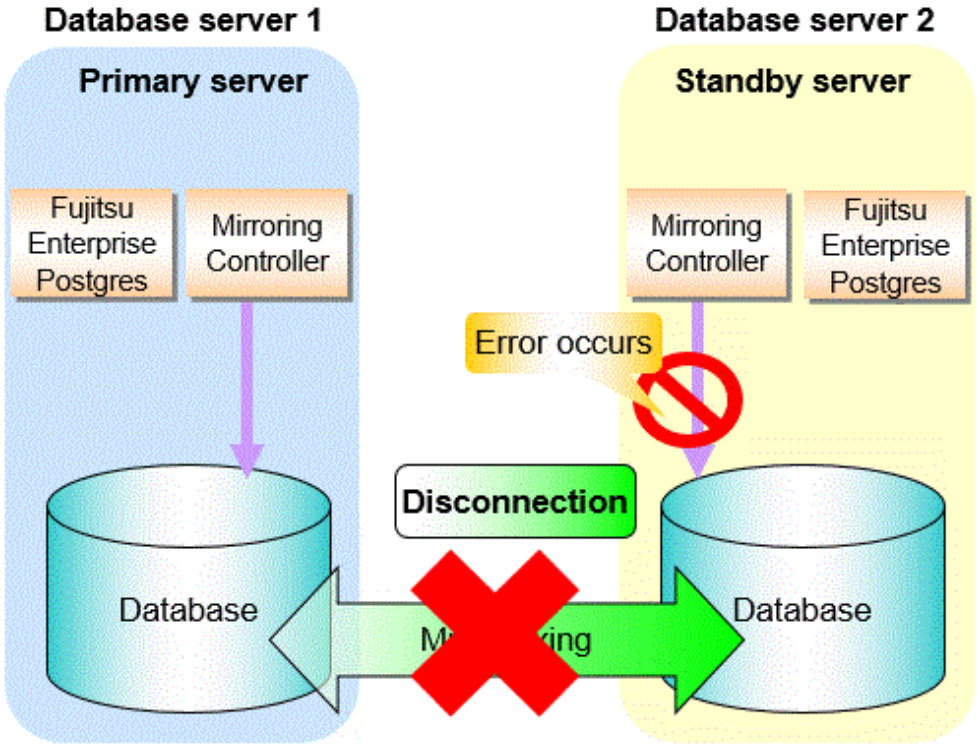


Database degradation using the arbitration server

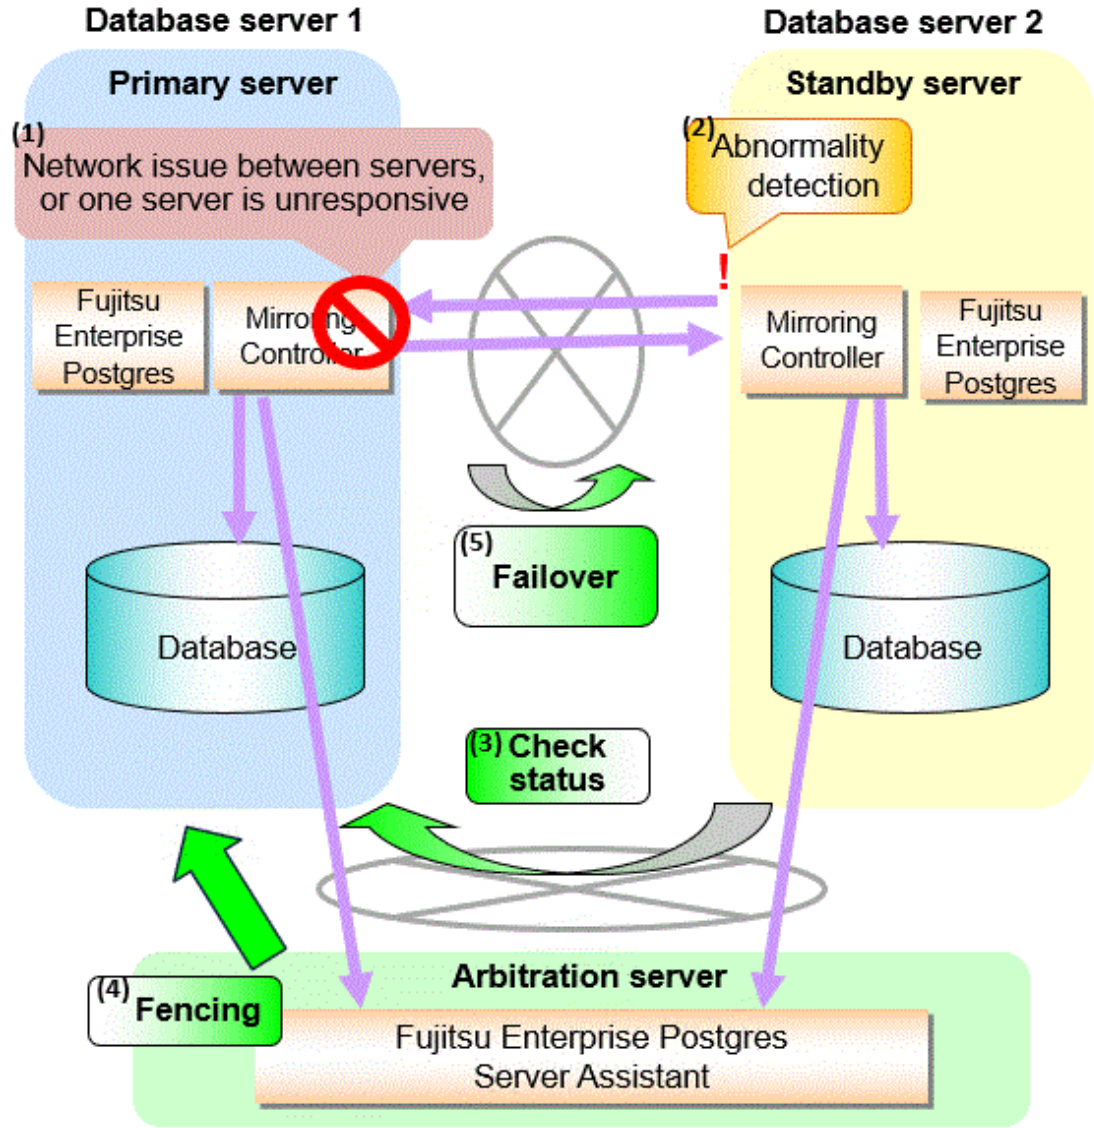
Fujitsu Enterprise Postgres provides the Server Assistant that objectively determines the status of database servers as a third party, and if necessary, isolates affected databases if the database servers are unable to accurately ascertain their mutual statuses in database multiplexing

mode, such as due to a network error between database servers, or server instability. Database degradation can be performed by using the server (arbitration server) on which the Server Assistant is installed. Install the arbitration server on a different physical server to that of the database server. Refer to "1.2 System Configuration for Database Multiplexing Mode" for information on the system configuration when using the arbitration server.

For database degradation using the arbitration server, if the database servers are unable to check their mutual statuses (due to a network error between database servers or server instability), then the database server queries the arbitration server for the status of the other database server. If it is determined based on the heartbeat result that the status is unstable, the applicable database server will be isolated from the cluster system (fencing). The arbitration server periodically heartbeats the database server so that it can respond immediately to queries from the database server. The fencing process can be customized according to the environment where Mirroring Controller is used.

Additionally, the database servers are always performing their heartbeats for the arbitration server so that it can perform check requests any time.

Figure 1.3 Database degradation using the arbitration server



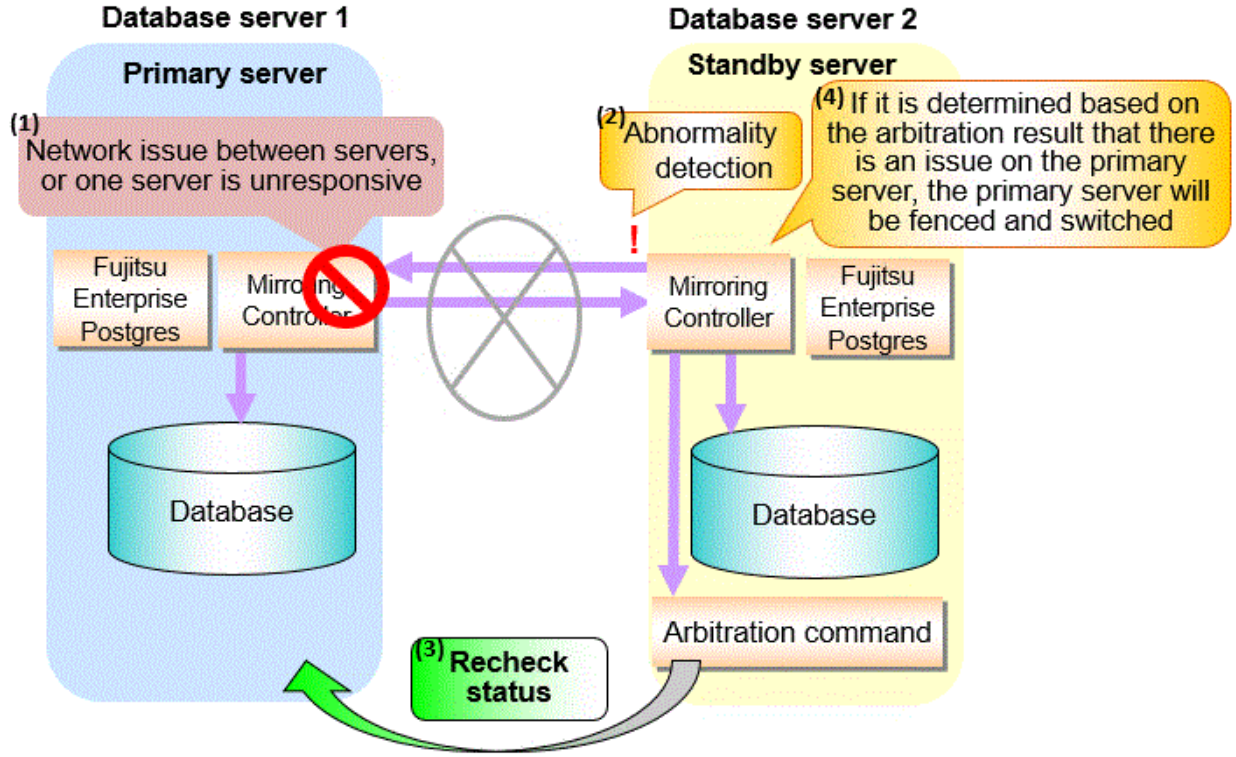
See

Refer to "2.3.2 Creating a User Exit for the Arbitration Server2.6 Creating a User Exit for a Database Server" or "Appendix C User Commands" for information on fencing commands.

Database degradation using the arbitration command

The arbitration command is a user command that performs arbitration processing in lieu of the arbitration server. If an arbitration server cannot be deployed, arbitration of the database server can be performed using the arbitration command.

Figure 1.4 Database degradation using the arbitration command



See

Refer to "2.6 Creating a User Exit for a Database Server" or "Appendix C User Commands" for information on user commands.

1.1.1 Monitoring Using Database Multiplexing Mode

In database multiplexing mode, perform the monitoring below.

- Operating system or server failures, and no-response state

  By generating a heartbeat between Mirroring Controller on each server, operating system or server errors are detected and acknowledged between the relevant servers.

  The optimal operating method for environments where database multiplexing mode is performed can be selected from the following:

  - Use the arbitration server to perform automatic degradation (switch/disconnect)

    This is the default method.

    The arbitration server objectively determines the status of database servers, then isolates and degrades from the cluster system the ones with an unstable status.

    Refer to "Database degradation using the arbitration server" for details.

  - Call the user exit (user command) that will perform the degradation decision, and perform automatic degradation

    If the arbitration server cannot be installed, select if arbitration processing can be performed by the user instead.

    Mirroring Controller queries the user exit on whether to degrade. The user exit determines the status of the database server, and notifies Mirroring Controller whether to perform degradation.

Refer to "Database degradation using the arbitration command" for details.

- Notification messages

  Use this method if using a two-database server configuration.

  Mirroring Controller outputs messages to the system log when an abnormality is detected. This ensures that a split brain will not occur due to a heartbeat abnormality - however, automatic switching will not be performed if the primary server operating system or server fails or becomes unresponsive.

- Perform automatic degradation unconditionally after a heartbeat abnormality

  This method is handled as in FUJITSU Enterprise Postgres 9.6 or earlier versions.

  This method is not recommended, because Mirroring Controller unconditionally will perform automatic degradation after heartbeat abnormalities.

- Database process failures, and no-response state

  Mirroring Controller periodically accesses the database processes and checks the status. A process error is detected by monitoring whether an access timeout occurs.

- Disk failure

  Mirroring Controller periodically creates files on the data storage destination disk below. A disk error is detected when an I/O error occurs.

  - Data storage destination disk
  - Transaction log storage destination disk
  - Tablespace storage destination disk

  Failures that can be detected are those that physically affect the entire system, such as disk header or device power failures.

- Streaming replication issue

  Mirroring Controller detects streaming replication issues (log transfer network and WAL send/receive processes) by periodically accessing the PostgreSQL system views.

- Mirroring Controller process failure and no response

  In order to continue the monitoring process on Mirroring Controller, Mirroring Controller process failures and no responses are also monitored.

  The Mirroring Controller monitoring process detects Mirroring Controller process failures and no responses by periodically querying the Mirroring Controller process. If an issue is detected, Mirroring Controller is automatically restarted by the Mirroring Controller monitoring process.

Information

If the role of primary server was switched to another server and then starts degrading, the original primary server will not become the standby server automatically. Remove the cause of the error, and then change the role of the original primary server to the server currently acting as standby server. Refer to "4.1 Action Required when Server Degradation Occurs" for details.

Point

- If output of messages is selected as the operation to be performed when a heartbeat abnormality is detected during heartbeat monitoring of the operating system or server, automatic degradation will not be performed.
  However, if an issue in the WAL send process is detected on the primary server, then the standby server will be disconnected, and as a result an automatic disconnection may be performed even if the standby server operating system or server fails or becomes unresponsive.
- You can select in the parameters if the primary server will be switched if a database process is unresponsive or if tablespace storage destination disk failure is detected. Refer to "Appendix A Parameters" for details.

- If the standby server was disconnected, Mirroring Controller will automatically comment out the synchronous_standby_names parameter and synchronized_standby_slots parameter in the postgresql.conf file of the primary server. Accordingly, you can prevent the application processing for the primary server being stopped.

1.1.2 Referencing on the Standby Server

1.1.2.1 If Prioritizing the Main Job on the Primary Server

If a reference job is performed on the standby server and the primary server is switched, this may impact the main job from the point of view of load and conflict. This is because, on the new primary server (that is, the original standby server), both the main job that was being executed on the original primary server and the reference job that was being continued on the original standby server will be processed.

Therefore, to degrade the reference job (so that the impact on the main job is reduced), you can select the user exit below to disconnect the reference job that was performed on the original standby server.

- Post-switch command

If continuing with the referencing job after switching the primary server, give careful consideration to the server resource estimates, and the likely impact on performance.

1.1.2.2 If Performing the Referencing Job on the Synchronous Standby Server

If an issue such as a log transfer network failure obstructs the continuation of a job on the primary server, the standby server may be automatically disconnected from the cluster system.

Therefore, if operating the reference job on the assumption that the connection destination is the synchronous standby server, you can select to temporarily stop the job by using the user exit or the feature below, so that unexpected referencing of past data does not occur as a result of the disconnection.

- Pre-detach command
- Forced stoppage of the standby server instance on disconnection (specify in the parameter of the server configuration file)

Additionally, if the standby server is incorporated into the cluster system, reference jobs can be started or resumed by using the user exit below.

- Post-attach command

See

- Refer to "2.6 Creating a User Exit for a Database Server" or "Appendix C User Commands" for information on each user exit.
- Refer to "A.4.1 Server Configuration File for the Database Servers" for information on the server configuration file of the database server.

Point

Mirroring Controller will continue processing regardless of the processing result of the above user exits and features.

1.2 System Configuration for Database Multiplexing Mode

This section explains the system configuration for database multiplexing mode, as well as the products, features, and network that make up the system. The system for database multiplexing mode uses the following network.

Network type	Description
Job network	Network between the application that accesses the database, and the database server.

Network type	Description
Arbitration network	Network used by the arbitration server to check the status of the primary server and standby server, and communicate with Mirroring Controller of the database servers. Additionally, if the job network is disconnected from outside, it can also be used as the arbitration network. Refer to "1.4 Security in Database Multiplexing" for details on network security.
Admin network	Network used by the primary server and the standby server to monitor each other using Mirroring Controller, and to control Mirroring Controller of other servers.
Log transfer network	Network used to transfer the transaction logs of the database, which is part of database multiplexing.

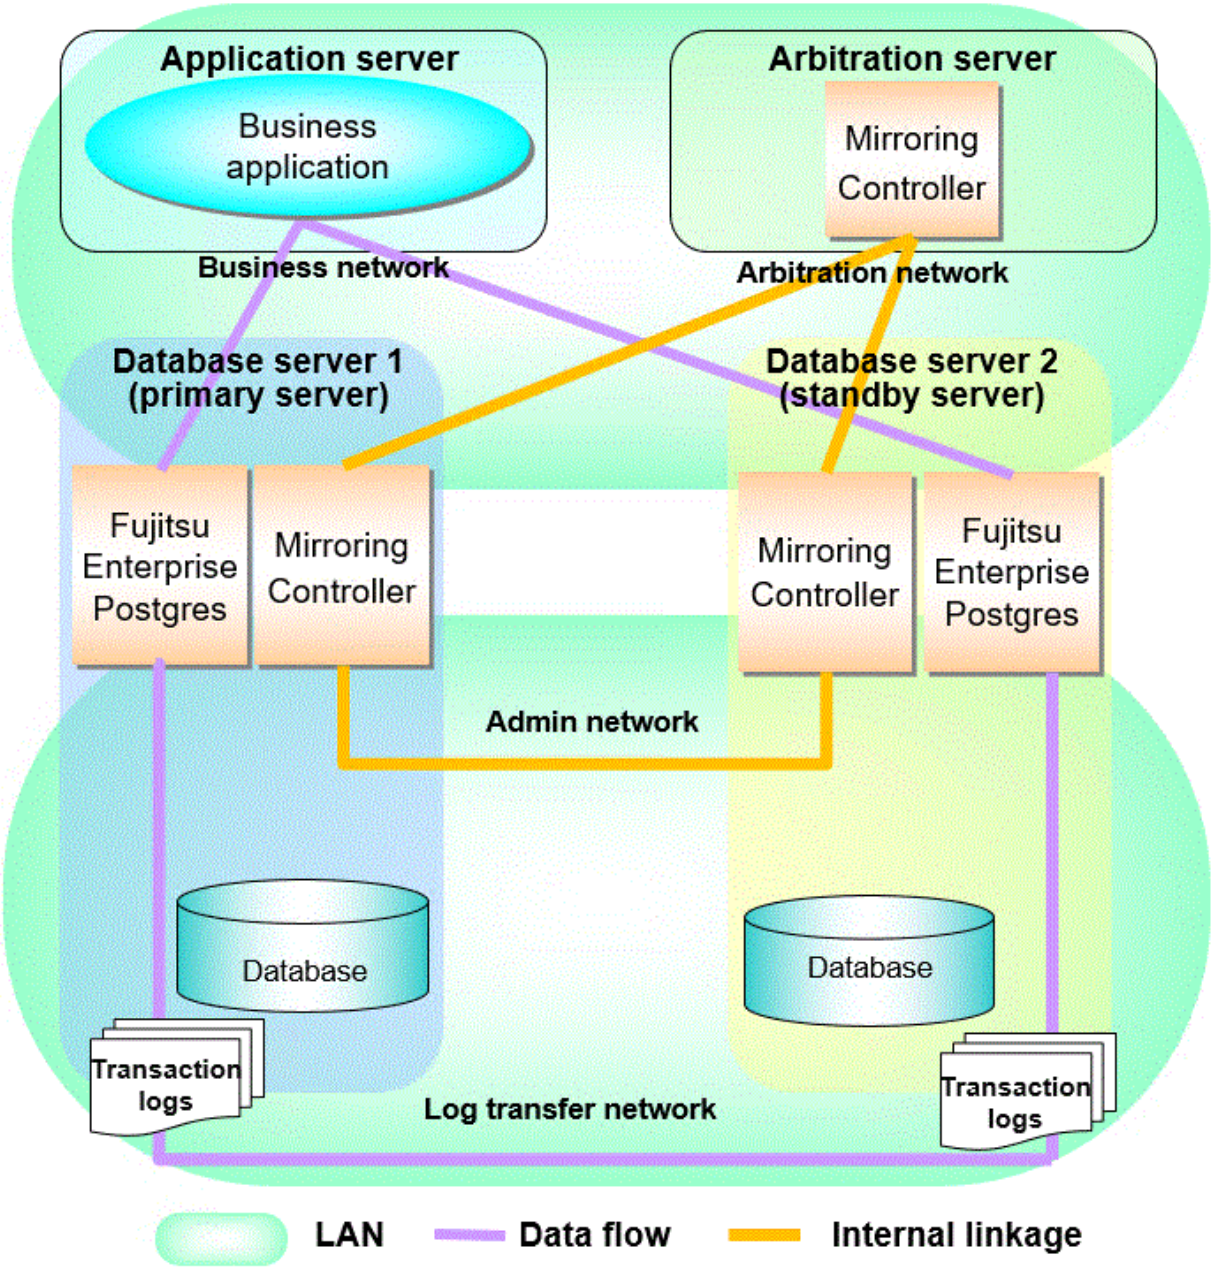
Information

Because the ping command of the operating system is used for heartbeat monitoring of the database server, configure the network so that ICMP can be used on the admin network and the arbitration network.

Point

- The arbitration server can also be used as an application server. However, consider the server load.
- It is recommended to link the arbitration server with other cluster systems, in order to provide redundancy.
- Use the arbitration server in combination with the same version of Fujitsu Enterprise Postgres as that of the primary server and standby server.
- The arbitration server can be built on a different platform to that of the database server.

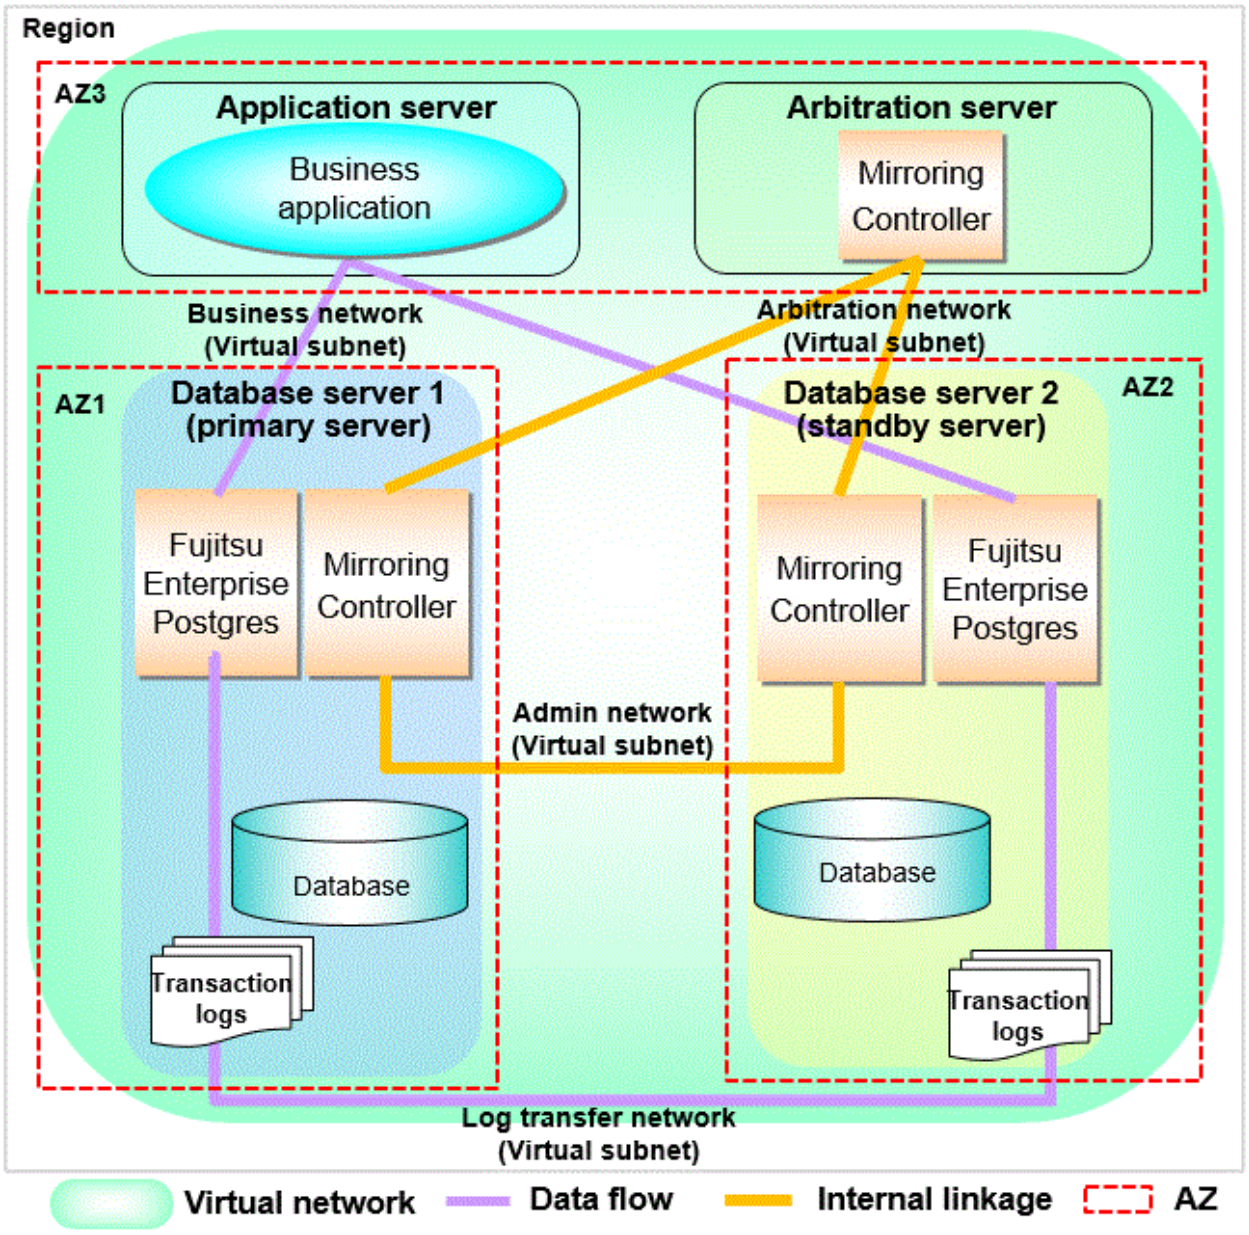
Figure 1.5 System configuration for database multiplexing mode



The arbitration server is installed to check the database server status as a third party, and to perform fencing. Therefore, to obtain the intended benefits, consider the following.

- Install the arbitration server on a different server to that of the database server.
- Recommend that the arbitration network be a network that is not affected by line failures or loads on the admin and log transfer networks, so that any abnormalities in the admin and log transfer networks can be correctly identified.

Figure 1.6 System configuration for database multiplexing mode in a cloud environment



In a cloud environment, to prepare for cloud-specific failures such as AZ failures, we recommend the following configuration:

- Install each database server and arbitration server in different AZs.
- Prepare each network (business network, arbitration network, admin network, and log transfer network) using the subnet function of the cloud service. In this manual, read each network as each subnet created by the cloud service.
- If you cannot prepare four networks, or if you cannot add network interface cards to the server, it is possible to adopt a configuration that shares some networks. For details, refer to "1.2.5 When There are not Enough Networks Available".
- If a virtual network failure occurs, you cannot use the database multiplexing mode feature. Wait for the cloud service to recover, and after recovery, check the redundancy of the database.
- If a temporary failure of the cloud service occurs, there is a possibility of split-brain occurring, where both database servers operate as primary servers simultaneously due to unintended server reboots or network recovery. To prevent split brain, ensure reliable fencing processing. For details on fencing processing, refer to "C.1 Fencing Command".

1.2.1 Mirroring Controller Resources

This section describes the database server and arbitration server resources of Mirroring Controller.

1.2.1.1 Database Server Resources

The only Mirroring Controller resource is the Mirroring Controller management directory, which stores the files that define the Mirroring Controller behavior, and the temporary files that are created when Mirroring Controller is active.

Information

Do not create the Mirroring Controller management directory in a directory managed by Fujitsu Enterprise Postgres, otherwise it may be deleted by mistake or may cause unexpected problems when Fujitsu Enterprise Postgres recovery is performed (such as old version of files being restored).

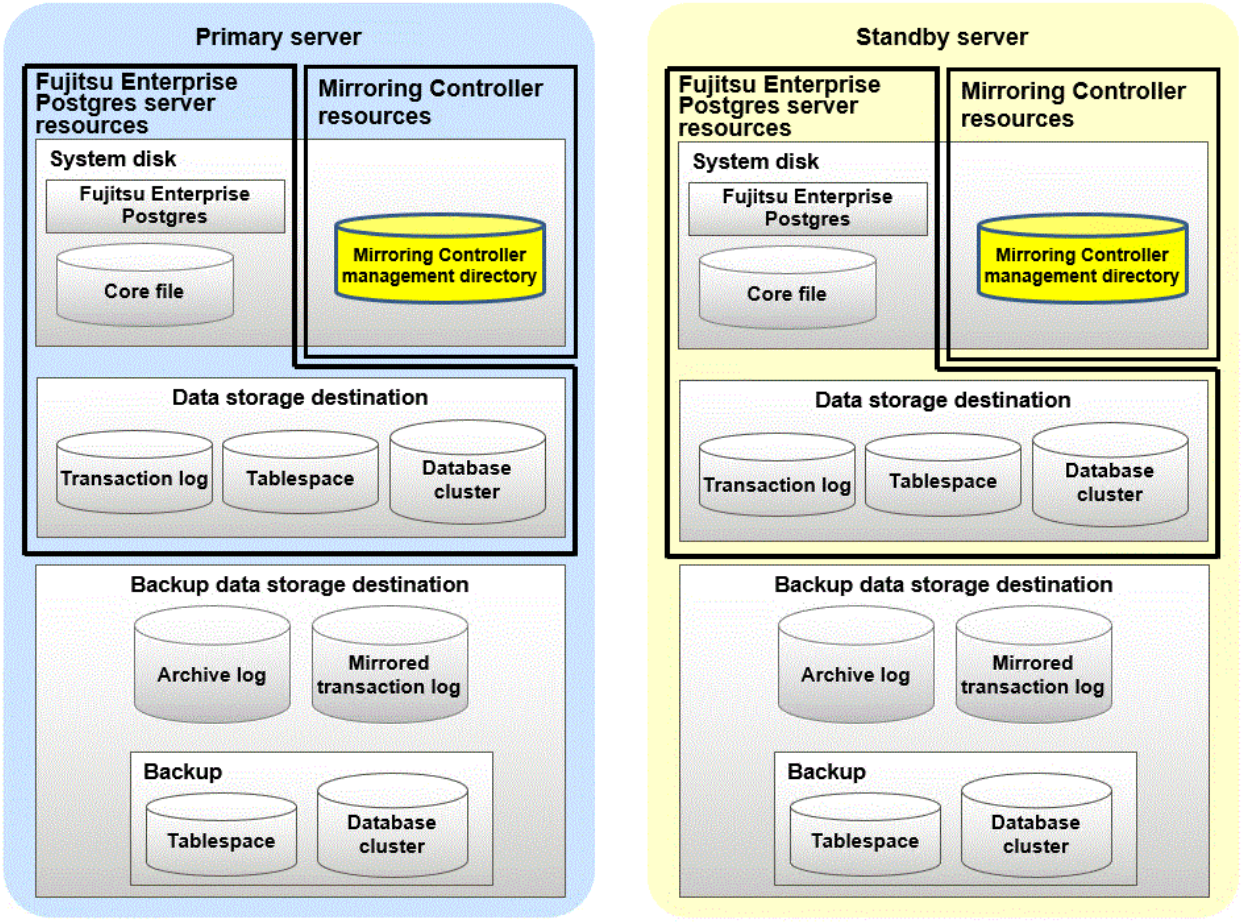
Refer to "Preparing Directories for Resource Deployment" in the Installation and Setup Guide for Server for information on the directories managed by Fujitsu Enterprise Postgres.

Point

- The backup methods described in "Backing Up the Database" in the Operation Guide cannot be used to back up the Mirroring Controller resources. Therefore, users must obtain their own backup of Mirroring Controller resources, in addition to Fujitsu Enterprise Postgres server resources. Retrieve backups after stopping Mirroring Controller.
- If you are building on a virtual machine or cloud, make sure the virtual machines are on different physical servers. Refer to your virtual machine software and cloud vendor documentation for instructions on how to deploy virtual machines.

The content on the primary server will be backed up. You cannot tell which server is the primary server to be backed up, because switching and failback may be performed between the servers. It is also impossible to tell which server is to be restored using the backed up data. Accordingly, ensure that you create a backup of each server when it is working as the primary server.

Figure 1.7 Configuration when backing up Mirroring Controller resources



1.2.1.2 Arbitration Server Resources

The only arbitration server resource is the Mirroring Controller arbitration process management directory. This directory stores the files that define the Mirroring Controller arbitration process behavior and the temporary files created when Mirroring Controller is active.

1.2.2 Mirroring Controller Processes

This section describes the database server and arbitration server processes of Mirroring Controller.

1.2.2.1 Database Server Processes

The database server processes comprise the Mirroring Controller process and Mirroring Controller monitoring process.

Process type	Description
Mirroring Controller process	Performs operating system/server and process heartbeat monitoring and disk abnormality monitoring between database servers. Additionally, it issues arbitration requests to the arbitration server.
Mirroring Controller monitoring process	Performs heartbeat monitoring of the Mirroring Controller process. If the Mirroring Controller process returns no response or is down, the monitoring process is restarted automatically.

1.2.2.2 Arbitration Server Process

The only arbitration process is the Mirroring Controller arbitration process.

Process type	Description
Mirroring Controller arbitration process	Performs rechecks for issues detected on the primary server or the standby server. Additionally, this process performs fencing if it determines that there is an issue on the primary server or the standby server.

1.2.3 Redundancy of the Admin and Log Transfer Networks

The admin network is an important one, because it is used by Mirroring Controller to check the status of each server.

Additionally, the log transfer network is an important one, because it is necessary to ensure data freshness.

Accordingly, configure a failure-resistant network by implementing network redundancy via channel bonding provided by the operating system or network driver vendor.

1.2.4 Notes on CPU Architecture and Products

Use the same CPU architecture (endian) for the primary server, standby server, and the arbitration server.

A server using only PostgreSQL streaming replication cannot be specified as the database multiplexing system log transfer destination.

1.2.5 When There are not Enough Networks Available

In Fujitsu Enterprise Postgres, it is recommended to use four networks (business network, arbitration network, admin network, and log transfer network) for database multiplexing mode.

However, if you cannot prepare four networks in environments such as public cloud, or cannot add network interface cards to the server, the following configurations that share some networks are possible:

- Share all networks
- Share business network, arbitration network, and admin network

When sharing networks, there are no impacts other than increased load due to network sharing during regular operations. However, there are impacts such as restrictions on features for multiplexed modes and the need for special designs for operations in response to network abnormality.

When sharing networks, the following measures are necessary.

- Network definition changes

  You need to configure the network definition file according to the configuration of the shared network.

  If you select automatic degradation by the arbitration server, set the same value for "IP address or host name of the database server used as the admin network" and "IP address or host name of the database server used as the arbitration network" in the network definition file. For details, refer to "When automatic degradation by the arbitration server is selected" under "2.4.1 Setting Up Database Multiplexing Mode on the Primary Server"

- Operational design for network abnormalities

  If the network is shared, it is necessary to design measures to address network abnormalities.

  In the event of a network abnormality, check the status of streaming replication after the network is restored. If the data is not synchronized, refer to "Chapter 4 Action Required when an Error Occurs in Database Multiplexing Mode" and restore to database multiplexing mode.

1.3 Deciding on Operation when a Heartbeat Abnormality is Detected

The operation to be performed when a heartbeat abnormality is detected using operating system/server heartbeat monitoring is decided on according to the environment where database multiplexing mode is performed or the operating method.

It is possible to select from the four operations below, and specify this in the parameters of Mirroring Controller:

- Use the arbitration server to perform automatic degradation (switch/disconnect)

- Call the user exit (user command) that will perform the degradation decision, and perform automatic degradation
- Notification messages
- Perform automatic degradation unconditionally (switch/disconnect)

The table below shows if jobs can be continued on the primary server when an issue is detected during heartbeat monitoring of the operating system/server.

Continuation of jobs on the primary server when an issue is detected during heartbeat monitoring of the operating system/server

Operation	Abnormal event				
	Server/operating system failures or no responses		Admin network issue	Log transfer network issue	Issue on a network for both admin and log transfer
	Primary server	Standby server			
Automatic degradation using the arbitration server	Y (switch)	Y (disconnect)	Y	Y (disconnect)	Y (disconnect)
Call a user exit and perform automatic degradation	Y (switch)	Y (disconnect)	Y	Y (disconnect)	Y (disconnect)
Notification messages	N (message notification only)	N (message notification only)	Y	Y (disconnect)	Y (disconnect)
Unconditional automatic degradation	Y (switch)	Y (disconnect)	N (split brain occurs)	Y (disconnect)	N (split brain occurs)

Y: Job can be continued

N: Job cannot be continued

1.4 Security in Database Multiplexing

The database server replicates the database on all servers that comprise the cluster system. It achieves this by transferring and reflecting the updated transaction logs of the database from the primary server to the standby server.

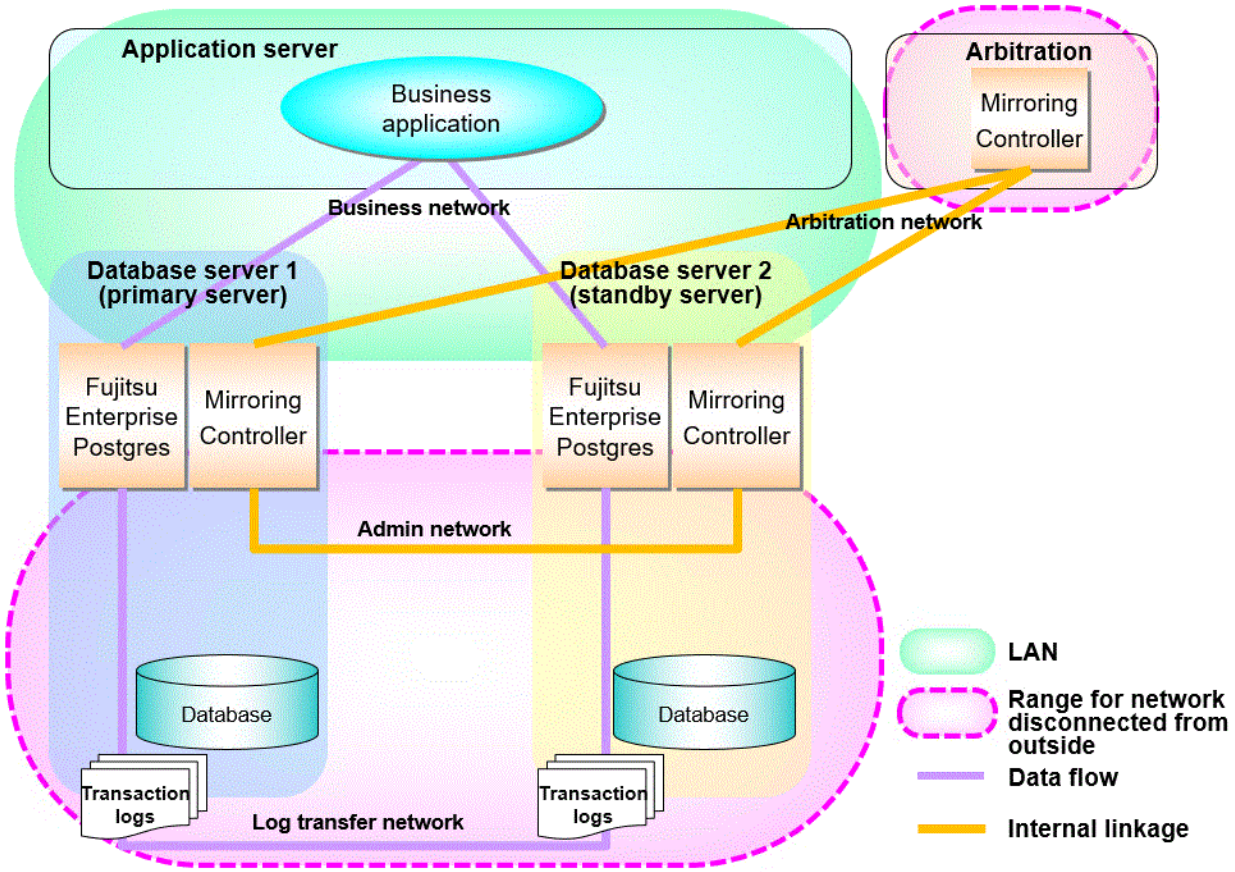
To safeguard the database against unauthorized access and preserve data confidentiality in transaction log transfers, carefully consider security and take note of the following when performing database multiplexing:

- Do not use trust authentication when using replication connection.
- Configure the admin network and the log transfer network so that they cannot be connected from the outside, as shown in Figure 1.8 Security.

Additionally, for the line on which Mirroring Controller connects from the database server to the arbitration server, take note of the following points and consider security carefully.

- Build a network with the arbitration server disconnected from outside, as shown in Figure 1.8 Security.

Figure 1.8 Security



However, it may not always be possible to adopt the configuration mentioned above. For example, you may want to place the servers in a nearby/neighboring office to minimize network delays.

In this case, combine the following features to enhance security:

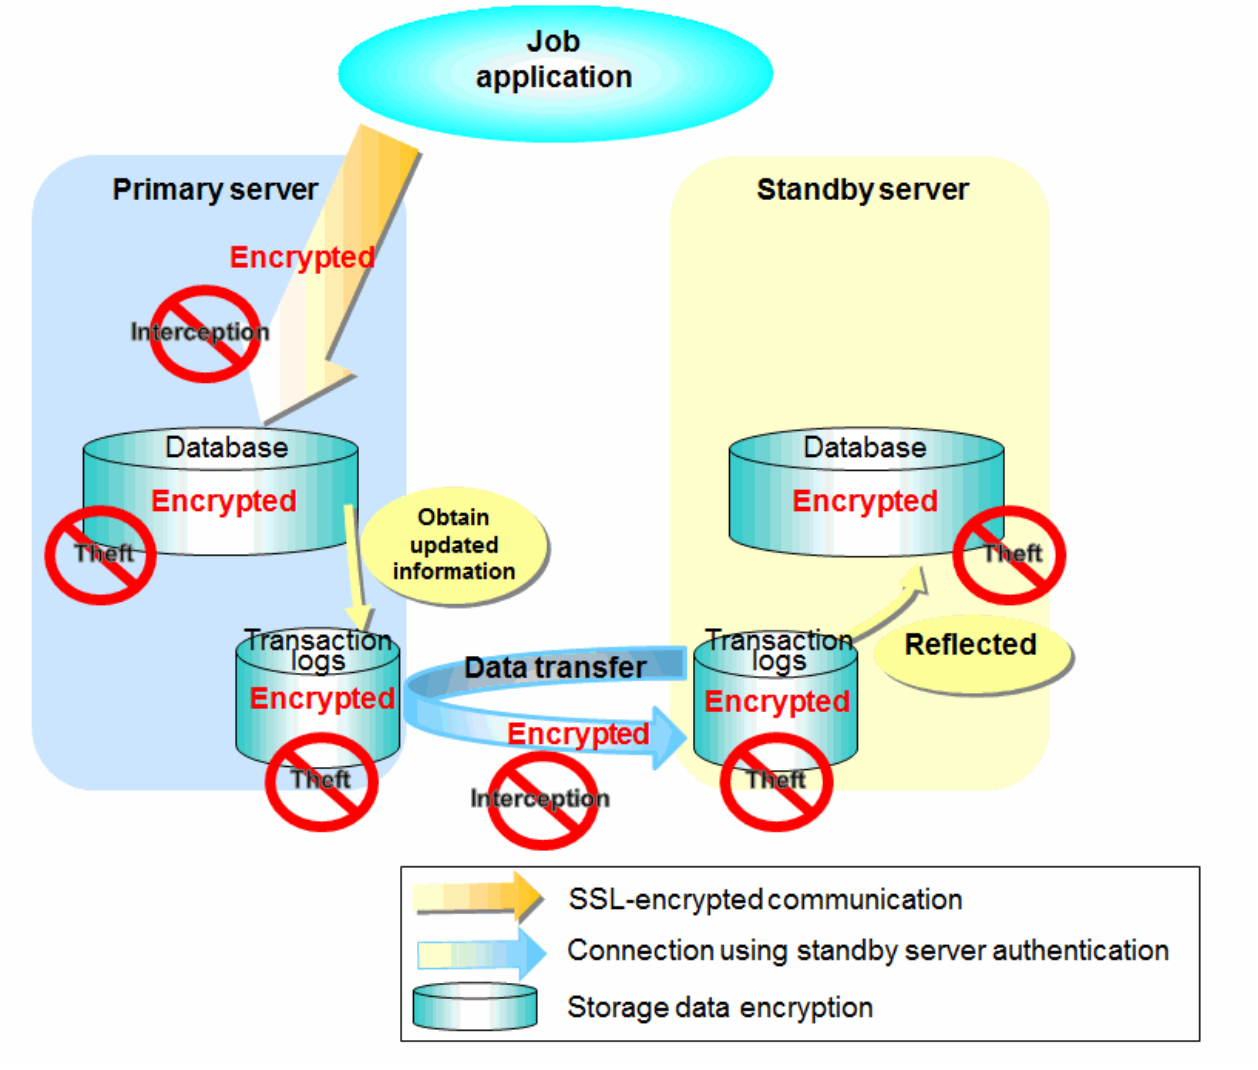
- Authentication of the Standby Server
- Encryption of Transaction Logs Transferred to the Standby Server

When these features are combined, security will be achieved as shown below.

Point

- If the job network is disconnected from outside, it can be used as the arbitration network. However, if a network is to be used as both a job network and arbitration network, consider the load on the network.
- If a port is blocked (access permission has not been granted) by a firewall, etc., enable use of the target port by granting access. Refer to the vendor document for information on how to open (grant access permission to) a port. Consider the security risks carefully when opening ports.

Figure 1.9 Security achieved when standby server authentication is combined with transaction log encryption



See

Refer to "Performing Database Multiplexing" under "Configuring Secure Communication Using Secure Sockets Layer" in the Operation Guide for information on encrypting SSL communications.

1.4.1 Authentication of the Standby Server

You can prevent spoofing connections from an external server purporting to be the standby server by using authentication with a user name and password.

Configure the setting in the primary server pg_hba.conf file so that authentication is performed for connections from the standby server in the same way as for connections from the client.

See

Refer to "Client Authentication" in the PostgreSQL Documentation for information on content that can be configured in pg_hba.conf.

Refer to "Policy-based Login Security" in the Operation Guide for information about security policy-based passwords operations for database multiplexing operations.

1.4.2 Encryption of Transaction Logs Transferred to the Standby Server

In case the authentication of the standby server is breached so that a malicious user purporting to be the standby server can spoof data, the transaction log data can be encrypted to prevent it from being deciphered. The transparent data encryption feature is used to encrypt the data.

See

Refer to "Protecting Storage Data Using Transparent Data Encryption" in the Operation Guide for details.

Chapter 2 Setting Up Database Multiplexing Mode

This chapter describes how to set up database multiplexing mode, and how to check it.

Users who perform setup and operations on the database server

Setup and operations of the database server must be performed by the instance administrator user.

Users who perform setup and operations on the arbitration server

The following users may perform setup and operations on the arbitration server when it is used for automatic degradation.

Linux

Any operating system user.

Windows

Any user with administrator privileges. This user must be assigned the "Log on as a service" user right.

Point

- Mirroring Controller selects a database superuser as the user who will connect to the database instance. This enables instance administrator users and database superusers who operate the Mirroring Controller commands to run database multiplexing mode in different environments.
- The application name for connecting to the database instance is "mc_agent".

Matching the system times

Before starting the setup, ensure that the times in the primary server, standby server and arbitration server match, by using the operating system time synchronization feature, for example.

The tolerated difference is approximately one second.

If the system times are not synchronized (because the tolerated difference is exceeded, for example), problem investigation may be affected.

Configuring ICMP

Because the ping command of the operating system is used for heartbeat monitoring of the database server, configure the network so that ICMP can be used on the admin network and the arbitration network. Refer to the relevant operating system procedure for details.

Setup

The setup procedure is shown in the table below. However, the procedure on the arbitration server should be performed only when the arbitration server is used for automatic degradation. A distinction is made between the procedures on the primary server and standby server according to whether the arbitration server is used.

Step	Task			Refer to
	Primary server	Standby server	Arbitration server	
1	Installation			2.1 Installation
2	Preparing the database server		Preparing the arbitration server	2.2 Preparing for Setup
3			Configuring the arbitration server	2.3.1 Configuring the Arbitration Server
4			Creating a user exit	2.3.2 Creating a User Exit for the Arbitration Server

Step	Task			Refer to
	Primary server	Standby server	Arbitration server	
5			Starting the arbitration process	2.3.3 Starting the Mirroring Controller Arbitration Process
6	Setting up database multiplexing mode			2.4.1 Setting Up Database Multiplexing Mode on the Primary Server
7	Creating, setting, and registering the instance			2.4.2 Creating, Setting, and Registering the Primary Server Instance
8	Creating a user exit			2.6 Creating a User Exit for a Database Server
9	Starting Mirroring Controller			2.4.3 Starting Mirroring Controller on the Primary Server
10		Setting up database multiplexing mode		2.5.1 Setting Up Database Multiplexing Mode on the Standby Server
11		Creating, setting, and registering the instance		2.5.2 Creating, Setting, and Registering the Standby Server Instance
12		Creating a user exit		2.6 Creating a User Exit for a Database Server
13		Starting Mirroring Controller		2.5.3 Starting Mirroring Controller on the Standby Server
14	Confirming the streaming replication status			2.7 Confirming the Streaming Replication Status
15	Checking the connection status			2.8.1 Checking the Connection Status on a Database Server
16		Checking the connection status		2.8.1 Checking the Connection Status on a Database Server
17			Checking the connection status	2.8.2 Checking the Connection Status on the Arbitration Server
18	Creating applications			2.9 Creating Applications
19	Checking the behavior			2.10 Checking the Behavior

Explanations for each step are provided below.

Information

- The setup procedure is also the same when changing the mode on a single server to database multiplexing mode. In this case, omit the installation of Fujitsu Enterprise Postgres and the creation of the instance.

  Refer to "3.9.2 Changing from Single Server Mode to Database Multiplexing Mode" for details.

- The primary and standby server can be pseudo-configured on the same server for system testing, for example. In this case, the setup can be performed using the same procedure, however there will be some supplementary steps.

  Before performing the setup, refer to "Appendix B Supplementary Information on Building the Primary Server and Standby Server on the Same Server".

2.1 Installation

Refer to the manuals below, and then install the product.

See

- Refer to the Installation and Setup Guide for Server for details on how to install Fujitsu Enterprise Postgres.
- Refer to the Installation and Setup Guide for Server Assistant for information on installing the Server Assistant on the arbitration server.

Information

Do not use the arbitration server also as a database server. The arbitration server is installed to check the database server status as a third party, and to perform fencing. Using the arbitration server also as a database server nullifies the effectiveness of the arbitration server.

2.2 Preparing for Setup

This section describes the preparation required before setting up Mirroring Controller.

2.2.1 Preparing the Database Server

2.2.1.1 Preparing the Backup Disk

In Mirroring Controller, by performing a backup, recovery is possible even if all server disks are corrupted.

The content on the primary server should be backed up. However, through switching and failback, the standby server may also become the primary server. Accordingly, prepare each of the backup disk devices for the primary and standby servers. Perform backup on the primary server used at the time of the backup.

2.2.1.2 JAVA_HOME Setting (SLES)

Specify the installation location of JRE 8 in the environment variable JAVA_HOME, and set it in the Mirroring Controller installation environment using the mc_update_jre_env command.

This procedure must be executed by the superuser.

```
Example)
/opt/fsepv<x>server64/bin is the installation directory where the server product is installed.
```

```
$ su -
Password:******
# export JAVA_HOME="Jre8InstallDir"
# /opt/fsepv<x>server64/bin/mc_update_jre_env
```

2.2.2 Preparing the Arbitration Server

2.2.2.1 Preparing to Output Error Logs to the Event Log (Windows)

This section explains the preparatory tasks for outputting error logs to the event log.

If no event source name is registered, messages output to the event log may be incomplete.

Configuring each server

Event logs for the Mirroring Controller commands on the arbitration server may be output with the default event source name "MirroringControllerArbiter". Therefore, register this default event source name beforehand.

```
Example)
The following is an example in which the DLL of a 64-bit product is registered under the default event
source name. Note that "<x>" indicates the product version.
```

```
> regsvr32 "c:\Program Files\Fujitsu\fsepv<x>assistant64\lib\mcarbevent.dll"
```

Setting each instance

You can output messages to any event source named by the user, so that messages output to the event log can be identified by each instance.

```
Example)
The following is an example in which the DLL of a 64-bit product is registered under the event source
name "Mirroring Controller arbiter1". Note that "<x>" indicates the product version.
```

```
> regsvr32 /n /i:"Mirroring Controller arbiter1" "c:\Program Files\Fujitsu\fsepv<x>assistant64\lib
\mcarbevent.dll"
```

The parameter must be edited for each instance. Refer to "A.4.2 Arbitration Configuration File" and set the event_source parameter.

If installing multiple versions

If Fujitsu Enterprise Postgres is already installed on the same machine, search for the key below in Registry Editor, and make a note of the path of the registered DLL. Afterwards, register a new DLL using the default event source name.

Use the DLL path that you made a note of in the above step when re-registering the default event source name during uninstallation.

```
MirroringControllerArbiter
```

2.2.2.2 Security Policy Settings (Windows)

On the arbitration server, operating system user accounts that operate the Mirroring Controller arbitration process must be assigned the "Log on as a service" user right in order to use Windows Services to start and stop the Mirroring Controller arbitration process.

If the security settings to enable this have not been configured, refer to "E.1 Security Policy Settings" and configure the settings.

2.2.2.3 JAVA_HOME Setting (SLES)

Specify the installation location of JRE 8 in the environment variable JAVA_HOME, and set it in the Server Assistant installation environment using the mc_update_jre_env command.

This procedure must be executed by the superuser.

```
Example)
/opt/fsepv<x>assistant/bin is the installation directory where the Server Assistant feature is
installed.
```

```
$ su -
Password:******
# export JAVA_HOME="Jre8InstallDir"
# /opt/fsepv<x>assistant/bin/mc_update_jre_env
```

2.3 Setting Up the Arbitration Server

This section explains how to set up the arbitration server.

2.3.1 Configuring the Arbitration Server

This section explains how to set up database multiplexing mode on the arbitration server.

In database multiplexing mode, the files that are required for operations are managed in the Mirroring Controller arbitration process management directory.

There is one Mirroring Controller arbitration process management directory for each arbitration process.

Point

The arbitration process for each database multiplexing system can be started on a single arbitration server.

See

- Refer to the Reference for information on the mc_arb command.
- Refer to "Appendix A Parameters" for information on the parameters to be edited for the setup.

Perform the following procedure:

Linux

1. On the arbitration server, log in as any operating system user who starts and stops the arbitration process.
2. Configure the environment variables.

   Set the following environment variables:

   - PATH

     Add the installation directory "/bin".

   - MANPATH

     Add the installation directory "/share/man".

   Example

   The following example configures environment variables when the installation directory is "/opt/fsepv<*x*>assistant".

   Note that "<*x*>" indicates the product version.

   sh, bash

   ```
   $ PATH=/opt/fsepv<x>assistant/bin:$PATH ; export PATH
   $ MANPATH=/opt/fsepv<x>assistant/share/man:$MANPATH ; export MANPATH
   ```

   csh, tcsh

   ```
   $ setenv PATH /opt/fsepv<x>assistant/bin:$PATH
   $ setenv MANPATH /opt/fsepv<x>assistant/share/man:$MANPATH
   ```

3. Create the Mirroring Controller arbitration process management directory that will store the files required by the arbitration server.

   Use ASCII characters in the Mirroring Controller arbitration process management directory.

4. In the network configuration file (network.conf), define the Mirroring Controller network configuration that will be managed by the Mirroring Controller arbitration process.

   Create network.conf in the Mirroring Controller arbitration process management directory, based on the sample file. For network.conf, set read and write permissions only for the operating system user who starts and stops the arbitration process in step 1.

   If users other than this are granted access permissions, the mc_arb command will not work. Accordingly, users other than the operating system user who starts and stops the arbitration process in step 1 are prevented from operating the Mirroring Controller arbitration process.

   Sample file

   ```
   /installDir/share/mcarb_network.conf.sample
   ```

   In network.conf, specify the IP address or host name and port number of the primary server and standby server, and define the Mirroring Controller network configuration that will be managed by the Mirroring Controller arbitration process.

Refer to "A.3 Network Configuration File" for details.

A definition example is shown below.

```
Example)
The IDs of the servers are set to "server1" and "server2", and their port numbers are set to
"27541".
```

```
server1 192.0.3.100 27541
server2 192.0.3.110 27541
```

5. In the arbitration configuration file (arbitration.conf), define the information related to control of the Mirroring Controller arbitration process.

   Create arbitration.conf in the Mirroring Controller arbitration process management directory, based on the sample file. For arbitration.conf, set read and write permissions only for the operating system user who starts and stops the arbitration process in step 1. If users other than this are granted access permissions, the mc_arb command will not work.

   ```
   Sample file
   ```

   ```
   /installDir/share/mcarb_arbitration.conf.sample
   ```

   Set the parameters shown in the table below in arbitration.conf.

   Refer to "A.4.2 Arbitration Configuration File" for information on the parameters and for other parameters.

   Table 2.1 Parameters

Parameter	Content specified	Remarks
port	Port number of the Mirroring Controller arbitration process	The port number must be 0 to 65535. Ensure that the port number does not conflict with other software. Do not specify an ephemeral port that may temporarily be assigned by another program.
my_address	'*ipAddrOrHostNameThatAcceptsConnectionFromMirroringControllerProcessOnDbServer*' [Setting example] my_address = '192.0.3.120'	IPv4 and IPv6 addresses can be specified. Specify the IP address, enclosed in single quotation marks (').
syslog_ident	'*programName*'	Specify using single quotation marks (') to enclose the program name used to identify the Mirroring Controller arbitration process message in the system log. Use ASCII characters excluding spaces to specify this parameter. The default is 'MirroringControllerArbiter'.
fencing_command	'*fencingCmdFilePath*' [Setting example] fencing_command = '/arbiter/fencing_dir/execute_fencing.sh'	Specify the full path of the fencing command that fences a database server where it is determined that an error has occurred. Enclose the path in single quotation marks ('). Specify the path using less than 1024 bytes.
fencing_command_timeout	Timeout for fencing command (seconds)	If the command does not respond within the specified number of seconds, it is determined that fencing has failed and a signal (SIGTERM) is sent to the fencing command execution process. Specify a value between 1 and 2147483647. The default is 20 seconds.

Windows

1. On the arbitration server, log in as any operating system user who starts and stops the arbitration process.
2. Configure the environment variables.

   Set the following environment variable:

   - PATH

     Add the installation folders "\bin" and "\lib".

   Example

   The following example configures environment variables when the installation folder is "c:\Program Files\Fujitsu \fsepv<*x*>assistant64".

   Note that "<*x*>" indicates the product version.

   ```
   > SET PATH=c:\Program Files\Fujitsu\fsepv<x>assistant64\bin;c:\Program Files\Fujitsu
   \fsepv<x>assistant64\lib;%PATH%
   ```

3. Create the Mirroring Controller arbitration process management directory that will store the files required by the arbitration server.

   Use ASCII characters in the Mirroring Controller arbitration process management directory.

4. In the network configuration file (network.conf), define the Mirroring Controller network configuration that will be managed by the Mirroring Controller arbitration process.

   Create network.conf in the Mirroring Controller arbitration process management directory, based on the sample file.

   Sample file

   ```
   installDir\share\mcarb_network.conf.sample
   ```

   In network.conf, specify the IP address or host name and port number of the primary server and standby server, and define the Mirroring Controller network configuration that will be managed by the Mirroring Controller arbitration process.

   Refer to "A.3 Network Configuration File" for details.

   A definition example is shown below.

   ```
   Example)
   The IDs of the servers are set to "server1" and "server2", and their port numbers are set to
   "27541".
   ```

   ```
   server1 192.0.3.100 27541
   server2 192.0.3.110 27541
   ```

5. Change the access permissions for network.conf.

   For network.conf, set read and write permissions only for the operating system user who starts and stops the arbitration process in step 1. If users other than this are granted access permissions, the mc_arb command will not work. Accordingly, users other than the operating system user who starts and stops the arbitration process in step 1 are prevented from operating the Mirroring Controller arbitration process.

   ```
   Example)
   The following is an execution example, in which the operating system user who starts and stops the
   arbitration process in step 1 is granted full access permissions as the owner when the user is
   "fsepuser". The following procedure applies when the user is logged in to the Windows server as
   "fsepuser".
   ```

   ```
   > takeown /f network.conf
   > icacls network.conf /reset
   > icacls network.conf /inheritance:r
   > icacls network.conf /grant fsepuser:F
   ```

6. In the arbitration configuration file (arbitration.conf), define the information related to control of the Mirroring Controller arbitration process.

   Create arbitration.conf in the Mirroring Controller arbitration process management directory, based on the sample file.

   Sample file

   ```
   installDir\share\mcarb_arbitration.conf.sample
   ```

   Set the parameters shown in the table below in arbitration.conf.

   Refer to "A.4.2 Arbitration Configuration File" for information on the parameters and for other parameters.

Table 2.2 Parameters

Parameter	Content specified	Remarks
port	Port number of the Mirroring Controller arbitration process	The port number must be 0 to 65535. Ensure that the port number does not conflict with other software. Do not specify an ephemeral port that may temporarily be assigned by another program.
my_address	'*ipAddrOrHostNameThatAcceptsConnectionFromMirroringControllerProcessOnDbServer*' [Setting example] my_address = '192.0.3.120'	IPv4 and IPv6 addresses can be specified. Enclose the parameter value in single quotation marks (').
service_name	'*registeredServiceNameOfArbitrationProcessInWindowsServices*'	Use ASCII characters excluding forward slash (/) and backslash (\) to specify this parameter. Enclose the parameter value in single quotation marks ('). The maximum length of the service name is 124 bytes.
event_source	'*eventSourceNameUsedToIdentifyArbitrationProcessMsgInEventLog*'	Use ASCII characters excluding spaces to specify this parameter. Enclose the parameter value in single quotation marks ('). The maximum length of the event source name is 255 bytes.
fencing_command	'*fencingCmdFilePath*' [Setting example] fencing_command = 'c:\\arbiter\\fencing_dir\\execute_fencing.bat'	Specify the full path of the fencing command that fences a database server where it is determined that an error has occurred. Specify "\\" as the delimiter. Enclose the path in single quotation marks ('). Specify the path using less than 260 bytes. Any multibyte characters must use the same encoding as the operating system.
fencing_command_timeout	Timeout for fencing command (seconds)	If the command does not respond within the specified number of seconds, it is determined that fencing has failed and a signal (SIGTERM) is sent to the fencing command execution process. Specify a value between 1 and 2147483647. The default is 20 seconds.

7. Change the access permissions for arbitration.conf.

   For arbitration.conf, set read and write permissions only for the operating system user who starts and stops the arbitration process in step 1. If users other than this are granted access permissions, the mc_arb command will not work.

   ```
   Example)
   The following is an execution example, in which the operating system user who starts and stops the
   arbitration process in step 1 is granted full access permissions as the owner when the user is
   "fsepuser". The following procedure applies when the user is logged in to the Windows server as
   "fsepuser".
   ```

   ```
   > takeown /f arbitration.conf
   > icacls arbitration.conf /reset
   > icacls arbitration.conf /inheritance:r
   > icacls arbitration.conf /grant fsepuser:F
   ```

8. Configure Windows Firewall.

   If Windows Firewall is used, enable the port number of Mirroring Controller specified in the network configuration file in step 3. Refer to "E.2 Windows Firewall Settings" for details.

9. Register the Mirroring Controller arbitration process as a Windows service.

   Execute the mc_arb command in register mode.

   For the -P option of the mc_arb command, specify the password of the operating system user who executes the command.

   ```
   Example)
   ```

   ```
   > mc_arb register -M D:\mcarb_dir\arbiter1 -P ********
   ```

   Note

   When specifying the password in the -P option of the mc_arb command, for security reasons, you should be careful not to allow other users to access it.

   Information

   Use the mc_arb command with the -S option to specify automatic start and stop of the Mirroring Controller arbitration process. Refer to "2.13 Setting Automatic Start and Stop of the Mirroring Controller Arbitration Process" for details.

   The Mirroring Controller arbitration process is registered as a Windows service using the service name specified in the service_name parameter of arbitration.conf in step 6.

   You can execute the sc qc command to check the registration status.

2.3.2 Creating a User Exit for the Arbitration Server

The only user exit for the arbitration server is the fencing command.

The fencing command is a user command that is called by the Mirroring Controller arbitration process if Mirroring Controller performs arbitration processing and determines that a database server is unstable.

In the fencing command, the user implements a process that isolates a database server from a cluster system by, for example, stopping the target operating system or server. The fencing command that was created is to be specified for the parameter in the arbitration configuration file. Refer to "A.4.2 Arbitration Configuration File" for information on the parameters.

- Fencing the primary server during the switch
  - Prevent the Mirroring Controller management process on the primary server from communicating with the Mirroring Controller management process on the other server.

    - Prevent applications from connecting to the primary server instance.

- Fencing the standby server during disconnection

    - Prevent the Mirroring Controller management process on the standby server from communicating with the Mirroring Controller management process on the other server.

    - Prevent applications from connecting to the standby server instance.

    - Prevent the standby server from continuing streaming replication.

See

Refer to "Appendix C User Commands" for information on user exits.

2.3.3 Starting the Mirroring Controller Arbitration Process

This section explains how to start the Mirroring Controller arbitration process.

An operating system user who has logged in to the arbitration server can start the Mirroring Controller arbitration process by executing the mc_arb command in start mode.

Linux

Example)

```
$ mc_arb start -M /mcarb_dir/arbiter1
```

Windows

Example)

```
> mc_arb start -M D:\mcarb_dir\arbiter1
```

2.4 Setting Up the Primary Server

This section explains how to set up the primary server.

2.4.1 Setting Up Database Multiplexing Mode on the Primary Server

This section explains how to set up database multiplexing mode on the primary server.

In database multiplexing, the files that are required for operations are managed in the Mirroring Controller management directory.

There is one Mirroring Controller management directory for each instance.

Information

Do not place the Mirroring Controller management directory in a directory managed by Fujitsu Enterprise Postgres, otherwise it may be deleted by mistake with the directories managed by Fujitsu Enterprise Postgres, and an old version of files may be restored.

See

- Refer to "Preparing Directories for Resource Deployment" in the Installation and Setup Guide for Server for details on the directories that are managed by Fujitsu Enterprise Postgres.

- Refer to "mc_ctl" in Reference for information on the command.

- Refer to "Appendix A Parameters" for details on each parameter to be edited for the setup.

Perform the following procedure:

1. Log in to the primary server.
2. Create the Mirroring Controller management directory that will store the files required by database multiplexing.

   Use ASCII characters in the Mirroring Controller management directory.

   Additionally, grant "Write" permission to the instance administrator user for the Mirroring Controller management directory.
3. In the network configuration file (network.conf), define the network configuration that will link between the Mirroring Controller processes.

   Create the network.conf file in the Mirroring Controller management directory, based on the sample file. For network.conf, set read and write permissions for the instance administrator user only.

   If users other than the instance administrator user are granted access, the mc_ctl command will not work. In this way, users other than the instance administrator user are prevented from operating Mirroring Controller.

   Sample file

   ```
   /installDir/share/mc_network.conf.sample
   ```

   In network.conf, specify the IP address or host name and port number of the primary server and standby server, and define the network configuration that will link between the Mirroring Controller processes, and between Mirroring Controller processes and the Mirroring Controller arbitration process.

   Refer to "A.3 Network Configuration File" for details.

   A definition example is shown below.

   The content to be defined depends on the operation settings at the time a heartbeat abnormality is detected.

   When automatic degradation by the arbitration server is selected

   ```
   Example)
   The IDs of the primary server and standby server are set to "server1" and "server2", and their
   port numbers are set to "27540" and "27541". The ID of the server of the Mirroring Controller
   arbitration process is set to "arbiter", and its port number is set to "27541".
   ```

   ```
   server1 192.0.2.100,192.0.3.100 27540,27541 server
   server2 192.0.2.110,192.0.3.110 27540,27541 server
   arbiter 192.0.3.120 27541 arbiter
   ```

   Ensure that the port numbers set for the primary server, standby server, and arbitration server do not conflict with other software. In addition, when the arbitration server is used for automatic degradation, use a network in which the arbitration network is not affected by a line failure in the admin network.

   When the server type is "server", two IP addresses or host names, and two port numbers need to be specified in the following order:

   - IP address or host name of the database server used as the admin network
   - IP address or host name of the database server used as the arbitration network
   - Port number of the database server used as the admin network
   - Port number of the database server used as the arbitration network

   If the server type is "arbiter", specify the IP address or host name set for the my_address parameter and the port number set for the port parameter in arbitration.conf of the arbitration server.

   When using the admin network and arbitration network together, the following IP addresses or host names must be assigned the same values.

   - IP address or host name of the database server used as the admin network
   - IP address or host name of the database server used as the arbitration network

   Example)
   Here is an example where the server identifiers for the primary server and standby server are "server1" and "server2", with port

numbers "27540" and "27541", and the server identifier for the Mirroring Controller arbitration process is "arbiter", with port number "27541".

```
server1 192.0.2.100,192.0.2.100 27540,27541 server
server2 192.0.2.110,192.0.2.110 27540,27541 server
arbiter 192.0.2.120 27541 arbiter
```

When operation other than automatic degradation by the arbitration server is selected

```
Example)
The IDs of the servers are set to "server1" and "server2", and their port numbers are set to
"27540".
```

```
server1 192.0.2.100 27540
server2 192.0.2.110 27540
```

Ensure that the port numbers for the primary and standby server do not conflict with other software.

Register in /etc/services the port number of the primary server, because programs such as WebAdmin use it to search for available port numbers.

Register any name as the service name.

4. Define the information related to Mirroring Controller monitoring and control in the *serverIdentifier*.conf file.

   Create the *serverIdentifier*.conf file in the Mirroring Controller management directory, based on the sample file.

   For *serverIdentifier*.conf, set read and write permissions for the instance administrator user only. If users other than the instance administrator user are granted access, the mc_ctl command will not work.

   As the file name for the *serverIdentifier*.conf file, use the server identifier name that was specified in the network.conf file in step 3.

   Sample file

   ```
   /InstallDir/share/mc_server.conf.sample
   ```

   Set the parameters shown in the table below in the *serverIdentifier*.conf file.

   Refer to "A.4.1 Server Configuration File for the Database Servers" for information on the parameters and for other parameters.

Table 2.3 Parameters

Parameter	Content specified	Remarks
db_instance	'*dataStorageDestinationDir*'	Use ASCII characters, enclosed in single quotation marks (').
db_instance_password	'*passwordOfInstanceAdminUser*'	If password authentication is performed, you must specify this parameter in the settings used when Mirroring Controller connects to a database instance. Use ASCII characters, enclosed in single quotation marks ('). If the specified value of this parameter includes ' or \, write \' or \\, respectively.
enable_hash_in_password	on or off	Specify on to treat the # in the db_instance_password specification as a password character, or off to treat it as a comment. The default is "off".
syslog_ident	'*programName*'	Specify the program name to be used to identify the Mirroring Controller messages in the system log. Use ASCII characters excluding spaces, enclosed in single quotation marks (').

Parameter	Content specified	Remarks
		Use the same program name as the parameter in the postgresql.conf file ensures that the Mirroring Controller output content can be referenced transparently, so log reference is easy.
remote_call_timeout	Admin communication timeout	Specify the timeout value (milliseconds) of the Mirroring Controller agent process for communication between servers. Specify a value that is less than the operation system TCP connection timeout. Also, when using the Mirroring Controller arbitrage process for arbitrage, fencing, and state transition commands, specify a value that is greater than the sum of the timeout values.
heartbeat_error_action	Operation when a heartbeat abnormality is detected using operating system or server heartbeat monitoring	arbitration: Perform automatic degradation using the arbitration server. command: Call a user exit to determine degradation, and perform automatic degradation if required. message: Notify messages. fallback: Perform automatic degradation unconditionally. Set the same value on the primary server and standby server.
heartbeat_interval	Interval time for abnormality monitoring during heartbeat monitoring of the operating system or server (milliseconds)	Abnormality monitoring of the operating system or server is performed at the interval (milliseconds) specified in heartbeat_interval. This parameter setting is used as the default for database process heartbeat monitoring, streaming replication abnormality monitoring, and disk abnormality monitoring. When setting the monitoring time, there are some considerations to take into account to optimize degradation using abnormality monitoring. Refer to "2.11.4.1 Tuning for Abnormality Monitoring of the Operating System or Server" for details.
heartbeat_timeout	Timeout for abnormality monitoring during heartbeat monitoring of the operating system or server (seconds)	
heartbeat_retry	Number of retries for abnormality monitoring during heartbeat monitoring of the operating system or server (number of times)	
fencing_command	'*fencingCmdFilePath*' [Setting example] fencing_command = '/mc/fencing_dir/execute_fencing.sh'	Specify the full path of the fencing command that fences a database server where an error is determined to have occurred. Enclose the path in single quotation marks ('). This parameter must be specified when "command" is set for heartbeat_error_action. Specify the path using less than 1024 bytes.
fencing_command_timeout	Fencing command timeout (seconds)	If the command does not respond within the specified number of seconds, fencing is determined to have failed and a signal

Parameter	Content specified	Remarks
		(SIGTERM) is sent to the fencing command execution process. Specify a value between 1 and 2147483647. The default is 20 seconds.
arbitration_timeout	Timeout for arbitration processing in the Mirroring Controller arbitration process (seconds)	The specified value must be at least equal to the heartbeat monitoring time of the operating system or server + fencing_command_timeout in the arbitration configuration file. If there is no response for at least the number of seconds specified, the primary server will not be switched and the standby server will not be disconnected. Therefore, perform degradation manually. Specify a value between 1 and 2147483647. This parameter does not need to be set for operation that does not use the arbitration server.
arbitration_command	'*arbitrationCmdFilePath*' [Setting example] arbitration_command = '/mc/arbitration_dir/execute_arbitration_command.sh'	Specify the full path of the arbitration command to be executed when an abnormality is detected during heartbeat monitoring of the operating system or server. Enclose the path in single quotation marks ('). This parameter must be specified when "command" is set for heartbeat_error_action. Specify the path using less than 1024 bytes.
arbitration_command_timeout	Timeout for arbitration command (seconds)	If the arbitration command does not respond within the specified number of seconds, it is determined that execution of the arbitration command has failed and a signal (SIGTERM) is sent to the arbitration command execution process. Specify a value between 1 and 2147483647. This parameter can be specified only when "command" is set for heartbeat_error_action.

2.4.2 Creating, Setting, and Registering the Primary Server Instance

This section explains how to create, set, and register the primary server instance.

See

- Refer to "Client Authentication" in the PostgreSQL Documentation for information on the pg_hba.conf file.
- Refer to "A.1 Parameters Set on the Primary Server" for information on the postgresql.conf file.
- Refer to "mc_ctl" in Reference for information on the command.

Perform the following procedure:

1. Refer to "Setup" in the Installation and Setup Guide for Server, and then perform the Fujitsu Enterprise Postgres setup and create the Fujitsu Enterprise Postgres instance.

   Use ASCII characters in the data storage destination directory.

   Point

   If degradation starts occurring due to an error during operations in database multiplexing mode, recovery is required for the standby server. There are some conditions to execute the pg_rewind command to recover the standby server. One of the conditions can be satisfied by enabling checksums when executing the initdb command. This is not mandatory. Refer to "4.1.1.1.3 Identify cause of error and perform recovery" for details.

2. When using transparent data encryption, configure the encryption settings for the storage data.

   If you want to use a file-based keystore, create a keystore file.

   If you want to use the key management system as a keystore, set the connection information for the key management system and declare the master encryption key.

   Refer to "Protecting Storage Data Using Transparent Data Encryption" or "Using Transparent Data Encryption with Key Management Systems as Keystores" in the Operation Guide for details, and then configure the settings.

3. Add the following entry to the pg_hba.conf file to authenticate connections from the standby server.

   Copy the file to the standby server later.

```
# TYPE    DATABASE        USER        ADDRESS                     METHOD
  host    replication     fsep        standbyServerAddress        authenticationMethod
  host    replication     fsep        primaryServerAddress        authenticationMethod
```

   For the primary and standby server addresses, specify the IP address that will connect to the log transfer network.

   Additionally, all servers can be used as the primary server or the standby server, so add entries for the addresses of all servers that comprise the database multiplexing system.

   Point

   Setting an authentication method other than trust authentication

   If the primary server becomes the standby server, to perform automatic authentication of connections to the primary server, create the .pgpass file in the home directory of the instance administrator user, and then specify a password for the replication database. Accordingly, the instance administrator operating system user and the user registered in the database will be the same, so you can verify that the connection was not made by an unspecified user. Additionally, the password that was set beforehand will be used in the authentication, so that the connection will be automatic.

   Information

   If trust authentication is set, all OS users who can log in to the primary server will be able to connect, and if one of these is a malicious user, then that user can corrupt the standby server data, or cause the job system to fail, by sending an erroneous transaction log. Therefore, decide on the authentication method according to the security requirements of the system using database multiplexing mode.

   Refer to "Authentication Methods" in the PostgreSQL Documentation for details on the authentication methods that can be set.

4. Configure this setting to enable the instance administrator user of the primary server to connect as a database application.

   This setting enables the connection to the instance using the user name of the instance administrator user, so that Mirroring Controller can monitor instance errors. Configure this setting to enable the connection to the postgres database.

   - If password authentication is used

     In the db_instance_password parameter of the *serverIdentifier*.conf file, specify the password for the instance administrator user. This password is used to connect to the database instance. If a password is not specified in the db_instance_password parameter,

the connection to the database instance from Mirroring Controller will fail, and it will not be possible to perform the process monitoring of the instance.

- If password authentication is not used

  There is no need to specify the password in the db_instance_password parameter.

  Even if the password for the instance administrator user is specified in the db_instance_password parameter, it will be ignored.

- If certificate authentication using SSL is used

  Specify connection parameters for SSL in the db_instance_ext_ pq_conninfo parameter and db_instance_ext_jdbc_conninfo parameter in the *serverIdentifier*.conf file. If the pasrameters are not specified, the connection to the database instance from Mirroring Controller will fail, and it will not be possible to perform the process monitoring of the instance. If certificate authentication using SSL is not performed, the parameters specification is not required.

  For information about the db_instance_ext_pq_conninfo and db_instance_ext_jdbc_conninfo parameters, refer to "A.4.1 Server Configuration File for the Database Servers".

An example of setting the authentication method is shown below.

```
# TYPE    DATABASE        USER        ADDRESS         METHOD
  host    postgres        fsep        127.0.0.1/32    authenticationMethod
```

Information

Mirroring Controller uses the PostgreSQL JDBC 4.2 driver to connect to the database instance. Therefore, for the authentication method, specify a method supported by the JDBC driver. If an authentication method not supported by the JDBC driver is specified, Mirroring Controller will fail to start. Refer to the PostgreSQL JDBC Driver Documentation for information on authentication methods supported by the JDBC driver.

5. To use database multiplexing mode, specify the parameters shown in the table below in the postgresql.conf file.

   The postgresql.conf file is copied when the standby server instance is created. Accordingly, set the required parameters in the standby server.

   To use database multiplexing mode, specify the parameters shown in the table below in the postgresql.conf file. After editing the postgresql.conf file, restart the instance.

Table 2.4 Parameters

Parameter	Content specified	Remarks
wal_level	replica or logical	Specify "logical" when logical decoding is also to be used.
max_wal_senders	2 or more	Specify "2" when building a Mirroring Controller cluster system. When additionally connecting asynchronous standby servers to the cluster system, add the number of simultaneous connections from these standby servers.
synchronous_standby_names	'*standbyServerName*'	Specify the name that will identify the standby server. Enclose the name in single quotation marks ('). Do not change this parameter while Mirroring Controller is running. Do not specify multiple names to this parameter as the Mirroring Controller can manage only one standby server.
synchronized_standby_slots	'*physicalReplicationSlotName*'	Specify this parameter if the primary server will be a logical replication publication. Setting this parameter ensures that the subscriber is updated after WAL is sent to the standby server. This allows logical replication to continue if the primary server fails and the standby server is promoted.

Parameter	Content specified	Remarks
		Do not change this parameter while the Mirroring Controller is running. Because the Mirroring Controller can manage only one standby server, do not specify multiple names for this parameter.
hot_standby	on	Specify whether queries can be run on the standby server.
wal_keep_size	WAL save size (megabytes)	If a delay exceeding the value set in this parameter occurs, the WAL segment required later by the primary server may be deleted. Additionally, if you stop a standby server (for maintenance, for example), consider the stop time and set a value that will not cause the WAL segment to be deleted. Refer to "Estimating Transaction Log Space Requirements" in the Installation and Setup Guide for Server for information on estimating the WAL save size.
wal_log_hints	on	When using the pg_rewind command to recover a standby server, specify this parameter or enable checksums when executing the initdb command.
wal_sender_timeout	Timeout (milliseconds)	Specify the time period after which it is determined that an error has occurred in the transaction log transfer on the primary server. By aligning this value with the value for the database process heartbeat monitoring time, you can unify the time after which it is determined that an error has occurred.
archive_mode	on	Specify the archive log mode.
archive_command	'*installDir*/bin/pgx_walcopy.cmd "%p" "*backupDataStorageDestinationDirectory*/archived_wal/%f"'	Specify the command and storage destination to save the transaction log.
backup_destination	Backup data storage destination directory	Specify the name of directory where to store the backup data. Set the permissions so that only the instance administrator user can access the specified directory. Specify the same full path on all servers, so that the backup data of other servers can be used to perform recovery.
max_connections	Number of simultaneous client connections to the instance + superuser_reserved_connections	The value specified is also used to restrict the number of connections from client applications and the number of connections for the management of instances. Refer to "When an Instance was Created with the initdb Command" in the Installation and Setup Guide for Server, and "Connections and Authentication" in the PostgreSQL Documentation, for details.
superuser_reserved_connections	Add the number of simultaneous executions of mc_ctl status (*1) + 2	Specify the number of connections reserved for connections from database superusers. Add the number of connections from Mirroring Controller processes. Also reflect the added value in the max_connections parameter.

Parameter	Content specified	Remarks
wal_receiver_timeout	Timeout (milliseconds)	Specify the time period after which it is determined that an error has occurred when the transaction log was received on the standby server. By aligning this value with the value for the heartbeat monitoring time of the database process, you can unify the time after which it is determined that an error has occurred.
restart_after_crash	off	If "on" is specified, or the default value is used for this parameter, behavior equivalent to restarting Fujitsu Enterprise Postgres, including crash recovery, will be performed when some server processes end abnormally. However, when database multiplexing monitoring is used, a failover will occur after an error is detected when some server processes end abnormally, and the restart of those server processes is forcibly stopped. Specify "off" to prevent behavior such as this from occurring for no apparent reason.
synchronous_commit	on or remote_apply	Specify up to what position WAL send is to be performed before transaction commit processing returns a normal termination response to a client. Set "on" or "remote_apply" to prevent data loss caused by operating system or server down immediately after a switch or switch.
recovery_target_timeline	latest	Specify "latest" so that the new standby server (original primary server) will follow the new primary server when a switch occurs. This parameter is required when the original primary server is incorporated as a new standby server after the primary server is switched.

*1: Number of simultaneous executions of the mc_ctl command in the status mode.

2.4.3 Starting Mirroring Controller on the Primary Server

This section explains how to start Mirroring Controller on the primary server.

When the arbitration server is used for automatic degradation, start the Mirroring Controller arbitration process on the arbitration server in advance.

1. Start the Mirroring Controller process.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

   ```
   $ mc_ctl start -M /mcdir/inst1
   ```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   Example)

   ```
   $ mc_ctl start -M /mcdir/inst1 -F
   ```

Information

- When the arbitration server is used for automatic degradation, the database server must connect to the arbitration server, and as a result, Mirroring Controller startup may take longer than when the arbitration server is not used.
- If the parameter for heartbeat monitoring of operating systems or servers set by the abitration server is greater than parameter for heartbeat monitoring of operating systems and servers of the Mirroring Controller, the Mirroring Controller may fail to start. In this case, check the contents of the message notification and review the parameters for heartbeat monitoring of operating systems or servers for the arbitration server or Mirroring Controller.
- If the heartbeat_error_action parameter in *serverIdentifier*.conf is set to "message", even if automatic switch/disconnection is enabled and Mirroring Controller is started, only message output is performed when a heartbeat abnormality is detected during heartbeat monitoring of operating systems and servers - switch/disconnection is not performed.
- Mirroring Controller startup usually fails if the standby server is mistakenly started as the primary server or if the old primary server is not recovered after the switch and is then mistakenly started as the primary server. However, if the admin network is disconnected, then startup does not fail, and both servers may become primary servers. Therefore ensure that the admin network is connected before starting Mirroring Controller.
- If the automatic switch/disconnection is enabled, do not edit synchronous_standby_names parameter and synchronized_standby_slots parameter for the Mirroring Controller monitoring target instance. If Mirroring Controller is switched after editing, data may be lost or SQL access may stop.

Point

- The mc_ctl command fails if the Mirroring Controller arbitration process has not been started on the arbitration server when the arbitration server is used for automatic degradation. However, if the Mirroring Controller arbitration process cannot be started in advance, it can be started by specifying the --async-connect-arbiter option in the mc_ctl command.
- After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

2. Obtain the backup.

   Use the pgx_dmpall command to collect the backup.

2.5 Setting Up the Standby Server

This section explains how to set up the standby server.

2.5.1 Setting Up Database Multiplexing Mode on the Standby Server

This section explains how to set up database multiplexing mode on the standby server.

In database multiplexing, the files that are required for operations are managed in the Mirroring Controller management directory.

There is one Mirroring Controller management directory for each instance.

Information

- Do not place the Mirroring Controller management directory in a directory managed by Fujitsu Enterprise Postgres, otherwise it may be deleted by mistake with the directories managed by Fujitsu Enterprise Postgres, and an old version of files may be restored.
- When creating a standby server for a large database, stop job system operations, specify a large value for the wal_keep_size parameter, or use replication slots.
  This is because WALs generated after the standby server is built using the pg_basebackup command, but before it is started, need to be retained. However, the number of WAL segments that can be retained is constrained by the wal_keep_size parameter.

Additionally, setting the wal_keep_size parameter requires consideration regarding stabilization of the database multiplexing mode (refer to "2.11.1 Tuning to Stabilize the Database Multiplexing Mode" for details).

See

- Refer to "Preparing Directories for Resource Deployment" in the Installation and Setup Guide for Server for details on the directories that are managed by Fujitsu Enterprise Postgres.
- Refer to "pg_basebackup" in "Reference" in the PostgreSQL Documentation for information on the pg_basebackup command.
- Refer to "mc_ctl" in Reference for information on the command.
- Refer to "Appendix A Parameters" for details on each parameter to be edited for the setup.
- Refer to "Replication Slots" in the PostgreSQL Documentation for information on replication slots.

Perform the following procedure:

1. Log in to the standby server.
2. Create the Mirroring Controller management directory that will store the files required by database multiplexing.

   Use ASCII characters in the Mirroring Controller management directory.

   Additionally, grant "Write" permission to the instance administrator user for the Mirroring Controller management directory.
3. Copy, and then deploy, the network.conf file of the primary server.

   Copy the network.conf file that was defined in the primary server setup, and deploy it to the Mirroring Controller management directory of the standby server.

   Set read and write permissions for the instance administrator user only. If users other than the instance administrator user are granted access, the mc_ctl command will not work. Accordingly, users other than the instance administrator user are prevented from operating Mirroring Controller.

   Register in /etc/services the port number of the standby server that was specified in the network.conf file, because programs such as WebAdmin use it to search for available port numbers.

   Register any name as the service name.
4. Copy, and then deploy, the *serverIdentifier*.conf file of the primary server.

   Copy the *serverIdentifier*.conf file that was defined in the primary server setup, and deploy it to the Mirroring Controller management directory of the standby server.

   Set read and write permissions for the instance administrator user only. If users other than the instance administrator user are granted access permissions, the mc_ctl command will not work.

2.5.2 Creating, Setting, and Registering the Standby Server Instance

This section explains how to create, set, and register the standby server instance.

See

- Refer to "Appendix A Parameters" for details on each parameter.
- Refer to "mc_ctl" in Reference for information on the command.

Perform the following procedure:

1. Set the kernel parameters.

   Refer to "Configuring Kernel Parameters" in the Installation and Setup Guide for Server for details.

2. When using transparent data encryption, configure the encryption settings for the storage data.

   Refer to "Protecting Storage Data Using Transparent Data Encryption" or "Using Transparent Data Encryption with Key Management Systems as Keystores" in the Operation Guide for details, and then configure the settings.

3. Execute the pg_basebackup command to create a copy of the primary server instance on the standby server.

   Example)

```
$ pg_basebackup -D /database/inst1 -X fetch --waldir=/transaction/inst1 --progress --verbose -R
--dbname='application_name=standbyServerName' -h primaryServerIpAddress -p
primaryServerPortNumber
```

Point

- Use the pg_basebackup command with the -R option to create a standby.signal file. If you do not create the standby.signal file, the Mirroring Controller cannot be started as a standby server.
- If using a method that requires password authentication for connections to the primary server, you will need to ensure that authentication is performed automatically. If the -R option is specified for the pg_basebackup command and the password parameter is specified for the --dbname option, the pg_basebackup command will set the password in the primary_conninfo parameter in postgresql.auto.conf file, enabling connections to be performed automatically.

  If a password is not set in the primary_conninfo parameter in postgresql.auto.conf file, it will be necessary to create a .pgpass file in the home directory of the instance administrator user, and specify a password for the replication database.
- The primary_conninfo parameter should not be set in the postgresql.conf file, but only in the postgresql.auto.conf file using the pg_basebackup command.
- When executing the pg_basebackup command, consider the following for collection of transaction logs.
  - When "fetch" is specified for the -X option of the command

    Transaction logs are collected at the end of the backup, so it is necessary to ensure that transaction logs that occur during backup are not deleted from the primary server. Therefore, allow for a sufficient value for the wal_keep_size parameter in postgresql.conf.
  - When the -X option is omitted or "stream" is specified for the -X option of the command

    Transaction logs are streamed, so when Mirroring Controller is running on the primary server, the connection is changed to a synchronous standby server on detection of a streaming replication connection using this command. Therefore, if a job has started on the primary server, the primary server will be impacted, therefore execute this command after stopping only the Mirroring Controller process on the primary server.

See

Refer to "Hot Standby" in the PostgreSQL Documentation for information on the standby.signal file.

4. Set the parameters shown in the table below in the postgresql.conf file.

Table 2.5 Parameters

Parameter	Content specified	Remarks
synchronous_standby_names	'*primaryServerName*'	Required after switching the primary server and then changing the original primary server to the new standby server. Enclose the name in single quotation marks ('). Do not change this parameter while Mirroring Controller is running. Do not specify multiple names to this parameter as the Mirroring Controller can manage only one standby server.

2.5.3 Starting Mirroring Controller on the Standby Server

This section explains how to start Mirroring Controller on the standby server.

When the arbitration server is used for automatic degradation, start the Mirroring Controller arbitration process on the arbitration server in advance.

1. After ensuring that the Mirroring Controller process of the primary server has started, start Mirroring Controller on the standby server.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -f option specified. This action enables automatic switch/disconnection.

   If you start Mirroring Controller and the instance without specifying the -f option, automatic switch/disconnection will not be enabled. To enable both, start Mirroring Controller and then execute the mc_ctl command in enable-failover mode or restart Mirroring Controller with the -f option specified.

   Example)

   ```
   $ mc_ctl start -M /mcdir/inst1
   ```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   Example)

   ```
   $ mc_ctl start -M /mcdir/inst1 -F
   ```

2. Check the status of the Mirroring Controller process.

   As the instance administrator user, execute the mc_ctl command in status mode. Ensure that "mirroring status" is switchable.

   Example)

   ```
   $ mc_ctl status -M /mcdir/inst1
   ```

Information

- When the arbitration server is used for automatic degradation, the time required for the database server to connect to the arbitration server is added on. Therefore, Mirroring Controller startup may take longer than when the arbitration server is not used.
- If the parameter for heartbeat monitoring of operating systems or servers set by the abitration server is greater than parameter for heartbeat monitoring of operating systems and servers of the Mirroring Controller, the Mirroring Controller may fail to start. In this case, check the contents of the message notification and review the parameters for heartbeat monitoring of operating systems or servers for the arbitration server or Mirroring Controller.
- If the heartbeat_error_action parameter in *serverIdentifier*.conf is set to "message", even if automatic switch/disconnection is enabled and Mirroring Controller is started, only message output is performed when a heartbeat abnormality is detected during heartbeat monitoring of operating systems and servers - switch/disconnection is not performed.
- Mirroring Controller startup usually fails if the standby server is mistakenly started as the primary server or if the old primary server is not recovered after the switch and is then mistakenly started as the primary server. However, if the admin network is disconnected, then startup does not fail, and both servers may become primary servers. Therefore, ensure that the admin network is connected before starting Mirroring Controller.
- If the automatic switch/disconnection is enabled, do not edit synchronous_standby_names parameter and synchronized_standby_slots parameter for the Mirroring Controller monitoring target instance. If Mirroring Controller is switched after editing, data may be lost or SQL access may stop.

Point

- The mc_ctl command fails if the Mirroring Controller arbitration process has not been started on the arbitration server when the arbitration server is used for automatic degradation. However, if the Mirroring Controller arbitration process cannot be started in advance, it can be started by specifying the --async-connect-arbiter option in the mc_ctl command.
- After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

2.6 Creating a User Exit for a Database Server

This section explains how to create a user exit for a database server.

The user command types explained below can be used as user exits. These commands are called by Mirroring Controller management processes.

The user can create user exits as required.

Specify the user commands that were created for the parameters in the server configuration file of the database server. Refer to "A.4.1 Server Configuration File for the Database Servers" for information on these parameters.

User command types

- Fencing command

  This user command performs fencing if Mirroring Controller performs arbitration processing and determines that a database server is unstable.

- Arbitration command

  This user command performs arbitration processing in lieu of the arbitration server when there is no arbitration server.

- State transition commands

  These user commands are called when Mirroring Controller performs state transition of a database server.
  It includes the following types:

  - Post-switch command

    This user command is called after a promotion from standby server to primary server.

  - Pre-detach command

    This user command is called before the standby server is disconnected from a cluster system.
    If the pre-detach command is specified on both the primary server and standby server, it is called first on the standby server and then on the primary server.

    If the settings are configured to forcibly stop the instance on the standby server when the standby server is disconnected, the pre-detach command is called on the standby server and then the instance on the standby server is stopped.

  - Post-attach command

    This user command is called after the standby server has been attached to a cluster system.
    If the post-attach command is specified on both the primary server and standby server, it is called first on the primary server and then on the standby server.

Point

When the arbitration server is used for automatic degradation and the requirements can be satisfied using the fencing command on the arbitration server only, the fencing command on the database server is not required. In addition, if the requirements can be satisfied using the fencing command on the database server only, create a fencing command on the arbitration server for termination processing only (without implementation).

Table 2.6 Availability of user commands, and database server calling the command

User command	Operation when a heartbeat abnormality is detected using operating system or server heartbeat monitoring				Database server calling the command	
	Message output	Automatic degradation by arbitration server	Automatic degradation by arbitration command	Unconditional automatic degradation	Primary server	Standby server
Fencing command	Y (*1)	Y (*2)	R	N	Y	Y
Arbitration command	N	N	R	N	Y	Y
Post-switch command	Y	Y	Y	Y	Y	N
Pre-detach command	Y	Y	Y	Y	Y	Y (*3)
Post-attach command	Y	Y	Y	Y	Y	Y (*3)

R: Required

Y: Can be used

N: Cannot be used

*1: Called only when the mc_ctl command is used to execute forced switching or forced disconnection.

*2: Creation of a fencing command on a database server is optional, but it must be created on the arbitration server.

*3: If message output or unconditional automatic degradation is selected, this command is called only from the primary server.

See

Refer to "Appendix C User Commands" for information on the interface for each user command.

2.7 Confirming the Streaming Replication Status

Before performing the setup of the database multiplexing mode, ensure that the prerequisite streaming replication feature has been set up correctly.

Perform the following procedure:

1. On the primary server, ensure that single-row searches can be performed using the pg_stat_replication statistics view.

   An example output of the psql command is shown below.

   Example)

```
postgres=# select * from pg_stat_replication;
-[ RECORD 1 ]----+------------------------------
pid              | 10651
usesysid         | 10
usename          | fsep
application_name | standby
client_addr      | 192.0.2.210
client_hostname  |
client_port      | 55098
backend_start    | 2022-03-23 11:17:49.628793+09
backend_xmin     |
state            | streaming
sent_lsn         | 0/3000060
write_lsn        | 0/3000060
flush_lsn        | 0/3000060
replay_lsn       | 0/3000060
write_lag        |
```

```
flush_lag        |
replay_lag       |
sync_priority    | 1
sync_state       | sync
reply_time       | 2022-03-23 11:23:27.703366+09
```

2. Confirm the search results of step 1.

   Ensure that the connection established with the intended standby server is in synchronous mode.

   Table 2.7 Items to be checked

Item	Required value
application_name	Value specified for synchronous_standby_names parameter in the postgresql.conf file of the primary server.
client_addr	IP address of the standby server.
state	"streaming".
sync_state	"sync".

See

- Refer to "The Statistics Collector" in "Server Administration" in the PostgreSQL Documentation for information on the pg_stat_replication statistics view.
- Note that the pg_stat_replication statistics view may change in the future.

2.8 Checking the Connection Status

This section explains how to check the connection status from a database server or the arbitration server.

2.8.1 Checking the Connection Status on a Database Server

This section explains how to use a database server to check the connection status of the Mirroring Controller arbitration process and the Mirroring Controller process on the primary server and standby server.

Perform the following procedure:

1. On the primary server and standby server, execute the mc_ctl command in status mode with the --arbiter option specified.

   ```
   Example)
   The mc_ctl command is executed with the --arbiter option specified, and the status is output.
   ```

   ```
   $ mc_ctl status --arbiter -M /mcdir/inst1

   arbiter_id   host            status
   ---------------------------------------
   arbiter      192.0.3.120     online
   ```

2. On the primary server and standby server, check the result displayed by executing the mc_ctl command in status mode in step 1.

   Items to be checked

   Check that the output status" is "online".

See

Refer to the Reference for information on the mc_ctl command.

2.8.2 Checking the Connection Status on the Arbitration Server

This section explains how to use the arbitration server to check the connection status of the Mirroring Controller arbitration process and the Mirroring Controller process on the primary server and standby server.

Perform the following procedure:

1. Execute the mc_arb command in status mode on the arbitration server.

   The example below executes the mc_arb command, and shows the status.

   Linux

   Example)

   ```
   $ mc_arb status -M /mcarb_dir/arbiter1

   server_id    host            status
   ---------------------------------------
   server1      192.0.3.100     online
   server2      192.0.3.110     online
   ```

   Windows

   Example)

   ```
   > mc_arb status -M D:\mcarb_dir\arbiter1

   server_id    host            status
   ---------------------------------------
   server1      192.0.3.100     online
   server2      192.0.3.110     online
   ```

2. Check the result displayed by executing the mc_arb command in step 1.

   Items to be checked

   Check that the output status is "online" on both lines.

See

Refer to the Reference for information on the mc_arb command.

2.9 Creating Applications

This section explains how to create applications using database multiplexing, and points that should be noted when you create the applications.

2.9.1 Application Connection Server Settings

If database multiplexing is used and a failover occurs, it will be necessary to switch the application connection server. Accordingly, use the application connection switch feature to create applications.

See

Refer to "Application Connection Switch Feature" in the Application Development Guide for details.

2.10 Checking the Behavior

To check if the environment setup was performed correctly, start the application and then check the behavior of the switch and rebuild.

2.11 Tuning

This section explains how to tune database multiplexing mode.

2.11.1 Tuning to Stabilize the Database Multiplexing Mode

When large amounts of data are updated, the write-to load for the database will become great, and the multiplexing state may become unstable.

Accordingly, by editing the parameters below in the postgresql.conf file, a stable multiplexing state can be maintained. Refer to "Estimating Transaction Log Space Requirements" in the Installation and Setup Guide for Server for information on transaction log space requirements.

Table 2.8 Parameters

Parameter	Content
wal_keep_size	Refer to "2.4.2 Creating, Setting, and Registering the Primary Server Instance" for details.
max_wal_size	The transaction log is written out according to the checkpoint trigger. If a transaction log with the capacity of the value specified in this parameter is generated, the checkpoint will be executed. If a large value is specified in this parameter, the time required for crash recovery will increase. If a small value is specified in this parameter, many checkpoints will be generated, which will affect the performance of the applications that connect to the primary server.

2.11.2 Tuning to Stabilize Queries on the Standby Server

Queries made using reference jobs on the standby server may be canceled by jobs executed on the primary server.

To reduce the possibility of a job being canceled, specify as large a value as possible for the max_standby_archive_delay parameter in the postgresql.conf file.

See

- Refer to "Handling Query Conflicts" in the PostgreSQL Documentation for details.
- Refer to "Standby Servers" in the PostgreSQL Documentation for details on the max_standby_archive_delay parameter.

2.11.3 Tuning to Stabilize Queries on the Standby Server (when Performing Frequent Updates on the Primary Server)

If jobs are updated on the primary server regularly and frequently, it will be easy for the query made by the reference job on the standby server to be canceled. In this case, edit the postgresql.conf file parameters shown in the table below.

Table 2.9 Parameters

Parameter	Description
hot_standby_feedback	When "on" is set, the deletion (vacuum) of the data area that was deleted or updated on the primary server is suppressed. Accordingly, the query on the standby server will not be canceled. (*1)

*1: Because the vacuum is delayed, the data storage destination disk space of the primary server comes under pressure.
Additionally, if there is conflict between accesses and queries executed on the standby server, transaction logs indicating this conflict will be transferred.
Accordingly, specify as large a value as possible for the max_standby_archive_delay parameter so that access conflicts do not occur.

See

Refer to "Standby Servers" in the PostgreSQL Documentation for details on the hot_standby_feedback parameter.

2.11.4 Tuning for Optimization of Degradation Using Abnormality Monitoring

Mirroring Controller uses a monitoring method that outputs an error if the timeout or number of retries is exceeded when accessing resources targeted for monitoring. Setting inappropriate values in these settings may lead to misdetection or a delay in automatic degradation, so you must design these values appropriately.

For example, the following type of issue occurs if the tuning related to abnormality monitoring is not performed appropriately.

- If the timeout is too short

  Results in redundant degradation and availability falls.

- If the timeout is too long

  It takes longer for automatic degradation to be performed even when an error affecting operational continuity occurs, potentially causing downtime.

You can optimize degrading operation by editing the values for the parameters in the server configuration file described below in accordance with the system. Refer to "A.4 Server Configuration File" for information on how to edit these parameters.

2.11.4.1 Tuning for Abnormality Monitoring of the Operating System or Server

Tuning for abnormal monitoring of the operating system or server depends on the operation when heartbeat abnormality is detected by the heartbeat monitoring of operating systems or servers.

See

Refer to "1.1.1 Monitoring Using Database Multiplexing Mode" for the operation when heartbeat abnormality is detected in the the heartbeat monitoring of operating systems or servers.

2.11.4.1.1 Tuning Abnormality Monitoring for Operations that Use an Arbitration Server for Automatic Degradation

In an operation that use an arbitration server for automatic degradation, the database server is periodically monitored for abnormalities so that the Mirroring Controller arbitration process can immediately respond to an arbitration request from the Mirroring Controller.The automatic degradation using the arbitration server can optimize the time from error detection to automatic degradation of the operating systems or servers by editing the following parameters.

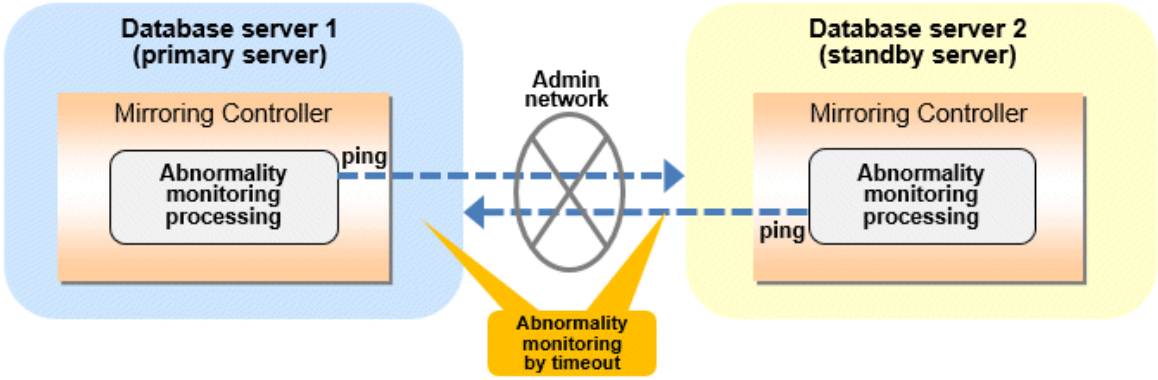
- Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server
- Parameters for the abnormality monitoring of the operating system or server in the arbitration configuration file
- Parameters for the arbitration processing and fencing

Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server

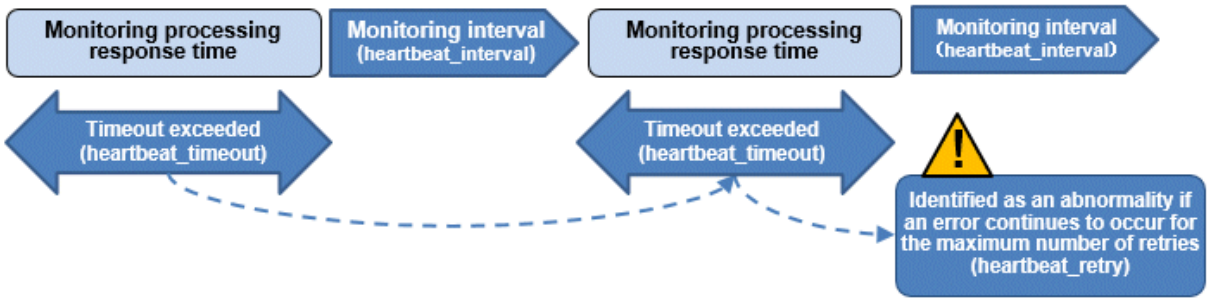
Table 2.10 Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server

Parameter	Description
Abnormality monitoring interval (heartbeat_interval)	Mirroring Controller is configured so that abnormality monitoring does not place a load on the system. This parameter does not normally need to be set. (The default is 800 milliseconds.)

Parameter	Description
Abnormality monitoring timeout (heartbeat_timeout)	Take into account the time during which a load is placed continuously on the server or admin network performance. For example, it is envisaged that this parameter will be used in situations such as when performing high-load batch jobs or when a large number of online jobs occur continuously and concurrently. (The default is 1 second.)
Abnormality monitoring retries (heartbeat_retry)	This parameter can be set when needing a safety value for situations in which the value specified for heartbeat_timeout is exceeded, for example, when using systems with fluctuating loads, however, this parameter does not normally need to be set. (The default is 2 times.)



Flow of abnormality monitoring by timeout



The expression for calculating the time required to detect an abnormality by Mirroring Controller is shown below.

```
Abnormality detection time of Mirroring Controller = ( heartbeat_timeout(seconds) +
heartbeat_interval(milliseconds) / 1000 ) x ( heartbeat_retry(number of times) + 1)
```

The abnormality detection time when the default value is used is shown below.

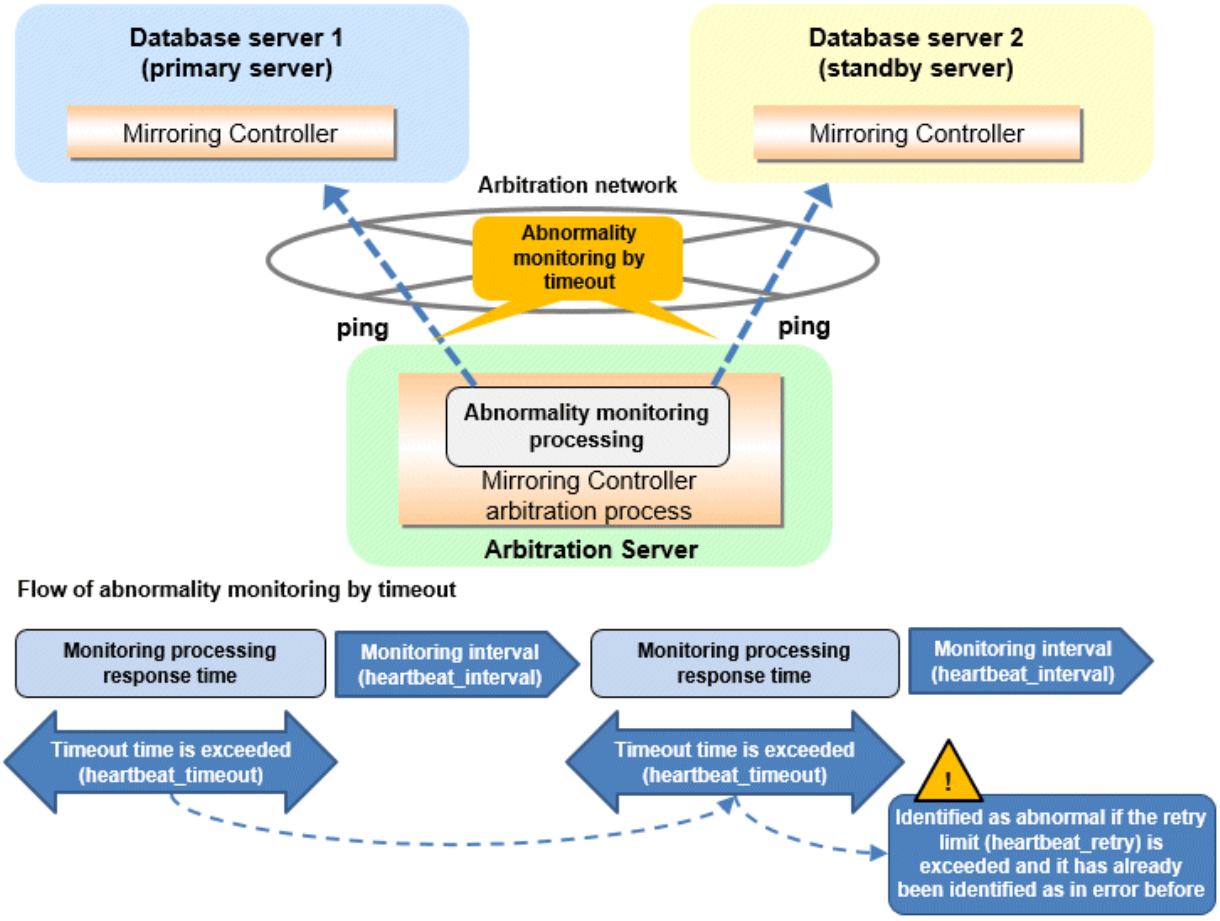
```
Abnormality detection time of Mirroring Controller = ( 1 + 800 / 1000 ) x ( 2 + 1 )
             = 5.4(seconds)
```

Parameters for the abnormality monitoring of the operating system or server in the arbitration configuration file

Table 2.11 Parameters for the abnormality monitoring of the operating system or server in the arbitration configuration file

Parameter	Description
Abnormality monitoring interval (heartbeat_interval)	Mirroring Controller arbitration process is configured so that abnormality monitoring does not place a load on the system. This parameter does not normally need to be set. (The default is the value set in heartbeat_interval in the server configuration file of the database server.) (milliseconds).

Parameter	Description
Abnormality monitoring timeout (heartbeat_timeout)	Take into account the time during which a load is placed continuously on the server and arbitration network capabilities. (The default is the value set in heartbeat_timeout in the server configuration file of the database server.) (seconds).
Abnormality monitoring retries (heartbeat_retry)	This parameter can be set when needing a safety value for situations in which the value specified for heartbeat_timeout is exceeded, for example, when using systems with fluctuating loads, however, this parameter does not normally need to be set. (The default is the value set in heartbeat_retry in the server configuration file of the database server.) (number of times)



The expression for calculating the time required to detect an abnormality by Mirroring Controller arbitration process is shown below.

```
Abnormality detection time of Mirroring Controller arbitration process = ( heartbeat_timeout(seconds)
+ heartbeat_interval(milliseconds) / 1000 ) x ( heartbeat_retry(number of times) + 1)
```

The abnormality detection time when the default value is used is shown below.

```
Abnormality detection time of Mirroring Controller arbitration process = ( 1 + 800 / 1000 ) x ( 2 + 1 )
            = 5.4(seconds)
```

Point

- The abnormality detection time of the operation for automatic degradation using the arbitration server can be calculated as follows.

```
Abnormality detection time = Max(Abnormality detection time by Mirroring Controller, Abnormality
detection time by Mirroring Controller arbitration process)
```

- If the heartbeat_interval is set in the arbitration configuration file, the relationship between the parameter for operating system or server abnormality monitoring specified in the server configuration file of the database server file and the heartbeat_interval of the arbitration configuration file must satisfy the following relational expression.

```
 Heartbeat_interval in the arbitration configuration file (milliseconds) / 1000 ) <
( heartbeat_timeout(seconds) + heartbeat_interval(milliseconds) / 1000 ) * heartbeat_retry(number
of times) + heartbeat_timeout(seconds)
```

Parameters for the arbitration processing and fencing

Table 2.12 Parameters for the arbitration processing and fencing

Parameter	Description
Arbitration processing timeout (arbitration_timeout in the server configuration file of the database server)	Take into account the time to perform arbitration processing on the Mirroring Controller arbitration process. The value must be greater than or equal to abnormality detection time of Mirroring Controller arbitration process + fencing_command_timeout in the arbitration configuration file (seconds).
Fencing timeout (fencing_command_timeout in the arbitration configuration file)	Take into account the time to execute the fencing command (seconds).

Information

If the fencing_command parameter is specified in the server configuration file of the database server, the fencing command is invoked on the database server if fencing is successful on the arbitration server. In that case, add the value of the fencing_command_timeout parameter in the server configuration file of the database server to the estimate.

Flow from the abnormality detection to the automatic degeneracy

When performing automatic degradation using the arbitration server, the flow from the abnormality detection in the operating system or server to the occurrence of automatic degeneracy and the parameters is shown below.

Flow from the abnormality detection to the automatic degeneracy	Description	Parameter	
(1) Abnormality detection	Mirroring Controller detect the database server operating system or server errors.	Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server	
(2) Arbitration request	Mirroring Controller that detect the operating system or server error asks the Arbitration Server to check the status of the other server's operating system or server.	-	arbitration_timeout in the server configuration file of the database server
(3) Arbitration processing	The Mirroring Controller arbitration process checks the status of the other server's operating system or server. However, if the result of the operating system or server abnormality	Parameters for the abnormality monitoring of the operating system or	

Flow from the abnormality detection to the automatic degeneracy	Description	Parameter	
	monitoring by the arbitration server has been determined before the arbitration request from the Mirroring Controller of the database server, this process is not performed.	server in the arbitration configuration file	
(4) Fencing	If the Mirroring Controller arbitration process determines that the other server is an abnomaly of the operating system or server, it fences the other server and isolates it from the cluster system. If the Mirroring Controller arbitration process determines that the operating system or server status is normal, this process and the (6) are not performed.	fencing_command_timeout in the arbitration configuration file	
(5) Return of the arbitration results	Returns the results of the arbitration to the Mirroring Controller of the database server that requested the arbitration.	-	
(6) Automatic degradation	The automatic degradation is performed. If fencing fails in (4), this procedure is not performed.	-	

-: No associated parameters

Figure 2.1 When the Mirroring Controller on the primary server detects an operating system or server error

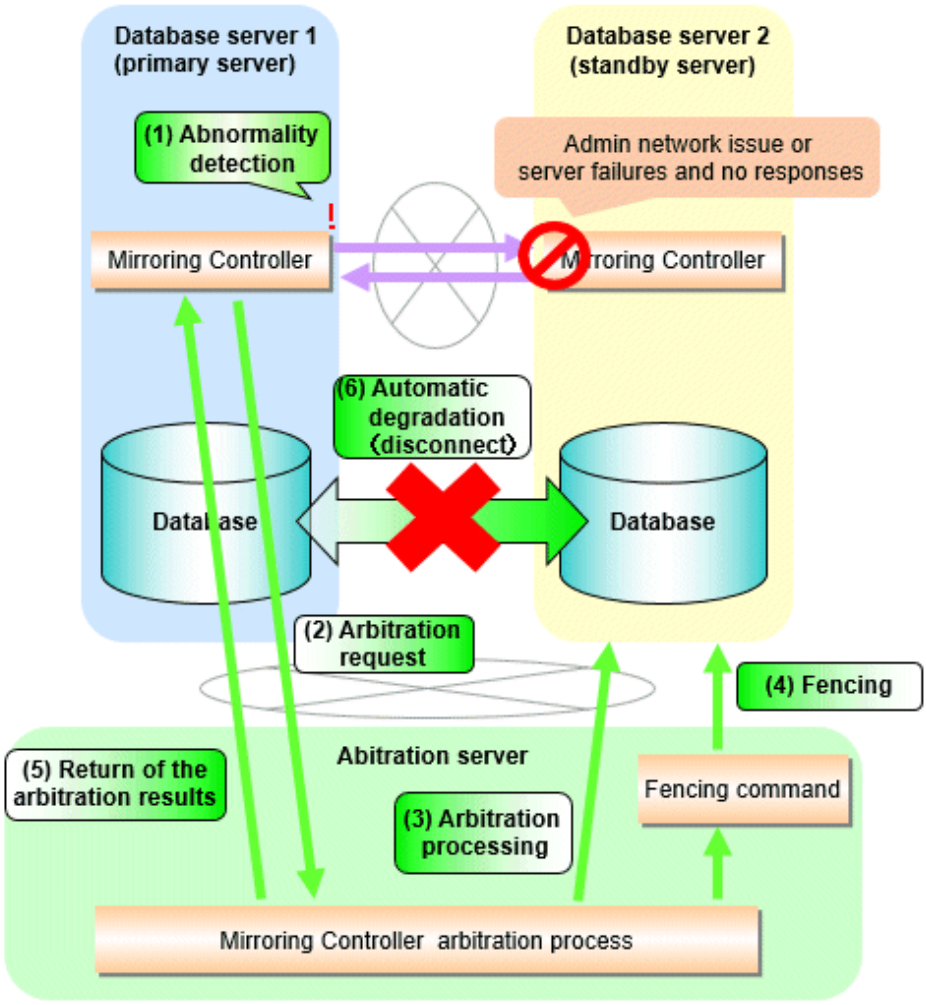

Figure 2.2 When the Mirroring Controller on the standby server detects an operating system or server error

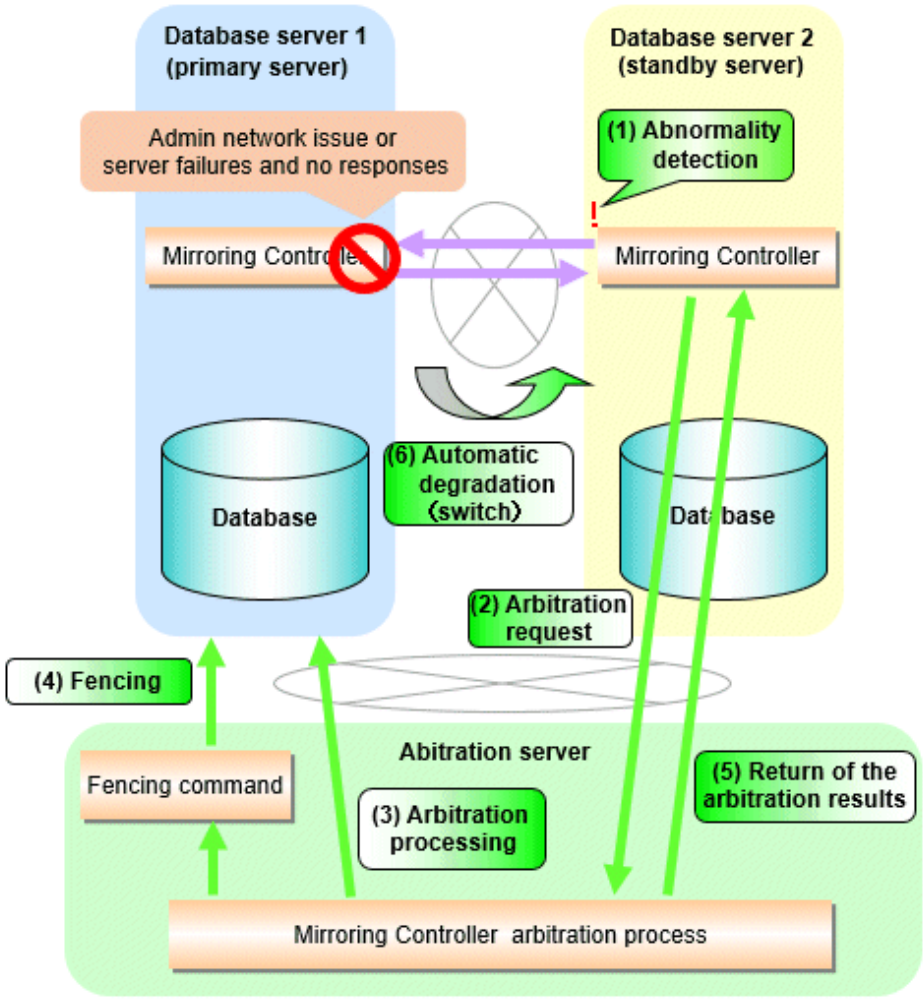

2.11.4.1.2 Tuning Abnormality Monitoring for Operations that Perform Automatic Degradation by Calling a User Exit that Determines Degradation

In an operation that perform automatic degradation by calling a user exit that determines degradation, you can optimize the time from operating system or server abnormality detection to automatic degradation by editing the operating system or server abnormality monitoring parameters and parameters related to arbitration processing and fencing in the server configuration file of the database server. Refer to "Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server" for information on the operating system or server abnormality monitoring parameters in the server configuration file of the database server.

Table 2.13 Parameters for the arbitration processing and fencing

Parameter	Description
Arbitration processing timeout (arbitration_command_timeout)	Take into account the time to execute the arbitration command(seconds).
Fencing timeout (fencing_command_timeout)	Take into account the time to execute the fencing command (seconds).

Flow from the abnormality detection to the automatic degeneracy

When performing automatic degradation by calling a user exit that determines degradation, the flow from the abnormality detection in the operating system or server to the occurrence of automatic degeneracy and the parameters is shown below.

Flow from the abnormality detection to the automatic degeneracy	Description	Parameter
(1) Abnormality detection	Mirroring Controller detect the database server operating system or server errors.	Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server
(2) Arbitration processing	An arbitration command is executed to check the status of the other server's operating system or server.	arbitration_command_timeout in the server configuration file of the database server
(3) Fencing	If the operating system or server status of the other server is abnomal in (2), it fences the other server and isolates it from the cluster system. If the operating system or server status of the other server is nomal in (2), this process and (4) are not executed.	fencing_command_timeout in the server configuration file of the database server
(4) Automatic degradation	The automatic degradation is performed. If fencing fails in (3), this procedure is not performed.	-

-: No associated parameters

Figure 2.3 When the Mirroring Controller on the primary server detects an operating system or server error

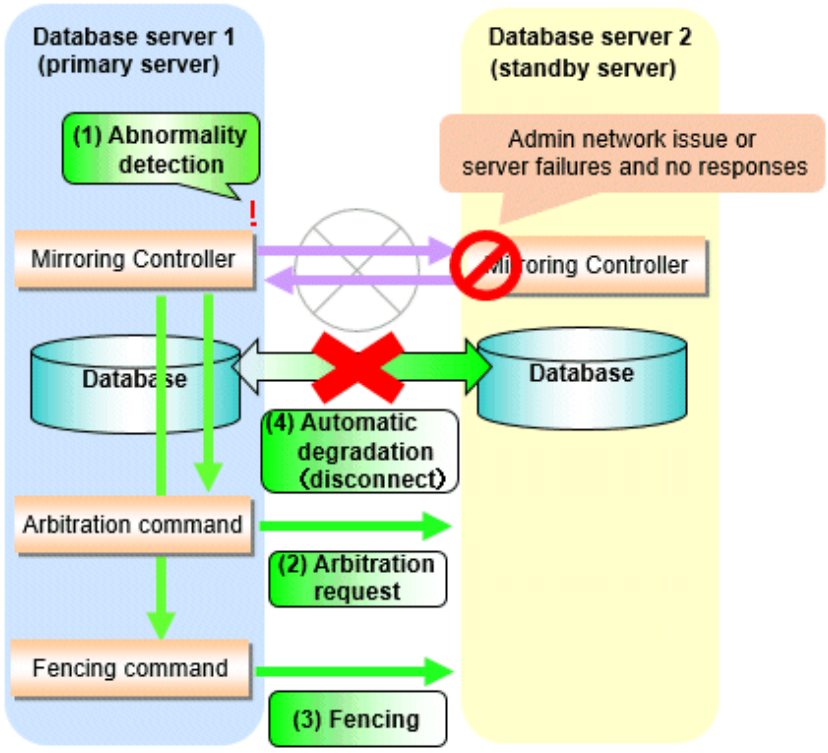

Figure 2.4 When the Mirroring Controller on the standby server detects an operating system or server error

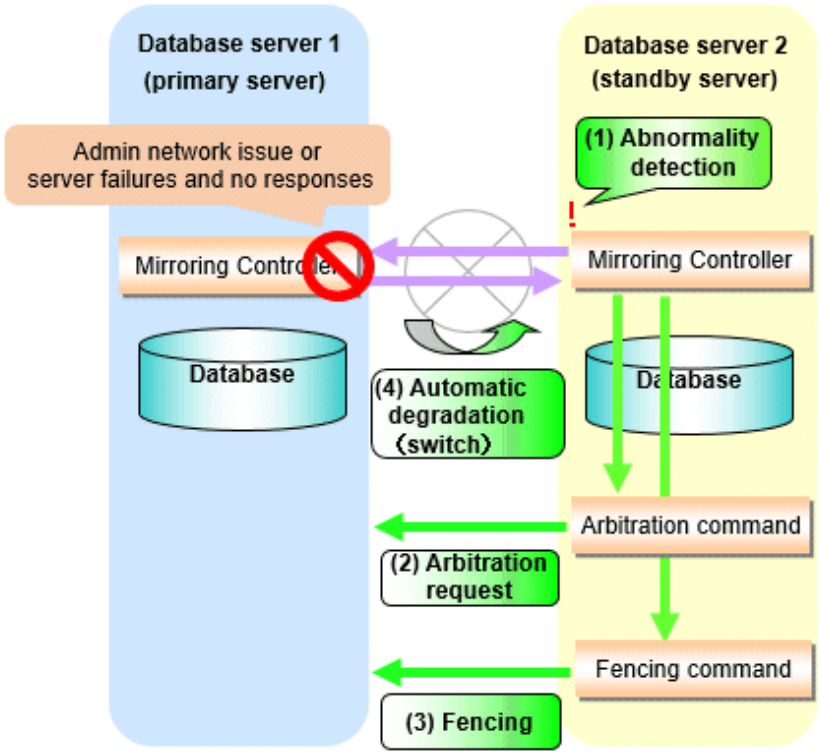


2.11.4.1.3 Tuning Abnormality Monitoring for Operations that Notify Messages

In an operation that notify messages, you can optimize the abnormality detection time by editing the operating system or server abnormality monitoring parameters in the server configuration file of the database server. Refer to "Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server" for information on the operating system or server abnormality monitoring parameters in the server configuration file of the database server. In addition, when the Mirroring Controller detects an error, it does not perform the arbitration processing, fencing, or automatic degradation, but only notification messages is performed.

2.11.4.1.4 Tuning Abnormality Monitoring for Operations that Perform Automatic Degenerate Unconditionally due to Heartbeat Abnormality

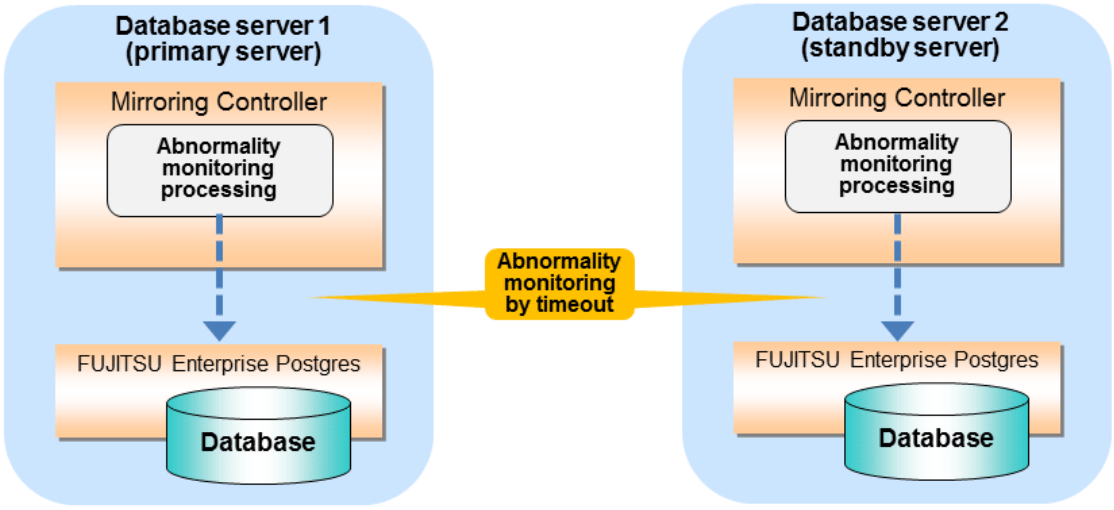
In an operation that perform automatic degenerate unconditionally due to heartbeat abnormality, you can optimize the time from operating system or server abnormality detection to automatic degradation by editing the operating system or server abnormality monitoring parameters in the server configuration file of the database server. Refer to "Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server" for information on the operating system or server abnormality monitoring parameters in the server configuration file of the database server. In addition, when the Mirroring Controller detects an error, it does not perform the arbitration processing, fencing, or automatic degradation, but only automatic degenerate unconditionally is performed. Refer to "Appendix D Notes on Performing Automatic Degradation Immediately after a Heartbeat Abnormality" for notes on the operation that perform automatic degenerate unconditionally due to heartbeat abnormality.

2.11.4.2 Tuning for Abnormality Monitoring of Darabase Processes

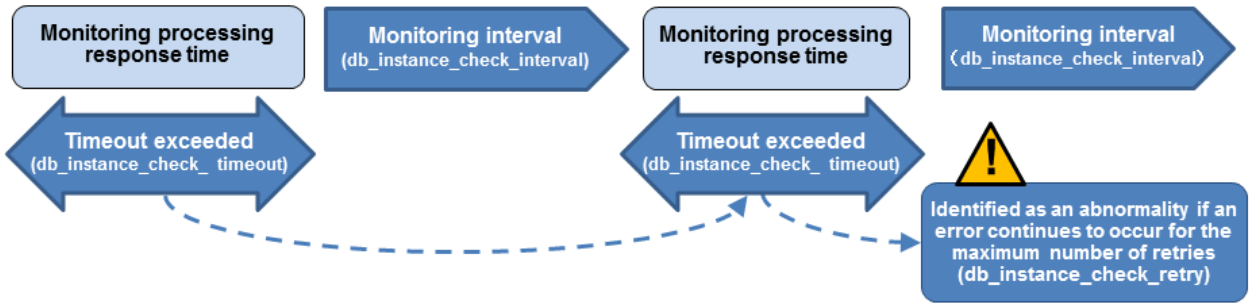
You can optimize database pocesses abnormality monitoring by editing the following parameters in the server configuration file of the database server.

Table 2.14 Parameters for abnormality monitoring of database processes

Parameter	Description
Abnormality monitoring interval (db_instance_check_interval)	Abnormality monitoring by Mirroring Controller is set so as not to place load on the system, but normally it does not need to be set. (The default is the value set in heartbeat_interval.) (milliseconds)
Timeout for abnormality monitoring of database processes (db_instance_check_timeout)	Take into account the time during which a load is placed continuously on the database. For example, it is envisaged that this parameter will be used in situations such as when performing high-load batch jobs or when a large number of online jobs occur continuously and concurrently. (The default is the value set in heartbeat_timeout.) (seconds)
Abnormality monitoring retries (db_instance_check_retry)	This parameter can be set when needing a safety value for situations in which the value specified for db_instance_check_timeout is exceeded, for example, when using systems with fluctuating loads, however, this parameter does not normally need to be set. (The default is the value set in heartbeat_retry.) (number of times)



Flow of abnormality monitoring by timeout



The expression for calculating the time required to detect an abnormality is shown below.

```
Abnormality detection time = ( db_instance_check_timeout(seconds) +
db_instance_check_interval(milliseconds) / 1000 ) x ( db_instance_check_retry(number of times) + 1 )
```

The abnormality detection time when the default value is used is shown below.

```
Abnormality detection time = ( 1 + 800 / 1000 ) x ( 2 + 1 )
            = 5.4(seconds)
```

Information

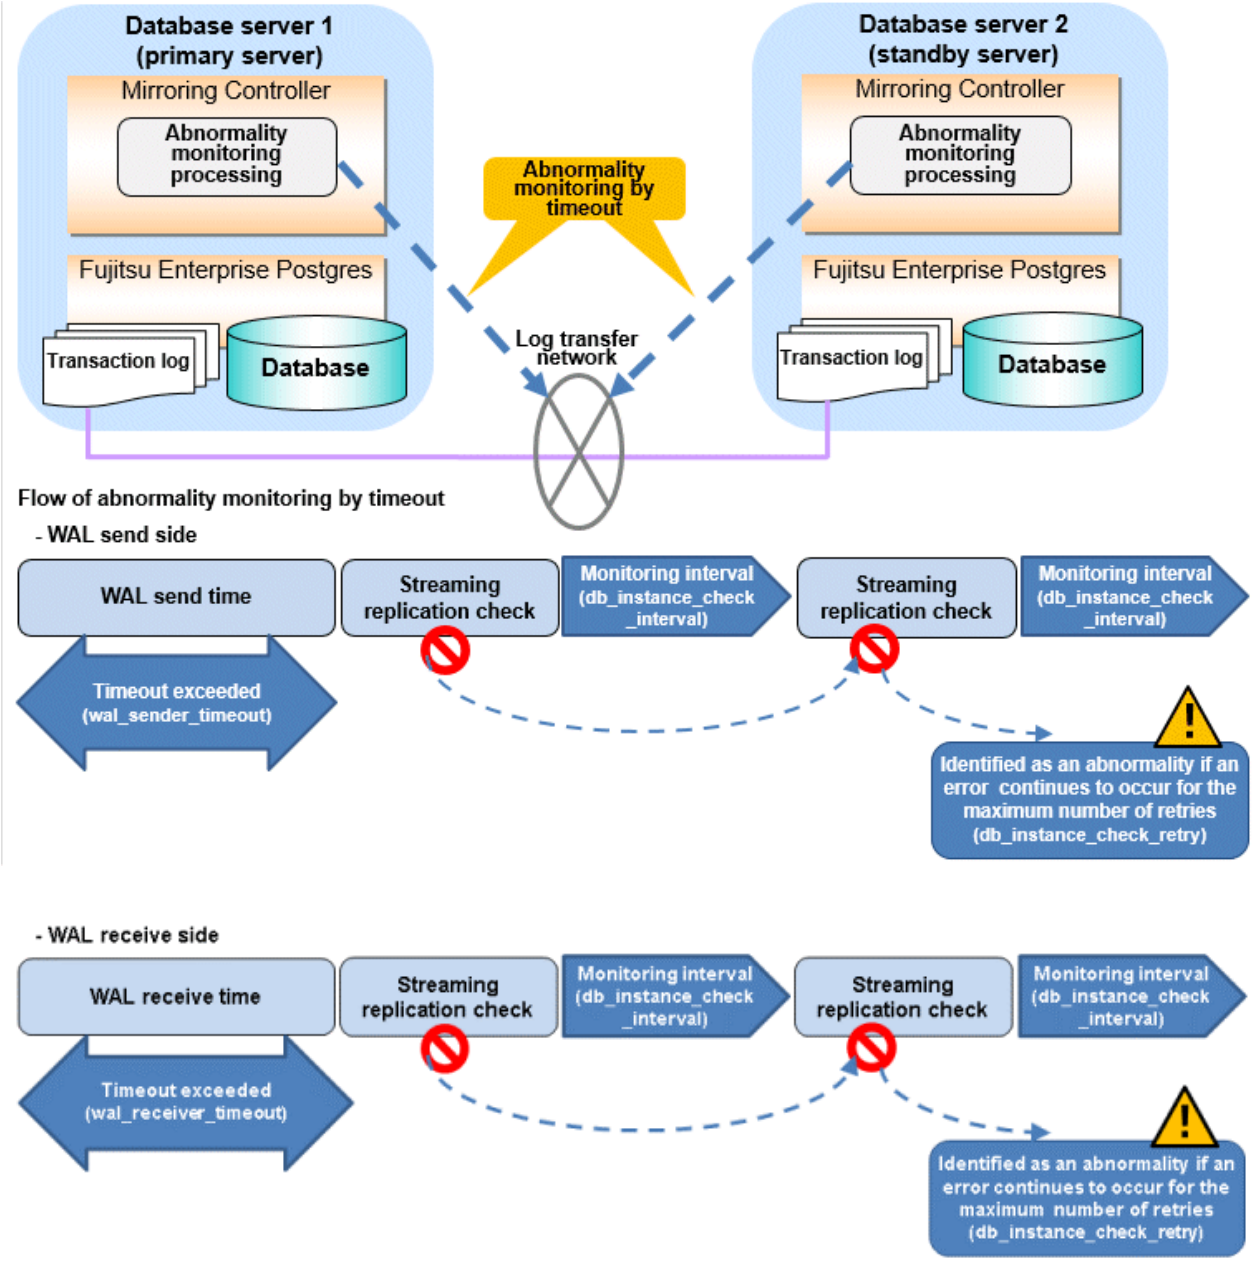
- If the db_instance_timeout_action parameter in *serverIdentifier*.conf is set to "message", and the db_instance_check_timeout parameter is set to a short value, a crash of the database process will be detected as "no response", and it may take time for automatic degradation to occur. Therefore, specify an appropriate timeout for db_instance_check_timeout.
- If a high load on the database and an event that prevents connection to an instance occur at the same time, it is judged as abnormal without retrying monitoring.

2.11.4.3 Tuning for Abnormality Monitoring of Streaming Replication

You can optimize streaming replication abnormality monitoring by editing the following parameters in the server configuration file of the database server.

Table 2.15 Parameters for abnormality monitoring of streaming replication

Parameter	Description
Abnormality monitoring interval (db_instance_check_interval)	Abnormality monitoring by Mirroring Controller is set so as not to place load on the system, but normally it does not need to be set. (The default is the value set in heartbeat_interval.) (milliseconds)
Abnormality monitoring retries (db_instance_check_retry)	This parameter can be set when needing a safety value, such as when it is anticipated that a temporary log transfer LAN error may occur, but it does not normally need to be set. (The default is the value set in heartbeat_retry.) (number of times)
Timeout for abnormality monitoring of streaming replication (wal_sender_timeout and wal_receiver_timeout in postgresql.conf)	Take into account the capacity and load of the log transfer network and the time during which a load is placed continuously on the database. For example, if there is a succession of data update jobs that generate a high WAL volume, you must configure the settings to avoid misdetection. (The default is 60 seconds.)



The expression for calculating the time required to detect an abnormality is shown below.

```
Abnormality detection time = ( wal_sender_timeout(seconds) +
db_instance_check_interval(milliseconds) / 1000 x ( disk_check_retry(number of times) + 1 ) )  Or,
            = ( wal_receiver_timeout(seconds) + db_instance_check_interval(milliseconds) / 1000 x
( disk_check_retry(number of times) + 1 ) )
```

The abnormality detection time when the default value is used is shown below.

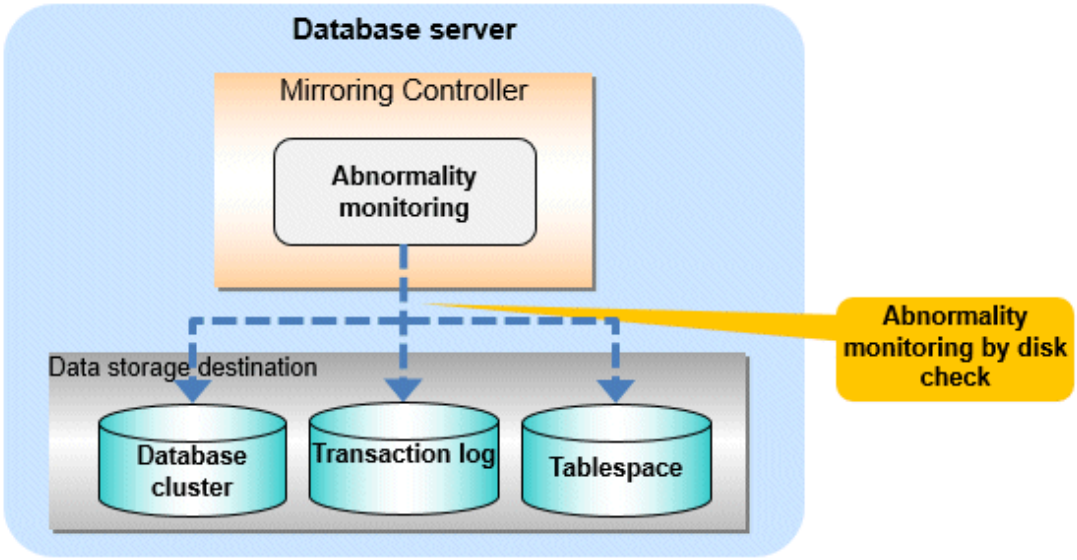
```
Abnormality detection time = 60 + (800 / 1000 x (2 + 1))
            = 62.4(seconds)
```

2.11.4.4 Tuning for Disk Abnormality Monitoring

You can optimize disk abnormality monitoring by editing the following parameters in the server configuration file of the database server.

Table 2.16 Parameters for disk abnormality monitoring

Parameter	Description
Abnormality monitoring interval (disk_check_interval)	Abnormality monitoring by Mirroring Controller is set so as not to place load on the system, but normally it does not need to be set. Set a value larger than the disk access time. (The default is the value set in heartbeat_interval.) (milliseconds)
Abnormality monitoring retries (disk_check_retry)	This parameter can be set when needing a safety value, such as when it is anticipated that a temporary disk input/output error may occur, but normally it does not need to be set. (The default is the value set in heartbeat_retry.) (number of times)
Abnormality monitoring timeout time (disk_check_timeout)	The time allowed from the start time of the next disk_check_interval after a disk error occurs until the error is determined to be due to timeout. (The default is 2147483.) (seconds). You can specify an integer between 0 and 2147483.
Upper limit on the number of threads used for abnormality monitoring (disk_check_max_threads)	Upper limit on the number of threads for disk monitoring. (The default is the number of processors available to the JVM.) You can specify an integer between 1 and 2147483647, but setting a value greater than the threads available on the machine may result in a system error. When you run the mc_ctl status command separately from the monitoring process, each mc_ctl status temporarily uses the same number of threads as the monitoring process. When setting disk_check_max_threads, consider the machine's thread limit, the number of tablespaces you plan to use, and the number of mc_ctl status commands that may be executed at the same time.



In disk error monitoring, a disk check is performed, and degradation is performed when an error is first detected within the error detection time or the time set in disk_check_timeout. However, in order to disconnect the standby server when disk_check_timeout detects an error on the standby server, shutdown_detached_synchronous_standby must be set to on.

The following shows how to calculate the abnormality detection time (the time until an error is determined).

```
Abnormality detection time = disk_check_interval (milliseconds) / 1000 x ( disk_check_retry(number of
times) + 1 )
```

The abnormality detection time when the default value is used is shown below.

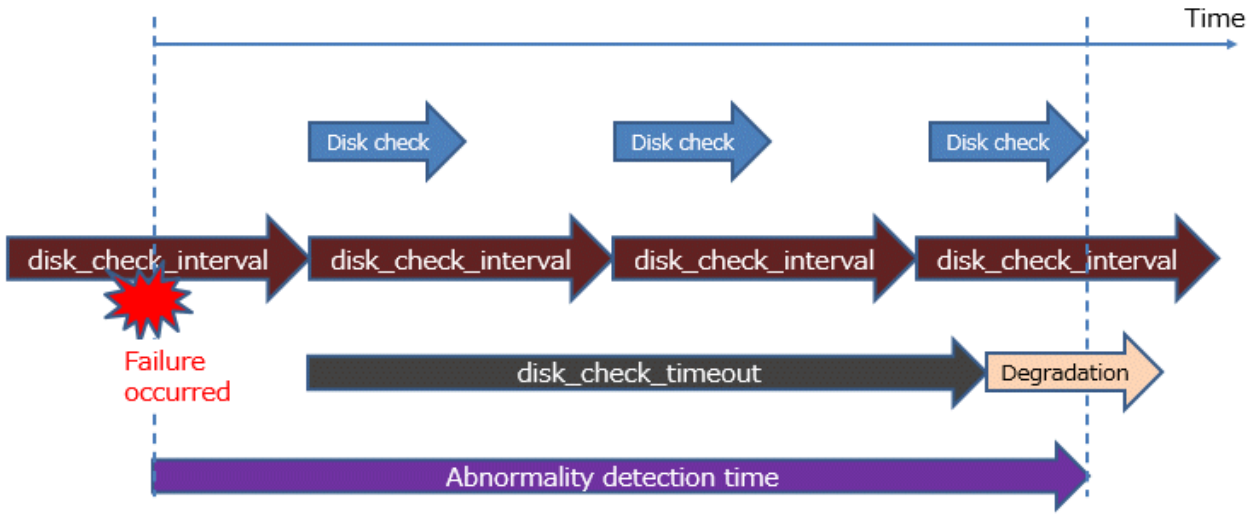
```
Abnormality detection time = 800 / 1000  x ( 2 + 1 )
            = 2.4(seconds)
```

An example of detecting disk abnormality monitoring is shown below.

Example 1)

One thread monitors one disk, set disk_check_retry = 2.

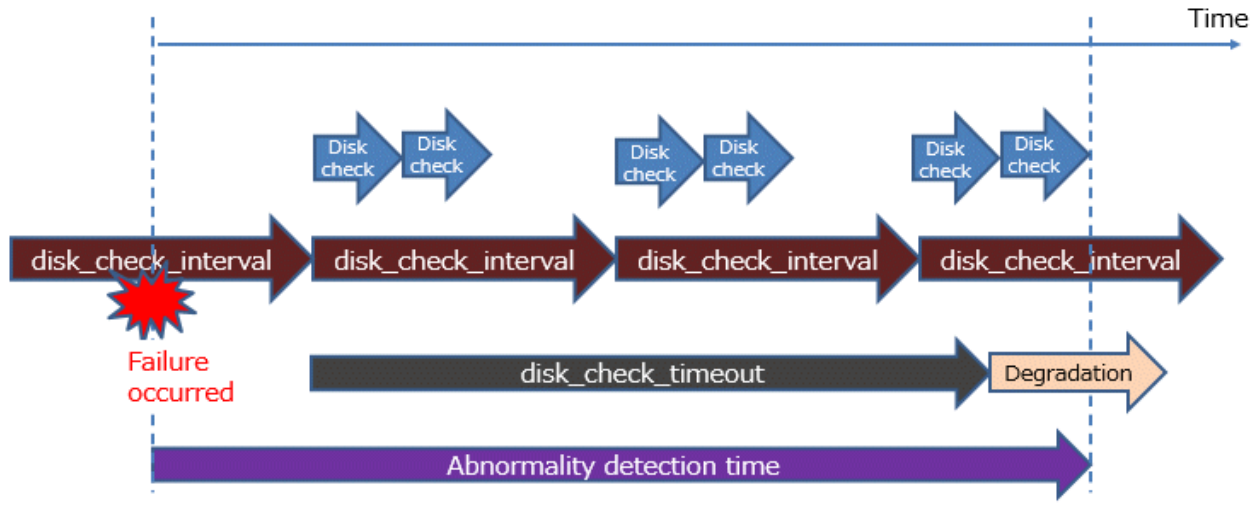
When the read or write cannot be completed within the disk access time because the response to the disk is slow.



Example 2)

One thread monitors two disks, set disk_check_retry = 2.

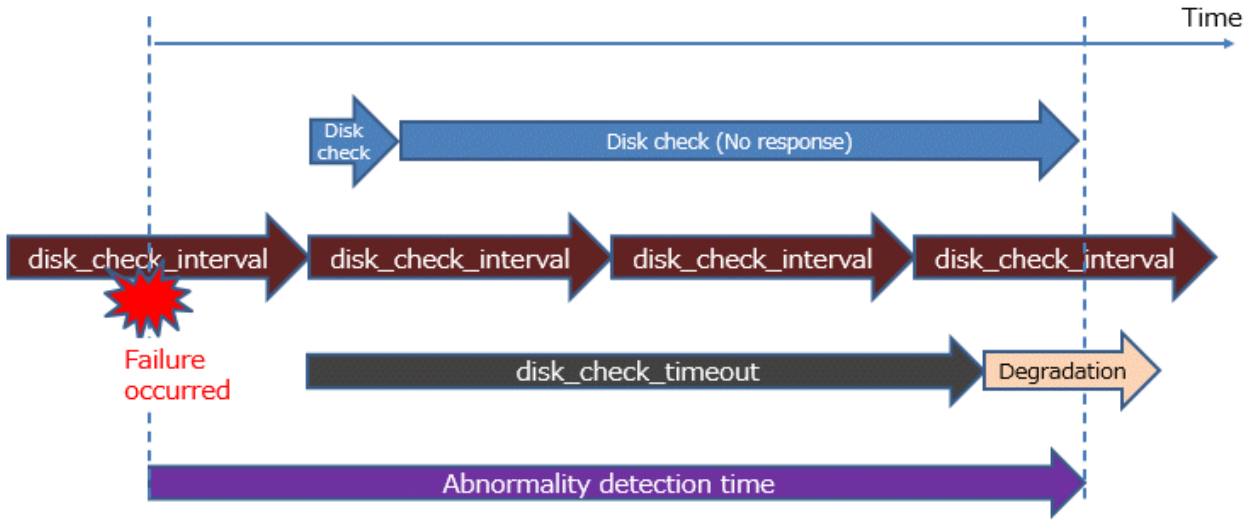
Due to the slow response to the disk, reading or writing to disk 1 could not be completed within the disk access time on the first and second attempts, but the reading or writing was successful on the third retry. All reads or writes to disk 2 fail within the disk access time.



Example 3)

One thread monitors two disks, set disk_check_retry = 2.

If disk 2 becomes unresponsive and monitoring results cannot be obtained within the timeout period.



Information

- The tuning described above impacts on the time taken from detection of a timeout until switching the primary server. Therefore, modify the values while taking into account the switch/disconnection time, using a design for which misdetection does not occur.
- Immediately selecting automatic degradation when a heartbeat abnormality occurs in operating system or server heartbeat monitoring risks causing split brain. Refer to "Appendix D Notes on Performing Automatic Degradation Immediately after a Heartbeat Abnormality" for details.
- Mirroring Controller uses connections to database instances and SQL access to monitor abnormality in some resources targeted for monitoring. The connection destination database names and connection user names used for abnormality monitoring conform to the parameters in the server configuration file. The application name is "mc_agent".

2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances

Multiplexed instances and Mirroring Controller can be started and stopped automatically in line with the starting and stopping of the operating system of the database server.

Perform the following procedure:

1. Create a unit file

   Copy the unit file sample stored in the directory below, and revise it to match the target instance.

   Sample file

   ```
   /installDir/share/mcoi.service.sample
   ```

   Example)

   In the following example, the installation directory is "/opt/fsepv<x>server64", and the instance name is "inst1". Note that "<x>" indicates the product version.

   ```
   # cp /opt/fsepv<x>server64/share/mcoi.service.sample /usr/lib/systemd/system/mcoi_inst1.service
   ```

   Revise the underlined portions of the options below in the unit file.

   Also, because starting the database instance or Mirroring Controller requires time correction, opening the network environment, and other synchronization steps, modify the unit that starts first in the After option of the unit file as appropriate.

Section	Option	Specified value	Description
Unit	Description	Fujitsu Enterprise Postgres MirroringController *instanceName*	Specifies the feature overview. Specifies the name of the target instance. (*1)
Service	ExecStart	/bin/bash -c '*installDir*/bin/mc_std start *installDir* *MirroringControllerManagementDir*' *mc_ctlOption*'	Command to be executed when the service is started. Specify the option you want to add when the mc_ctl command (start mode) is executed without the -M option in the mc_ctl option. Note that the content specified in this mc_ctl option is carried over from the mc_std command to the mc_ctl command.
	ExecStop	/bin/bash -c '*installDir*/bin/mc_std stop *installDir* *MirroringControllerManagementDir*' *mc_ctlOption*'	Command to be executed when the service is stopped. Specify the option you want to add when the mc_ctl command (stop mode) is executed without the -M option in the mc_ctl option. However, you cannot specify the -a option, which also stops the Mirroring Controller process on the other server. Note that the content specified in this mc_ctl option is carried over from the mc_std command to the mc_ctl command.
	User	User	OS user account of the instance administrator user.
	Group	Group	Group to which the instance administrator user belongs.

*1: The instance name should be as nameThatIdentifiesTheInstance.
The naming conventions for identifying the instance are as follows:

- Up to 16 bytes
- The first character must be an ASCII alphabetic character
- The other characters must be ASCII alphanumeric characters

2. Enable automatic start and stop

   As the OS superuser, use the systemctl command to enable automatic start and stop.

   Example)

```
# systemctl enable mcoi_inst1.service
```

Information

Since Mirroring Controller is automatically started and stopped on each server in accordance with the startup and shutdown of the OS, to prevent unnecessary automatic switching or errors by Mirroring Controller, start it from the OS of the primary server and stop it from the OS of the standby server.

Point

- The sample unit file assumes that the Mirroring Controller service will automatically start and stop the database instance at the same time, but it can be customized according to the operation. For example, if you want to stop only the Mirroring Controller process while the database is running, create the Mirroring Controller and the database instance as separate services. In addition, by linking these services, you can automatically start and stop the Mirroring Controller and the multiplexed instances.
  - Create a unit file for the multiplexed instances

  - In the Mirroring Controller unit file, specify the --mc-only mc_ctl option and define the dependency relationship with the multiplexed instance service and the order in which the instance will start after the service has started

- When using an arbitration server to perform automatic degradation, if you are considering starting the Mirroring Controller process on the database server before starting the Mirroring Controller arbitration process on the arbitration server, specify the --async-connect-arbiter option in the mc_ctl option and start the Mirroring Controller process.
- After the Mirroring Controller process is started by system service management using systemctl, you can use the mc_ctl command to display the server status, switch, and disconnect the server.
- To stop Mirroring Controller, use the systemctl command as an OS superuser, not the mc_ctl command.

  Example)

```
# systemctl stop mcoi_inst1.service
```

  If the instance does not stop, refer to "Actions in Response to Failure to Stop an Instance" in the Operation Guide to stop the instance. Then, specify the -e option in the mc_ctl command to forcibly stop Mirroring Controller.

  Example)

```
$ mc_ctl stop -M /mcdir/inst1 -e
```

  If Mirroring Controller is stopped using the mc_ctl command, the message below is output to the system log, however there is no issue because automatic stop is executed by systemd.

  Message

```
FATAL: failed to stop Mirroring Controller target server:"{0}" (MCA00043)
```

See

- For information about creating a unit file for a database instance, refer to "Configuring Automatic Start and Stop of an Instance" in the Installation and Setup Guide for Server.
- For more information about unit files, refer to the documentation from your vendor.

2.13 Setting Automatic Start and Stop of the Mirroring Controller Arbitration Process

You can automatically start or stop the Mirroring Controller arbitration process when the operating system on the arbitration server is started or stopped.

Linux

Perform the following procedure:

1. Create a unit file.

   Copy the unit file sample stored in the directory below, and revise it to match the target instance.

   Sample file

```
/installDir/share/mcarboi.service.sample
```

   Example)
   In the following example, the installation directory is "/opt/fsepv<x>assistant", and the identifier of the arbitration process is "arbiter1". Note that "<x>" indicates the product version.

```
# cp /opt/fsepv<x>assistant/share/mcarboi.service.sample /usr/lib/systemd/system/
mcarboi_arbiter1.service
```

Revise the underlined portions of the options below in the unit file.

Also, because starting the Mirroring Controller arbitration process requires time correction, opening the network environment, and other wait times, modify the unit that starts first in the After option of the unit file as appropriate.

Section	Option	Specified value	Description
Unit	Description	Fujitsu Enterprise Postgres Mirroring Controller Arbiter <*arbitrationProcessId*>	Specifies the feature overview. Specifies the identifier of the targeted arbitration process. (*1)
Service	ExecStart	/bin/bash -c '*installDir*/bin/mc_arb_std start *installDir mirroringControllerArbitrationProcessMgmtDir mc_arbOption*'	Command to be executed when the service is started. Specify the option you want to add when the mc_arb command (start mode) is executed without the -M option in the mc_arb option. Note that the content specified in this mc_arb option is carried over from the mc_arb_std command in "Specified value" to the mc_arb command.
	ExecStop	/bin/bash -c '*installDir*/bin/ mc_arb_std stop *installDir mirroringControllerArbitrationProcessMgmtDir mc_arbOption*'	Command to be executed when the service is stopped. Specify the option you want to add when the mc_arb command (stop mode) is executed without the -M option in the mc_arb option. Note that the content specified in this mc_arb option is carried over from the mc_arb_std command in "Specified value" to the mc_arb command.
	User	User	Specify the account of the operating system user.
	Group	Group	Specify the group to which the user belongs.

*1: The arbitration process identifier used here is a name for identifying the Mirroring Controller arbitration process.

The naming conventions for identifying the Mirroring Controller arbitration process are as follows:

- Up to 16 bytes

- The first character must be an ASCII alphabetic character

- The other characters must be ASCII alphanumeric characters

2. Enable automatic start and stop.

   As the operating system superuser, use the systemctl command to enable automatic start and stop.

   Example)

```
# systemctl enable mcarboi_arbiter1.service
```

Windows

You can configure the Windows service to perform automatic start and stop.

Configuring during setup

When registering the Mirroring Controller arbitration process as a Windows service in "2.3.1 Configuring the Arbitration Server", specify "auto" for the -S option of the register mode used with the mc_arb command.

Example)

```
> mc_arb register -M D:\mcdir\inst1 -P ******** -S auto
```

Changing the configuration after setup

Use the sc config command to change the configuration of the Windows service of the Mirroring Controller arbitration process.

Example)
The configuration of the registered service name "Mirroring_Controller_Arbiter1" is changed.

```
> sc config "Mirroring_Controller_Arbiter1" start= auto
```

See

Refer to sc command help for information on how to configure the service.

Information

You can check the registration status in the Windows service window or by using the sc qc command.

2.14 Backup Operation

This section explains the backup operation for database multiplexing mode.

2.14.1 Backing up Database Multiplexing Mode Information

When changing the Mirroring Controller settings, in addition to backing up the database, back up the configuration file in the Mirroring Controller management directory so that the Mirroring Controller settings are not lost.

When the arbitration server is used for automatic degradation, also back up the configuration file in the Mirroring Controller arbitration process management directory.

2.14.2 Database Backup Operation

Using database multiplexing mode is the same as obtaining the backup data on the standby server as a safeguard against a disk failure. Note that all server disks may be corrupted due to some cause.

As a safeguard against this type of case, execute the pgx_dmpall command on the primary server to create the backup data.

However, it is not definite as to which server runs as the primary server, so ensure that the pgx_dmpall command is executed periodically on all servers, so that the backup data will be obtained. For example, create a script to obtain the backup data, and set it in the operation management software.

Point

When the pgx_dmpall command is executed on the standby server, it will not match the statuses, however the error message shown below will be output and return the value "1".

If a script that ignores only this type of error is executed on all servers, the backup data of the primary server can be obtained.

Error message

```
ERROR:recovery is in progress (10095)
```

Information

- Consider the possibility that the server that runs as the primary server may be destroyed alongside the backup data, so it is recommended to promote another server to become the primary server, and then back up the data on the new primary server without waiting for the next scheduled backup.
- Specify the same backup directory name for the primary and standby servers. If different backup directory names are specified, and recovery is performed using the backup data of the other server, the recovery cannot be performed correctly.

See

- Period backups allow shorter recovery time and reduction in disk usage. Refer to "Backing Up the Database" in the Operation Guide for details on the backup operation.
- Refer to "Chapter 4 Action Required when an Error Occurs in Database Multiplexing Mode" for details on recovery based on the backup data that was obtained using the pgx_dmpall command.

Chapter 3 Operations in Database Multiplexing Mode

This chapter describes the periodic operations that are performed when running database multiplexing mode.

The periodic operations are the same as the operations on a single server.

See

Refer to "Periodic Operations" in the Operation Guide for information on the periodic operations.

3.1 Starting and Stopping the Mirroring Controller Arbitration Process

This section describes how to start and stop the Mirroring Controller arbitration process.

3.1.1 Starting the Mirroring Controller Arbitration Process

Linux

While the Mirroring Controller arbitration process is in a stopped state, execute the mc_arb command in start mode to start the Mirroring Controller arbitration process.

```
Example)
```

```
$ mc_arb start -M /mcarb_dir/arbiter1
```

Windows

The Mirroring Controller arbitration process can be started using one of the following options:

- Using the mc_arb command
- Starting the service on system startup

Using the mc_arb command

While the Mirroring Controller arbitration process is in a stopped state, execute the mc_arb command from the command prompt to start the Mirroring Controller arbitration process.

```
Example)
```

```
> mc_arb start -M D:\mcarb_dir\arbiter1
```

Starting the service on system startup

Specify automatic start when registering the Mirroring Controller arbitration process to the Windows service during setup of database multiplexing mode. Accordingly, the Mirroring Controller arbitration process service will start on startup of the operating system.

See

Refer to the Reference for information on how to specify the mc_arb command.

3.1.2 Stopping the Mirroring Controller Arbitration Process

Linux

While the Mirroring Controller arbitration process is running, execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

Example)

```
$ mc_arb stop -M /mcarb_dir/arbiter1
```

Windows

The Mirroring Controller arbitration process can be stopped using one of the following options:

- Using the mc_arb command
- Stopping the service

Using the mc_arb command

While the Mirroring Controller arbitration process is running, execute the mc_arb command in stop mode from the command prompt to stop the Mirroring Controller arbitration process.

Example)

```
> mc_arb stop -M D:\mcarb_dir\arbiter1
```

Stopping the service

Select [Administrative Tools], then [Services] to open the [Services] window, and then select the Mirroring Controller service and click the [Stop] menu.

The arbitration server will be forcibly stopped when the service is stopped.

See

Refer to the Reference for information on how to specify the mc_arb command.

Information

Before shutting down the operating system on the arbitration server, either stop the Mirroring Controller on the primary server or standby server or shut down the operating system on the primary server or standby server.

3.2 Starting and Stopping Mirroring Controller

When database multiplexing mode is used, use the mc_ctl command to start and stop the instance and Mirroring Controller at the same time.

Do not start or stop the instance by itself.

3.2.1 Starting Mirroring Controller

While Mirroring Controller is in a stopped state, execute the mc_ctl command in start mode to start Mirroring Controller.

Enabling automatic switch/disconnection

Execute the mc_ctl command in start mode.

Example)

```
$ mc_ctl start -M /mcdir/inst1
```

Disabling automatic switch/disconnection

Execute the mc_ctl command in start mode with the -F option specified.

Example)

```
$ mc_ctl start -M /mcdir/inst1 -F
```

Point

- To start the Mirroring Controller process only, execute the mc_ctl command in start mode with the --mc-only option specified.
- After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.
- When the arbitration server is used for automatic degradation, the Mirroring Controller process startup fails on the database server if the Mirroring Controller arbitration process has not been started on the arbitration server in advance. However, even if the Mirroring Controller arbitration process cannot be started in advance, the Mirroring Controller process can be started by specifying the --async-connect-arbiter option in the mc_ctl command.

See

Refer to the Reference for information on how to specify the mc_ctl command.

Information

- When the arbitration server is used for automatic degradation, the database server must connect to the arbitration server, and as a result, Mirroring Controller startup may take longer.
- Mirroring Controller startup usually fails if the standby server is mistakenly started as the primary server or if the old primary server is not recovered after the switch and is then mistakenly started as the primary server. However, if the admin network is disconnected, then startup does not fail, and both servers may become primary servers. Therefore, ensure that the admin network is connected before starting Mirroring Controller.

3.2.2 Stopping Mirroring Controller

While Mirroring Controller is running, execute the mc_ctl command in stop mode to stop Mirroring Controller process.

Example)

```
$ mc_ctl stop -M /mcdir/inst1
```

Point

- To stop the Mirroring Controller process only, execute the mc_ctl command in stop mode with the --mc-only option specified.
- To prevent an unintended automatic switch, before shutting down the operating system on the primary server, you must stop the Mirroring Controller, or shut down the operating system on the standby server.

See

Refer to the Reference for information on how to specify the mc_ctl command.

3.3 Checking the Database Multiplexing Mode Status

3.3.1 Checking the Status of the Database Server

This section describes how to check the status of the database server.

Check the multiplexed database status by executing the mc_ctl command in status mode.

Additionally, errors can be detected by monitoring the Mirroring Controller messages. If the status or messages are monitored periodically, you can react quickly following an automatic switch failure.

Checking the status of the multiplexing database

When the mc_ctl command is executed, the details of the multiplexing configuration, information about whether switch is possible following the error, and location and details of the error that caused the switch or disconnection are displayed.

After starting database multiplexing mode, execute the mc_ctl command in status mode to check the multiplexing status.

An example of the status displayed when the mc_ctl command is executed is shown below.

Example)

```
$ mc_ctl status -M /mcdir/inst1

mirroring status
----------------
switchable
server_id  host_role       host            host_status  db_proc_status       disk_status
-------------------------------------------------------------------------------------------------
----
server1    primary         192.0.2.100     normal       normal                 normal
server2    standby         192.0.2.110     normal       normal                 normal
```

Checking the status of connection to the Mirroring Controller arbitration process

When the arbitration server is used for automatic degradation, the status of the connection to the Mirroring Controller arbitration process can be checked by specifying the --arbiter option. If the output status is "online", it indicates that an arbitration request can be made from the database server to the arbitration server. When the arbitration server is used for automatic degradation, regularly execute the command in status mode with the --arbiter option specified and check that the output status is "online".

Example)
The mc_ctl command is executed with the --arbiter option specified, and the status is output.

```
$ mc_ctl status --arbiter -M /mcdir/inst1

arbiter_id   host            status
-------------------------------------
arbiter      192.0.3.120     online
```

Checking the status of data synchronization

Additionally, by referencing the pg_stat_replication statistics view on the primary server, the data synchronization status can be confirmed. However, when creating the monitoring program, note that the content of pg_stat_replication may be changed in the future.

The following example shows that the locations of the transaction log after it is sent and received (sent_lsn, replay_lsn) match, and that they are fully synchronized.

Example)

```
postgres=# select * from pg_stat_replication;
-[ RECORD 1 ]----+------------------------------
pid              | 10651
usesysid         | 10
usename          | fsep
```

```
application_name | standby
client_addr      | 192.0.2.210
client_hostname  |
client_port      | 55098
backend_start    | 2022-03-23 11:17:49.628793+09
backend_xmin     |
state            | streaming
sent_lsn         | 0/3000060
write_lsn        | 0/3000060
flush_lsn        | 0/3000060
replay_lsn       | 0/3000060
write_lag        |
flush_lag        |
replay_lag       |
sync_priority    | 1
sync_state       | sync
reply_time       | 2022-03-23 11:23:27.703366+09
```

See

- Refer to "mc_ctl" in Reference for information on the command.
- Refer to "Notes on Application Compatibility" in the Application Development Guide for information on retaining application compatibility.
- Refer to "The Statistics Collector" in "Server Administration" in the PostgreSQL Documentation for details on pg_stat_replication.

3.3.2 Checking the Status of the Arbitration Server

This section describes how to check the status of the arbitration server.

The status of the connection between the Mirroring Controller arbitration process and primary server/standby server can be checked by executing the mc_arb command in status mode.

The example below executes the mc_arb command, and shows the status.

Linux

Example)

```
$ mc_arb status -M /mcarb_dir/arbiter1

server_id    host            status
--------------------------------------
server1      192.0.3.100     online
server2      192.0.3.110     online
```

Windows

Example)

```
> mc_arb status -M D:\mcarb_dir\arbiter1

server_id    host            status
--------------------------------------
server1      192.0.3.100     online
server2      192.0.3.110     online
```

3.4 Manually Switching the Primary Server

The primary server cannot be switched automatically in the following case:

- If automatic switch/disconnection is disabled
- If output of messages is selected for heartbeat abnormalities during heartbeat monitoring of the operating system or server and the operating system/server crashes or becomes unresponsive

In this case, to manually switch the primary server, execute the mc_ctl command in switch mode on either the primary server or the standby server.

```
Example)
```

```
$ mc_ctl switch -M /mcdir/inst1
```

Point

If automatic switch/disconnection is enabled, it is possible to perform switch of primary server at any time.

3.5 Manually Disconnecting the Standby Server

The procedure to perform disconnection of the standby server differs depending on whether the automatic switch/disconnection is enabled or disabled.

If automatic switch/disconnection is enabled

Execute the mc_ctl command in stop mode on the standby server.

```
Example)
```

```
$ mc_ctl stop -M /mcdir/inst1
```

If automatic switch/disconnection is disabled

1. Execute the mc_ctl command in stop mode on the standby server.

   ```
   Example)
   ```

   ```
   $ mc_ctl stop -M /mcdir/inst1
   ```

2. Comment out the synchronous_standby_names parameter in the postgresql.conf file on the primary server. If you have set the synchronized_standby_slots parameter, comment out the synchronized_standby_slots parameter as well.
3. Execute the pg_ctl command in reload mode on the primary server.

   ```
   Example)
   ```

   ```
   $ pg_ctl reload -D /database/inst1
   ```

Point

If automatic start and stop of Mirroring Controller has been configured using systemd, do not use the mc_ctl command, but instead use the systemctl command. Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

3.6 Action Required when a Heartbeat Abnormality is Detected

The message below is output when a heartbeat abnormality is detected during heartbeat monitoring of operating systems or servers:

```
detected an error on the monitored object "server(server identifier name)": no response:ping timeout
(MCA00019)
```

If the heartbeat_error_action parameter in *serverIdentifier*.conf is set to "message", even if automatic switch/disconnection is enabled and Mirroring Controller is started, automatic switch/disconnection is not performed when a heartbeat abnormality is detected. Therefore, user action will be necessary.

This section explains the action required when the heartbeat_error_action parameter is set to "message" and a heartbeat abnormality is detected.

1. Identify the cause of the heartbeat abnormality. The possible causes are below:
   - The remote operating system or server crashed or is unresponsive
   - An admin network issue occurred
2. Address the cause identified in step 1.
   - The remote operating system or server crashed or is unresponsive

     Manually perform switch or disconnection using the mc_ctl command.
   - An admin network issue occurred

     Refer to "Chapter 4 Action Required when an Error Occurs in Database Multiplexing Mode", and recover the database multiplexing system.

3.7 Monitoring Mirroring Controller Messages

The messages that are output by Mirroring Controller are output to both the database server and the arbitration server. If the automatic switch fails, for example, an important message related to the continuation of the operation may be output, so ensure that the system log messages are monitored.

If the arbitration server is used for automatic degradation, monitor messages on both the database server and the arbitration server.

Message output destination on the database server

Messages are output to the system log.

Message output destination on the arbitration server

Linux

Messages are output to the system log.

Windows

Messages are output to the event log.

Point

- To monitor message types considered to be important, an operating system setting must be configured beforehand. Refer to the operating system manuals, check if the message is of a message type that is monitored to be output to the system log, and configure the setting if required.
- If the heartbeat_error_action parameter in *serverIdentifier*.conf is set to "message", only message output is performed when a heartbeat abnormality is detected during heartbeat monitoring of operating systems and servers - automatic switch/disconnection is not performed. Therefore users need to monitor the messages. Refer to "3.6 Action Required when a Heartbeat Abnormality is Detected" for details.

Display format on the database server

```
programName[processId]: messageType:messageText (messageNumber)
```

Specify the program name in the syslog_ident parameter of the serverIdentifier.*conf* file of the database server.

The message types output by Mirroring Controller, their severity, and their corresponding value in the system log are shown in the table below.

Table 3.1 Message type, severity, and corresponding value in the system log

Message type	Severity	Meaning	System log
INFO	Information	Provides information that does not fall under LOG or NOTICE.	INFO
LOG		Provides information recognized as a particularly important event in tracing the operation history. (Example: Automatic switch is complete)	
NOTICE	Notice	Outputs information that takes into account the user instructions within the program in response to an executed or automatically executed process.	NOTICE
WARNING	Warning	Provides a warning, for example it will soon be impossible to maintain the multiplexing state.	WARNING
ERROR	Error	Reports that an error other than FATAL or PANIC has occurred.	ERROR
FATAL		Reports that an abnormality was detected in multiplexed database systems requiring recovery of the system, and also the content and cause of the abnormality.	CRIT
PANIC		Reports that an abnormality was detected in all multiplexed database systems requiring immediate recovery of the system, and also the content and cause of the abnormality.	ALERT

The message severity has the following meanings:

- Information

  Informational status. A message that was reported by the system is displayed. No action is required.

- Notice

  Informational status, but a message that should be noted is displayed. If necessary, take the actions described in the "Action" section of the message.

- Warning

  No error has occurred, but the user is requested to check, and take action. Take the actions described in the "Action" section of the message.

- Error

  An error has occurred. Take the actions described in the "Action" section of the message.

Display format on the arbitration server

Linux

```
programName[processId]: messageType: messageText (messageNumber)
```

Specify the program name in the syslog_ident parameter of the arbitration.conf file of the arbitration server.

Windows

```
eventSourceName[processId]: messageType: messageText (messageNumber)
```

Specify the event source name in the event_source parameter of the arbitration.conf file of the arbitration server.

The message types output by Mirroring Controller, their severity, and their corresponding value in the output destination log are shown in the table below.

Table 3.2 Message type, severity, and corresponding value in the output destination log

Message type	Severity	Meaning	System log (Linux)	Event log (Windows)
INFO	Information	Provides information not categorized as LOG or NOTICE.	INFO	INFORMATION
LOG		Provides information recognized as a particularly important event in tracing the operation history. (Example: Automatic switch is complete)		
NOTICE	Notice	Outputs information that takes into account the user instructions within the program in response to an executed or automatically executed process.	NOTICE	
WARNING	Warning	Provides a warning, for example it will soon be impossible to perform the arbitration process.	WARNING	WARNING
ERROR	Error	Reports that an error other than FATAL or PANIC has occurred.	ERROR	ERROR
FATAL		Reports that an abnormality was detected in the arbitration server requiring recovery of the system, and also the content and cause of the abnormality.	CRIT	
PANIC		Reports that an abnormality was detected in the arbitration server requiring immediate recovery of the system, and also the content and cause of the abnormality.	ALERT	

The message severity has the following meanings:

- Information

  Informational status. A message that was reported by the system is displayed. No action is required.

- Notice

  Informational status, but a message that should be noted is displayed. If necessary, take the actions described in the "Action" section of the message.

- Warning

  No error has occurred, but the user is requested to check, and take action. Take the actions described in the "Action" section of the message.

- Error

  An error has occurred. Take the actions described in the "Action" section of the message.

3.8 Server Maintenance

To perform maintenance tasks such as periodic server inspections and the application of updates for software products including the operating system, you must perform a planned stop of the server, and then perform the maintenance.

3.8.1 Rolling Updates

In database multiplexing mode, rolling updates, that perform the maintenance for the servers that comprise the cluster system, can be performed while jobs continue.

First, perform the maintenance for the standby server, and then switch the standby server to the primary server. Then, perform the maintenance for the original primary server that was switched to the standby server. This enables maintenance to be performed while jobs continue. Obtain a backup as soon as this task is complete.

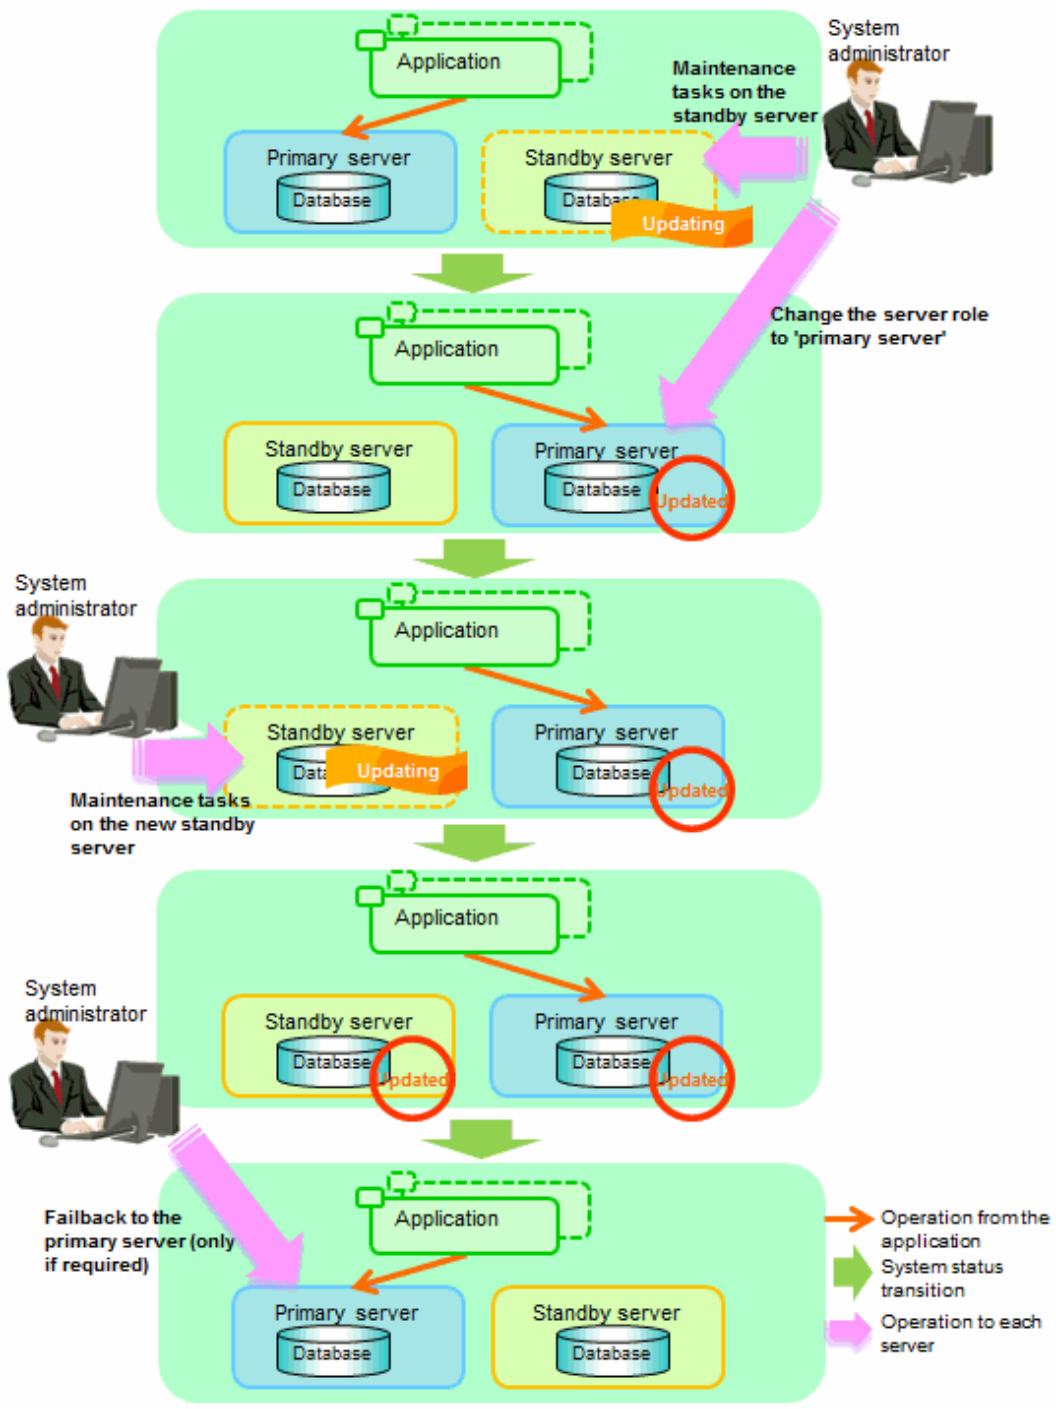
Note that arbitration server maintenance can be performed without affecting database server operation, so it is not necessary to consider rolling update.

See

If the downtime due to the maintenance of the standby server is expected to be long, refer to "Standby server downtime" in "3.9.1 Changes Required when the Standby Server is Stopped".

The flow of a rolling update is shown below.

Figure 3.1 Performing a Rolling Update



Perform the following procedure as shown in the above figure:

Standby server maintenance tasks

1. To perform the maintenance on the standby server, stop Mirroring Controller.

   Example)

   ```
   $ mc_ctl stop -M /mcdir/inst1
   ```

2. Ensure that Mirroring Controller has completely stopped.

   If the multiplexed instances and Mirroring Controller have been configured on the standby server to start and stop automatically when the operating system of the database server is started or stopped, cancel the setting to start and stop automatically.

   See

   Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for information on how to configure the multiplexed instances and Mirroring Controller to start and stop automatically when the operating system of the database server start and stops.

   As the OS superuser, execute the systemctl command to disable automatic start and stop.

   The example below disables automatic start and stop of "mcoi_inst1.service".

   Example)

   ```
   # systemctl disable mcoi_inst1.service
   ```

3. Perform maintenance tasks.

4. Create a copy of the primary server instance on the standby server.

   Execute the pg_basebackup command to create data in the standby server by synchronizing with the primary server.

   Example)

   ```
   $ pg_basebackup -D /database/inst1 -X fetch --waldir=/transaction/inst1 --progress --verbose -R
   --dbname='application_name=standbyServerName' -h primaryServerHostName -p
   primaryServerPortNumber
   ```

   See

   The procedure for copying the primary server instance to the standby server is the same as the procedure for setting up the standby server.

   Refer to "2.5.2 Creating, Setting, and Registering the Standby Server Instance", and then perform the recovery.

5. Check the settings for automatic start and stop of the multiplexed instances and Mirroring Controller.

   If the multiplexed instances and Mirroring Controller were configured in step 2 to not start and stop automatically when the operating system of the database server starts and stops, then change the settings back. This step can be skipped if automatic start and stop are not required.

   As the OS superuser, execute the systemctl command to enable automatic start and stop.

   The example below disables automatic start and stop of "mcoi_inst1.service".

   Example)

   ```
   # systemctl enable mcoi_inst1.service
   ```

6. Start (rebuild) Mirroring Controller on the standby server.

   This operation is required when determining the maintenance tasks on the standby server.

Enabling automatic switch/disconnection

As the instance administrator user, execute the mc_ctl command in start mode.

Example)

```
$ mc_ctl start -M /mcdir/inst1
```

Disabling automatic switch/disconnection

As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

Example)

```
$ mc_ctl start -M /mcdir/inst1 -F
```

Point

After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

Switching to the primary server

To perform the maintenance on the primary server, execute the mc_ctl command in the switch mode on the primary server or the standby server.

Example)

```
$ mc_ctl switch -M /mcdir/inst1
```

When the switch is complete, the synchronous_standby_names parameter and synchronized_standby_slots parameter in the postgresql.conf file of the new primary server will be commented as follows:

Example)

```
#synchronous_standby_names = 'primary'
#synchronized_standby_slots = 'slot'
```

New standby server maintenance tasks

1. Stop the Mirroring Controller.

   On the new standby server (the primary server before the switch), execute the mc_ctl command in stop mode.

   If automatic start and stop of Mirroring Controller has been configured using systemd, do not use the mc_ctl command, but instead use the systemctl command. Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

   Example)

   ```
   $ mc_ctl stop -M /mcdir/inst1
   ```

2. Ensure that Mirroring Controller has completely stopped.

   If the multiplexed instances and Mirroring Controller have been configured on the new standby server to start and stop automatically when the operating system of the database server is started or stopped, cancel the setting to start and stop automatically now.

See

Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for information on how to configure the multiplexed instances and Mirroring Controller to start and stop automatically when the operating system of the database server starts and stops.

As the OS superuser, execute the systemctl command to disable automatic start and stop.

The example below disables automatic start and stop of "mcoi_inst1.service".

Example)

```
# systemctl disable mcoi_inst1.service
```

3. Perform the maintenance on the new standby server that was stopped.
4. Create a copy of the new primary server instance on the new standby server.

   Execute the pg_basebackup command to create data in the new standby server by synchronizing with the new primary server.

   Example)

```
$ pg_basebackup -D /database/inst1 -X fetch --waldir=/transaction/inst1 --progress --verbose -R
--dbname='application_name=standbyServerName' -h primaryServerHostName -p
primaryServerPortNumber
```

See

The procedure for copying the primary server instance to the standby server is the same as the procedure for setting up the standby server.

Refer to "2.5.2 Creating, Setting, and Registering the Standby Server Instance", and then perform the recovery.

5. Check the settings for automatic start and stop of the multiplexed instances and Mirroring Controller.

   If the multiplexed instances and Mirroring Controller were configured in step 2 to not start and stop automatically when the operating system of the database server starts and stops, then change the settings back. This step can be skipped if automatic start and stop are not required.

   As the OS superuser, execute the systemctl command to enable automatic start and stop.

   The example below disables automatic start and stop of "mcoi_inst1.service".

   Example)

```
# systemctl enable mcoi_inst1.service
```

6. After the maintenance is complete, edit the following parameters in the postgresql.conf file of the standby server as required.

   Copying an instance results in the value of the synchronous_standby_names parameter becoming the specified value on the primary server. Therefore, correct it to the specified value on the standby server. If the parameter was commented out, then you must uncomment it.

7. If you are using a replication slot, create a communication replication slot on the primary server before rebuilding.

   Example)

```
$ psql -h primaryServerHostName -p primaryServerPortNumber -d databaseName -c "SELECT * FROM
pg_create_physical_replication_slot('replicationSlotName')"
```

8. On the standby server, start (rebuild) Mirroring Controller.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

```
$ mc_ctl start -M /mcdir/inst1
```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

Example)

```
$ mc_ctl start -M /mcdir/inst1 -F
```

Point

After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

9. If you are using a replication slot, replication slot may remain on the standby server. Delete the replication slot on the standby server side as needed.

   Example)

```
$ psql -h standbyServerHostName -p standbyServerPortNumber -d databaseName -c "SELECT * FROM
pg_drop_replication_slot('replicationSlotName')"
```

Information

If unused replication slots remain on the standby server, WAL files may not be deleted on the standby server.

Failback of the Primary Server

Revert the primary server and standby server to the original server configuration. Do this to execute the main job on the previous primary server. Refer to "4.1.1.3 Failback of the Primary Server" for details.

3.8.2 Stopping for Maintenance

Perform this procedure to stop all servers for periodic inspections, for example. On the server on which Mirroring Controller is running, execute the mc_ctl command in stop mode to stop the instance and Mirroring Controller.

If automatic start and stop of Mirroring Controller has been configured using systemd, do not use the mc_ctl command, but instead use the systemctl command. Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

After that, on the server where the Mirroring Controller arbitration process is running, execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

Stopping Mirroring Controller

Example)

```
$ mc_ctl stop -M /mcdir/inst1 -a
```

Stopping the Mirroring Controller arbitration process

Linux

Example)

```
$ mc_arb stop -M /mcarb_dir/arbiter1
```

Windows

Example)

```
> mc_arb stop -M D:\mcarb_dir\arbiter1
```

3.8.3 Arbitration Server Maintenance

Arbitration server maintenance can be performed without affecting database server operation.

Follow the procedure below to perform arbitration server maintenance.

1. Execute the mc_arb command in stop mode to forcibly stop the Mirroring Controller arbitration process.

   Linux

   Example)

   ```
   $ mc_arb stop -M /mcarb_dir/arbiter1 -e
   ```

   Windows

   Example)

   ```
   > mc_arb stop -M D:\mcarb_dir\arbiter1 -e
   ```

2. Perform maintenance tasks.

3. Execute the mc_arb command in start mode to restart the Mirroring Controller arbitration process.

   Linux

   Example)

   ```
   $ mc_arb start -M /mcarb_dir/arbiter1
   ```

   Windows

   Example)

   ```
   > mc_arb start -M D:\mcarb_dir\arbiter1
   ```

4. Execute the mc_arb command in status mode to check that the arbitration server is connected to the database server.

   The example below executes the mc_arb command, and shows the status.

   Linux

   Example)

   ```
   $ mc_arb status -M /mcarb_dir/arbiter1

   server_id    host            status
   -------------------------------------
   server1      192.0.3.100     online
   server2      192.0.3.110     online
   ```

   Windows

   Example)

   ```
   > mc_arb status -M D:\mcarb_dir\arbiter1

   server_id    host            status
   -------------------------------------
   server1      192.0.3.100     online
   server2      192.0.3.110     online
   ```

5. Check the command output.

   Items to be checked

   Check that the output status is "online" on both lines.

3.9 Changes in Operation

The following changes in operation may be required:

- Changes required when the standby server is stopped
- Changing from single server mode to database multiplexing mode
- Changing from database multiplexing mode to single server mode
- Changing to database multiplexing mode when the arbitration server is used for automatic degradation
- Changing parameters
- Uninstalling in the database multiplexing mode

3.9.1 Changes Required when the Standby Server is Stopped

Operation when the standby server is stopped

Before performing maintenance for the primary server instance when the standby server has been stopped, stop Mirroring Controller on the primary server, comment out the synchronous_standby_names parameter and synchronized_standby_slots parameter in the postgresql.conf file of the primary server, and then execute the pg_ctl command in reload mode.

If this operation is not performed, operations performed on the primary server for the instance will remain in a wait state.

See

Refer to "pg_ctl" in Reference for information on the command.

Information

The standby server must be rebuilt if the pending transaction log to be transferred to the standby server is lost when the standby server is started after the maintenance task is complete.

Take the action advised in the recovery operation that starts from "4.1.1.1.3 Identify cause of error and perform recovery" through to "4.1.1.2 Rebuild the Standby Server".

Standby server downtime

If you specified the synchronous_standby_names parameter of the postgresql.conf file and then the standby server instance is stopped, consider the points below.

- The wal_sender_timeout parameter in the postgresql.conf file

  If the standby server is stopped after the timeout set in this parameter was exceeded, an error stating that the transaction log could not be received may be output to the primary server system log, and all transaction logs that should be transferred to the standby server are accumulated.

- The wal_keep_size parameter in the postgresql.conf file

  If a transaction log that exceeds the value set in this parameter was generated while the standby server was stopped, the transaction log may be deleted.

  Additionally, setting this parameter requires consideration regarding stabilization of the database multiplexing mode. Refer to "2.11.1 Tuning to Stabilize the Database Multiplexing Mode" for details.

3.9.2 Changing from Single Server Mode to Database Multiplexing Mode

The procedure for switching single server mode to database multiplexing mode for the purposes of high reliability and load distribution of the system is explained below.

This procedure is equivalent to the setup procedure explained in "Chapter 2 Setting Up Database Multiplexing Mode".

Point

If the data storage destination directory name is not comprised of ASCII characters

Stop the application job and then migrate to a directory with a name that uses only ASCII characters:

1. Stop the database instance on the primary server.
2. Change the name of the data storage destination directory to one that uses only ASCII characters.

See

When encrypting the storage data, refer to "Database Multiplexing Mode" in the Operation Guide, and then perform the setup for encryption on the primary and standby servers.

1. Install on the arbitration server

   Perform this step only if the arbitration server is used for automatic degradation.

   Install the Server Assistant on the server where the Mirroring Controller arbitration process is started.

   Refer to "Installation" in the Installation and Setup Guide for Server Assistant for information on how to install the Server Assistant.

2. Install on the standby server

   Install Fujitsu Enterprise Postgres on the server to be started as the standby server.

   Refer to "Installation" in the Installation and Setup Guide for Server for information on how to install Fujitsu Enterprise Postgres.

   Use ASCII characters in the data storage destination directory.

3. Stop the application jobs

   Stop the application jobs to be connected to the primary server.

4. Change the primary server settings

   To allow connections from the server to be started as the standby server, configure the settings in step 2 and thereafter of "2.4.2 Creating, Setting, and Registering the Primary Server Instance" on the primary server.

5. Set up the arbitration server

   Refer to "2.3 Setting Up the Arbitration Server" for details.

   Perform this step only if the arbitration server is used for automatic degradation.

6. Set up database multiplexing mode on the primary server

   Refer to "2.4.1 Setting Up Database Multiplexing Mode on the Primary Server" for details.

7. Set up database multiplexing mode on the standby server

   Refer to "2.5.1 Setting Up Database Multiplexing Mode on the Standby Server" for details.

8. Create the standby server instance and start it

   Refer to "2.5.2 Creating, Setting, and Registering the Standby Server Instance" for details.

After the above steps are completed, refer to the remaining explanations in "Chapter 2 Setting Up Database Multiplexing Mode" and ensure that the required settings and operations are completed.

3.9.3 Changing from Database Multiplexing Mode to Single Server Mode

The procedure for stopping database multiplexing mode and changing to single server mode is explained below.

Some tasks must be performed on the database server, and others must be performed on the arbitration server.

The tasks on the arbitration server are required only if the arbitration server is used for automatic degradation.

Tasks on the database server

1. Determine the server for which the instance is to be stopped, and switch this server

   Determine the server that is to be excluded as the database multiplexing mode target, and for which the instance is to be stopped.

   If the server for which the instance is to be stopped is the primary server, execute the mc_ctl command in the switch mode to switch the standby server to the primary server.

   The standby server after the switch is complete will be the server for which the instance is to be stopped.

   If the server for which the instance is to be stopped is the standby server, there is no need to perform the switch operation.

   Example)

   ```
   $ mc_ctl switch -M /mcdir/inst1
   ```

2. Stop Mirroring Controller and the instance, and delete the file resources

   On the server that was determined in step 1, execute the mc_ctl command in stop mode to stop Mirroring Controller and the instance.

   If automatic start and stop of Mirroring Controller has been configured using systemd, do not use the mc_ctl command, but instead use the systemctl command. Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

   Example)

   ```
   $ mc_ctl stop -M /mcdir/inst1
   ```

   Then, delete the following file resources:

   - Data storage destination directory
   - Mirroring Controller management directory

   Example)

   ```
   $ rm -rf /database/inst1
   $ rm -rf /mcdir/inst1
   ```

   See

   Refer to "Security-Related Notes" in the Operation Guide for details on deleting the data securely.

3. Stop the application jobs

   Stop the application jobs to be connected to the primary server.

4. Stop Mirroring Controller and the instance on the primary server

   Execute the mc_ctl command in stop mode on the primary server.

   If automatic start and stop of Mirroring Controller has been configured using systemd, do not use the mc_ctl command, but instead use the systemctl command. Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

   Example)

   ```
   $ mc_ctl stop -M /mcdir/inst1
   ```

5. Delete the database multiplexing mode settings that were configured for the primary server instance.

   Reset the postgresql.conf file parameters to their values before the database multiplexing operation was set.

   Delete the file resources from the Mirroring Controller management directory.

If the backup operation was performed, delete the following resources:

- Mirroring Controller management directory backup data obtained in database multiplexing mode
- Instance backup data obtained in database multiplexing mode

Additionally, if the primary_conninfo parameter is set in the postgresql.auto.conf file, execute the ALTER SYSTEM RESET statement to delete the setting.

```
Example)
An example execution of the psql command is shown below.
```

```
postgres=# ALTER SYSTEM RESET primary_conninfo;
```

After these actions are performed, ensure that the backup data is collected when starting the single operation.

See

- Refer to "Security-Related Notes" in the Operation Guide for details on deleting the data securely.
- Refer to "2.14 Backup Operation" for details on the backup operation.
- Refer to "Appendix A Parameters" for details on the postgresql.conf file parameters.

Point

In the above procedure, if the postgresql.conf file of the single primary server can be changed by reloading the file, the operation mode can be changed without stopping the application job.

In that case, execute the mc_ctl command in stop mode with the --mc-only option specified to stop only Mirroring Controller in relation to stopping the primary server.

Tasks on the arbitration server

Linux

1. Execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

   ```
   Example)
   ```

   ```
   $ mc_arb stop -M /mcarb_dir/arbiter1
   ```

2. Delete the Mirroring Controller arbitration process management directory.

   ```
   Example)
   ```

   ```
   $ rm -rf /mcarb_dir/arbiter1
   ```

Windows

1. Execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

   ```
   Example)
   ```

   ```
   > mc_arb stop -M D:\mcarb_dir\arbiter1
   ```

2. Unregister the Mirroring Controller arbitration process from the Windows service.

   Execute the mc_arb command in unregister mode to unregister the Mirroring Controller arbitration process from the Windows service.

   ```
   Example)
   ```

```
> mc_arb unregister -M D:\mcarb_dir\arbiter1
```

3. Delete registrations related to the event log

   If error logs are output to the event log in "2.2.2.1 Preparing to Output Error Logs to the Event Log (Windows)", delete the registered event source name for each instance.

   Example)

```
> regsvr32 /u /i:"Mirroring Controller arbtier1" "c:\Program Files\Fujitsu
\fsepv<x>assistant64\lib\mcarbevent.dll"
```

   Note that "<*x*>" indicates the product version.

4. Delete the Mirroring Controller arbitration process management directory.

   Example)

```
> rmdir /S /Q D:\mcarb_dir\arbiter1
```

3.9.4 Changing to Database Multiplexing Mode when the Arbitration Server is Used for Automatic Degradation

This section provides the procedure to change to database multiplexing mode using the Mirroring Controller only on the database server when the arbitration server is used for automatic degradation.

Some tasks must be performed on the database server, and others must be performed on the arbitration server.

Tasks on the arbitration server

1. Set up the arbitration server.

   Refer to "2.3 Setting Up the Arbitration Server" for information on how to set up the arbitration server.

Tasks on the database server

1. On the server where Mirroring Controller is running, execute the mc_ctl command in stop mode to stop Mirroring Controller on the primary server and standby server.

   Example)

```
$ mc_ctl stop -M /mcdir/inst1 -a --mc-only
```

2. Edit the network.conf file of the primary server and standby server to add the information of the arbitration server.

   Refer to "A.3 Network Configuration File" for details.

   The definition example of the network.conf file of the primary server is shown below:

   Example)

   The IDs of the primary server and standby server are set to "server1" and "server2", and their port numbers are set to "27540" and "27541". The ID of the server of the Mirroring Controller arbitration process is set to "arbiter", and its port number is set to "27541".

```
server1 192.0.2.100,192.0.3.100 27540,27541 server
server2 192.0.2.110,192.0.3.110 27540,27541 server
arbiter 192.0.3.120 27541 arbiter
```

Information

Ensure that the port numbers set for the primary server, standby server, and arbitration server do not conflict with other software. Also do not configure the same segment for the admin network and arbitration network.

Point

- If the server type is "server", two IP addresses or host names, and two port numbers need to be specified in the following order:
  - IP address or host name of the database server used as the admin network
  - IP address or host name of the database server used as the arbitration network
  - Port number of the database server used as the admin network
  - Port number of the database server used as the arbitration network
- If the server type is "arbiter", specify the IP address or host name set for the my_address parameter and the port number set for the port parameter in arbitration.conf.
- When using the admin network and arbitration network together, the following IP addresses or host names must be assigned the same values.
  - IP address or host name of the database server used as the admin network
  - IP address or host name of the database server used as the arbitration network

  Example)
  Here is an example where the server identifiers for the primary server and standby server are "server1" and "server2", with port numbers "27540" and "27541", and the server identifier for the Mirroring Controller arbitration process is "arbiter", with port number "27541".

```
server1 192.0.2.100,192.0.2.100 27540,27541 server
server2 192.0.2.110,192.0.2.110 27540,27541 server
arbiter 192.0.2.120 27541 arbiter
```

3. Edit the *serverIdentifier*.conf file of the primary server and standby server to add parameters required for the operation where the arbitration server is used for automatic degradation.

   Refer to "A.4.1 Server Configuration File for the Database Servers" for information on the parameters required when the arbitration server is used for automatic degradation.

4. On the primary server and standby server, execute the mc_ctl command in start mode to start the Mirroring Controller process.

   Example)

```
$ mc_ctl start -M /mcdir/inst1 --mc-only
```

Common tasks

1. Check the connection status from the database server or arbitration server.

   Refer to "2.8 Checking the Connection Status" for details.

3.9.5 Changing Parameters

Stop Mirroring Controller before editing the Mirroring Controller server configuration file and network configuration file.

If the Mirroring Controller process crashes or becomes unresponsive, restart is performed automatically by the Mirroring Controller monitoring process, and the configuration file is reloaded. Therefore, if the configuration file was being edited, unintended behavior will occur.

3.9.6 Uninstalling in Database Multiplexing Mode

This section explains how to uninstall Fujitsu Enterprise Postgres on a server using database multiplexing mode.

Some tasks must be performed on the database server, and others must be performed on the arbitration server.

The tasks on the arbitration server are required only if the arbitration server is used for automatic degradation.

Tasks on the database server

1. Stop the multiplexed instances and Mirroring Controller

   Refer to "3.2 Starting and Stopping Mirroring Controller" for information on how to stop the instance.

2. Uninstall Fujitsu Enterprise Postgres

   Refer to "Uninstallation" in the Installation and Setup Guide for Server for information on how to uninstall Fujitsu Enterprise Postgres.

Tasks on the arbitration server

Refer to "Uninstallation" in the Installation and Setup Guide for Server Assistant, and uninstall the Server Assistant.

Chapter 4 Action Required when an Error Occurs in Database Multiplexing Mode

This chapter describes the action required if an error occurs in database multiplexing mode.

In database multiplexing mode, when an error is detected, the switch or disconnection of the standby server is performed automatically, so that only the primary server starts degrading. In this case, the recovery tasks will be required for the standby server on which the switch or disconnection was performed.

Other possible cases are as follows:

- When automatic switch fails
- When automatic disconnection fails
- When all servers or instances were stopped

4.1 Action Required when Server Degradation Occurs

If the server has started degrading, the recovery tasks will vary depending on whether the cause was the switch (failover or switchover), or the disconnection.

Execute the mc_ctl command in status mode, or refer to the system log, and check if the cause of the server degradation was the switch or the disconnection.

In the example below, the mc_ctl command is executed in status mode.

If a switch has occurred, "switched" (the switch is complete and the server is in a degrading state) is displayed for "mirroring status".

Example)

```
$ mc_ctl status -M /mcdir/inst1
mirroring status
----------------
switched

   :
```

If a disconnection has occurred, "not-switchable" (disconnection was performed so the server cannot be switched) is displayed for "mirroring status".

Example)

```
$ mc_ctl status -M /mcdir/inst1
mirroring status
----------------
not-switchable

  :
```

Information

If Mirroring Controller detects any errors on the server on which operations are continuing during recovery to database multiplexing mode from a degrading operation state, perform the procedure in "4.1.3 Addressing Errors During Degrading Operation", and then recover to database multiplexing mode.

4.1.1 Operations when the Server has Started Degrading after a Switch has Occurred

This section explains the operations when the server has started degrading after a switch has occurred.

Information

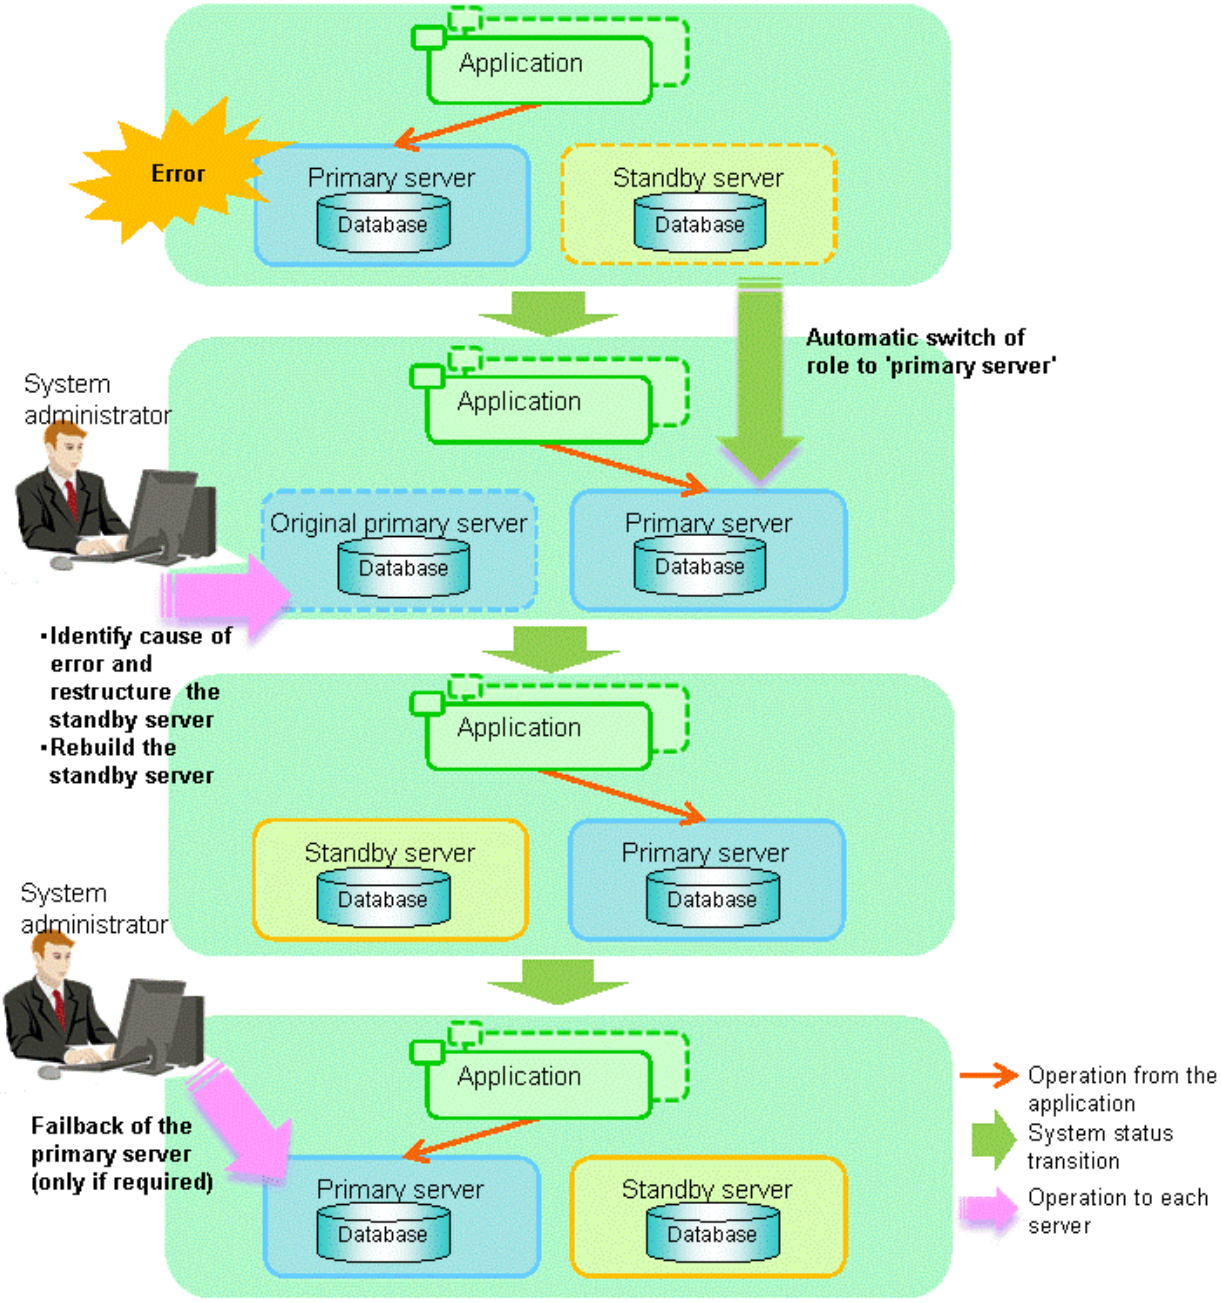
- After a switch has occurred as a result of an abnormality on the primary server, the database will not have a multiplexed configuration until the standby server is rebuilt. Remove the cause of the error as quickly as possible, and then rebuild the standby server.
- If the reference job was executed on the standby server, and the servers are switched because an error occurred on the primary server, the load is concentrated on the new primary server. Accordingly, pause the reference job on the original standby server, rebuild the original primary server as the new standby server, and then resume the reference job for the new standby server.
- If the instance on the new primary server is stopped before the original primary server where the error occurred is rebuilt as the new standby server, a split brain occurs at startup from the instance on the original primary server. Therefore, start the instance on the new primary server before rebuilding the standby server.

If the switch occurred and the server has started degrading, perform the following operations to recover the standby server and revert it to its original state:

- Identify Cause of Error and Restore the Standby Server
- Rebuild the Standby Server
- Failback of the Primary Server (only if required)

The flow of these operations is shown in the figure below.

Figure 4.1 Flow of operations



4.1.1.1 Identify Cause of Error and Restore the Standby Server

Perform the recovery according to the following procedure:

1. Stop Mirroring Controller
2. Recovery of the Mirroring Controller management directory
3. Identify cause of error and perform recovery

4.1.1.1.1 Stop Mirroring Controller

Execute the mc_ctl command in stop mode for the original primary server on which the error occurred.

If automatic start and stop of Mirroring Controller has been configured using systemd, do not use the mc_ctl command, but instead use the systemctl command. Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

Example)

```
$ mc_ctl stop -M /mcdir/inst1
```

This also stops the instance that is required to perform the recovery.

Point

If the instance does not stop, refer to "Actions in Response to Failure to Stop an Instance" in the Operation Guide, and then stop the instance.

Then, specify the -e option in the above command to forcibly stop Mirroring Controller.

4.1.1.1.2 Recovery of the Mirroring Controller management directory

Copy the files in the Mirroring Controller management directory from the backup data, and then perform the recovery.

4.1.1.1.3 Identify cause of error and perform recovery

Refer to the system log of the primary server and the standby server to identify the cause of the error, and then perform recovery.

The following commands can be used to recover a standby server. Select depending on the recovery and the situation.

- pg_basebackup

  Creates a copy of all resources of the primary server instance.

- pg_rewind

  Creates a copy of only the updated files on the new primary server. For this reason, if this command is used to incorporate a new standby server, recovery time can be shortened. To use this command to build the original primary server as a new standby server, at least one of the following must be met:

  a. Checksums were enabled when an instance was created, or

  b. The wal_log_hints parameter of postgresql.conf was enabled when an instance was started.

  Additionally, full_page_writes must be enabled, which is its default value.

See

- Refer to "pg_basebackup" in "Reference" in the PostgreSQL Documentation for information on the pg_basebackup command.
- Refer to "pg_rewind" in "Reference" in the PostgreSQL Documentation for information on the pg_rewind command.

The example below executes the pg_rewind command to perform recovery by synchronizing data on the original primary server with the new primary server.

Information

If the pg_rewind command is executed immediately after promotion of the new primary server, the processing in steps 1 and 2 is required. If update-type SQL can be executed on the new primary server and checkpoint processing is executed after promotion, the processing in steps 1 and 2 will not be necessary.

1. Wait for the application of unapplied update transaction logs on the new primary server.

   Execute the SQL below on the new primary server, and wait until the result is false.

   ```
   # select pg_is_in_recovery();
   ```

   Example)

```
$ psql -h hostNameOfNewPrimaryServer -p portNumOfNewPrimaryServer -d dbName -c "select
pg_is_in_recovery();"
```

Any database can be connected to.

2. Update the timeline ID.

   Execute checkpoint processing, and update the timeline ID.

```
$ psql -h hostNameOfNewPrimaryServer -p portNumOfNewPrimaryServer -d dbName -c "checkpoint;"
```

   Any database can be connected to.

3. Create a copy of the new primary server instance in the original primary server (new standby server).

   Execute the pg_rewind command to synchronize the new standby server data with the new primary server.

   Example)

```
$ pg_rewind -D /database/inst1 -R --source-server='user=userName host=newPrimaryServerHostName
port=newPrimaryServerPortNumber dbname=dbName application_name=newStandbyServerName'
```

Point

- Use the pg_rewind command with the -R option to create a standby.signal file. If you do not create the standby.signal file, the Mirroring Controller cannot be started as a standby server.
- If using a method that requires password authentication for connections to the primary server, you will need to ensure that authentication is performed automatically. If the -R option is specified for the pg_rewind command and the password parameter is specified for the --dbname option, the pg_rewind command will set the password in the primary_conninfo parameter in postgresql.auto.conf file, enabling connections to be performed automatically.

  If a password is not set in the primary_conninfo parameter in postgresql.auto.conf file, it will be necessary to create a .pgpass file in the home directory of the instance administrator user, and specify a password for the replication database.
- If you need to set a connection string other than host, port and application_name, include it in the setting of the primary_conninfo parameter.
- The primary_conninfo parameter should not be set in the postgresql.conf file, but only in the postgresql.auto.conf file using the pg_rewind command.

4. Specify parameters in the postgresql.conf file of the original primary server (new standby server).

   Set the parameters required for the standby server in postgresql.conf.

   Refer to "Table 2.5 Parameters" for information on the parameters to set in postgresql.conf.

Information

A new timeline is branched for the new primary server due to promotion, so 'latest' needs to be specified for the recovery_target_timeline parameter so that the old primary server (new standby server) follows the new primary server.

See

- Refer to "Hot Standby" in the PostgreSQL Documentation for details on the standby.signal file.
- Refer to "Setting Up a Standby Server" in the PostgreSQL Documentation for details on the primary_conninfo.

4.1.1.2 Rebuild the Standby Server

The starting of the recovered original primary server as the standby server is referred to as the "standby server rebuild".

Perform the following procedure:

1. If you are using a replication slot, create a communication replication slot on the primary server before rebuilding.

   Example)

   ```
   $ psql -h primaryServerHostName -p primaryServerPortNumber -d databaseName -c "SELECT * FROM
   pg_create_physical_replication_slot('replicationSlotName')"
   ```

2. On the original primary server, start Mirroring Controller and the instance.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

   ```
   $ mc_ctl start -M /mcdir/inst1
   ```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   Example)

   ```
   $ mc_ctl start -M /mcdir/inst1 -F
   ```

   Point

   After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

3. If you are using a replication slot, replication slot may remain on the standby server. Delete the replication slot on the standby server side as needed.

   Example)

   ```
   $ psql -h standbyServerHostName -p standbyServerPortNumber -d databaseName -c "SELECT * FROM
   pg_drop_replication_slot('replicationSlotName')"
   ```

   Information

   If unused replication slots remain on the standby server, WAL files may not be deleted on the standby server.

4.1.1.3 Failback of the Primary Server

To revert the primary server and standby server to the original server configuration after rebuilding the standby server, perform failback for the primary server.

Do this to execute the main job on the previous primary server.

Perform the following procedure:

1. Failback of the primary server

   Execute the mc_ctl command in switch mode on the primary server or the standby server.

   Example)

   ```
   $ mc_ctl switch -M /mcdir/inst1
   ```

   After executing the mc_ctl command in switch mode, the status will be as follows:

   Example)

```
$ mc_ctl status -M /mcdir/inst1
mirroring status
----------------
switched
server_id  host_role                  host         host_status  db_proc_status       disk_status
-------------------------------------------------------------------------------------------------
server1    primary                  192.0.2.100 normal        abnormal(postmaster) normal
server2    none(inactivated primary) 192.0.2.110 normal        abnormal(postmaster) normal
```

2. Stop the original primary server

   On the original primary server, execute the mc_ctl command in stop mode to stop Mirroring Controller and the instance.

   If automatic start and stop of Mirroring Controller has been configured using systemd, do not use the mc_ctl command, but instead use the systemctl command. Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

   Example)

```
$ mc_ctl stop -M /mcdir/inst1
```

3. Create a copy of the new primary server instance in the original primary server (new standby server)

   Execute the pg_basebackup command to create data in the new standby server by synchronizing with the new primary server.

   Example)

```
$ pg_basebackup -D /database/inst1 -X fetch --waldir=/transaction/inst1 --progress --verbose -R
--dbname='application_name=standbyServerName' -h primaryServerHostName -p
primaryServerPortNumber
```

See

The procedure for copying the new primary server instance to the new standby server is the same as the procedure for setting up the new standby server.

Refer to "2.5.2 Creating, Setting, and Registering the Standby Server Instance", and then perform the recovery.

4. If you are using a replication slot, create a communication replication slot on the primary server before rebuilding.

   Example)

```
$ psql -h primaryServerHostName -p primaryServerPortNumber -d databaseName -c "SELECT * FROM
pg_create_physical_replication_slot('replicationSlotName')"
```

5. Rebuild the standby server

   On the standby server, start Mirroring Controller and the instance.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

```
$ mc_ctl start -M /mcdir/inst1
```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   Example)

```
$ mc_ctl start -M /mcdir/inst1 -F
```

Point

After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

6. If you are using a replication slot, replication slot may remain on the standby server. Delete the replication slot on the standby server side as needed.

   Example)

```
$ psql -h standbyServerHostName -p standbyServerPortNumber -d databaseName -c "SELECT * FROM
pg_drop_replication_slot('replicationSlotName')"
```

Information

If unused replication slots remain on the standby server, WAL files may not be deleted on the standby server.

4.1.2 Operations when the Server has Started Degrading after a Disconnection has Occurred

This section explains the operations when the server has started degrading after a disconnection has occurred.

Information

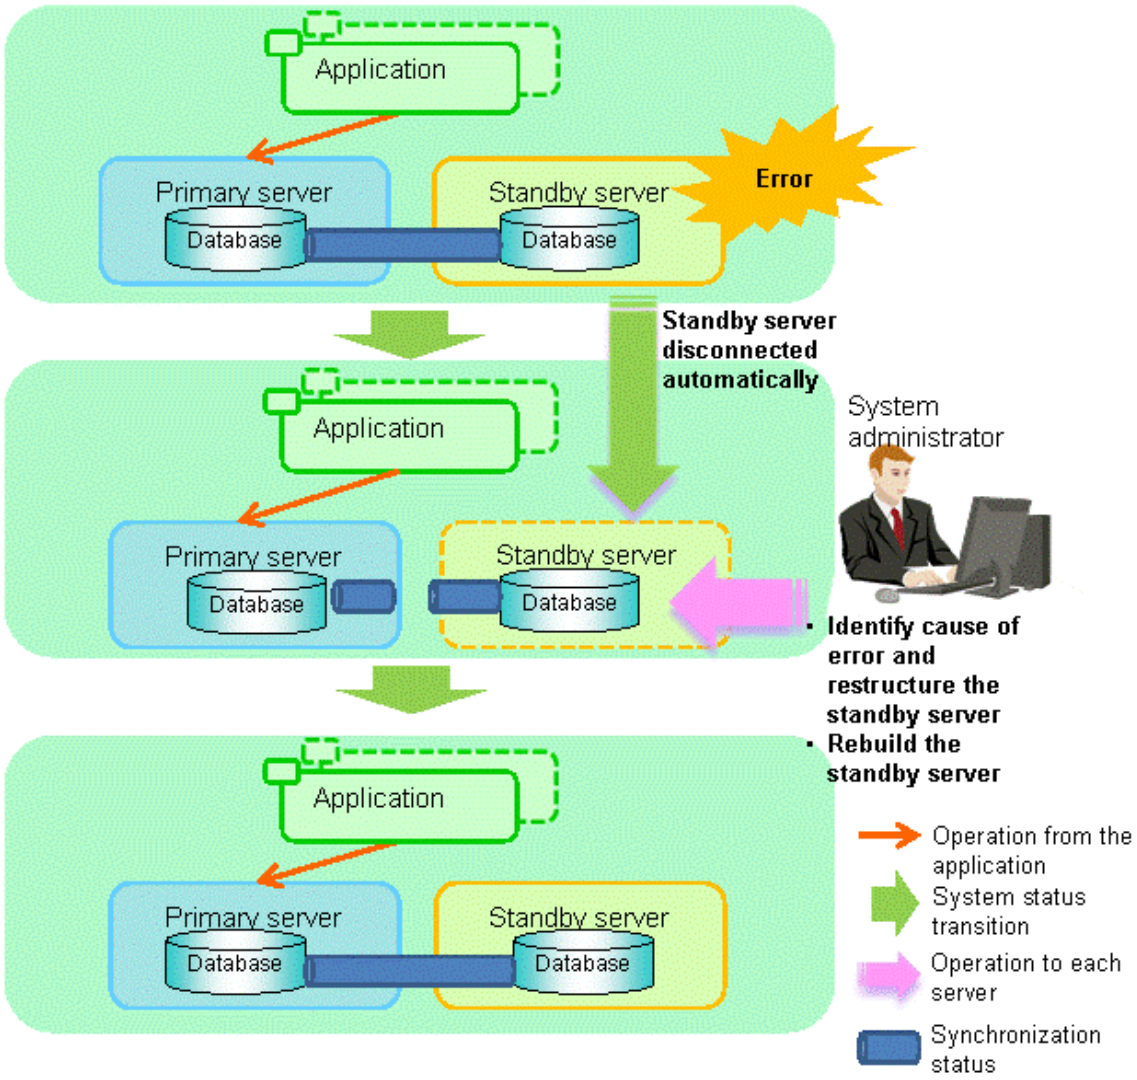
After a disconnection has occurred as a result of an abnormality on the standby server, the database will not have a multiplexed configuration until the standby server is rebuilt. Remove the cause of the error as quickly as possible, and then rebuild the standby server.

If the disconnection occurred and the server has started degrading, perform the following operations to recover the standby server and revert it to its original state:

- Identify Cause of Error and Restore the Standby Server
- Rebuild the Standby Server

The flow of these operations is shown in the figure below.

Figure 4.2 Flow of operations



4.1.2.1 Identify Cause of Error and Restore the Standby Server

Perform the recovery according to the following procedure:

1. Stop Mirroring Controller
2. Recovery of the Mirroring Controller management directory
3. Identify cause of error and perform recovery

4.1.2.1.1 Stop Mirroring Controller

Execute the mc_ctl command in stop mode for the standby server on which the error occurred.

If automatic start and stop of Mirroring Controller has been configured using systemd, do not use the mc_ctl command, but instead use the systemctl command. Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

Example)

```
$ mc_ctl stop -M /mcdir/inst1
```

This also stops the instance that is required to perform the recovery.

Point

If the instance does not stop, refer to "Actions in Response to Failure to Stop an Instance" in the Operation Guide, and then stop the instance.

Then, specify the -e option in the above command to forcibly stop Mirroring Controller.

4.1.2.1.2 Recovery of the Mirroring Controller management directory

Copy the files in the Mirroring Controller management directory from the backup data, and then perform the recovery.

4.1.2.1.3 Identify cause of error and perform recovery

Refer to the system logs of the primary server and the standby server to identify the cause of the error, and then perform recovery.

Execute the pg_basebackup command to perform recovery by synchronizing data in the primary server with the standby server.

```
Example)
```

```
$ pg_basebackup -D /database/inst1 -X fetch --waldir=/transaction/inst1 --progress --verbose -R --
dbname='application_name=standbyServerName' -h primaryServerHostName -p primaryServerPortNumber
```

See

This recovery procedure is the same as the procedure for setting up the standby server.

Refer to "2.5.2 Creating, Setting, and Registering the Standby Server Instance", and then perform the recovery.

4.1.2.2 Rebuild the Standby Server

Start the Mirroring Controller and the instance of the standby server, and rebuild the standby server.

Enabling automatic switch/disconnection

As the instance administrator user, execute the mc_ctl command in start mode.

```
Example)
```

```
$ mc_ctl start -M /mcdir/inst1
```

Disabling automatic switch/disconnection

As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

```
Example)
```

```
$ mc_ctl start -M /mcdir/inst1 -F
```

Point

After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

4.1.3 Addressing Errors During Degrading Operation

This section explains how to address errors that may occur on the server on which operation is continuing during degrading operation triggered by a switch or disconnection.

If needing to recover from backup data

If it is necessary to recover the database using backup data due to data becoming corrupted from disk failure or user operation error, refer to the following for information on recovery to database multiplexing mode:

- Action Required when All Database Servers or Instances Stopped
- Recovering from an Incorrect User Operation

If a temporary error occurs

If a temporary error occurs, such as due to a high load on the server or insufficient system resources, remove the cause of the error and restart Mirroring Controller, and then refer to the following for details on recovery to database multiplexing mode:

- Operations when the Server has Started Degrading after a Switch has Occurred
- Operations when the Server has Started Degrading after a Disconnection has Occurred

See

Refer to "3.2 Starting and Stopping Mirroring Controller" for information on restarting Mirroring Controller.

4.2 Action Required when Automatic Switch Fails

If the system behavior is unstable, for example there are insufficient temporary system resources, the Mirroring Controller automatic switch may fail.

Perform the switch manually using one of the following methods:

- Refer to the procedures in "3.4 Manually Switching the Primary Server".
- In the standby server, execute the mc_ctl command in switch mode with the -force option specified to forcibly perform the switch.

  Example)

```
$ mc_ctl switch -M /mcdir/inst1 --force
```

Point

- Even if connection cannot be established between database servers, it is possible to fence the primary server and forcibly switch by executing the mc_ctl command in switch mode with the --force option specified.
- The primary server is not fenced in the cases below, so stop Mirroring Controller and instances of the primary server database in advance:
  - The --no-fencing option is specified when performing forced switch.
  - The heartbeat_error_action parameter in *serverIdentifier*.conf is set to "message" and the fencing command is not configured to be used (the fencing_command parameter is omitted in *serverIdentifier*.conf).
  - The heartbeat_error_action parameter in *serverIdentifier*.conf is set to "fallback".

See

Recovery to database multiplexing mode

Refer to "4.1.1.2 Rebuild the Standby Server" and "4.1.1.3 Failback of the Primary Server" for information on recovery to database multiplexing mode.

4.3 Action Required when Automatic Disconnection Fails

If the system behavior is unstable, for example there are insufficient system resources such as available memory or free disk space, automatic disconnection using Mirroring Controller may not be possible.

Perform the disconnection manually using one of the following methods:

- Refer to the procedures in "3.5 Manually Disconnecting the Standby Server".
- In the primary server, execute the mc_ctl command in detach mode to perform forced disconnection.

  Example)

```
$ mc_ctl detach -M /mcdir/inst1
```

Point

- Even if connection cannot be established between database servers, it is possible to fence the standby server and forcibly disconnect by executing the mc_ctl command in detach mode.
- In the cases below, stop Mirroring Controller and instances of the standby server database in advance so that the standby server is not fenced:
  - The --no-fencing option is specified when performing forced disconnection.
  - The heartbeat_error_action parameter in *serverIdentifier*.conf is set to "message" and the fencing command is not configured to be used (the fencing_command parameter is omitted in *serverIdentifier.conf*).
  - The heartbeat_error_action parameter in *serverIdentifier*.conf is set to "fallback".

See

Recovery to database multiplexing mode

Refer to "4.1.2.2 Rebuild the Standby Server" for information on recovery to database multiplexing mode.

4.4 Action Required when All Database Servers or Instances Stopped

This section explains what happens when all database servers or instances on the database server have stopped, so jobs cannot continue.

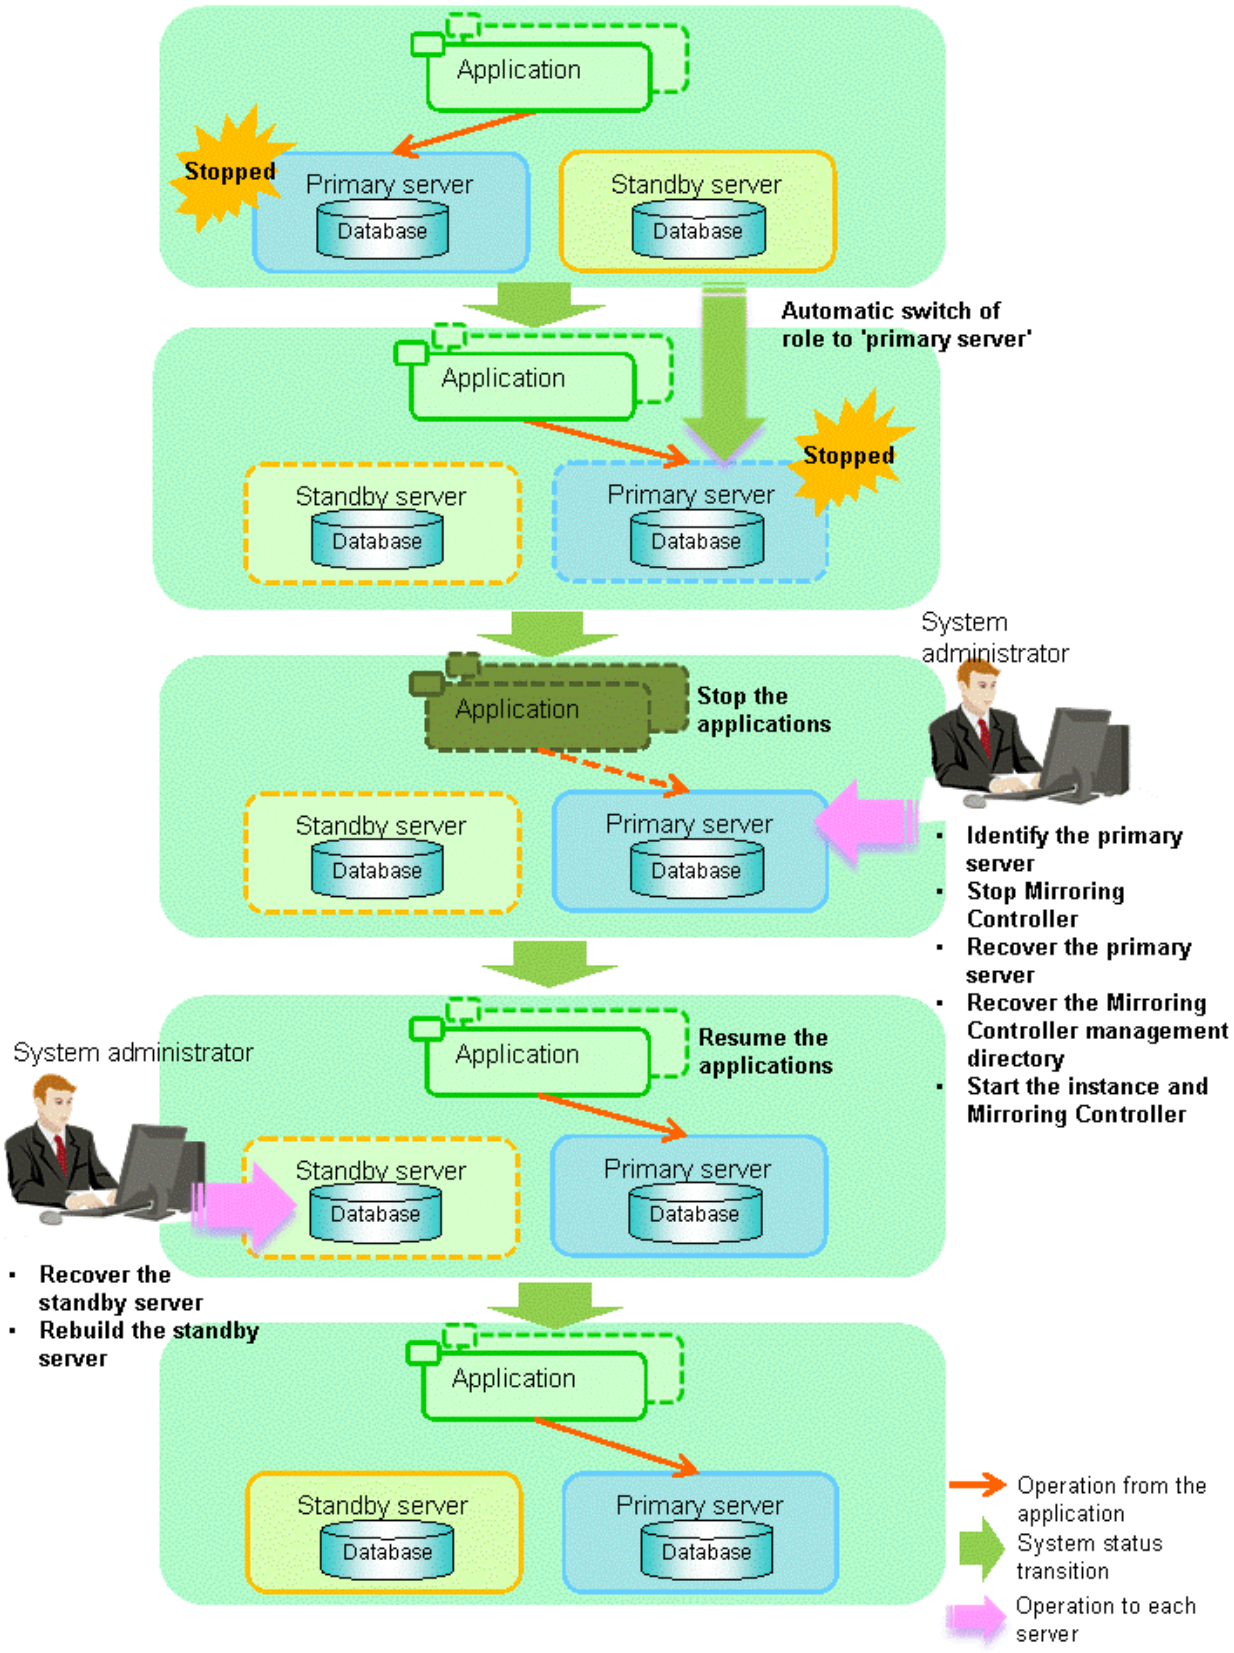
See

Recovery to database multiplexing mode

Refer to "4.1.1.2 Rebuild the Standby Server" and "4.1.1.3 Failback of the Primary Server" for information on recovery to database multiplexing mode.

The flow of these recovery operations is shown in the figure below.

Figure 4.3 Flow of operations



Perform the following procedure:

1. Stop the applications

   Stop the applications from running.

2. Identify the primary server

   Use one of the following methods to identify the primary server that was running before the servers or instances stopped:

   - Refer to the system log on each server and identify the server where the following message was output.

     Message:

     ```
     MirroringControllerOpen[30017]: LOG:  promotion processing completed (MCA00062)
     ```

   - On each server, execute the mc_ctl command in status mode to search the servers for which "none(inactivated primary)" is displayed.

3. Stop Mirroring Controller on the primary server

   Execute the mc_ctl command in stop mode on the primary server.

   If automatic start and stop of Mirroring Controller has been configured using systemd, do not use the mc_ctl command, but instead use the systemctl command. Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

   Example)

   ```
   $ mc_ctl stop -M /mcdir/inst1
   ```

   Point

   Forcibly stopping Mirroring Controller

   If Mirroring Controller does not stop, specify the -e option in the stop mode of the mc_ctl command and then execute the command.

   Example)

   ```
   $ mc_ctl stop -M /mcdir/inst1 -e
   ```

4. Recover the primary server

   First, refer to "Actions when an Error Occurs" in the Operation Guide, and then identify the cause of the error and perform recovery.

   Next, recover the primary server using the recovery method that uses the pgx_rcvall command based on the backup data.

   If the backup operation was performed using the pgx_dmpall command based on the instructions in "2.14.2 Database Backup Operation", perform the following procedure for the recovery.

   Information

   - The backup data may contain a symbolic link, so copy the backup data so that the symbolic link is not converted to an ordinary file (with the tar command, for example).
   - If you can save a copy of the backup storage destination directory, do so without overwriting it.

   a. Perform the following operations on both the primary server and the standby server, and check the server containing the backup data and the archive log that show the latest date.

      - Execute the pgx_rcvall command with the -l option specified and identify the backup data that shows the latest date.
      - Identify the archive log that shows the latest date, as shown below.

        Example)

        ```
        $ ls -ltr backupDataStorageDir/*_wal
        ```

   b. If the latest backup data exists on the standby server, copy the backup data and overwrite it to each backup storage destination directory on the primary server.

c. If the latest archive log and transaction log file exist on the standby server, copy the archive log and overwrite it to the backup storage destination directory on the primary server.

d. Execute the pgx_rcvall command on the primary server, specifying the backup storage destination directory of the primary server.

See

Refer to "Actions when an Error Occurs" in the Operation Guide for information on the pgx_rcvall command.

5. Recover the Mirroring Controller management directory

   Copy the files in the Mirroring Controller management directory from the backup data, and then perform the recovery.

6. Start the primary server instance and Mirroring Controller

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

```
$ mc_ctl start -M /mcdir/inst1
```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   Example)

```
$ mc_ctl start -M /mcdir/inst1 -F
```

Point

After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

7. Resume applications

   Resume the applications.

8. Stop Mirroring Controller on the standby server

   Execute the mc_ctl command in stop mode on the standby server.

   If automatic start and stop of Mirroring Controller has been configured using systemd, do not use the mc_ctl command, but instead use the systemctl command. Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

   Example)

```
$ mc_ctl stop -M /mcdir/inst1
```

9. Recover the standby server

   Refer to "2.5.2 Creating, Setting, and Registering the Standby Server Instance", and then recover (set up) the standby server from the primary server.

10. Rebuild the standby server

    On the standby server, start Mirroring Controller and the instance.

    Enabling automatic switch/disconnection

    As the instance administrator user, execute the mc_ctl command in start mode.

    Example)

```
$ mc_ctl start -M /mcdir/inst1
```

Disabling automatic switch/disconnection

As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

Example)

```
$ mc_ctl start -M /mcdir/inst1 -F
```

Point

After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

4.5 Recovering from an Incorrect User Operation

This section describes how to recover an instance when data has been corrupted due to incorrect user operation.

For example, when data has been corrupted due to incorrect user operation, such as data being unintentionally changed or deleted by an application or command, it is necessary to restore the original data on the primary server and resynchronize with the standby server.

Use the following procedure to perform recovery.

1. Identify the primary server

   Execute the mc_ctl command in status mode on each server, and search for a server for which "primary" or "none(inactivated primary)" is displayed.

2. Stop the applications and commands that caused the incorrect operation to occur

   Stop applications and commands that are running on the primary server. This will minimize the impact caused by the incorrect data.

   Also, if any applications used for reference by the standby server are running, stop them too.

3. Stop the instance and Mirroring Controller

   Stop the instance and Mirroring Controller on both the primary server and standby server.

   Example)

   ```
   $ mc_ctl stop -a -M /mcdir/inst1
   ```

4. Recover the database on the primary server

   Recover the database using the recovery method in which the pgx_rcvall command uses the backup data to recover the database to a restore point prior to the time when the incorrect operation was performed.

   See

   Refer to "Recovering from an Incorrect User Operation" in the Operation Guide for information on using the pgx_rcvall command to recover the database to a restore point, and then perform only the database recovery procedure while the instance is in a stop state.

5. Start the instance and Mirroring Controller

   Start the instance and Mirroring Controller on the primary server.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

   ```
   $ mc_ctl start -M /mcdir/inst1
   ```

Disabling automatic switch/disconnection

As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

Example)

```
$ mc_ctl start -M /mcdir/inst1 -F
```

Point

After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

6. Build the new standby server

Refer to "2.5 Setting Up the Standby Server" for information on building (setting up) a standby server from the primary server.

Chapter 5 Managing Mirroring Controller Using WebAdmin

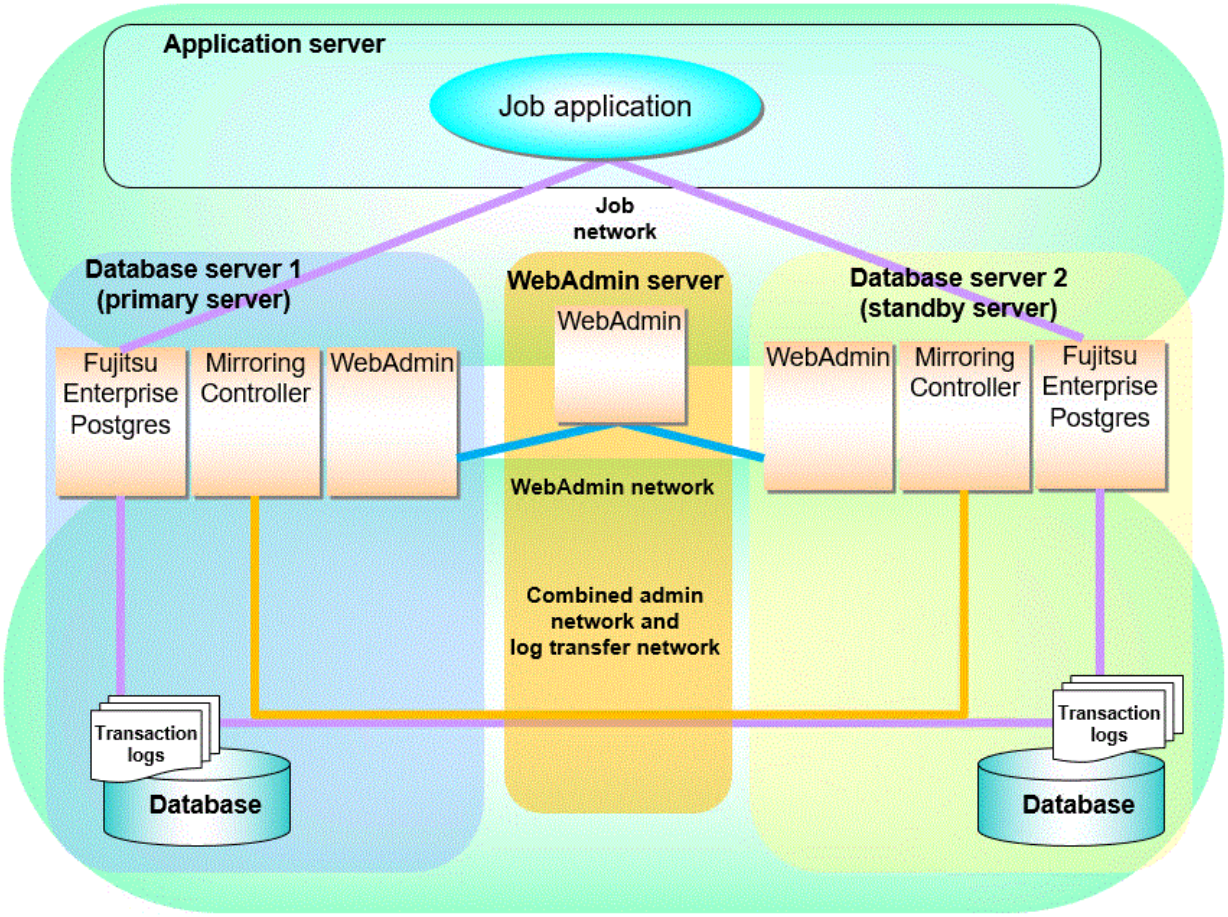
This chapter describes how to set up and manage Mirroring Controller in a streaming replication cluster using WebAdmin.

Mirroring Controller can be used to monitor a streaming replication cluster and perform automatic switching or disconnect synchronous replication when there is an error.

WebAdmin can be used to set up Mirroring Controller in an existing replication cluster. Mirroring Controller can be set up for either synchronous standby instances or asynchronous standby instances.

The configuration of the database multiplexing system built using WebAdmin is shown below:

Figure 5.1 Configuration of database multiplexing operation system using WebAdmin



Point

- If you set up the arbitration server using WebAdmin, install WebAdmin on the arbitration server.
- If Mirroring Controller is set up to the replication cluster using WebAdmin, the network with the host name (or IP address) specified in [Host name] will be used as the admin network and the log transfer network.
- To use a network other than the job network as the log transfer network, before building the replication cluster specify a host name other than the job network one in [Host name].

5.1 Mirroring Controller Setup

Perform the following procedure to set up Mirroring Controller in a streaming replication cluster.

1. In the [Instances] tab, select the standby instance on which Mirroring Controller needs to be set up.

2. Click .

3. Enter the information for the Mirroring Controller to be set up.

   - [Enable automatic switch over]: Toggles the automatic switch/disconnection functionality. Select "Yes". The default is "No".
   - [Mirroring Controller management directory]: Directory where the Mirroring Controller configuration files will be stored. When the [Mirroring Controller management directory] is entered, WebAdmin will search the Mirroring Controller configuration files in the entered directory based on the [Data storage path] of the corresponding DB instance. If Mirroring Controller configuration files are found, the Mirroring Controller fields will be auto filled.
   - [Mirroring Controller port]: Port number of Mirroring Controller. Note that if the Windows firewall feature is enabled, you must enable the port number of Mirroring Controller. Refer to "E.2 Windows Firewall Settings" for details.
   - [Heartbeat interval (milliseconds)]: Number of milliseconds between two consecutive heartbeat checks. The default is "800".
   - [Heartbeat timeout (seconds)]: Number of seconds for the heartbeat timeout. The default is "1".
   - [Heartbeat retry]: Number of retries for heartbeat monitoring, before failover occurs. The default is "2".
   - [Heartbeat error action]: Operation when a heartbeat abnormality is detected. The default is "Fallback".

     When using FUJITSU Enterprise Postgres 10 or 11 instance which was created with FUJITSU Enterprise Postgres WebAdmin 10 or 11, the mode in the [Heartbeat error action] for Mirroring Controller setup cannot be changed.

     When setting up Mirroring Controller for FUJITSU Enterprise Postgres 9.5 and 9.6 instances, the [Heartbeat error action] is not supported and therefore is not displayed.

   When the [Heartbeat error action] is set to "Arbitration", the following extra items are displayed:

   - [Arbitration network IP address]: IP address of the arbitration network.
   - [Mirroring Controller Arbitration port]: Port number of Mirroring Controller for communicating with the arbitration server.

   The [Arbitration server configuration] section is also displayed with the following items. The [Arbitration server configuration] will not be auto filled.

   - [Location]: Location of the arbitration server. "Local" or "Remote" can be selected depending on your configuration.

     If the arbitration server and WebAdmin server are located on the same server, you can select "Local" and the following items are displayed:

     - [Arbitration management directory]: Directory where the arbitration server configuration files will be stored.
     - [Arbitration server host or IP address]: Host name or IP address of the arbitration server.
     - [Arbitration process port]: Port number for the arbitration process.
     - [Fencing command]: Full path of the fencing command that fences a database server when an abnormality is detected.

     If "Remote" is set for the item, the items below are displayed in addition to the above items.

     - In the [Arbitration server configuration] section, [Operating system credential] is displayed where you can enter the following information. Operating system credential (User name, Password) should not contain hazardous characters. Refer to "Appendix F WebAdmin Disallow User Inputs Containing Hazardous Characters".

       [User name]: User name to access the arbitration server.

       [Password]: Password to access the arbitration server.

     - In the [Remote WebAdmin for Arbitration server] section, the following items are displayed:

       [Remote WebAdmin address]: IP address of the remote WebAdmin installed on the arbitration server.

       [Remote WebAdmin port]: Port number for the WebAdmin installed on the arbitration server.

   When the [Heartbeat error action] is set to "Command", the following extra items are displayed:

- [Arbitration command]: Full path of the arbitration command to be executed when an abnormality is detected.
- [Fencing command]: Full path of the fencing command that fences a database server when an abnormality is detected.

4. Click to set up Mirroring Controller.
5. Upon successful completion, Mirroring Controller will be started on master and standby instances.

After the Mirroring Controller has been set up, ([Edit Mirroring Controller] button) and ([Mirroring Controller Configuration] button) are available. These buttons are displayed only when FUJITSU Enterprise Postgres 10 or later instances are created with FUJITSU Enterprise Postgres WebAdmin 12 or later.

For FUJITSU Enterprise Postgres 9.5 and 9.6 instances, the [Heartbeat error action] will not be displayed.

When the [Heartbeat error action] is "Arbitration", the following information is displayed: whether the arbitration status is "online" or "offline", the arbitration server IP address and the arbitration process port.

5.2 Edit Mirroring Controller Setup

Settings made in "5.1 Mirroring Controller Setup" can be updated in either the master instance or a standby instance using WebAdmin.

Perform the following procedure to edit Mirroring Controller configuration:

1. In the [Instances] tab, select the instance for which the Mirroring Controller configuration is to be edited.
2. Click .
3. Enter the information for the Mirroring Controller to be updated. Refer to "5.1 Mirroring Controller Setup".
4. Click to update the Mirroring Controller.
5. Upon successful completion, Mirroring Controller will be started on master and standby instances.

Editing and saving the [Edit Mirroring Controller] page will reset all other settings that are not listed on this page to default values.

5.3 Mirroring Controller Configuration

The information related to Mirroring Controller monitoring and control (refer to "A.4.1 Server Configuration File for the Database Servers") and the information related to arbitration and control of the Mirroring Controller arbitration process (refer to "A.4.2 Arbitration Configuration File") can be set using WebAdmin. You can view and update the configuration on either the master instance or the standby instance.

Perform the following procedure:

1. In the [Instances] tab, select the instance for the Mirroring Controller configuration you want to view.
2. Click to view the Mirroring Controller configuration.
3. Click to show the editing page for the Mirroring Controller configuration. The Mirroring Controller configurations defined during [Mirroring Controller Setup] are read-only on this page. Refer to "5.1 Mirroring Controller Setup".

   Additionally, refer to the "Appendix A Parameters" for information about the settings and the corresponding parameter names.

   The items common to all [Heartbeat error action] are:

   - Target DB
   - Core file path
   - Syslog facility
   - Syslog identity
   - Remote call timeout (milliseconds)
   - Agent alive timeout (seconds)

- DB instance check interval (milliseconds)
- DB instance check timeout (seconds)
- DB instance check retry
- DB instance timeout action
- Disk check interval (milliseconds)
- Disk check retry
- Tablespace directory error action
- Post-switch command
- Post-promote command
  (Post-promote command is replaced in FUJITSU Enterprise Postgres 12. The Post-promote command is still valid and will be displayed when it is used in the server configuration file of Mirroring Controller.)
- Post-attach command
- Pre-detach command
- State transition command timeout (seconds)
- Check synchronous standby names validation

When the [Heartbeat error action] is set to "Arbitration", the following extra items are displayed:

- Arbitration timeout (seconds)
- Arbiter alive interval (milliseconds)
- Arbiter alive retry
- Arbiter alive timeout (seconds)
- Arbiter connect interval (milliseconds)
- Arbiter connect timeout (seconds)
- Fencing command
- Fencing command timeout (seconds)
- Shutdown detached synchronous standby

When the [Heartbeat error action] is set to "Arbitration", the [Arbitration server configuration] section is displayed with the following items:

- Core file path
- Syslog facility
- Syslog identity
- Fencing command timeout (seconds)
- Heartbeat interval (milliseconds)
- Heartbeat timeout (seconds)
- Heartbeat retry

When the [Heartbeat error action] is set to "Command", the following extra items are available:

- Fencing command timeout (seconds)

- Arbitration command timeout (seconds)
- Shutdown detached synchronous standby

When the [Heartbeat error action] is set to "Message", the following extra items are available:

- Fencing command
- Fencing command timeout (seconds)

In addition, the following configurations are provided:

- DB instance JDBC connection SSL parameters
- DB instance libpq connection SSL parameters

4. Click to update the Mirroring Controller configurations.

5.4 Stopping Mirroring Controller

Mirroring Controller can be stopped either in master instance or in standby instance using WebAdmin.

Perform the following procedure to stop Mirroring Controller.

1. In the [Instances] tab, select the instance where to stop Mirroring Controller.
2. Click .
3. In the confirmation dialog box, click [Yes].

Mirroring Controller will be stopped on the selected instance. The Mirroring Controller status will be updated, and a confirmation message entry will be displayed in the [Message] section.

5.5 Starting Mirroring Controller

Mirroring Controller can be started either in master instance or in standby instance using WebAdmin.

Perform the following procedure to start Mirroring Controller.

1. In the [Instances] tab, select the instance where to start Mirroring Controller.
2. Click .
3. In the confirmation dialog box, select the desired failover mode, and then click [Yes].

Mirroring Controller will be started on the selected instance. The Mirroring Controller status will be updated, and a confirmation message entry will be displayed in the [Message] section.

5.6 Disabling Failover Mode

Disabling failover mode in Mirroring Controller disables automatic switch/disconnection between master and standby instances.

Perform the following procedure to disable failover mode.

1. In the [Instances] tab, select the instance.
2. Click .
3. In the confirmation dialog box, click [Yes].

Failover mode will be disabled in Mirroring Controller. The Mirroring Controller status will be updated and a confirmation message entry will be displayed in the [Message] section.

5.7 Enabling Failover Mode

Enabling failover mode in Mirroring Controller enables automatic switch/disconnection between master and standby instances.

Perform the following procedure to enable failover.

1. In the [Instances] tab, select the instance.
2. Click .
3. In the confirmation dialog box, click [Yes].

Failover mode will be enabled in Mirroring Controller. The Mirroring Controller status will be updated and a confirmation message entry will be displayed in the [Message] section.

5.8 Deleting Mirroring Controller Setup

Deleting Mirroring Controller setup removes its setup from master and standby instances.

1. In the [Instances] tab, select the instance.
2. Click .
3. In the confirmation dialog box, click [Yes].

Mirroring Controller setup will be removed from the cluster. The cluster status will be updated and a confirmation message entry will be displayed in the [Message] section.

For the instances in FUJITSU Enterprise Postgres 12 or later, WebAdmin does not delete the Mirroring Controller management directory and the configuration files.

5.9 Status Update after Failover

When Mirroring Controller performs a failover, standby instance will be promoted to standalone instance. The Mirroring Controller setup will be removed from both standby and master instances.

The following scenario describes one of the ways in which failover can be triggered, and the results achieved by the use of Mirroring Controller in WebAdmin.

1. In the [Instances] tab, select the master instance "inst1".
2. Click .
3. In the confirmation dialog box, the warning "This instance is being monitored by Mirroring Controller. Stopping the instance may result in cluster failover." is displayed.
4. Choose the stop mode and click [Yes].

   In the server, the following takes place:

   a. The master instance is stopped.
   b. Failover is triggered in Mirroring Controller.
   c. The Mirroring Controller setup is removed from both master and standby instances
   d. Standby instance is promoted to standalone.
5. When the instance is refreshed in WebAdmin, the latest status of the instances will be displayed.

Information

When failover is performed, the Mirroring Controller setup is removed from both master and standby instances. Therefore, to manage the Mirroring Controller using WebAdmin again, create the standby instance and set up Mirroring Controller.

Refer to "Creating a Standby Instance" in the Operation Guide for details.

Refer to "5.1 Mirroring Controller Setup" for details.

5.10 Action Required when an Error Occurs in the Combined Admin Network and Log Transfer Network

Communication errors may temporarily occur in the network used as the admin network and log transfer network due to reasons such as high load on the server or insufficient system resources. Because of this, there is a risk of causing a split-brain situation by mistake even though the server has no issues.

Split brain is a phenomenon in which both servers temporarily operate as primary servers, causing data updates to be performed on both servers.

Point

The admin network is important because Mirroring Controllers use it to confirm the status of each server.

The log transfer network is also important to maintain the data freshness.

Therefore, use network configurations resistant to faults for these networks by using the network redundancy channel bonding feature provided by the operating system or network driver vendor.

How to detect split brain using WebAdmin

If the conditions below are met, split brain may occur. Refer to "Split-brain detection method" and "How to recover from a split-brain" in "Appendix D Notes on Performing Automatic Degradation Immediately after a Heartbeat Abnormality" and take the actions described.

1. A standby instance is selected in the [Instances] tab, and
2. "Standalone" is displayed in [Instance type], and
3. A master instance is selected in the [Instances] tab, and
4. "Standalone" is displayed in [Instance type].

5.11 Performing Automatic Degradation Using the Arbitration Server

If database multiplexing is performed using WebAdmin, it is also possible to perform automatic degradation using the arbitration server. In such cases, it is necessary to perform tasks on the database server and the arbitration server after setting up Mirroring Controller in WebAdmin.

Tasks on the arbitration server

Perform setup of the arbitration server using Mirroring Controller commands.

1. Set up the arbitration server.

   Refer to "2.3 Setting Up the Arbitration Server" in "Chapter 2 Setting Up Database Multiplexing Mode" for information on how to set up the arbitration server.

Tasks on the database server

Change some of the settings after setting up Mirroring Controller in WebAdmin.

1. Set up Mirroring Controller in WebAdmin.

   Refer to "5.1 Mirroring Controller Setup" for details.

2. Use WebAdmin to stop Mirroring Controller on the master and standby instances.

   Refer to "5.4 Stopping Mirroring Controller" for details.

3. Edit the network configuration file of the master and standby instances, and add the arbitration server information.

   The network configuration file is network.conf, which exists in the Mirroring Controller management directory specified during Mirroring Controller setup. Refer to "A.3 Network Configuration File" for details.

   A definition example of network.conf is shown below.

   ```
   Example:
   The port number of the database server to be used as the arbitration network is set to "27541".
   The ID of the server of the Mirroring Controller arbitration process is set to "arbiter", and its
   port number is set to "27541".
   ```

   ```
   dbsvm27500 192.0.2.100,192.0.3.100 27540,27541 server
   dbsvs27500 192.0.2.110,192.0.3.110 27540,27541 server
   arbiter 192.0.3.120 27541 arbiter
   ```

   Information

   Ensure that the port numbers set for the database server and the arbitration server do not conflict with other software. In addition, do not configure the same segment for the admin network and the arbitration network.

   Point

   - If the server type is "server", two IP addresses or host names, and two port numbers need to be specified in the following order:
     - IP address or host name of the database server used as the admin network
     - IP address or host name of the database server used as the arbitration network
     - Port number of the database server used as the admin network
     - Port number of the database server used as the arbitration network
   - If the server type is "arbiter", specify the IP address or host name set for the my_address parameter and the port number set for the port parameter in arbitration.conf of the arbitration server.
   - When using the admin network and arbitration network together, the following IP addresses or host names must be assigned the same values.
     - IP address or host name of the database server used as the admin network
     - IP address or host name of the database server used as the arbitration network

     Example)
     Here is an example where the server identifiers for the primary server and standby server are "server1" and "server2", with port numbers "27540" and "27541", and the server identifier for the Mirroring Controller arbitration process is "arbiter", with port number "27541".

     ```
     server1 192.0.2.100,192.0.2.100 27540,27541 server
     server2 192.0.2.110,192.0.2.110 27540,27541 server
     arbiter 192.0.2.120 27541 arbiter
     ```

4. Edit the server configuration file of the master and standby instances, and add the parameters required for automatic degradation using the arbitration server.

   The server configuration file is *instanceName*.conf or *instancePort*.conf, which exists in the Mirroring Controller management directory specified during Mirroring Controller setup.

   To perform automatic degradation using the arbitration server, set the heartbeat_error_action parameter to "arbitration".

   Refer to "A.4.1 Server Configuration File for the Database Servers" for information on other parameters.

5. Use WebAdmin to start Mirroring Controller on the master and standby instances.

   Refer to "5.5 Starting Mirroring Controller" for details.

Common tasks

1. Use the Mirroring Controller command to check the connection status from the database server or the arbitration server.

   Refer to "2.8 Checking the Connection Status" for information on how to check the connection status.

Appendix A Parameters

This appendix describes the configuration files and parameters required by the database multiplexing mode.

See

Refer to "Server Configuration" in the PostgreSQL Documentation for information on the postgresql.conf file.

A.1 Parameters Set on the Primary Server

The content for the parameters set in the postgresql.conf file of the primary server is shown in the table below.

Table A.1 postgresql.conf file

Parameter	Value set	Explanation
wal_level	replica or logical	Specify the output level for the transaction log. Specify "logical" when logical decoding is also to be used.
max_wal_senders	2 or more	Specify "2" when building a Mirroring Controller cluster system. When additionally connecting asynchronous standby servers to the cluster system, add the number of simultaneous connections from these standby servers.
synchronous_standby_names	'*standbyServerName*'	Use single quotation marks (') to enclose the name that will identify the standby server. Any name can be specified. Do not change this parameter while Mirroring Controller is running. Do not specify multiple names to this parameter as the Mirroring Controller can manage only one standby server.
synchronized_standby_slots	'*physicalReplicationSlotName*'	Specify this parameter if the primary server will be a logical replication publication. Setting this parameter ensures that the subscriber is updated after WAL is sent to the standby server. This allows logical replication to continue if the primary server fails and the standby server is promoted. Do not change this parameter while the Mirroring Controller is running. Because the Mirroring Controller can manage only one standby server, do not specify multiple names for this parameter.
hot_standby	on	Specify whether queries can be run on the standby server. Specify "on".
wal_keep_size	WAL save size (megabytes)	If a delay exceeding the value set in this parameter occurs, the WAL segment required later by the primary server may be deleted. Additionally, if you stop a standby server (for maintenance, for example), consider the stop time and set a value that will not cause the WAL segment to be deleted. Refer to "Estimating Transaction Log Space Requirements" in the Installation and Setup Guide for Server for information on estimating the WAL save size.

Parameter	Value set	Explanation
wal_log_hints	on	When using the pg_rewind command to recover a standby server, specify this parameter or enable checksums when executing the initdb command.
wal_sender_timeout	Timeout (milliseconds)	Specify the time period after which it is determined that the receiver process (walreceiver) of the transaction log is in an abnormal state on the primary server. The specified value must be larger than the value set for the wal_receiver_status_interval parameter set in the postgresql.conf file of the standby server. By aligning this value with the value for the database process heartbeat monitoring time, you can unify the time after which it is determined that an error has occurred.
wal_receiver_timeout	Timeout (milliseconds)	Specify the time period after which it is determined that an error has occurred when the transaction log was received on the standby server. By aligning this value with the value for the database process heartbeat monitoring time, you can unify the time after which it is determined that an error has occurred.
archive_mode	on	Specify the archive log mode.
archive_command	'*installDir*/bin/pgx_walcopy.cmd "%p" "*backupDataStorageDestinationDirectory*/archived_wal/%f"'	Specify the command and storage destination to save the transaction log.
backup_destination	Backup data storage destination directory	Specify the name of directory where to store the backup data. Set the permissions so that only the instance administrator user can access the specified directory. Specify the same full path on all servers, so that the backup data of other servers can be used to perform recovery.
listen_addresses	Primary server IP address, host name, or "*"	Specify the IP address or host name of the primary server. Specify the IP address or corresponding host name that will be used to connect to the log transfer network. The content specified is also used to allow connections from client applications. To receive the connection and the transaction log from any client or standby server, specify "*". Refer to "Connections and Authentication" in the PostgreSQL Documentation for details.
max_connections	Number of simultaneous client connections to the instance + superuser_reserved_connections value	The value specified is also used to restrict the number of connections from client applications and the number of connections for the management of instances. Refer to "When an Instance was Created with the initdb Command" in the Installation and Setup Guide for Server, and "Connections and Authentication" in the PostgreSQL Documentation, for details.
superuser_reserved_connections	Add the number of simultaneous executions of mc_ctl status (*1) + 2	Specify the number of connections reserved for connections from database superusers.

Parameter	Value set	Explanation
		Add the number of connections from Mirroring Controller processes. Also reflect the added value in the max_connections parameter.
restart_after_crash	off	If "on" is specified, or the default value is used for this parameter, behavior equivalent to restarting Fujitsu Enterprise Postgres, including crash recovery, will be performed when some server processes end abnormally. However, when database multiplexing monitoring is used, a failover will occur after an error is detected when some server processes end abnormally, and the restart of those server processes is forcibly stopped. Specify "off" to prevent behavior such as this from occurring for no apparent reason.
synchronous_commit	on or remote_apply	Specify up to what position WAL send is to be performed before transaction commit processing returns a normal termination response to a client. Set "on" or "remote_apply" to prevent data loss caused by operating system or server down immediately after a switch or switch.
recovery_target_timeline	latest	Specify "latest" so that the new standby server (original primary server) will follow the new primary server when a switch occurs. This parameter is required when the original primary server is incorporated as a new standby server after the primary server is switched.

*1: Number of simultaneous executions of the mc_ctl command in the status mode.

A.2 Parameters Set on the Standby Server

This section explains the content of the file and parameters set on the standby server. After editing postgresql.conf file, start the instance.

The content for the parameters specified in postgresql.conf file is shown in the table below.

Table A.2 postgresql.conf file

Parameter	Value set	Explanation
wal_level	replica or logical	Specify the output level for the transaction log. Specify "logical" when logical decoding is also to be used.
max_wal_senders	2 or more	Specify "2" when building a Mirroring Controller cluster system. When additionally connecting asynchronous standby servers to the cluster system, add the number of simultaneous connections from these standby servers.
synchronous_standby_names	'*primaryServerName*'	Use single quotation marks (') to enclose the name that will identify the primary server. Any name can be specified. This name will be required to rebuild the original primary server as the new standby server after the primary server was switched.

Parameter	Value set	Explanation
		Do not change this parameter while Mirroring Controller is running. Do not specify multiple names to this parameter as the Mirroring Controller can manage only one standby server.
hot_standby	on	Specify whether queries can be run on the standby server. Specify "on".
wal_keep_size	WAL save size (megabytes)	If a delay exceeding the value set in this parameter occurs, the WAL segment required later by the standby server may be deleted by the primary server. Additionally, if you stop a standby server (for maintenance, for example), consider the stop time and set a value that will not cause the WAL segment to be deleted. Refer to "Estimating Transaction Log Space Requirements" in the Installation and Setup Guide for Server for information on estimating the WALsave size.
wal_log_hints	on	When using the pg_rewind command to recover a standby server, specify this parameter or enable checksums when executing the initdb command.
wal_sender_timeout	Timeout (milliseconds)	Specify the time period after which it is determined that the receiver process (walreceiver) of the transaction log is in an abnormal state on the primary server. The specified value must be larger than the value set for the wal_receiver_status_interval parameter set in the postgresql.conf file of the standby server. By aligning this value with the value for the database process heartbeat monitoring time, you can unify the time after which it is determined that an error has occurred.
wal_receiver_timeout	Timeout (milliseconds)	Specify the time period after which it is determined that an error has occurred when the transaction log was received on the standby server. By aligning this value with the value for the database process heartbeat monitoring time, you can unify the time after which it is determined that an error has occurred.
backup_destination	Backup data storage destination directory	Specify the name of the backup data storage directory. Set the permissions so that only the instance administrator user can access the specified directory. Specify the same full path on all servers so that the backup data of other servers can be used to perform recovery.
archive_mode	on	Specify the archive log mode.
archive_command	'*installDir*/bin/pgx_walcopy.cmd "%p" "*backupDataStorageDestinationDirectory*/archived_wal/%f"'	Specify the command and storage destination to save the transaction log.

Parameter	Value set	Explanation
listen_addresses	Standby server IP address, host name, or "*"	Specify the IP address or host name of the standby server. Specify the IP address or corresponding host name that will be used to connect to the log transfer network. The content specified is also used to allow connections from client applications. To receive the connection and the transaction log from any client or standby server, specify "*". Refer to "Connections and Authentication" in the PostgreSQL Documentation for details.
max_connections	Number of simultaneous client connections to the instance + superuser_reserved_connections value	The value specified is also used to restrict the number of connections from client applications and the number of connections for the management of instances. Refer to "When an Instance was Created with the initdb Command" in the Installation and Setup Guide for Server, and "Connections and Authentication" in the PostgreSQL Documentation, for details.
superuser_reserved_connections	Add the number of simultaneous executions of mc_ctl status (*1) + 2	Specify the number of connections reserved for connections from database superusers. Add the number of connections from Mirroring Controller processes. Also reflect the added value in the max_connections parameter.
restart_after_crash	off	If "on" is specified, or the default value is used for this parameter, behavior equivalent to restarting Fujitsu Enterprise Postgres, including crash recovery, will be performed when some server processes end abnormally. However, when database multiplexing monitoring is used, a failover will occur after an error is detected when some server processes end abnormally, and the restart of those server processes is forcibly stopped. Specify "off" to prevent behavior such as this from occurring for no apparent reason.
synchronous_commit	on or remote_apply	Specify up to what position WAL send is to be performed before transaction commit processing returns a normal termination response to a client. Set "on" or "remote_apply" to prevent data loss caused by operating system or server down immediately after a switch or switch.
primary_conninfo	'*streamingReplicationConnectionDestinationInfo*'	Use single quotation marks (') to enclose the connection destination information of the streaming replication. The default value of this parameter is automatically set to postgresql.auto.conf in the procedure to run pg_basebackup for instance setup.
recovery_target_timeline	latest	Specify "latest" so that the new standby server (original primary server) will follow the new primary server when a switch occurs. This parameter is required when the original primary server is incorporated as a new standby server after the primary server is switched.

A.3 Network Configuration File

This section explains the network configuration file (network.conf) to be defined individually for the database servers and the arbitration server. Define the same content on the primary server and standby server.

For database multiplexing mode, define the network configuration for the following in network.conf.

- Integration between Mirroring Controller processes
- Integration between a Mirroring Controller process and the Mirroring Controller arbitration process

Items to be defined in network.conf

Format:

```
serverIdentifier hostName[,hostName] portNum[,portNum] [serverType]
Or,
serverIdentifier ipAddr[,ipAddr] portNum[,portNum] [serverType]
```

Specify the server identifier, IP address or host name, port number, and server type, using a space as the delimiter.

The items are explained in the table below.

Table A.3 network.conf file

Item	Description
serverIdentifier	Specify any identifier for the server. The maximum length is 64 bytes. Use ASCII characters excluding spaces and number signs (#) to specify this parameter.
ipAddrOrHostName	Specify the IP address or its corresponding host name that will connect to the admin network that performs communication between the database servers, and to the arbitration network that performs communication between a database server and the arbitration server. When specifying two IP addresses or host names delimited by a comma, do not insert a space after the comma. Use ASCII characters excluding spaces to specify the host name.
portNum	A port number cannot be specified if it exceeds the range 0 to 65535. Ensure that the port number does not conflict with other software. Do not specify an ephemeral port that may temporarily be assigned by another program. Note that the value specified in this parameter must also be set in the services file. When specifying two port numbers delimited by a comma, do not insert a space after the comma.
serverType	Specify "server" for a database server ("server" can be omitted), or "arbiter" for the arbitration server.

Content to be defined on the database servers

This section explains the network.conf content to be defined on the database servers.

The content to be defined depends on the operation settings at the time a heartbeat abnormality is detected.

When automatic degradation by the arbitration server is selected

- Specify definitions related to the admin network and arbitration network.
- Specify the IP address or host name and port number according to the server type (database server or arbitration server) as shown in the table below.

Server type	IP address or host name		Port number	
	First	Second	First	Second
server	IP address or host name used as the admin network	IP address or host name used as the arbitration network (*1)	Port number used as the admin network	Port number used as the arbitration network (*1)

Server type	IP address or host name		Port number	
	First	Second	First	Second
arbiter	IP address or host name of the arbitration server Specify the same value as that specified in the my_address parameter of arbitration.conf on the arbitration server.	Not required	Port number on the arbitration server Specify the same value as that specified in the port parameter of arbitration.conf on the arbitration server.	Not required

*1: This value can be omitted from definitions not related to the local server. If it is omitted, network.conf must be created on both the primary server and standby server.

Example)

IPv4

```
server1 192.0.2.100,192.0.3.100 27540,27541 server
server2 192.0.2.110,192.0.3.110 27540,27541 server
arbiter 192.0.3.120 27541 arbiter
```

IPv6

```
server1 2001:258:8404:1217:250:56ff:fea7:559f,2001:258:8404:1217:250:56ff:fea8:559f
27540,27541 server
server2 2001:258:8404:1217:250:56ff:fea7:55a0,2001:258:8404:1217:250:56ff:fea8:55a0
27540,27541 server
arbiter 2001:258:8404:1217:250:56ff:fea8:55a0 27541 arbiter
```

When operation other than automatic degradation by the arbitration server is selected

- Specify definitions related to the admin network.
- Define the same content on the primary server and standby server.
- Define lines for database servers only.
- Specify only one IP address or host name and port number.

IP address or host name		Port number	
First	Second	First	Second
IP address or host name to be used as the admin network	Not required	Port number used as the admin network	Not required

Example)

The literal space represents a space.

IPv4

```
server1 192.0.2.100 27540
server2 192.0.2.110 27540
```

IPv6

```
server1 2001:258:8404:1217:250:56ff:fea7:559f 27540
server2 2001:258:8404:1217:250:56ff:fea7:55a0 27540
```

Content to be defined on the arbitration server

This section explains the network.conf content to be defined on the arbitration server.

- Specify definitions related to the arbitration network.
- Define lines for database servers only.
- For the IP address or host name, specify the same value as the second IP address or host name specified in the database server line in network.conf of the database server.
- For the port number, specify the same value as the second port number specified in the database server line in network.conf of the database server.

Example)

The literal space represents a space.

IPv4

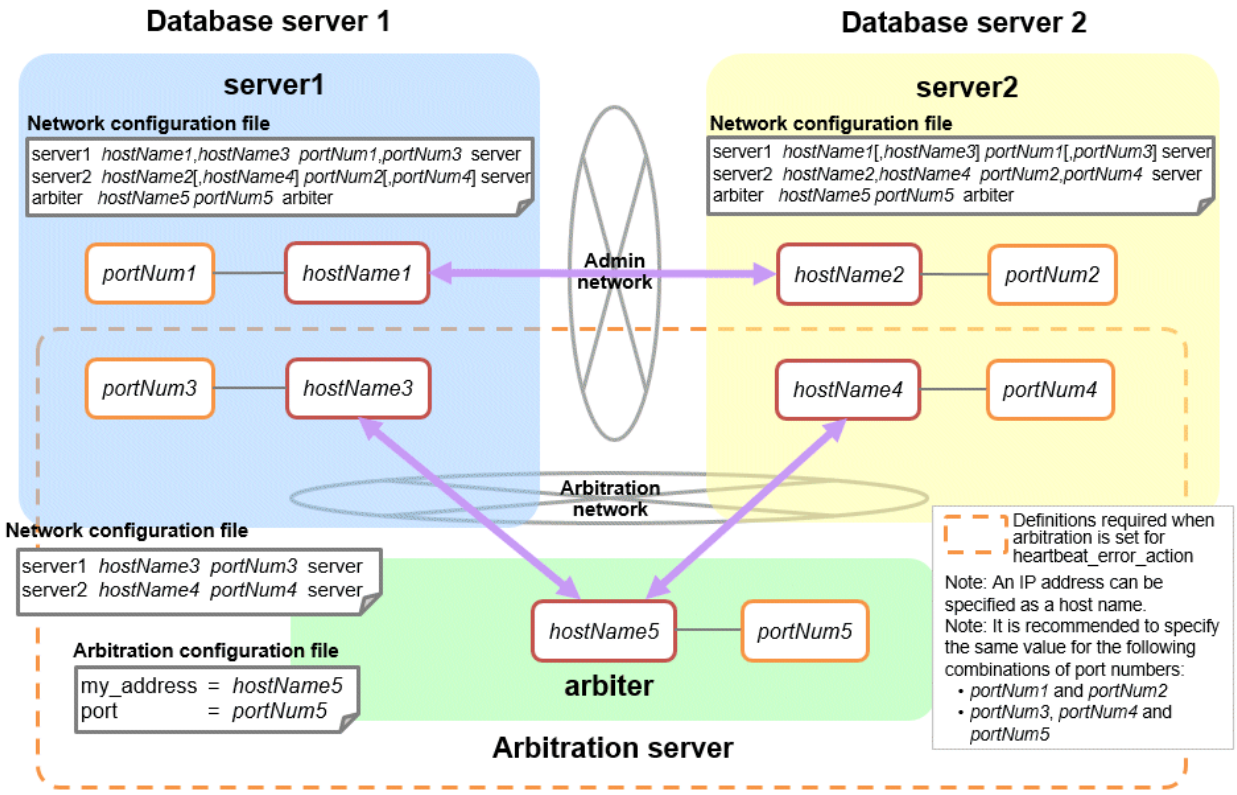
```
server1 192.0.3.100 27541
server2 192.0.3.110 27541
```

IPv6

```
server1 2001:258:8404:1217:250:56ff:fea8:559f 27541
server2 2001:258:8404:1217:250:56ff:fea8:55a0 27541
```

Relationship between network-related definitions

Refer to the diagram below for the relationship between the host names and IP addresses or port numbers specified in the network configuration file (network.conf) and arbitration configuration file (arbitration.conf).



A.4 Server Configuration File

A.4.1 Server Configuration File for the Database Servers

Define the information related to Mirroring Controller monitoring and control in the serverIdentifier.conf file. The maximum length of the server identifier is 64 bytes. Use ASCII characters excluding spaces to specify this parameter.

If the primary server and standby server environments are different, define content that is different, according to the environment.

Table A.4 serverIdentifier.conf file

Parameter	Value set	Explanation
db_instance	'*dataStorageDestinationDir*' [Example] db_instance = '/database1/inst1'	Specify using single quotation marks (') to enclose the data storage destination directory used to identify the monitoring target instance. Use ASCII characters to specify this parameter.
target_db	postgres or template1	Specify the name of the database to be connected to the database instance. The default is "postgres".
db_instance_username	'*usernameToConnectToDbInstance*'	Specify the username to connect to the database instance. Use ASCII characters to specify this parameter. Specify this parameter if the database administrator user is different from the operating system user who starts Mirroring Controller. Enclose the username of the database superuser in single quotation marks ('). The maximum length of the username is 63 bytes.

Parameter	Value set	Explanation
		The default is the operating system user who starts Mirroring Controller.
db_instance_password	'*passwordOfInstanceAdminUser*'	Specify the password used when Mirroring Controller connects to a database instance, enclosed in single quotation marks ('). Use ASCII characters to specify this parameter. If password authentication is performed, you must specify this parameter in the settings used when Mirroring Controller connects to a database instance. If you specify this parameter when password authentication is not performed, the parameter will be ignored. If the specified value of this parameter includes ' or \, write \' or \\, respectively.
enable_hash_in_password	on or off	Specify on to treat the # in the db_instance_password specification as a password character, or off to treat it as a comment. The default is "off".
core_file_path	*'coreFileOutputDir'*	Specify the directory to which the core file is to be output, enclosed in single quotation marks ('). Use ASCII characters to specify this parameter. If this parameter is omitted, it will be assumed that the Mirroring Controller management directory was specified.
syslog_facility	Specify LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, LOCAL5, LOCAL6, or LOCAL7.	When the import of logs to the syslog is enabled, the value of this parameter will be used for "facility" of the syslog. The default is "LOCAL0".
syslog_ident (*1)	'*programName*'	Specify using single quotation marks (') to enclose the program name used to identify the Mirroring Controller message in the system log. Use ASCII characters excluding spaces to specify this parameter. The default is 'MirroringControllerOpen'.
remote_call_timeout	Admin communication timeout	Specify the timeout value (milliseconds) of the Mirroring Controller agent process for communication between servers. Specify a value between 0 and 2147483647 to be less than the operation system TCP connection timeout (*2). In addition, when using the Mirroring Controller arbitrage process, fencing commands, and state transition commands, specify a value that is greater than the sum of the timeout values (*3). The value 0 indicates that there is no timeout limit. The default is 70000 milliseconds (70 seconds).
agent_alive_timeout	Timeout for Mirroring Controller process heartbeat monitoring (seconds)	If there is no response for at least the number of seconds specified, the Mirroring Controller process is restarted.

Parameter	Value set	Explanation
		Specify 0 or a value between 2 and 2147483647. The value 0 indicates that there is no timeout limit. The default is 0 seconds.
heartbeat_error_action	Operation when a heartbeat abnormality is detected using operating system or server heartbeat monitoring	arbitration: Perform automatic degradation using the arbitration server. command: Call a user exit to determine degradation, and perform automatic degradation if required. message: Notify messages. fallback: Perform automatic degradation unconditionally. The default is "arbitration". Set the same value on the primary server and standby server.
heartbeat_interval	Interval time for abnormality monitoring during heartbeat monitoring of the operating system or server (milliseconds)	Abnormality monitoring of the operating system or server is performed at the interval specified in heartbeat_interval. If an error is detected, operation will conform to the value specified for heartbeat_error_action. If "arbitration" is specified in heartbeat_error_action, the error detection time during monitoring of the operating system or server becomes longer than when the arbitration server is not used, by up to the value specified for arbitration_timeout. Specify a value between 1 and 2147483647. The specified value is used as the default for db_instance_check_interval and disk_check_interval. The default is 800 milliseconds.
heartbeat_timeout	Timeout for abnormality monitoring during heartbeat monitoring of the operating system or server (seconds)	If there is no response for at least the number of seconds specified, it will be assumed that an error has occurred that requires the primary server to be switched, or the standby server to be disconnected. If an error is detected, operation will conform to the value specified for heartbeat_error_action. If "arbitration" is specified in heartbeat_error_action, the error detection time during monitoring of the operating system or server becomes longer than when the arbitration server is not used, by up to the value specified for arbitration_timeout. Specify a value between 1 and 2147483647. The specified value is used as the default for db_instance_check_timeout. The default is 1 second.
heartbeat_retry	Number of retries for abnormality monitoring during heartbeat monitoring of the operating system or server (number of times)	Specify the number of retries to be performed when an error has been detected that requires the primary server to be switched, or the standby server to be disconnected. If an error is detected in succession more than the specified number of times, switch or disconnection will be performed. If an error is detected, operation will conform to the value specified for heartbeat_error_action. If "arbitration" is specified in heartbeat_error_action, the error detection time during monitoring of the operating system or server

Parameter	Value set	Explanation
		becomes longer than when the arbitration server is not used, by up to the value specified for arbitration_timeout. Specify a value between 0 and 2147483647. The specified value is used as the default for db_instance_check_retry and disk_check_retry. The default is 2 times.
db_instance_check_interval	Database process heartbeat monitoring interval (milliseconds)	Heartbeat monitoring of the database process is performed at the interval specified in db_instance_check_interval. This parameter setting is also used for abnormality monitoring of streaming replication. Specify a value between 1 and 2147483647. The default is the value set for heartbeat_interval.
db_instance_check_timeout	Database process heartbeat monitoring timeout (seconds)	If there is no response for at least the number of seconds specified, it will be assumed that an error has occurred that requires the primary server to be switched, or the standby server to be disconnected. Specify a value between 1 and 2147483647. The default is the value set for heartbeat_timeout.
db_instance_check_retry	Number of retries for database process heartbeat monitoring (number of times)	Specify the number of retries to be performed when an error has been detected that requires the primary server to be switched, or the standby server to be disconnected. If an error is detected in succession more than the specified number of times, switch or disconnection will be performed. However, if it detects that the database process is down, it will immediately switch or disconnect regardless of the setting of this parameter. This parameter setting is also used for abnormality monitoring of streaming replication. Specify a value between 0 and 2147483647. The default number of retries is the value set for heartbeat_retry.
db_instance_timeout_action	none, message, or failover	Specify the behavior for no-response monitoring of the instance. none: Do not perform no-response monitoring. message: Notify messages if an error is detected during no-response monitoring. failover: Perform automatic degradation if an error is detected during no-response monitoring. The default is "failover".
disk_check_interval	Interval time for disk abnormality monitoring (milliseconds)	Abnormality monitoring of disk failure is performed at the interval specified in disk_check_interval. If the file cannot be created, it will be assumed that an error has occurred that requires the primary server to be switched, or the standby server to be disconnected. Specify a value between 1 and 2147483647. Set a value larger than the disk access time.

Parameter	Value set	Explanation
		The default is the value set for heartbeat_interval.
disk_check_retry	Number of retries for disk abnormality monitoring (number of times)	Specify the number of retries to be performed when an error has been detected that requires the primary server to be switched, or the standby server to be disconnected. If an error is detected in succession more than the specified number of times, switch or disconnection will be performed. Specify a value between 0 and 2147483647. The default number of retries is the value set for heartbeat_retry.
disk_check_timeout	Abnormality monitoring timeout time (seconds)	The time allowed from the start time of the next disk_check_interval after a disk error occurs until the error is determined to be due to timeout. To disconnect the standby server when a disk error due to this timeout is detected on the standby server, set shutdown_detached_synchronous_standby to on. The default is 2147483. Specify an integer between 0 and 2147483.
disk_check_max_threads	Upper limit on the number of threads used for abnormality monitoring	Upper limit on the number of threads for disk monitoring. The default is the number of processors available to the JVM) Specify an integer between 1 and 2147483647, but setting a value greater than the threads available on the machine may result in a system error. When you run the mc_ctl status command separately from the monitoring process, each mc_ctl status temporarily uses the same number of threads as the monitoring process. When setting disk_check_max_threads, consider the machine's thread limit, the number of table spaces you plan to use, and the number of mc_ctl status commands that may be executed at the same time.
tablespace_directory_error_action	message or failover	Specify the behavior to be implemented if an error is detected in the tablespace storage directory. message: Notify messages. failover: Perform automatic degradation. The default is "failover".
arbiter_alive_interval	Interval time for monitoring connection to the Mirroring Controller arbitration process (milliseconds)	A heartbeat is sent to the Mirroring Controller arbitration process at the specified interval. Specify a value between 1 and 2147483647. The default is 16000 milliseconds. This parameter does not need to be set for operation that does not use the arbitration server.
arbiter_alive_timeout	Timeout for monitoring connection to the Mirroring Controller arbitration process (seconds)	If the heartbeat does not respond within the specified number of seconds, the Mirroring Controller arbitration process is determined to have been disconnected, a message is output, and reconnection is attempted.

Parameter	Value set	Explanation
		Specify a value between 1 and 2147483647. The default is 20 seconds. This parameter does not need to be set for operation that does not use the arbitration server.
arbiter_alive_retry	Number of retries for monitoring connection to the Mirroring Controller arbitration process (number of times)	Specify the number of heartbeat retries to be performed if an error is detected in the heartbeat to the Mirroring Controller arbitration process. If the heartbeat does not respond within the specified number of retries, the Mirroring Controller arbitration process is determined to have been disconnected. Specify a value between 0 and 2147483647. The default is 0 times. This parameter does not need to be set for operation that does not use the arbitration server.
arbiter_connect_interval	Attempt interval for connection to the Mirroring Controller arbitration process (milliseconds)	Reconnection is attempted at the specified interval if connection fails at startup of the Mirroring Controller process or if the Mirroring Controller arbitration process is disconnected. Specify a value between 1 and 2147483647. The default is 16000 milliseconds. This parameter does not need to be set for operation that does not use the arbitration server.
arbiter_connect_timeout	Timeout for connection to the Mirroring Controller arbitration process (seconds)	If reconnection at startup of the Mirroring Controller process or after disconnection of the Mirroring Controller arbitration process does not succeed within the specified number of seconds, connection to the Mirroring Controller arbitration process is determined to have failed and reconnection is attempted. Specify a value between 1 and 2147483647. The default is 20 seconds. This parameter does not need to be set for operation that does not use the arbitration server.
fencing_command	'*fencingCmdFilePath*' [Setting example] fencing_command = '/mc/fencing_dir/execute_fencing.sh'	Specify the full path of the fencing command that fences a database server where an error is determined to have occurred. Enclose the path in single quotation marks ('). Specify the path using less than 1024 bytes. This parameter must be specified when "command" is set for heartbeat_error_action.
fencing_command_timeout	Fencing command timeout (seconds)	If the command does not respond within the specified number of seconds, fencing is determined to have failed and a signal (SIGTERM) is sent to the fencing command execution process. Specify a value between 1 and 2147483647. The default is 20 seconds.

Parameter	Value set	Explanation
arbitration_timeout	Arbitration processing timeout in the Mirroring Controller arbitration process (seconds)	The specified value must be at least equal to the value of fencing_command_timeout in the arbitration configuration file, which is the heartbeat monitoring time of the operating system or server. If there is no response for at least the number of seconds specified, the primary server will not be switched and the standby server will not be disconnected. Therefore, perform degradation manually. If the heartbeat_interval, heartbeat_timeout, and heartbeat_retry values are specified in arbitration.conf for the arbitration server, use the arbitration server values to design arbitration_timeout. Specify a value between 1 and 2147483647. The default is 30 seconds. This parameter does not need to be set for operation that does not use the arbitration server.
arbitration_command	'*arbitrationCmdFilePath*' [Setting example] arbitration_command = '/mc/arbitration_dir/execute_arbitration_command.sh'	Specify the full path of the arbitration command to be executed when an abnormality is detected during heartbeat monitoring of the operating system or server. Enclose the path in single quotation marks ('). Specify the path using less than 1024 bytes. This parameter must be specified when "command" is set for heartbeat_error_action.
arbitration_command_timeout	Arbitration command timeout (seconds)	If the arbitration command does not respond within the specified number of seconds, it is determined that execution of the arbitration command has failed and a signal (SIGTERM) is sent to the arbitration command execution process. Specify a value between 1 and 2147483647. The default is 30 seconds. This parameter can be specified only when "command" is set for heartbeat_error_action.
shutdown_detached_synchronous_standby	on or off	Specify whether to forcibly stop the instance on the standby server when the standby server is disconnected. on: Stop the instance. off: Do not stop the instance. If "on" is specified and the pre-detach command was created, the pre-detach command is executed and then the instance is stopped. The default is "off".
post_switch_command	'*postSwitchCmdFilePath*' [Setting example] post_switch_command = '/mc/status_change/execute_post_switch.sh'	Specify the full path of the command to be called by Mirroring Controller after a new primary server is promoted during a failover of the primary server. Enclose the path in single quotation marks ('). Specify the path using less than 1024 bytes.

Parameter	Value set	Explanation
post_attach_command	'*postAttachCmdFilePath*' [Setting example] post_attach_command = '/mc/status_change/execute_post_attach.sh'	Specify the full path of the command to be called by Mirroring Controller after the standby server is attached to the cluster system. Enclose the path in single quotation marks ('). Specify the path using less than 1024 bytes.
pre_detach_command	'*preDetachCmdFilePath*' [Setting example] pre_detach_command = '/mc/status_change/execute_pre_detach.sh'	Specify the full path of the command to be called by Mirroring Controller before the standby server is disconnected from the cluster system. Enclose the path in single quotation marks ('). Specify the path using less than 1024 bytes.
status_change_command_timeout	State transition command timeout (seconds)	Specify the timeout value of the post-switch command, post-attach command, and pre-detach command. If the command does not respond within the specified number of seconds, a signal (SIGTERM) is sent to the execution process of the status change command. Specify a timeout between 1 and 2147483647. The default is 20 seconds.
enable_promote_on_os_and_admin_network_error	on or off	If on is specified, if a admin network error occurs and replication is further lost, the system will ask the arbitration server to verify that the primary server and databases are running, and if they are down, promote the standby server. The default is "off".
startup_process_check_timeout	Timeout period for error monitoring in startup process monitoring (seconds)	If this parameter is not specified, startup process monitoring is disabled. If this parameter is specified, startup process monitoring is enabled, and a startup process anomaly is considered to occur if pending WAL has not been applied in the specified number of seconds or more. This parameter takes effect when running as a standby server. The startup process monitor checks for WAL application at intervals specified by db_instance_check_interval. This delays detection of unresponsive conditions by up to db_instance_check_interval. Set shutdown_detached_synchronous_standby to on to automatically shutdown and disconnect the standby server when an error is detected. Note that depending on the server parameter settings, WAL application on the standby server might be delayed, so set the monitoring time. For example, the max_standby_streaming_delay and recovery_min_apply_delay parameters delay WAL application. Set the monitoring time parameters so that the startup process is not falsely detected as not responding due to the effect of these parameter settings. Specify a number between 1 and 2147483647.

Parameter	Value set	Explanation
check_synchronous_standby_names_validation	on or off	Specify whether Mirroring Controller is to periodically check during operations whether the synchronous_standby_names parameter in postgresql.conf was changed by an incorrect user operation. However, it is not recommended to enable this parameter, because performing this check causes Mirroring Controller to use the CPU of the database server redundantly and execute SQL statements at high frequency. This parameter is compatible with operations in FUJITSU Enterprise Postgres 9.6 or earlier. The default is "off".
db_instance_ext_pq_conninfo	*'libpqConnectionSSLParmToConnectToDbinstance'*	Specify, in key-value form, the connection parameter for libpq that Mirroring Controller adds when connecting to a database. The connection parameters you can specify are those related to SSL. Use ASCII characters to specify this parameter. If you want to validate the server certificate using the destination host name, such as specifying sslmode=verify-full as the connection parameter, specify the host name in the Common Name of the server certificate in the sslservercertcn connection parameter. For information about the sslservercertcn connection parameter, refer to "Using the C Library (libpq)" in "Application Connection Switch Feature" in the Application Development Guide. The connection parameter specified in this parameter must also be specified in the db_instance_ext_jdbc_conninfo.
db_instance_ext_jdbc_conninfo	*'JDBCConnectionSSLParmToConnectToDbinstance'*	Specify, in URI form, the connection parameter for JDBC that Mirroring Controller adds when connecting to a database. The connection parameters you can specify are those related to SSL. Use ASCII characters to specify this parameter. If you want to validate the server certificate using the destination host name, such as specifying sslmode=verify-full as the connection parameter, specify the host name in the Common Name of the server certificate in the sslservercertcn connection parameter. For information about the sslservercertcn connection parameter, refer to "Using the JDBC Driver" in "Application Connection Switch Feature" in the Application Development Guide. The connection parameter specified in this parameter must also be specified in the db_instance_ext_pq_conninfo.

*1: By specifying the syslog_ident parameter of the postgresql.conf file, the Mirroring Controller output content can be referenced transparently, so log reference is easy.

*2: The operating system TCP connection timeout period is determined by the kernel parameter tcp_syn_retries. The remote_call_timeout parameter must be set to a value that is shorter than the timeout period for the operating system TCP connection timeout, so change either parameter as necessary.

*3: In management communications, arbitrage processing, fencing commands, and state transition commands may be executed in succession by the Mirroring Controller arbitrage process. Therefore, the value specified for the remote_call_timeout parameter must be greater than the sum of these timeout values. Depending on the value specified for the heartbeat_error_action parameter, set the remote_call_timeout parameter using the following formula:

- arbitration: (arbitration_timeout + fencing_command_timeout + status_change_command_timeout) * 1000
- command: (fencing_command_timeout + status_change_command_timeout) * 1000
- message: (fencing_command_timeout + status_change_command_timeout) * 1000
- fallback: (status_change_command_timeout) * 1000

Because other internal processing may be performed in the management communication, set the value obtained by multiplying the calculation result of the above equation by the safety factor (about 1.2).

Also, for the fencing_command_timeout parameter, use the value of the parameter in the database server's server definition file, not in the arbitration definition file.

The availability of some parameters depends on the value set for the heartbeat_error_action parameter that sets the operation to be performed if heartbeat monitoring of the operating system or server detects a heartbeat abnormality.

Table A.5 Parameter availability depending on the value set for the heartbeat_error_action parameter

Parameter	Value set			
	arbitration	command	message	fallback
arbiter_alive_interval	Y	N	N	N
arbiter_alive_timeout	Y	N	N	N
arbiter_alive_retry	Y	N	N	N
arbiter_connect_interval	Y	N	N	N
arbiter_connect_timeout	Y	N	N	N
arbitration_timeout	Y	N	N	N
arbitration_command	N	R	N	N
arbitration_command_timeout	N	Y	N	N
fencing_command	Y	R	Y	N
fencing_command_timeout	Y	Y	Y	N
shutdown_detached_synchronous_standby	Y	Y	N	N

R: Required

Y: Can be specified

N: Cannot be specified

A.4.2 Arbitration Configuration File

In arbitration.conf, define the information related to arbitration and control of the Mirroring Controller arbitration process.

Linux

Table A.6 arbitration.conf file (Linux)

Parameter	Value set	Description
port	Port number of the Mirroring Controller arbitration process	The specified value must not exceed the range 0 to 65535. Ensure that the port number does not conflict with other software. Do not specify an ephemeral port that may temporarily be assigned by another program. For the port number of the arbitration server to be specified in network.conf on the database server, specify the same value as the port number specified in this parameter.

Parameter	Value set	Description
my_address	'*ipAddrOrHostNameThatAcceptsConnectionFromMirroringControllerProcessOnDbServer*' [Setting example] my_address = '192.0.3.120'	For the IP address or host name of the arbitration server to be specified in network.conf on the database server, specify the same value as the IP address or host name specified in this parameter. IPv4 and IPv6 addresses can be specified. Specify the IP address or host name, enclosed in single quotation marks (').
core_file_path	'*coreFileOutputDir*'	Specify the directory to which the core file is to be output, enclosed in single quotation marks ('). Use ASCII characters to specify this parameter. If this parameter is omitted, it will be assumed that the Mirroring Controller arbitration process management directory was specified.
syslog_facility	Specify LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, LOCAL5, LOCAL6, or LOCAL7.	When the import of logs to the syslog is enabled, the value of this parameter will be used for "facility" of the syslog. The default is "LOCAL0".
syslog_ident	'*programName*'	Specify using single quotation marks (') to enclose the program name used to identify the Mirroring Controller arbitration process message in the system log. Use ASCII characters excluding spaces to specify this parameter. The default is 'MirroringControllerArbiter'.
fencing_command	'*fencingCmdFilePath*' [Setting example] fencing_command = '/arbiter/fencing_dir/execute_fencing.sh'	Specify the full path of the fencing command that fences a database server where an error is determined to have occurred. Enclose the path in single quotation marks ('). Specify the path using less than 1024 bytes.
fencing_command_timeout	Fencing command timeout (seconds)	If the command does not respond within the specified number of seconds, fencing is determined to have failed and a signal (SIGTERM) is sent to the fencing command execution process. Specify a value between 1 and 2147483647. The default is 20 seconds.
heartbeat_interval(*1)	Interval time for heartbeat monitoring of the operating system or server (milliseconds)	The heartbeat monitoring of the database server is checked at the specified interval and arbitration is performed. Specify a value between 1 and 2147483647. The default is the value specified in *serverIdentifier*.conf of the database server. Specify this parameter to perform optimization taking into account differences in the line load to the admin network and the reduction in the time it takes to degrade.
heartbeat_timeout	Timeout for heartbeat monitoring of the operating system or server (seconds)	If there is no response for at least the number of seconds specified, it will be assumed that an error has occurred that requires the primary server or standby server to be fenced.

Parameter	Value set	Description
		Specify a value between 1 and 2147483647. The default is the value specified in *serverIdentifier*.conf of the database server. Specify this parameter to perform optimization taking into account differences in the line load to the admin network and the reduction in the time it takes to degrade.
heartbeat_retry	Number of retries for heartbeat monitoring of the operating system or server (number of times)	Specify the number of retries to be performed when an error has been detected that requires the primary server or standby server to be fenced. If an error is detected in succession more than the specified number of times, fencing will be performed. Specify a value between 0 and 2147483647. The default is the value specified in *serverIdentifier*.conf of the database server. Specify this parameter to perform optimization taking into account differences in the line load to the admin network and the reduction in the time it takes to degrade.

*1:Refer to "2.11.4 Tuning for Optimization of Degradation Using Abnormality Monitoring" for information on the tuning parameters for operating system or server abnormality monitoring when using an arbitration server.

Windows

Table A.7 arbitration.conf file (Windows)

Parameter	Value set	Description
port	Port number of the Mirroring Controller arbitration process	The specified value must not exceed the range 0 to 65535. Ensure that the port number does not conflict with other software. Do not specify an ephemeral port that may temporarily be assigned by another program. For the port number of the arbitration server to be specified in network.conf on the database server, specify the same value as the port number specified in this parameter.
my_address	'*ipAddrOrHostNameThatAcceptsConnectionFromMirroringControllerProcessOnDbServer*' [Setting example] my_address = '192.0.3.120'	For the IP address or host name of the arbitration server to be specified in network.conf on the database server, specify the same value as the IP address or host name specified in this parameter. IPv4 and IPv6 addresses can be specified. Specify the IP address or host name, enclosed in single quotation marks (').
core_file_path	'*coreFileOutputDir*'	Specify the directory to which the core file is to be output, enclosed in single quotation marks ('). Use ASCII characters. Specify \\ as file separator.

Parameter	Value set	Description
		If this parameter is omitted, it will be assumed that the Mirroring Controller arbitration process management directory was specified.
service_name	'*registeredServiceNameOfMirroringControllerArbitrationProcess*'	Specify the Mirroring Controller arbitration process service name to be registered as a Windows service, enclosed in single quotation marks ('). Use ASCII characters excluding forward slash (/) and backslash (\) to specify this parameter. The service name is up to 124 bytes. The default is 'MirroringControllerArbiter'.
event_source	*'eventSourceName'*	Specify the event source name to be used to identify the Mirroring Controller arbitration process message in the event log, enclosed in single quotation marks ('). Use ASCII characters to specify this parameter. The maximum length of the event source name is 255 bytes. The default is 'MirroringControllerArbiter'.
fencing_command	'*fencingCmdFilePath*' [Setting example] fencing_command = 'c:\\arbiter\ \fencing_dir\\execute_fencing.bat'	Specify the full path of the fencing command that fences a database server where an error is determined to have occurred. Specify \\ as file separator. Enclose the path in single quotation marks ('). Specify the path using less than 260 bytes. Any multibyte characters must use the same encoding as the operating system.
fencing_command_timeout	Fencing command timeout (seconds)	If the command does not respond within the specified number of seconds, fencing is determined to have failed and a signal (SIGTERM) is sent to the fencing command execution process. Specify a value between 1 and 2147483647. The default is 20 seconds.
heartbeat_interval(*1)	Interval time for heartbeat monitoring of the operating system or server (milliseconds)	The heartbeat monitoring of the database server is checked at the specified interval and arbitration is performed. Specify a value between 1 and 2147483647. The default is the value specified in *serverIdentifier*.conf of the database server. Specify this parameter to perform optimization taking into account differences in the line load to the admin network and the reduction in the time it takes to degrade.
heartbeat_timeout	Timeout for heartbeat monitoring of the operating system or server (seconds)	If there is no response for at least the number of seconds specified, it will be assumed that an error has occurred that requires the primary server or standby server to be fenced. Specify a value between 1 and 2147483647.

Parameter	Value set	Description
		The default is the value specified in *serverIdentifier*.conf of the database server. Specify this parameter to perform optimization taking into account differences in the line load to the admin network and the reduction in the time it takes to degrade.
heartbeat_retry	Number of retries for heartbeat monitoring of the operating system or server (number of times)	Specify the number of retries to be performed when an error has been detected that requires the primary server or standby server to be fenced. If an error is detected in succession more than the specified number of times, fencing will be performed. Specify a value between 0 and 2147483647. The default is the value specified in *serverIdentifier*.conf of the database server. Specify this parameter to perform optimization taking into account differences in the line load to the admin network and the reduction in the time it takes to degrade.

*1:Refer to "2.11.4 Tuning for Optimization of Degradation Using Abnormality Monitoring" for information on the tuning parameters for operating system or server abnormality monitoring when using an arbitration server.

Appendix B Supplementary Information on Building the Primary Server and Standby Server on the Same Server

The primary server and standby server can be pseudo-configured on the same server for system testing, for example. Out of consideration for performance and reliability, do not use this type of configuration for any other purposes. For this reason, do not use this type of configuration in a production environment.

Note that the setup and operations is the same as if the primary and standby servers are built on different servers.

This appendix provides supplementary information explaining how to configure the primary server and standby server on the same server.

Information

Even if automatic degradation by an arbitration server is set when the primary server and standby server are configured on the same server, there will be no effect of it.

B.1 Backup Data Storage Destination Directory

It is not a problem if the same backup data storage destination directory is used on the primary server and standby server.

B.2 How to Execute the mc_ctl Command

When executing the mc_ctl command, specify the server identifier in the --local-server option in order to identify the operation destination server.

Below is an example of starting Mirroring Controller of the server "server1" defined in the network.conf file. For mc_ctl command operations using another mode, also specify the --local-server option.

Define two server identifiers for the same IP address with different port numbers in the network.conf file.

```
Example)
```

```
server1 192.0.2.100 27540
server2 192.0.2.100 27541
```

Ensure that the port numbers of both primary server and standby server do not conflict with any other software.

Enabling automatic switch/disconnection

Start Mirroring Controller of the server "server1":

```
Example)
```

```
$ mc_ctl start -M /mcdir/inst1 --local-server server1
```

Stop Mirroring Controller of the server "server1":

```
Example)
```

```
$ mc_ctl stop -M /mcdir/inst1 --local-server server1
```

Disabling automatic switch/disconnection

Start Mirroring Controller of the server "server1":

```
Example)
```

```
$ mc_ctl start -M /mcdir/inst1 -F --local-server server1
```

Stop Mirroring Controller of the server "server1":

Example)

```
$ mc_ctl stop -M /mcdir/inst1 --local-server server1
```

Point

Add the --local-server option to the mc_ctl option specification for ExecStart and ExecStop of the unit file for systemd.

Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

Appendix C User Commands

This appendix describes three categories of commands:

- Fencing command
- Arbitration command
- State transition commands

This appendix describes each category of user command.

C.1 Fencing Command

Format

The syntax for calling the fencing command from the Mirroring Controller process or the Mirroring Controller arbitration process is described below.

Fencing command of the database server

```
fencingCmd executionMode mcDegradationOper cmdServerId targetServerId primarycenter
```

Fencing command of the arbitration server

```
fencingCmd executionMode mcDegradationOper targetServerId
```

Input

Fencing command of the database server

Execution mode

monitor: Detect issues via automatic monitoring of the Mirroring Controller process

command: Mirroring Controller command execution (switch mode or detach mode of the mc_ctl command)

Degradation operation to be performed by Mirroring Controller

switch: Switch

detach: Disconnect

cmdServerId

ID of the database server that called the command

targetServerId

ID of the database server to be fenced

primarycenter

Fixed value

Fencing command of the arbitration server

Execution mode

monitor: Detect issues via automatic monitoring of the Mirroring Controller process

command: Mirroring Controller command execution (switch mode or detach mode of the mc_ctl command)

Degradation operation to be performed by Mirroring Controller

switch: Switch

detach: Disconnect

targetServerId

ID of the database server to be fenced

Output

Return value

0: Mirroring Controller will continue the degradation process.

Other than 0: Mirroring Controller will cancel the degradation process.

Description

Identifies the database server targeted for fencing based on the input server identifier, and implements the process that isolates it from the cluster system.

Notes

- The command is executed by the operating system user who started Mirroring Controller or the Mirroring Controller arbitration process. Therefore, if the command is to be executed by a specific operating system user, change the executing user of the command accordingly.
- The operating system user who started Mirroring Controller or the Mirroring Controller arbitration process must have execution privileges to the command. Otherwise, the degradation process will be canceled.
- From a security point of view, set the access privileges as necessary so that the fencing command is not overwritten and unauthorized operations are not performed by unintended operating system users.
- If the fencing command returns a value other than 0, Mirroring Controller will cancel the degradation process, so it is necessary for the user to check the status of the server, and switch or disconnect it manually.
- Before executing the fencing command, check if the server is already fenced, to avoid the command terminating abnormally.
- If the command times out, Mirroring Controller will stop the command, output an error message, and cancel the degradation process.

Information

The fencing command can be implemented by simply stopping the operating system or server. For example, if stopping the power for the database server, it is possible to use a utility to control the hardware control board in environments equipped with boards compatible with IPMI hardware standard.

If power operations via IPMI are not available in a cloud environment, check and manage the state of the VM using CLI commands or APIs provided by the cloud service. For details on the cloud service's CLI commands or APIs, refer to the manual of each cloud service.

Linux

Below is a sample script of a fencing command that powers off the database server using the IPMI tool.

```
Sample shell script
```

```
/installDir/share/mcarb_execute_fencing.sh.sample
```

Below is a sample script of a fencing command to stop the power of the database server using the CLI command of the cloud service.

```
Sample shell script for Amazon Web Services
```

```
/installDir/share/mcarb_execute_fencing.sh.aws.sample
```

```
Sample shell script for Microsoft Azure
```

```
/installDir/share/mcarb_execute_fencing.sh.az.sample
```

Windows

Below is a sample script of a fencing command that powers off the database server using IPMIUTIL.

```
Sample shell script
```

```
installDir\share\mcarb_execute_fencing.bat.sample
```

Below is a sample script of a fencing command to stop the power of the database server using the CLI command of the cloud service.

Sample shell script for Amazon Web Services

```
installDir\share\mcarb_execute_fencing.bat.aws.sample
```

Sample shell script for Microsoft Azure

```
installDir\share\mcarb_execute_fencing.bat.az.sample
```

C.2 Arbitration Command

Format

The syntax for calling the arbitration command from the Mirroring Controller process is described below.

```
arbitrationCmd cmdServerId targetServerId primarycenter
```

Input

cmdServerId

ID of the database server that called the command

targetServerId

ID of the database server to arbitrate

primarycenter

Fixed value

Output

Return value

0: The database server to arbitrate has an issue, and Mirroring Controller will continue the degradation process.

Other than 0: The database server to arbitrate is normal, and Mirroring Controller will cancel the degradation process.

Description

Identifies the database server to arbitrate based on the input server identifier, and checks the status of the server.

Notes

- The command is executed by the operating system user who started Mirroring Controller.
- The operating system user who started Mirroring Controller must have execution privileges to the command. Otherwise, the command will not be called, and the degradation process will be canceled.
- If the command times out, Mirroring Controller will stop the command, output an error message, and cancel the degradation process.

Information

One way to implement an arbitration command is to check the server status using the OS's ping command. It is recommended to execute the ping command on a network separate from the admin network to accurately check the server status. Adjust the following parameters of the sample script according to your environment, considering factors such as business load, network line load, and reduction of degradation time.

Parameter	Description
HEARTBEAT_TIMEOUT	Timeout duration for OS/server health monitoring (seconds) If there is no response for more than the specified number of seconds, it is considered that an abnormality has occurred that requires fencing of the primary server or standby server.

Parameter	Description
	Consider the time during which continuous load is applied to the server or arbitration network capabilities. For example, when executing high-load batch operations or when high-concurrency online operations occur continuously.
RETRY_COUNT	Retry count for monitoring the life and death of OS/servers (count) Specify the number of retries when an anomaly is detected. Fencing will be performed if an anomaly is detected consecutively for the specified number of times + 1 or more.
RETRY_INTERVAL	Interval time for monitoring the life and death of OS/servers (seconds) Monitoring the life and death of the database server at the specified interval.

Linux

Below is a sample script for the arbitration command.

Sample shell script

```
/installDir/share/mc_execute_arbitration_command.sh.sample
```

Windows

Below is a sample script for the arbitration command.

Sample shell script

```
installDir\share\mc_execute_arbitration_command.bat.sample
```

C.3 State Transition Commands

State transition commands include the three types of user commands below. Any of the commands can be implemented by Mirroring Controller in conjunction with database server status transitions.

- Post-switch command
- Pre-detach command
- Post-attach command

C.3.1 Post-switch Command

Format

The syntax for calling the post-switch command from the Mirroring Controller process is described below.

```
postswitchCmd serverIdentifier primarycenter
```

Input

serverIdentifier

ID of the database server (new primary server) that was switched

primarycenter

Fixed value

Output

Return value

None

Notes

- The command is executed by the operating system user who started Mirroring Controller.
- The operating system user who started Mirroring Controller must have execution privileges to the command. Otherwise, the command will not be called.
- If the command times out, Mirroring Controller will stop the command, output an error message, and cancel the process.

C.3.2 Pre-detach Command

Format

The syntax for calling the pre-detach command from the Mirroring Controller process is described below.

```
predetachCmd cmdServerId serverRole targetServerId primarycenter
```

Input

cmdServerId

ID of the database server that called the command

Server role

Role of the database server that called the command

primary: Primary

standby: Standby

targetServerId

ID of the standby server to be disconnected from the cluster system

primarycenter

Fixed value

Output

Return value

None

Notes

- The command is executed by the operating system user who started Mirroring Controller.
- The operating system user who started Mirroring Controller must have execution privileges to the command. Otherwise, the command will not be called, however, Mirroring Controller will output an error message and continue the process.
- If the command times out, Mirroring Controller will stop the command, output an error message, and cancel the process.

C.3.3 Post-attach Command

Format

The syntax for calling the post-attach command from the Mirroring Controller process is described below.

```
postattachCmd cmdServerId serverRole targetServerId primarycenter
```

Input

cmdServerId

ID of the database server that called the command

Server role

Role of the database server that called the command

primary: Primary

standby: Standby

targetServerId

ID of the standby server to be attached to the cluster system

primarycenter

Fixed value

Output

Return value

None

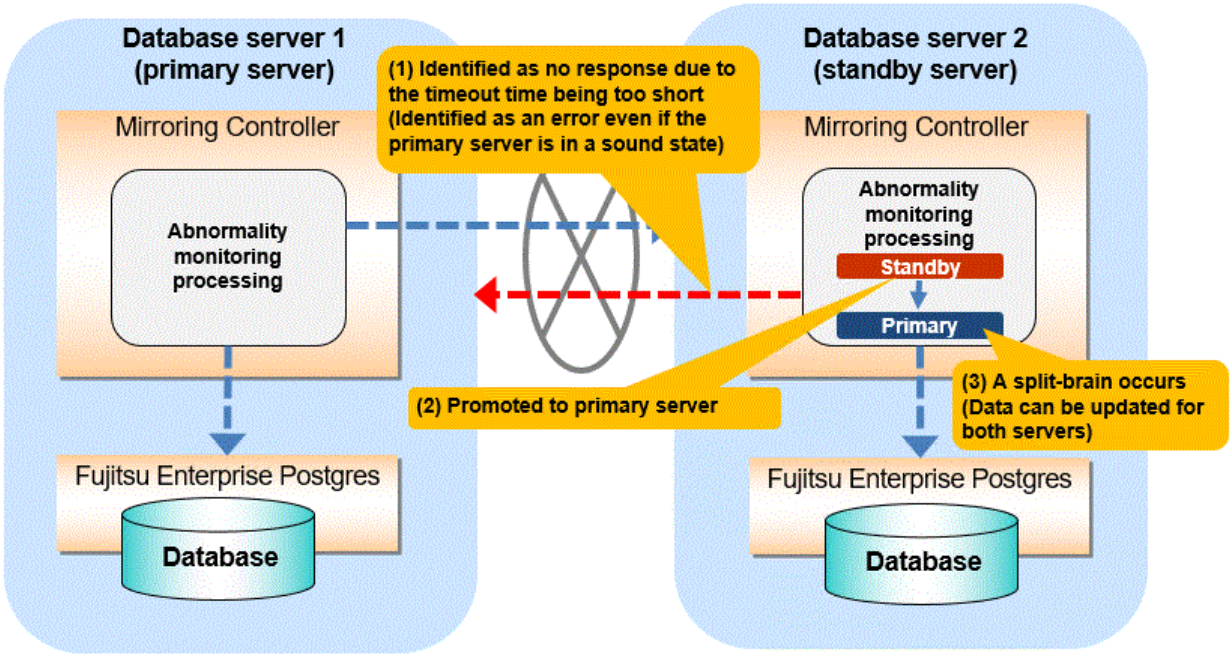
Notes

- The command is executed by the operating system user who started Mirroring Controller.
- The operating system user who started Mirroring Controller must have execution privileges to the command. Otherwise, the command will not be called.
- If the command times out, Mirroring Controller will stop the command, output an error message, and cancel the process.

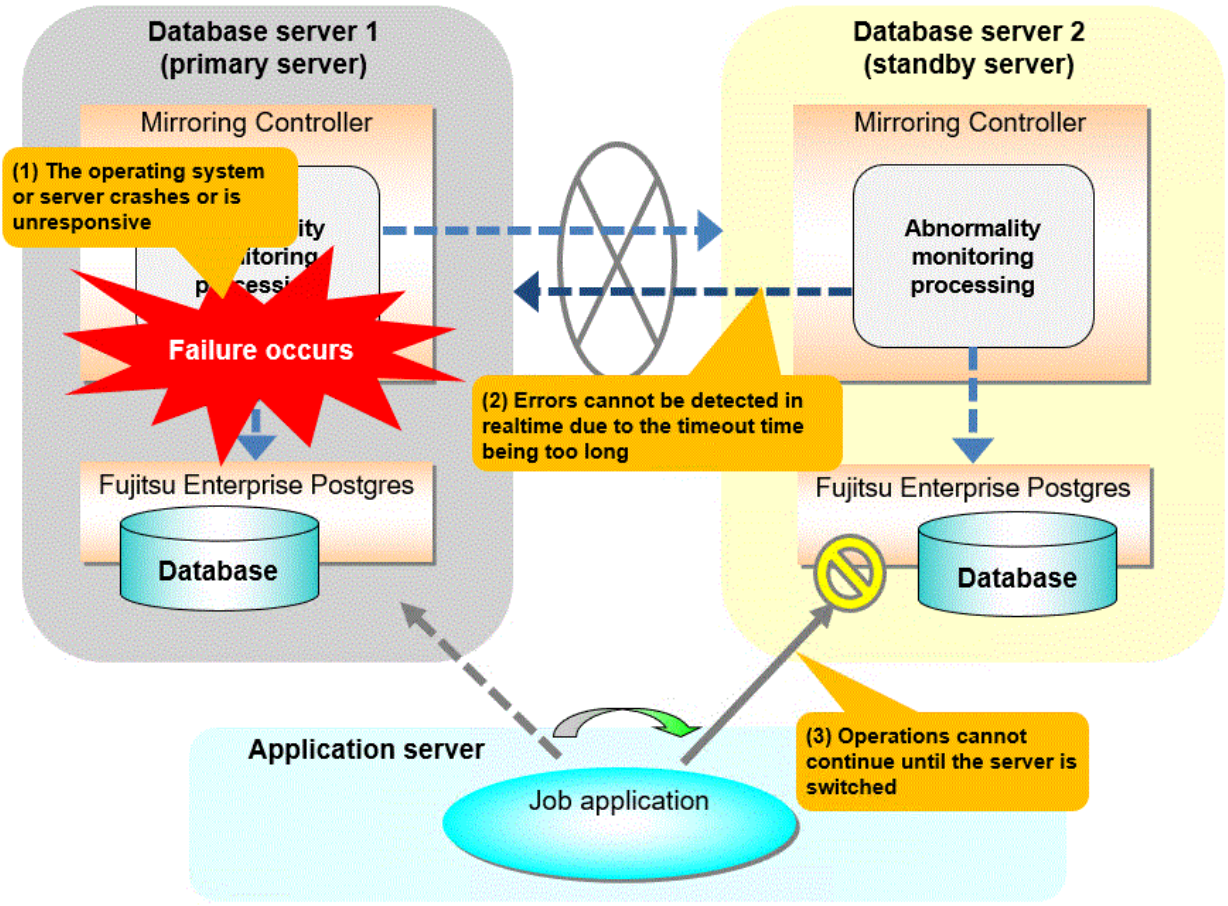
Appendix D Notes on Performing Automatic Degradation Immediately after a Heartbeat Abnormality

The type of issue below occurs if automatic degradation is performed unconditionally after an issue is detected during heartbeat monitoring of an operating system or server, and heartbeat monitoring was not properly tuned.

- **If the timeout time is too short**



● If the timeout time is too long



Notes on monitoring when the operating system or server crashes or is unresponsive

As illustrated in the diagram above, timeout is used to monitor whether the operating system or server crashes or is unresponsive. Therefore, if tuning has not been performed correctly, there is a risk of a split-brain mistakenly occurring even if the server is in a sound state.

Split-brain is a phenomenon in which both servers temporarily operate as primary servers, causing data updates to be performed on both servers.

Split-brain detection method

It can be confirmed that split-brain occurs under the following conditions:

1. When the mc_ctl command is executed in status mode on both servers, the "host_role" of both servers is output as "primary", and
2. The following message is output to the system log of one of the servers:

```
promotion processing completed (MCA00062)
```

How to recover from a split-brain

Use the procedure described below. Note that the new primary server is the server that was confirmed in step 2 of the aforementioned detection method.

1. Stop all applications that are running on the old and new primary servers.
2. Investigate and recover the database.
   Investigate the update results that have not been reflected to the new primary server from the database of the old primary server, and apply to the new primary server as necessary.
3. Stop the old primary server instance and the Mirroring Controller.
4. Resume the applications that were stopped in step 1.

5. Recover the old primary server.
   While referring to "2.5 Setting Up the Standby Server", build (set up) the old primary server as the new standby server, from the new primary server.

Notes on monitoring by restarting the OS

The heartbeat monitoring of the database server uses the OS ping command. Therefore, if the timeout period is too long and the OS restarts, an error might not be detected. This can result in a business shutdown without automatic switchover even though the primary server is down. There are several ways to avoid this situation:

- Refer to "Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server" and perform tuning so that the timeout time is shorter than the time required to restart the OS.
- Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" to set automatic startup of Mirroring Controller.

Appendix E Supplementary Procedure on Configuring for Operation in Database Multiplexing Mode

This appendix explains a supplementary procedure on the configuration required for operation in database multiplexing mode.

E.1 Security Policy Settings

This section explains how to configure the security settings to enable an operating system user account designated as an instance administrator user to log on as a service.

1. Displaying the [Local Security Policy] window

   In Windows, select [Administrative Tools], and then click [Local Security Policy].

2. Setting up security

   1. In the [Local Security Policy] window, select [Security Settings], select [Local Policies], and then click [User Rights Assignment].
   2. Under [Policy] in the [User Rights Assignment] window, double-click [Log on as a service].
   3. In the [Log on as a service Properties] window, set the following:
      a. Select the [Local Security Setting] tab.
      b. On the [Local Security Setting] tab, click [Add User or Group].
      c. In the [Select Users or Groups] window, enter the operating system user account of the instance administrator user in [Enter the object names to select].
      d. Click [OK].
   4. In the [Log on as a service Properties] window, click [OK].
   5. From the [Local Security Policy] tree, click [Local Policies], and then double-click [Security Options].
   6. Scroll down and double-click [User Account Control: Behavior of the elevation prompt for administrators in Admin Approval Mode].
   7. From the drop-down menu, select the "Elevate without prompting" in the [Local Security Setting] tab.
   8. Click [OK].

E.2 Windows Firewall Settings

This section explains how to enable the port number used by Mirroring Controller, if the Windows firewall feature is enabled.

Windows Server(R) 2016:

1. In the [Windows Firewall] window, click [Advanced settings] on the left side of the window.
2. In the [Windows Firewall with Advanced Security] window, click [Inbound Rules] on the left side of the window.
3. Click [New Rule] on the right side of the window.
4. In the [New Inbound Rule Wizard] window, select [Port], and then click [Next].
5. Select [TCP] and [Specific local ports], then specify the port number defined in the network definition file, and then click [Next].
6. Select [Allow the connection], and then click [Next].
7. Select the profiles for which this rule applies, and then click [Next].
8. In [Name], specify the desired name, and then click [Finish].
9. In the [Windows Firewall with Advanced Security] window, check if the added rule is enabled under [Inbound Rules] in the center of the window.

Other than above:

1. In the [Windows Defender Firewall] window, click [Advanced settings] on the left side of the window.
2. In the [Windows Defender Firewall with Advanced Security] window, click [Inbound Rules] on the left side of the window.
3. Click [New Rule] on the right side of the window.
4. In the [New Inbound Rule Wizard] window, select [Port], and then click [Next].
5. Select [TCP] and [Specific local ports], then specify the port number defined in the network definition file, and then click [Next].
6. Select [Allow the connection], and then click [Next].
7. Select the profiles for which this rule applies, and then click [Next].
8. In [Name], specify the desired name, and then click [Finish].
9. In the [Windows Defender Firewall with Advanced Security] window, check if the added rule is enabled under [Inbound Rules] in the center of the window.

Appendix F WebAdmin Disallow User Inputs Containing Hazardous Characters

WebAdmin considers the following as hazardous characters, which are not allowed in user inputs.

```
| (pipe sign)

& (ampersand sign)

; (semicolon sign)

$ (dollar sign)

% (percent sign)

@ (at sign)

' (single apostrophe)

" (quotation mark)

\' (backslash-escaped apostrophe)

\" (backslash-escaped quotation mark)

<> (triangular parenthesis)

() (parenthesis)

+ (plus sign)

CR (Carriage return, ASCII 0x0d)

LF (Line feed, ASCII 0x0a)

, (comma sign)

\ (backslash)
```

Appendix G Collecting Failure Investigation Data

For information on collecting failure investigation data, refer to the following.

Using a database server to collect data

"Collecting Failure Investigation Data" in the Installation and Setup Guide for Server

Using an arbitration server to collect data

"Collecting Failure Investigation Data" in the Installation and Setup Guide for Server Assistant

Database Multiplexing

Windows

B1WS-1494-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document describes the tasks required for using the database multiplexing feature of Fujitsu Enterprise Postgres.

Intended readers

This document is intended for those who set up and use the database multiplexing feature.

Readers of this document are also assumed to have general knowledge of:

- PostgreSQL
- SQL
- Windows

Structure of this document

This document is structured as follows:

Chapter 1 Overview of Database Multiplexing Mode

Provides an overview of database multiplexing mode.

Chapter 2 Setting Up Database Multiplexing Mode

Describes how to set up database multiplexing mode.

Chapter 3 Operations in Database Multiplexing Mode

Explains periodic database multiplexing mode.

Chapter 4 Action Required when an Error Occurs in Database Multiplexing Mode

Explains the action required when an error occurs during a database multiplexing mode.

Chapter 5 Managing Mirroring Controller Using WebAdmin

Explains how to set up and manage Mirroring Controller in a streaming replication cluster using WebAdmin.

Appendix A Parameters

Explains the configuration files and parameters required for database multiplexing mode.

Appendix B Supplementary Information on Building the Primary Server and Standby Server on the Same Server

Explains supplementary information on building the primary server and standby server on the same server.

Appendix C User Commands

Explains the user commands.

Appendix D Notes on Performing Automatic Degradation Immediately after a Heartbeat Abnormality

Provides notes when performing automatic degradation unconditionally after a heartbeat abnormality is detected during heartbeat monitoring of an operating system or server.

Appendix E Supplementary Procedure on Configuring for Operation in Database Multiplexing Mode

Explains supplementary procedure on the configuration required for operation in database multiplexing mode.

Appendix F WebAdmin Disallow User Inputs Containing Hazardous Characters

Explains characters not allowed in WebAdmin.

Appendix G Collecting Failure Investigation Data

Explains how to collect data for initial investigation.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Chapter 1 Overview of Database Multiplexing Mode

This chapter provides an overview of database multiplexing mode.

Point

In this and subsequent chapters, the word "Mirroring Controller" may be used in the process or management directory name or explanation.

1.1 What is Database Multiplexing Mode

Database multiplexing mode is an operation mode (log shipping mode) based on PostgreSQL streaming replication. Other software such as cluster software is not required.

This mode replicates the database on all servers that comprise the cluster system. It achieves this by transferring the updated transaction logs of the database from the server that receives the updates (primary server) to another server (standby server), and then reflecting them on the standby server. The client driver automatically distinguishes between the primary and standby servers, so applications can be connected transparently regardless of the physical server.

It consists of a feature that detects faults in the elements that are essential for the continuity of the database operation (such as the database process, disk, and network), as well as simplified switchover and standby server disconnection features. Furthermore, referencing can be performed on the standby server. The database will be copied in synchronous mode.

Information

If using WebAdmin or Mirroring Controller, Fujitsu Enterprise Postgres supports cluster systems comprising one primary server and one standby server.

- Although it is possible to connect an asynchronous standby server to the cluster system as an additional server, the standby server is not targeted for monitoring by Mirroring Controller.
- A synchronous standby server cannot be connected to the cluster system as an additional server.

See

The streaming replication feature is not described in this manual.

Refer to "High Availability, Load Balancing, and Replication" in the PostgreSQL Documentation for information on the streaming replication feature.

Figure 1.1 Failover from the primary server to the standby server

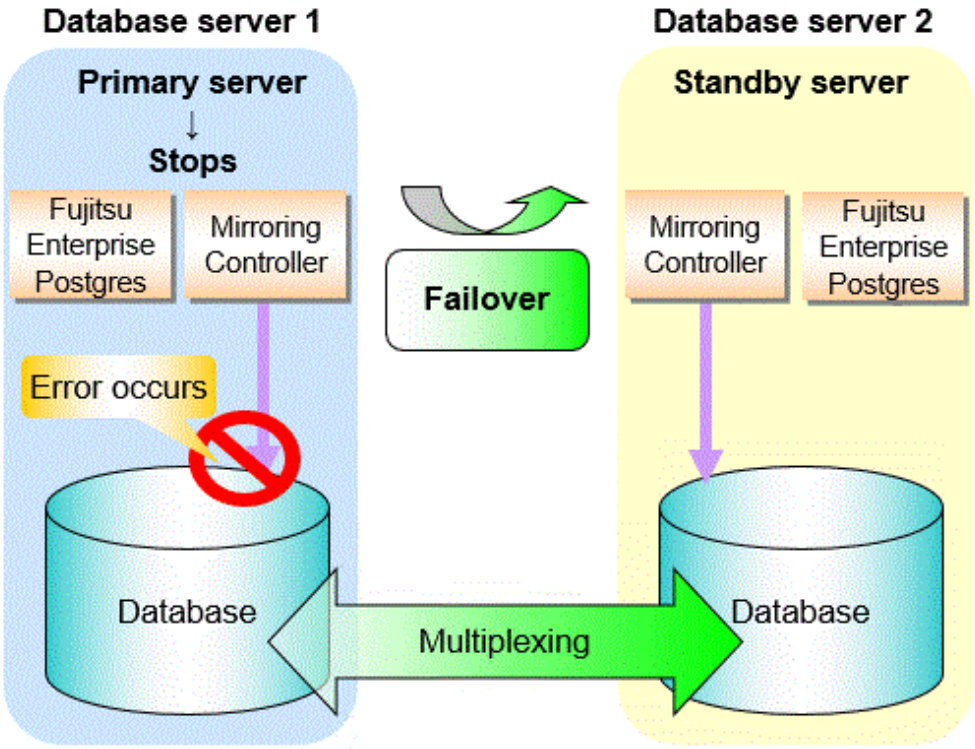

Figure 1.2 Standby server disconnection

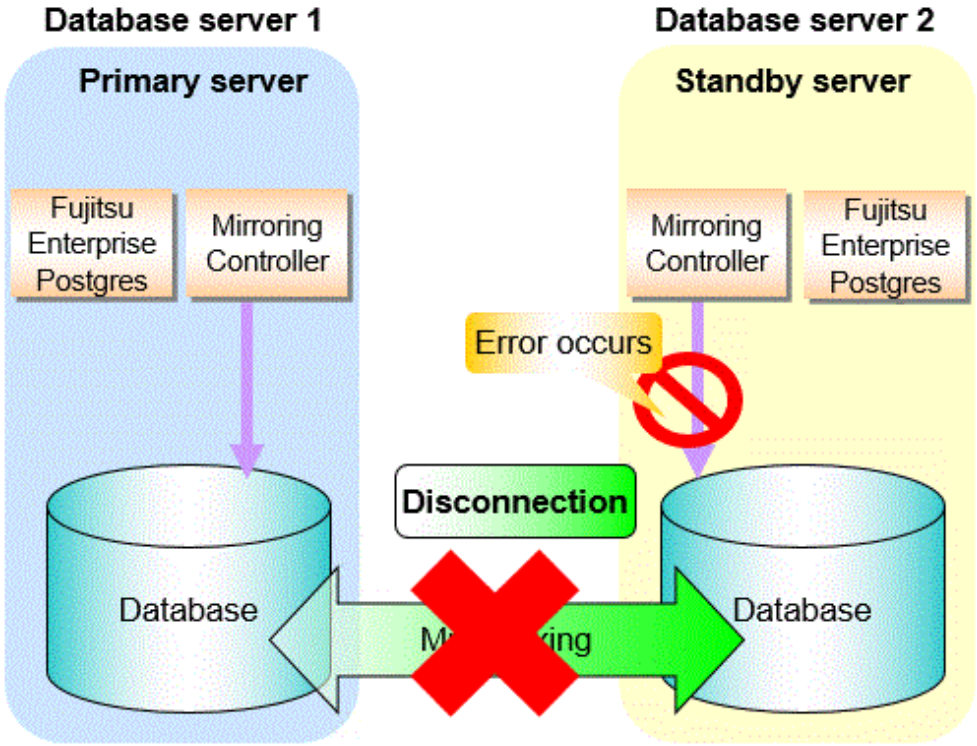


Database degradation using the arbitration server

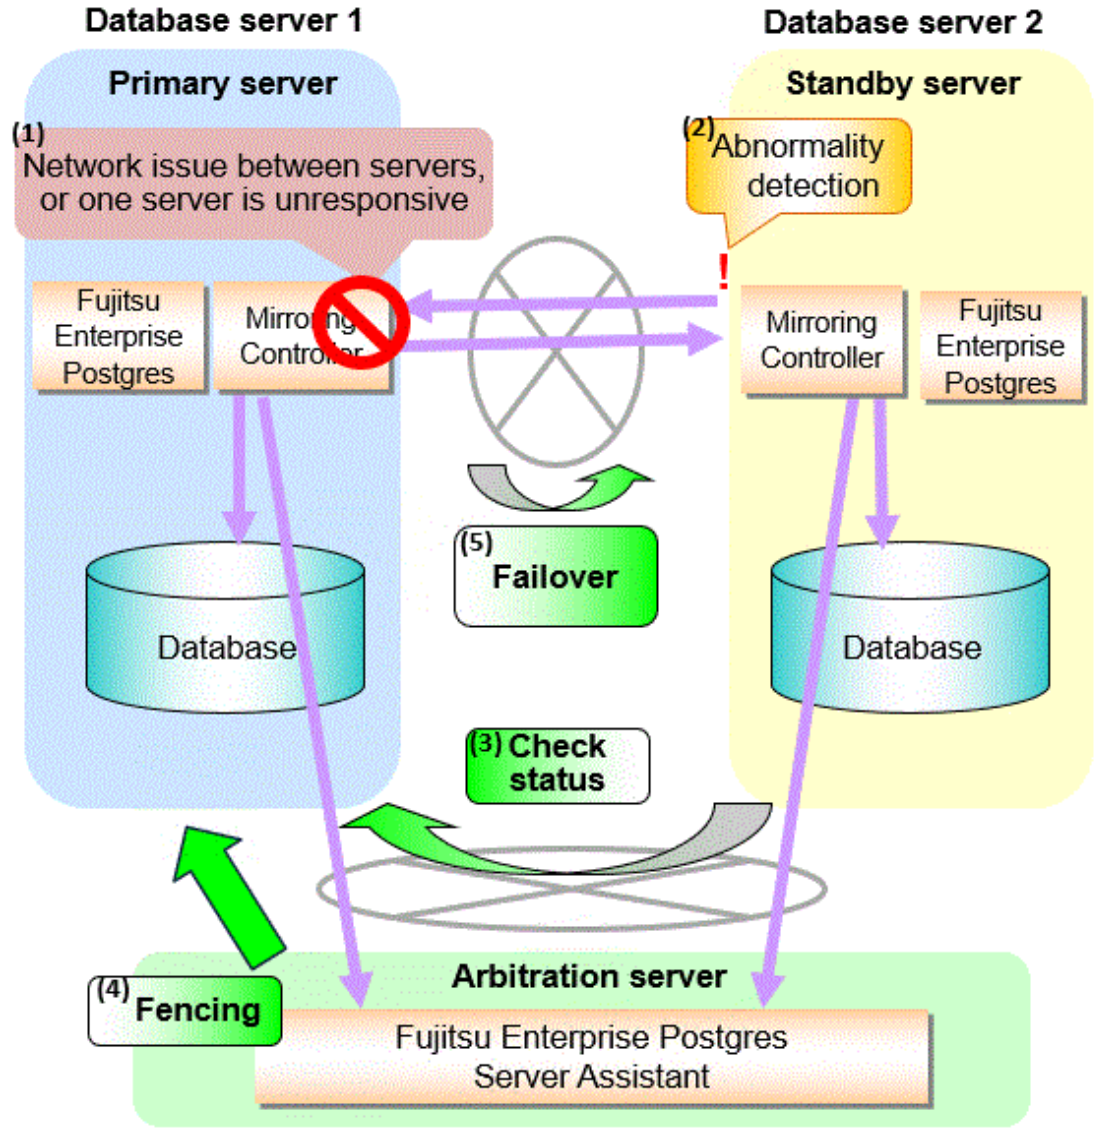
Fujitsu Enterprise Postgres provides the Server Assistant that objectively determines the status of database servers as a third party, and if necessary, isolates affected databases if the database servers are unable to accurately ascertain their mutual statuses in database multiplexing

mode, such as due to a network error between database servers, or server instability. Database degradation can be performed by using the server (arbitration server) on which the Server Assistant is installed. Install the arbitration server on a different physical server to that of the database server. Refer to "1.2 System Configuration for Database Multiplexing Mode" for information on the system configuration when using the arbitration server.

For database degradation using the arbitration server, if the database servers are unable to check their mutual statuses (due to a network error between database servers or server instability), then the database server queries the arbitration server for the status of the other database server. If it is determined based on the heartbeat result that the status is unstable, the applicable database server will be isolated from the cluster system (fencing). The arbitration server periodically heartbeats the database server so that it can respond immediately to queries from the database server. The fencing process can be customized according to the environment where Mirroring Controller is used.

Additionally, the database servers are always performing their heartbeats for the arbitration server so that it can perform check requests any time.

Figure 1.3 Database degradation using the arbitration server



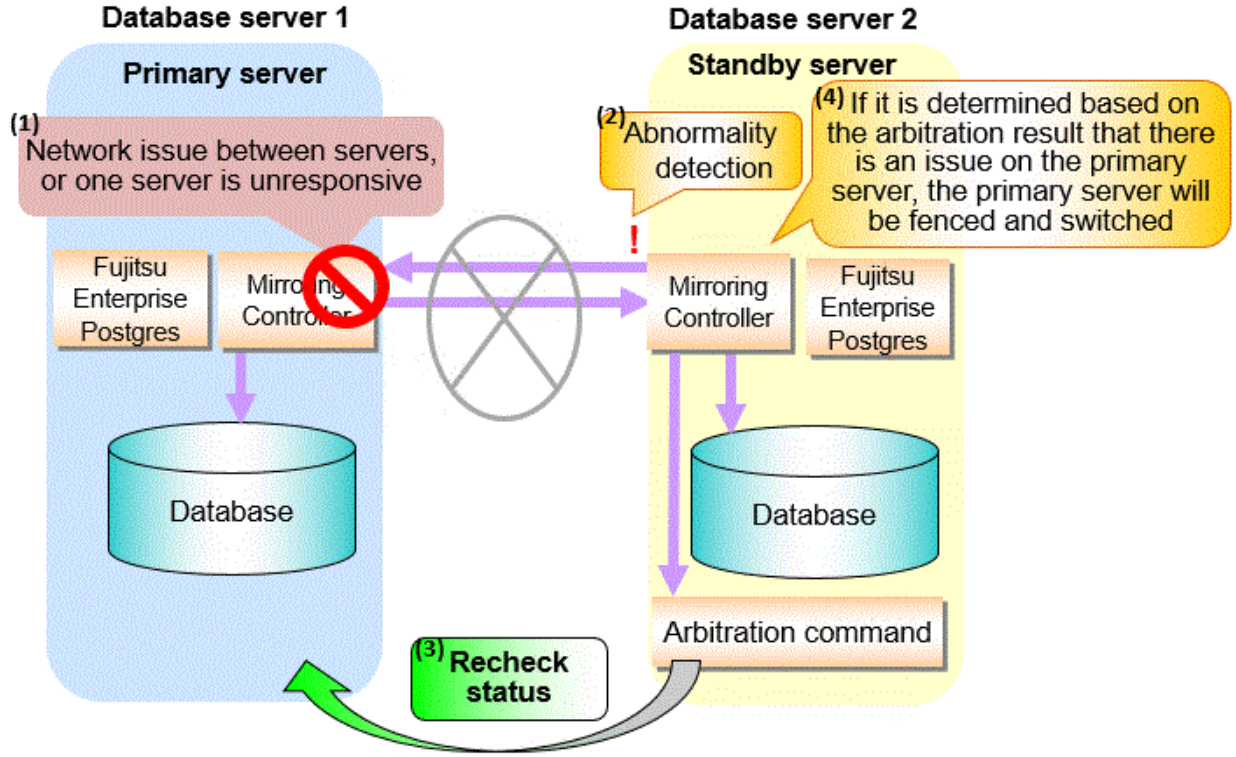
See

Refer to "2.3.2 Creating a User Exit for the Arbitration Server2.6 Creating a User Exit for a Database Server" or "Appendix C User Commands" for information on fencing commands.

Database degradation using the arbitration command

The arbitration command is a user command that performs arbitration processing in lieu of the arbitration server. If an arbitration server cannot be deployed, arbitration of the database server can be performed using the arbitration command.

Figure 1.4 Database degradation using the arbitration command



See

Refer to "2.6 Creating a User Exit for a Database Server" or "Appendix C User Commands" for information on user commands.

1.1.1 Monitoring Using Database Multiplexing Mode

In database multiplexing mode, perform the monitoring below.

- Operating system or server failures, and no-response state

  By generating a heartbeat between Mirroring Controller on each server, operating system or server errors are detected and acknowledged between the relevant servers.

  The optimal operating method for environments where database multiplexing mode is performed can be selected from the following:

  - Use the arbitration server to perform automatic degradation (switch/disconnect)

    This is the default method.

    The arbitration server objectively determines the status of database servers, then isolates and degrades from the cluster system the ones with an unstable status.

    Refer to "Database degradation using the arbitration server" for details.

  - Call the user exit (user command) that will perform the degradation decision, and perform automatic degradation

    If the arbitration server cannot be installed, select if arbitration processing can be performed by the user instead.

    Mirroring Controller queries the user exit on whether to degrade. The user exit determines the status of the database server, and notifies Mirroring Controller whether to perform degradation.

Refer to "Database degradation using the arbitration command" for details.

- Notification messages

  Use this method if using a two-database server configuration.

  Mirroring Controller outputs messages to the event log when an abnormality is detected. This ensures that a split brain will not occur due to a heartbeat abnormality - however, automatic switching will not be performed if the primary server operating system or server fails or becomes unresponsive.

- Perform automatic degradation unconditionally after a heartbeat abnormality

  This method is handled as in FUJITSU Enterprise Postgres 9.6 or earlier versions.

  This method is not recommended, because Mirroring Controller unconditionally will perform automatic degradation after heartbeat abnormalities.

- Database process failures, and no-response state

  Mirroring Controller periodically accesses the database processes and checks the status. A process error is detected by monitoring whether an access timeout occurs.

- Disk failure

  Mirroring Controller periodically creates files on the data storage destination disk below. A disk error is detected when an I/O error occurs.

  - Data storage destination disk
  - Transaction log storage destination disk
  - Tablespace storage destination disk

  Failures that can be detected are those that physically affect the entire system, such as disk header or device power failures.

- Streaming replication issue

  Mirroring Controller detects streaming replication issues (log transfer network and WAL send/receive processes) by periodically accessing the PostgreSQL system views.

- Mirroring Controller process failure and no response

  In order to continue the monitoring process on Mirroring Controller, Mirroring Controller process failures and no responses are also monitored.

  The Mirroring Controller monitoring process detects Mirroring Controller process failures and no responses by periodically querying the Mirroring Controller process. If an issue is detected, Mirroring Controller is automatically restarted by the Mirroring Controller monitoring process.

Information

If the role of primary server was switched to another server and then starts degrading, the original primary server will not become the standby server automatically. Remove the cause of the error, and then change the role of the original primary server to the server currently acting as standby server. Refer to "4.1 Action Required when Server Degradation Occurs" for details.

Point

- If output of messages is selected as the operation to be performed when a heartbeat abnormality is detected during heartbeat monitoring of the operating system or server, automatic degradation will not be performed.
  However, if an issue in the WAL send process is detected on the primary server, then the standby server will be disconnected, and as a result an automatic disconnection may be performed even if the standby server operating system or server fails or becomes unresponsive.
- You can select in the parameters if the primary server will be switched if a database process is unresponsive or if tablespace storage destination disk failure is detected. Refer to "Appendix A Parameters" for details.

- If the standby server was disconnected, Mirroring Controller will automatically comment out the synchronous_standby_names parameter and synchronized_standby_slots parameter in the postgresql.conf file of the primary server. Accordingly, you can prevent the application processing for the primary server being stopped.

1.1.2 Referencing on the Standby Server

1.1.2.1 If Prioritizing the Main Job on the Primary Server

If a reference job is performed on the standby server and the primary server is switched, this may impact the main job from the point of view of load and conflict. This is because, on the new primary server (that is, the original standby server), both the main job that was being executed on the original primary server and the reference job that was being continued on the original standby server will be processed.

Therefore, to degrade the reference job (so that the impact on the main job is reduced), you can select the user exit below to disconnect the reference job that was performed on the original standby server.

- Post-switch command

If continuing with the referencing job after switching the primary server, give careful consideration to the server resource estimates, and the likely impact on performance.

1.1.2.2 If Performing the Referencing Job on the Synchronous Standby Server

If an issue such as a log transfer network failure obstructs the continuation of a job on the primary server, the standby server may be automatically disconnected from the cluster system.

Therefore, if operating the reference job on the assumption that the connection destination is the synchronous standby server, you can select to temporarily stop the job by using the user exit or the feature below, so that unexpected referencing of past data does not occur as a result of the disconnection.

- Pre-detach command
- Forced stoppage of the standby server instance on disconnection (specify in the parameter of the server configuration file)

Additionally, if the standby server is incorporated into the cluster system, reference jobs can be started or resumed by using the user exit below.

- Post-attach command

See

- Refer to "2.6 Creating a User Exit for a Database Server" or "Appendix C User Commands" for information on each user exit.
- Refer to "A.4.1 Server Configuration File for the Database Servers" for information on the server configuration file of the database server.

Point

Mirroring Controller will continue processing regardless of the processing result of the above user exits and features.

1.2 System Configuration for Database Multiplexing Mode

This section explains the system configuration for database multiplexing mode, as well as the products, features, and network that make up the system. The system for database multiplexing mode uses the following network.

Network type	Description
Job network	Network between the application that accesses the database, and the database server.

Network type	Description
Arbitration network	Network used by the arbitration server to check the status of the primary server and standby server, and communicate with Mirroring Controller of the database servers. Additionally, if the job network is disconnected from outside, it can also be used as the arbitration network. Refer to "1.4 Security in Database Multiplexing" for details on network security.
Admin network	Network used by the primary server and the standby server to monitor each other using Mirroring Controller, and to control Mirroring Controller of other servers.
Log transfer network	Network used to transfer the transaction logs of the database, which is part of database multiplexing.

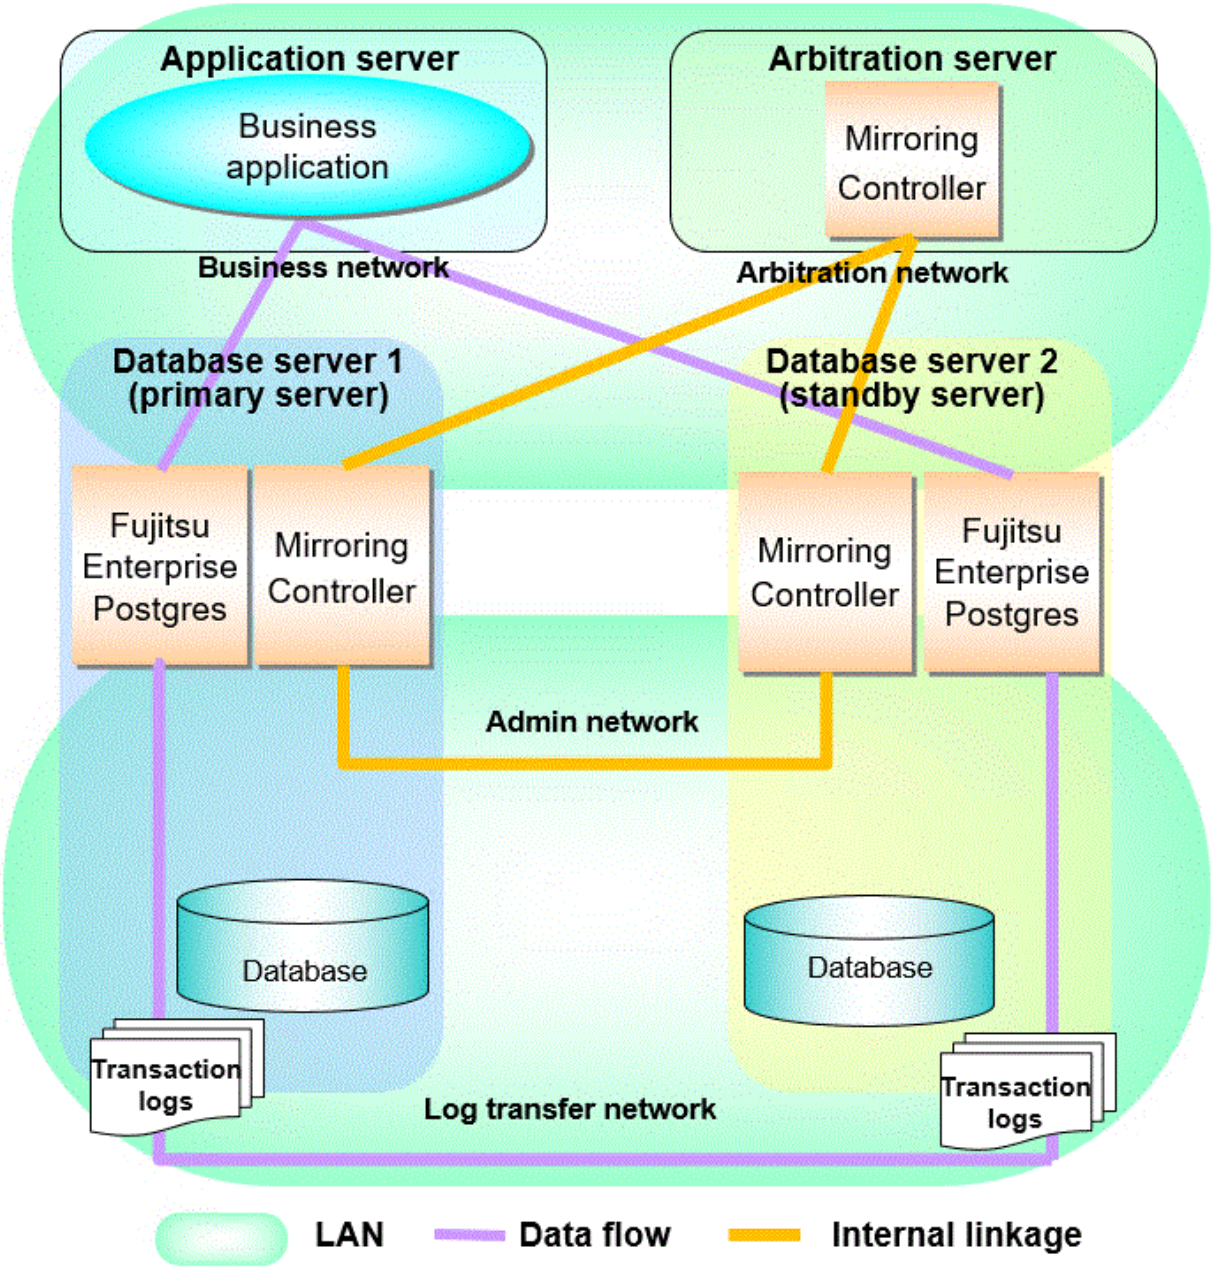
Information

Because the ping command of the operating system is used for heartbeat monitoring of the database server, configure the network so that ICMP can be used on the admin network and the arbitration network.

Point

- The arbitration server can also be used as an application server. However, consider the server load.
- It is recommended to link the arbitration server with other cluster systems, in order to provide redundancy.
- Use the arbitration server in combination with the same version of Fujitsu Enterprise Postgres as that of the primary server and standby server.
- The arbitration server can be built on a different platform to that of the database server.

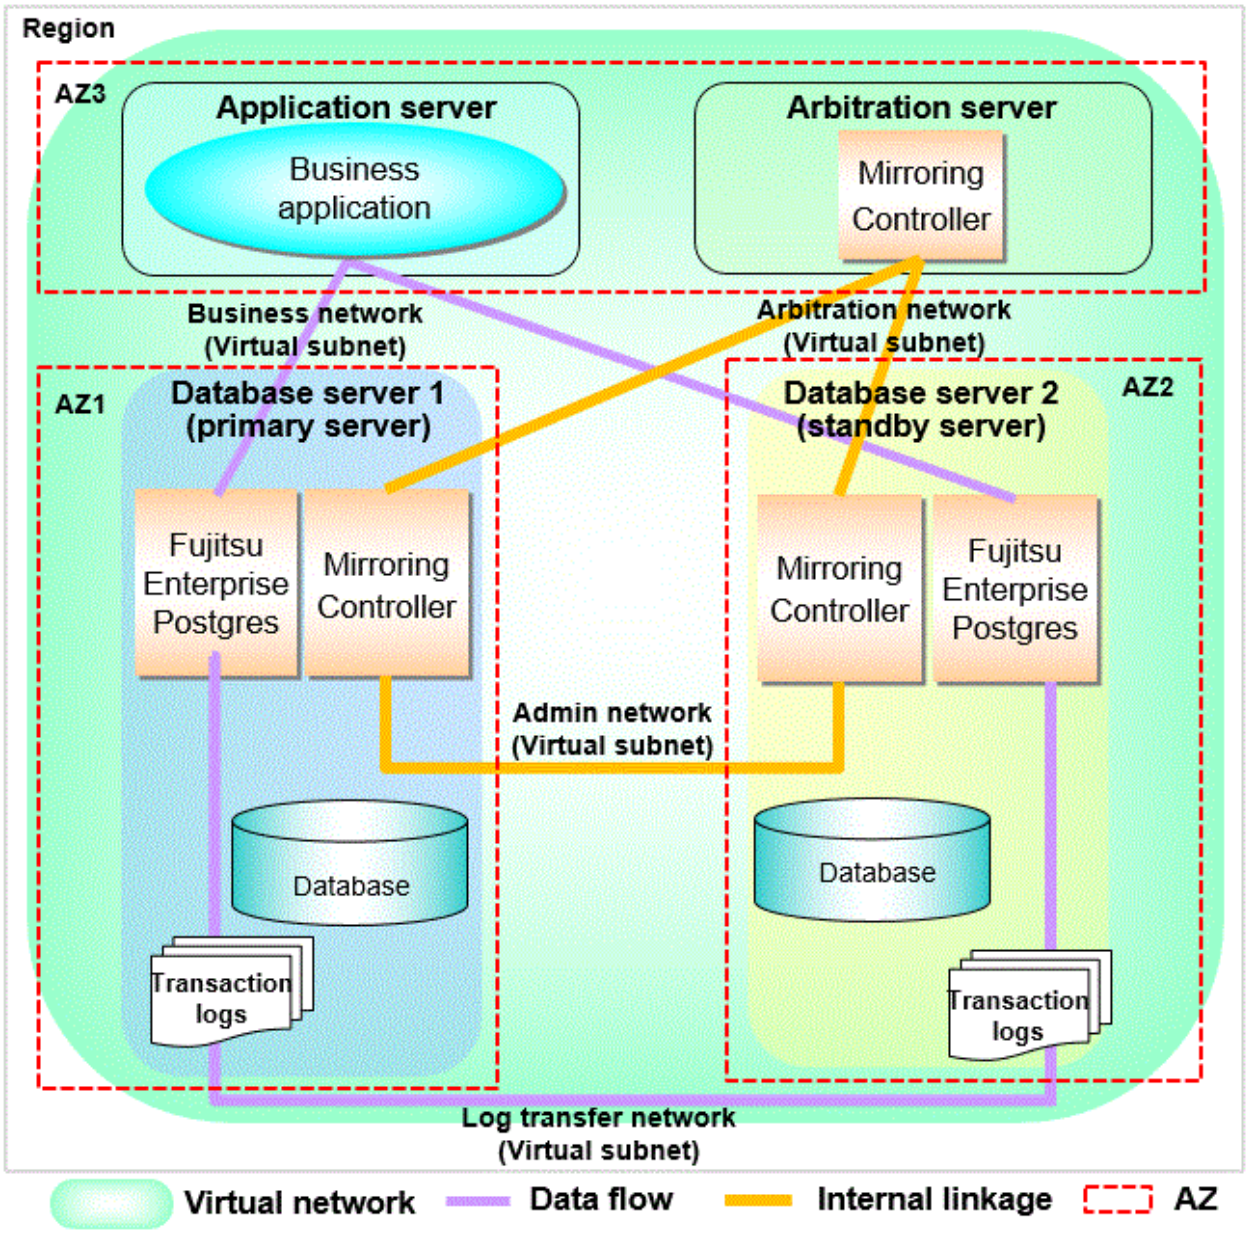
Figure 1.5 System configuration for database multiplexing mode



The arbitration server is installed to check the database server status as a third party, and to perform fencing. Therefore, to obtain the intended benefits, consider the following.

- Install the arbitration server on a different server to that of the database server.
- Recommend that the arbitration network be a network that is not affected by line failures or loads on the admin and log transfer networks, so that any abnormalities in the admin and log transfer networks can be correctly identified.

Figure 1.6 System configuration for database multiplexing mode in a cloud environment



In a cloud environment, to prepare for cloud-specific failures such as AZ failures, we recommend the following configuration:

- Install each database server and arbitration server in different AZs.
- Prepare each network (business network, arbitration network, admin network, and log transfer network) using the subnet function of the cloud service. In this manual, read each network as each subnet created by the cloud service.
- If you cannot prepare four networks, or if you cannot add network interface cards to the server, it is possible to adopt a configuration that shares some networks. For details, refer to "1.2.5 When There are not Enough Networks Available".
- If a virtual network failure occurs, you cannot use the database multiplexing mode feature. Wait for the cloud service to recover, and after recovery, check the redundancy of the database.
- If a temporary failure of the cloud service occurs, there is a possibility of split-brain occurring, where both database servers operate as primary servers simultaneously due to unintended server reboots or network recovery. To prevent split brain, ensure reliable fencing processing. For details on fencing processing, refer to "C.1 Fencing Command".

1.2.1 Mirroring Controller Resources

This section describes the database server and arbitration server resources of Mirroring Controller.

1.2.1.1 Database Server Resources

The only Mirroring Controller resource is the Mirroring Controller management directory, which stores the files that define the Mirroring Controller behavior, and the temporary files that are created when Mirroring Controller is active.

Information

Do not create the Mirroring Controller management directory in a directory managed by Fujitsu Enterprise Postgres, otherwise it may be deleted by mistake or may cause unexpected problems when Fujitsu Enterprise Postgres recovery is performed (such as old version of files being restored).

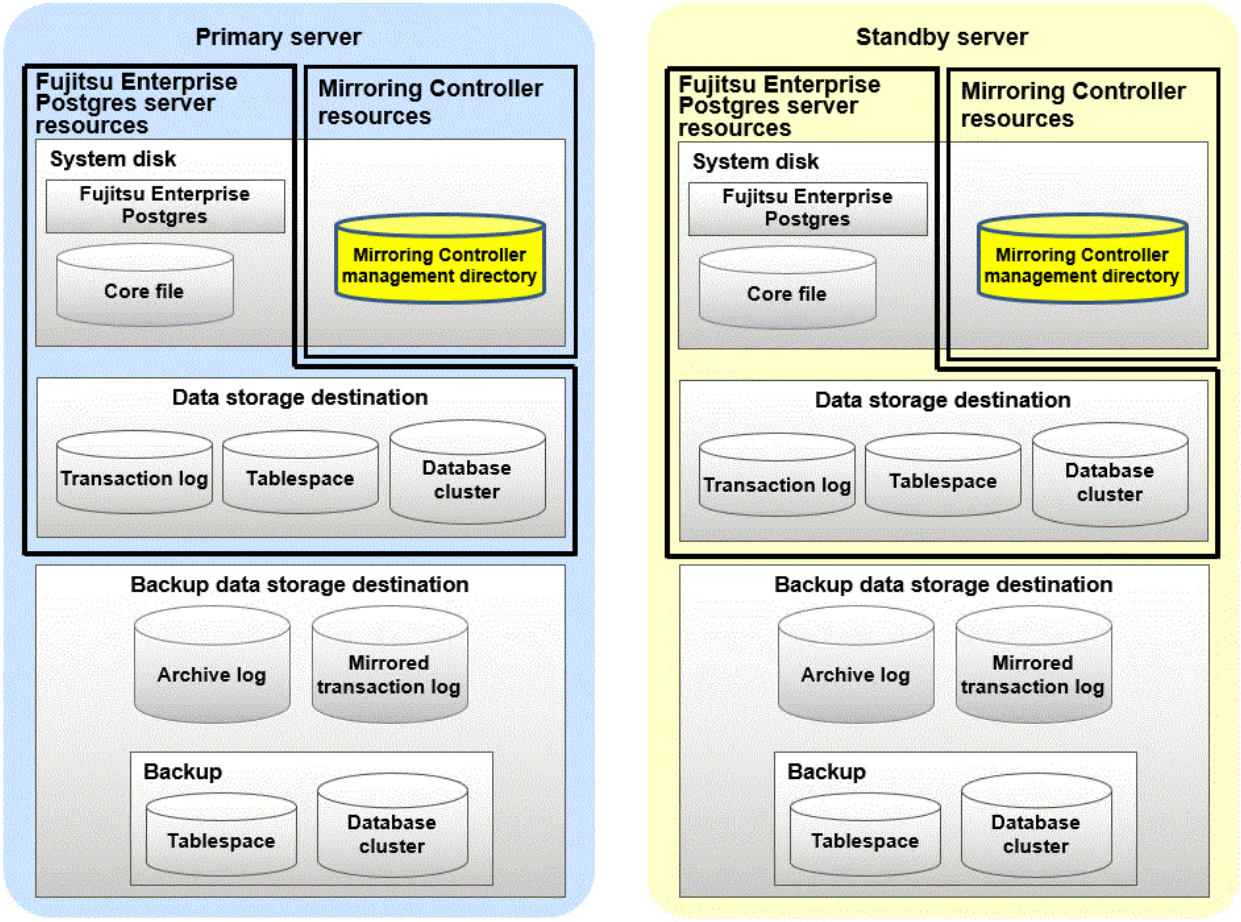
Refer to "Preparing Directories for Resource Deployment" in the Installation and Setup Guide for Server for information on the directories managed by Fujitsu Enterprise Postgres.

Point

- The backup methods described in "Backing Up the Database" in the Operation Guide cannot be used to back up the Mirroring Controller resources. Therefore, users must obtain their own backup of Mirroring Controller resources, in addition to Fujitsu Enterprise Postgres server resources. Retrieve backups after stopping Mirroring Controller.
- If you are building on a virtual machine or cloud, make sure the virtual machines are on different physical servers. Refer to your virtual machine software and cloud vendor documentation for instructions on how to deploy virtual machines.

The content on the primary server will be backed up. You cannot tell which server is the primary server to be backed up, because switching and failback may be performed between the servers. It is also impossible to tell which server is to be restored using the backed up data. Accordingly, ensure that you create a backup of each server when it is working as the primary server.

Figure 1.7 Configuration when backing up Mirroring Controller resources



1.2.1.2 Arbitration Server Resources

The only arbitration server resource is the Mirroring Controller arbitration process management directory. This directory stores the files that define the Mirroring Controller arbitration process behavior and the temporary files created when Mirroring Controller is active.

1.2.2 Mirroring Controller Processes

This section describes the database server and arbitration server processes of Mirroring Controller.

1.2.2.1 Database Server Processes

The database server processes comprise the Mirroring Controller process and Mirroring Controller monitoring process.

Process type	Description
Mirroring Controller process	Performs operating system/server and process heartbeat monitoring and disk abnormality monitoring between database servers. Additionally, it issues arbitration requests to the arbitration server.
Mirroring Controller monitoring process	Performs heartbeat monitoring of the Mirroring Controller process. If the Mirroring Controller process returns no response or is down, the monitoring process is restarted automatically.

1.2.2.2 Arbitration Server Process

The only arbitration process is the Mirroring Controller arbitration process.

Process type	Description
Mirroring Controller arbitration process	Performs rechecks for issues detected on the primary server or the standby server. Additionally, this process performs fencing if it determines that there is an issue on the primary server or the standby server.

1.2.3 Redundancy of the Admin and Log Transfer Networks

The admin network is an important one, because it is used by Mirroring Controller to check the status of each server.

Additionally, the log transfer network is an important one, because it is necessary to ensure data freshness.

Accordingly, configure a failure-resistant network by implementing network redundancy via the NIC teaming feature provided by the operating system or network driver vendor.

Information

NIC teaming feature is provided by the operating system by default.

1.2.4 Notes on CPU Architecture and Products

Use the same CPU architecture (endian) for the primary server, standby server, and the arbitration server.

A server using only PostgreSQL streaming replication cannot be specified as the database multiplexing system log transfer destination.

1.2.5 When There are not Enough Networks Available

In Fujitsu Enterprise Postgres, it is recommended to use four networks (business network, arbitration network, admin network, and log transfer network) for database multiplexing mode.

However, if you cannot prepare four networks in environments such as public cloud, or cannot add network interface cards to the server, the following configurations that share some networks are possible:

- Share all networks
- Share business network, arbitration network, and admin network

When sharing networks, there are no impacts other than increased load due to network sharing during regular operations. However, there are impacts such as restrictions on features for multiplexed modes and the need for special designs for operations in response to network abnormality.

When sharing networks, the following measures are necessary.

- Network definition changes

  You need to configure the network definition file according to the configuration of the shared network.

  If you select automatic degradation by the arbitration server, set the same value for "IP address or host name of the database server used as the admin network" and "IP address or host name of the database server used as the arbitration network" in the network definition file. For details, refer to "When automatic degradation by the arbitration server is selected" under "2.4.1 Setting Up Database Multiplexing Mode on the Primary Server"

- Operational design for network abnormalities

  If the network is shared, it is necessary to design measures to address network abnormalities.

  In the event of a network abnormality, check the status of streaming replication after the network is restored. If the data is not synchronized, refer to "Chapter 4 Action Required when an Error Occurs in Database Multiplexing Mode" and restore to database multiplexing mode.

1.3 Deciding on Operation when a Heartbeat Abnormality is Detected

The operation to be performed when a heartbeat abnormality is detected using operating system/server heartbeat monitoring is decided on according to the environment where database multiplexing mode is performed or the operating method.

It is possible to select from the four operations below, and specify this in the parameters of Mirroring Controller:

- Use the arbitration server to perform automatic degradation (switch/disconnect)
- Call the user exit (user command) that will perform the degradation decision, and perform automatic degradation
- Notification messages
- Perform automatic degradation unconditionally (switch/disconnect)

The table below shows if jobs can be continued on the primary server when an issue is detected during heartbeat monitoring of the operating system/server.

Continuation of jobs on the primary server when an issue is detected during heartbeat monitoring of the operating system/server

Operation	Abnormal event				
	Server/operating system failures or no responses		Admin network issue	Log transfer network issue	Issue on a network for both admin and log transfer
	Primary server	Standby server			
Automatic degradation using the arbitration server	Y (switch)	Y (disconnect)	Y	Y (disconnect)	Y (disconnect)
Call a user exit and perform automatic degradation	Y (switch)	Y (disconnect)	Y	Y (disconnect)	Y (disconnect)
Notification messages	N (message notification only)	N (message notification only)	Y	Y (disconnect)	Y (disconnect)
Unconditional automatic degradation	Y (switch)	Y (disconnect)	N (split brain occurs)	Y (disconnect)	N (split brain occurs)

Y: Job can be continued

N: Job cannot be continued

1.4 Security in Database Multiplexing

The database server replicates the database on all servers that comprise the cluster system. It achieves this by transferring and reflecting the updated transaction logs of the database from the primary server to the standby server.

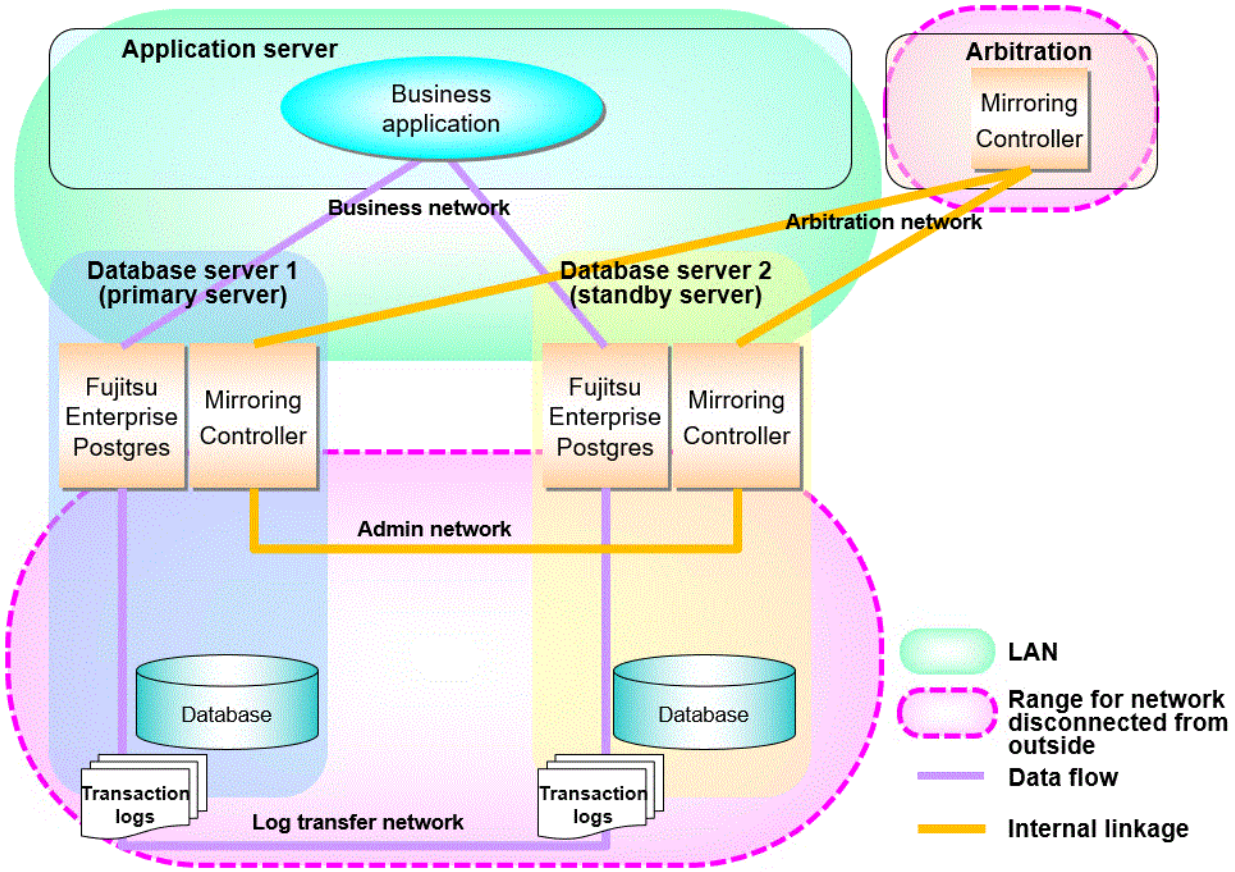
To safeguard the database against unauthorized access and preserve data confidentiality in transaction log transfers, carefully consider security and take note of the following when performing database multiplexing:

- Do not use trust authentication when using replication connection.
- Configure the admin network and the log transfer network so that they cannot be connected from the outside, as shown in Figure 1.8 Security.

Additionally, for the line on which Mirroring Controller connects from the database server to the arbitration server, take note of the following points and consider security carefully.

- Build a network with the arbitration server disconnected from outside, as shown in Figure 1.8 Security.

Figure 1.8 Security



However, it may not always be possible to adopt the configuration mentioned above. For example, you may want to place the servers in a nearby/neighboring office to minimize network delays.

In this case, combine the following features to enhance security:

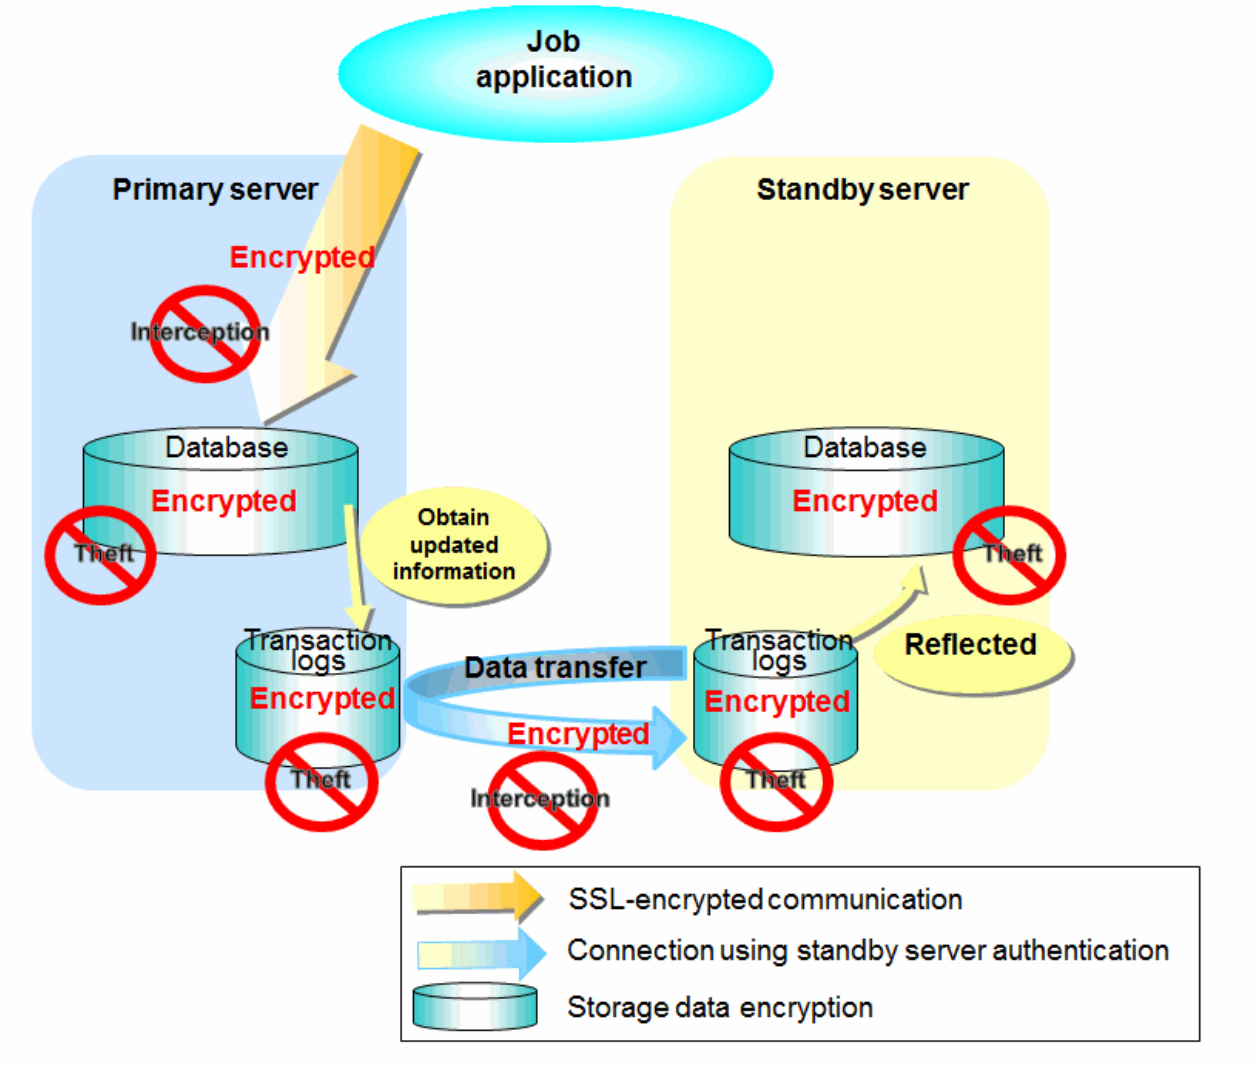
- Authentication of the Standby Server
- Encryption of Transaction Logs Transferred to the Standby Server

When these features are combined, security will be achieved as shown below.

Point

- If the job network is disconnected from outside, it can be used as the arbitration network. However, if a network is to be used as both a job network and arbitration network, consider the load on the network.
- If a port is blocked (access permission has not been granted) by a firewall, etc., enable use of the target port by granting access. Refer to the vendor document for information on how to open (grant access permission to) a port. Consider the security risks carefully when opening ports.

Figure 1.9 Security achieved when standby server authentication is combined with transaction log encryption



See

Refer to "Performing Database Multiplexing" under "Configuring Secure Communication Using Secure Sockets Layer" in the Operation Guide for information on encrypting SSL communications.

1.4.1 Authentication of the Standby Server

You can prevent spoofing connections from an external server purporting to be the standby server by using authentication with a user name and password.

Configure the setting in the primary server pg_hba.conf file so that authentication is performed for connections from the standby server in the same way as for connections from the client.

See

Refer to "Client Authentication" in the PostgreSQL Documentation for information on content that can be configured in pg_hba.conf.

Refer to "Policy-based Login Security" in the Operation Guide for information about security policy-based passwords operations for database multiplexing operations.

1.4.2 Encryption of Transaction Logs Transferred to the Standby Server

In case the authentication of the standby server is breached so that a malicious user purporting to be the standby server can spoof data, the transaction log data can be encrypted to prevent it from being deciphered. The transparent data encryption feature is used to encrypt the data.

See

Refer to "Protecting Storage Data Using Transparent Data Encryption" in the Operation Guide for details.

Chapter 2 Setting Up Database Multiplexing Mode

This chapter describes how to set up database multiplexing mode, and how to check it.

Users who perform setup and operations on the database server

Setup and operations of the database server must be performed by the instance administrator user with administrator privileges (operating system user ID belonging to the Administrators group). The instance administrator user must be assigned the "Log on as a service" user right.

Users who perform setup and operations on the arbitration server

The following users may perform setup and operations on the arbitration server when it is used for automatic degradation.

Linux

Any operating system user.

Windows

Any user with administrator privileges. This user must be assigned the "Log on as a service" user right.

Point

- Mirroring Controller selects a database superuser as the user who will connect to the database instance. This enables instance administrator users and database superusers who operate the Mirroring Controller commands to run database multiplexing mode in different environments.
- The application name for connecting to the database instance is "mc_agent".

Matching the system times

Before starting the setup, ensure that the times in the primary server, standby server and arbitration server match, by using the operating system time synchronization feature, for example.

The tolerated difference is approximately one second.

If the system times are not synchronized (because the tolerated difference is exceeded, for example), problem investigation may be affected.

Configuring ICMP

Because the ping command of the operating system is used for heartbeat monitoring of the database server, configure the network so that ICMP can be used on the admin network and the arbitration network. Refer to the relevant operating system procedure for details.

Setup

The setup procedure is shown in the table below. However, the procedure on the arbitration server should be performed only when the arbitration server is used for automatic degradation. A distinction is made between the procedures on the primary server and standby server according to whether the arbitration server is used.

Step	Task			Refer to
	Primary server	Standby server	Arbitration server	
1	Installation			2.1 Installation
2	Preparing the database server		Preparing the arbitration server	2.2 Preparing for Setup
3			Configuring the arbitration server	2.3.1 Configuring the Arbitration Server
4			Creating a user exit	2.3.2 Creating a User Exit for the Arbitration Server

Step	Task			Refer to
	Primary server	Standby server	Arbitration server	
5			Starting the arbitration process	2.3.3 Starting the Mirroring Controller Arbitration Process
6	Setting up database multiplexing mode			2.4.1 Setting Up Database Multiplexing Mode on the Primary Server
7	Creating, setting, and registering the instance			2.4.2 Creating, Setting, and Registering the Primary Server Instance
8	Creating a user exit			2.6 Creating a User Exit for a Database Server
9	Starting Mirroring Controller			2.4.3 Starting Mirroring Controller on the Primary Server
10		Setting up database multiplexing mode		2.5.1 Setting Up Database Multiplexing Mode on the Standby Server
11		Creating, setting, and registering the instance		2.5.2 Creating, Setting, and Registering the Standby Server Instance
12		Creating a user exit		2.6 Creating a User Exit for a Database Server
13		Starting Mirroring Controller		2.5.3 Starting Mirroring Controller on the Standby Server
14	Confirming the streaming replication status			2.7 Confirming the Streaming Replication Status
15	Checking the connection status			2.8.1 Checking the Connection Status on a Database Server
16		Checking the connection status		2.8.1 Checking the Connection Status on a Database Server
17			Checking the connection status	2.8.2 Checking the Connection Status on the Arbitration Server
18	Creating applications			2.9 Creating Applications
19	Checking the behavior			2.10 Checking the Behavior

Explanations for each step are provided below.

Information

- The setup procedure is also the same when changing the mode on a single server to database multiplexing mode. In this case, omit the installation of Fujitsu Enterprise Postgres and the creation of the instance.

  Refer to "3.9.2 Changing from Single Server Mode to Database Multiplexing Mode" for details.

- The primary and standby server can be pseudo-configured on the same server for system testing, for example. In this case, the setup can be performed using the same procedure, however there will be some supplementary steps.

  Before performing the setup, refer to "Appendix B Supplementary Information on Building the Primary Server and Standby Server on the Same Server".

2.1 Installation

Refer to the manuals below, and then install the product.

See

- Refer to the Installation and Setup Guide for Server for details on how to install Fujitsu Enterprise Postgres.
- Refer to the Installation and Setup Guide for Server Assistant for information on installing the Server Assistant on the arbitration server.

Information

Do not use the arbitration server also as a database server. The arbitration server is installed to check the database server status as a third party, and to perform fencing. Using the arbitration server also as a database server nullifies the effectiveness of the arbitration server.

2.2 Preparing for Setup

This section describes the preparation required before setting up Mirroring Controller.

2.2.1 Preparing the Database Server

2.2.1.1 Preparing the Backup Disk

In Mirroring Controller, by performing a backup, recovery is possible even if all server disks are corrupted.

The content on the primary server should be backed up. However, through switching and failback, the standby server may also become the primary server. Accordingly, prepare each of the backup disk devices for the primary and standby servers. Perform backup on the primary server used at the time of the backup.

2.2.1.2 Preparatory Tasks for the Output of Error Logs to the Event Log

This section explains the preparatory tasks required to output error logs to the event log.

If you do not register an event source name, the message content output to the event log may be incomplete.

Setting each server

You should register this default event source name beforehand because the default event source name "MirroringControllerOpen" may be output to the event log when Mirroring Controller commands on the database server are used.

Example)
The following is an example in which the DLL of a 64-bit product is registered under the default event source name. Note that "<*x*>" indicates the product version.

```
> regsvr32 "c:\Program Files\Fujitsu\fsepv<x>server64\lib\mcevent.dll"
```

Setting each instance

You can output messages to any event source named by the user, so that messages output to the event log can be identified by each instance.

Example)
The following is an example in which the DLL of a 64-bit product is registered under the event source name "Mirroring Controller inst1". Note that "<*x*>" indicates the product version.

```
> regsvr32 /n /i:"Mirroring Controller inst1" "c:\Program Files\Fujitsu\fsepv<x>server64\lib
\mcevent.dll"
```

The parameter must be edited for each instance. Refer to "A.4.1 Server Configuration File for the Database Servers" to set the event_source parameter.

If installing multiple versions

If Fujitsu Enterprise Postgres is already installed on the same machine, search for the key below in a registry editor, and make a note of the path of the registered DLL. Afterwards, register a new DLL using the default event source name.

Use the DLL path that you made a note of in the above step when re-registering the default event source name during uninstallation.

```
MirroringControllerOpen
```

2.2.1.3 Security Policy Settings

Security settings that allow logon as a service are required in Mirroring Controller for the operating system user account of the instance administrator user in order to start and stop Mirroring Controller and an instance using a Windows service.

If the security settings have not been configured, refer to "E.1 Security Policy Settings" for information on configuring the settings.

2.2.2 Preparing the Arbitration Server

2.2.2.1 Preparing to Output Error Logs to the Event Log (Windows)

This section explains the preparatory tasks for outputting error logs to the event log.

If no event source name is registered, messages output to the event log may be incomplete.

Configuring each server

Event logs for the Mirroring Controller commands on the arbitration server may be output with the default event source name "MirroringControllerArbiter". Therefore, register this default event source name beforehand.

Example)
The following is an example in which the DLL of a 64-bit product is registered under the default event source name. Note that "<*x*>" indicates the product version.

```
> regsvr32 "c:\Program Files\Fujitsu\fsepv<x>assistant64\lib\mcarbevent.dll"
```

Setting each instance

You can output messages to any event source named by the user, so that messages output to the event log can be identified by each instance.

Example)
The following is an example in which the DLL of a 64-bit product is registered under the event source name "Mirroring Controller arbiter1". Note that "<*x*>" indicates the product version.

```
> regsvr32 /n /i:"Mirroring Controller arbiter1" "c:\Program Files\Fujitsu\fsepv<x>assistant64\lib
\mcarbevent.dll"
```

The parameter must be edited for each instance. Refer to "A.4.2 Arbitration Configuration File" and set the event_source parameter.

If installing multiple versions

If Fujitsu Enterprise Postgres is already installed on the same machine, search for the key below in Registry Editor, and make a note of the path of the registered DLL. Afterwards, register a new DLL using the default event source name.

Use the DLL path that you made a note of in the above step when re-registering the default event source name during uninstallation.

```
MirroringControllerArbiter
```

2.2.2.2 Security Policy Settings (Windows)

On the arbitration server, operating system user accounts that operate the Mirroring Controller arbitration process must be assigned the "Log on as a service" user right in order to use Windows Services to start and stop the Mirroring Controller arbitration process.

If the security settings to enable this have not been configured, refer to "E.1 Security Policy Settings" and configure the settings.

2.2.2.3 JAVA_HOME Setting (SLES)

Specify the installation location of JRE 8 in the environment variable JAVA_HOME, and set it in the Server Assistant installation environment using the mc_update_jre_env command.

This procedure must be executed by the superuser.

Example)
/opt/fsepv<*x*>assistant/bin is the installation directory where the Server Assistant feature is installed.

```
$ su -
Password:******
# export JAVA_HOME="Jre8InstallDir"
# /opt/fsepv<x>assistant/bin/mc_update_jre_env
```

2.3 Setting Up the Arbitration Server

This section explains how to set up the arbitration server.

2.3.1 Configuring the Arbitration Server

This section explains how to set up database multiplexing mode on the arbitration server.

In database multiplexing mode, the files that are required for operations are managed in the Mirroring Controller arbitration process management directory.

There is one Mirroring Controller arbitration process management directory for each arbitration process.

Point

The arbitration process for each database multiplexing system can be started on a single arbitration server.

See

- Refer to the Reference for information on the mc_arb command.
- Refer to "Appendix A Parameters" for information on the parameters to be edited for the setup.

Perform the following procedure:

Linux

1. On the arbitration server, log in as any operating system user who starts and stops the arbitration process.
2. Configure the environment variables.

   Set the following environment variables:

   - PATH

     Add the installation directory "/bin".

   - MANPATH

     Add the installation directory "/share/man".

   Example

   The following example configures environment variables when the installation directory is "/opt/fsepv<*x*>assistant".

   Note that "<*x*>" indicates the product version.

   sh, bash

```
$ PATH=/opt/fsepv<x>assistant/bin:$PATH ; export PATH
$ MANPATH=/opt/fsepv<x>assistant/share/man:$MANPATH ; export MANPATH
```

csh, tcsh

```
$ setenv PATH /opt/fsepv<x>assistant/bin:$PATH
$ setenv MANPATH /opt/fsepv<x>assistant/share/man:$MANPATH
```

3. Create the Mirroring Controller arbitration process management directory that will store the files required by the arbitration server.

   Use ASCII characters in the Mirroring Controller arbitration process management directory.

4. In the network configuration file (network.conf), define the Mirroring Controller network configuration that will be managed by the Mirroring Controller arbitration process.

   Create network.conf in the Mirroring Controller arbitration process management directory, based on the sample file. For network.conf, set read and write permissions only for the operating system user who starts and stops the arbitration process in step 1.

   If users other than this are granted access permissions, the mc_arb command will not work. Accordingly, users other than the operating system user who starts and stops the arbitration process in step 1 are prevented from operating the Mirroring Controller arbitration process.

   Sample file

   ```
   /installDir/share/mcarb_network.conf.sample
   ```

   In network.conf, specify the IP address or host name and port number of the primary server and standby server, and define the Mirroring Controller network configuration that will be managed by the Mirroring Controller arbitration process.

   Refer to "A.3 Network Configuration File" for details.

   A definition example is shown below.

   ```
   Example)
   The IDs of the servers are set to "server1" and "server2", and their port numbers are set to
   "27541".
   ```

   ```
   server1 192.0.3.100 27541
   server2 192.0.3.110 27541
   ```

5. In the arbitration configuration file (arbitration.conf), define the information related to control of the Mirroring Controller arbitration process.

   Create arbitration.conf in the Mirroring Controller arbitration process management directory, based on the sample file. For arbitration.conf, set read and write permissions only for the operating system user who starts and stops the arbitration process in step 1. If users other than this are granted access permissions, the mc_arb command will not work.

   Sample file

   ```
   /installDir/share/mcarb_arbitration.conf.sample
   ```

   Set the parameters shown in the table below in arbitration.conf.

   Refer to "A.4.2 Arbitration Configuration File" for information on the parameters and for other parameters.

Table 2.1 Parameters

Parameter	Content specified	Remarks
port	Port number of the Mirroring Controller arbitration process	The port number must be 0 to 65535. Ensure that the port number does not conflict with other software. Do not specify an ephemeral port that may temporarily be assigned by another program.

Parameter	Content specified	Remarks
my_address	'*ipAddrOrHostNameThatAcceptsConnectionFromMirroringControllerProcessOnDbServer*' [Setting example] my_address = '192.0.3.120'	IPv4 and IPv6 addresses can be specified. Specify the IP address, enclosed in single quotation marks (').
syslog_ident	'*programName*'	Specify using single quotation marks (') to enclose the program name used to identify the Mirroring Controller arbitration process message in the system log. Use ASCII characters excluding spaces to specify this parameter. The default is 'MirroringControllerArbiter'.
fencing_command	'*fencingCmdFilePath*' [Setting example] fencing_command = '/arbiter/fencing_dir/execute_fencing.sh'	Specify the full path of the fencing command that fences a database server where it is determined that an error has occurred. Enclose the path in single quotation marks ('). Specify the path using less than 1024 bytes.
fencing_command_timeout	Timeout for fencing command (seconds)	If the command does not respond within the specified number of seconds, it is determined that fencing has failed and a signal (SIGTERM) is sent to the fencing command execution process. Specify a value between 1 and 2147483647. The default is 20 seconds.

Windows

1. On the arbitration server, log in as any operating system user who starts and stops the arbitration process.
2. Configure the environment variables.

   Set the following environment variable:

   - PATH

     Add the installation folders "\bin" and "\lib".

   Example

   The following example configures environment variables when the installation folder is "c:\Program Files\Fujitsu \fsepv<*x*>assistant64".

   Note that "<*x*>" indicates the product version.

   ```
   > SET PATH=c:\Program Files\Fujitsu\fsepv<x>assistant64\bin;c:\Program Files\Fujitsu
   \fsepv<x>assistant64\lib;%PATH%
   ```

3. Create the Mirroring Controller arbitration process management directory that will store the files required by the arbitration server.

   Use ASCII characters in the Mirroring Controller arbitration process management directory.

4. In the network configuration file (network.conf), define the Mirroring Controller network configuration that will be managed by the Mirroring Controller arbitration process.

   Create network.conf in the Mirroring Controller arbitration process management directory, based on the sample file.

   `Sample file`

```
installDir\share\mcarb_network.conf.sample
```

In network.conf, specify the IP address or host name and port number of the primary server and standby server, and define the Mirroring Controller network configuration that will be managed by the Mirroring Controller arbitration process.

Refer to "A.3 Network Configuration File" for details.

A definition example is shown below.

```
Example)
The IDs of the servers are set to "server1" and "server2", and their port numbers are set to
"27541".
```

```
server1 192.0.3.100 27541
server2 192.0.3.110 27541
```

5. Change the access permissions for network.conf.

   For network.conf, set read and write permissions only for the operating system user who starts and stops the arbitration process in step 1. If users other than this are granted access permissions, the mc_arb command will not work. Accordingly, users other than the operating system user who starts and stops the arbitration process in step 1 are prevented from operating the Mirroring Controller arbitration process.

   ```
   Example)
   The following is an execution example, in which the operating system user who starts and stops the
   arbitration process in step 1 is granted full access permissions as the owner when the user is
   "fsepuser". The following procedure applies when the user is logged in to the Windows server as
   "fsepuser".
   ```

   ```
   > takeown /f network.conf
   > icacls network.conf /reset
   > icacls network.conf /inheritance:r
   > icacls network.conf /grant fsepuser:F
   ```

6. In the arbitration configuration file (arbitration.conf), define the information related to control of the Mirroring Controller arbitration process.

   Create arbitration.conf in the Mirroring Controller arbitration process management directory, based on the sample file.

   ```
   Sample file
   ```

   ```
   installDir\share\mcarb_arbitration.conf.sample
   ```

   Set the parameters shown in the table below in arbitration.conf.

   Refer to "A.4.2 Arbitration Configuration File" for information on the parameters and for other parameters.

   Table 2.2 Parameters

Parameter	Content specified	Remarks
port	Port number of the Mirroring Controller arbitration process	The port number must be 0 to 65535. Ensure that the port number does not conflict with other software. Do not specify an ephemeral port that may temporarily be assigned by another program.
my_address	'*ipAddrOrHostNameThatAcceptsConnectionFromMirroringControllerProcessOnDbServer*' [Setting example] my_address = '192.0.3.120'	IPv4 and IPv6 addresses can be specified. Enclose the parameter value in single quotation marks (').
service_name	'*registeredServiceNameOfArbitrationProcessInWindowsServices*'	Use ASCII characters excluding forward slash (/) and backslash (\) to specify this parameter.

Parameter	Content specified	Remarks
		Enclose the parameter value in single quotation marks ('). The maximum length of the service name is 124 bytes.
event_source	'*eventSourceNameUsedToIdentifyArbitrationProcessMsgInEventLog*'	Use ASCII characters excluding spaces to specify this parameter. Enclose the parameter value in single quotation marks ('). The maximum length of the event source name is 255 bytes.
fencing_command	'*fencingCmdFilePath*' [Setting example] fencing_command = 'c:\\arbiter\\fencing_dir\\execute_fencing.bat'	Specify the full path of the fencing command that fences a database server where it is determined that an error has occurred. Specify "\\" as the delimiter. Enclose the path in single quotation marks ('). Specify the path using less than 260 bytes. Any multibyte characters must use the same encoding as the operating system.
fencing_command_timeout	Timeout for fencing command (seconds)	If the command does not respond within the specified number of seconds, it is determined that fencing has failed and a signal (SIGTERM) is sent to the fencing command execution process. Specify a value between 1 and 2147483647. The default is 20 seconds.

7. Change the access permissions for arbitration.conf.

   For arbitration.conf, set read and write permissions only for the operating system user who starts and stops the arbitration process in step 1. If users other than this are granted access permissions, the mc_arb command will not work.

   ```
   Example)
   The following is an execution example, in which the operating system user who starts and stops the
   arbitration process in step 1 is granted full access permissions as the owner when the user is
   "fsepuser". The following procedure applies when the user is logged in to the Windows server as
   "fsepuser".
   ```

   ```
   > takeown /f arbitration.conf
   > icacls arbitration.conf /reset
   > icacls arbitration.conf /inheritance:r
   > icacls arbitration.conf /grant fsepuser:F
   ```

8. Configure Windows Firewall.

   If Windows Firewall is used, enable the port number of Mirroring Controller specified in the network configuration file in step 3. Refer to "E.2 Windows Firewall Settings" for details.

9. Register the Mirroring Controller arbitration process as a Windows service.

   Execute the mc_arb command in register mode.

   For the -P option of the mc_arb command, specify the password of the operating system user who executes the command.

   ```
   Example)
   ```

```
> mc_arb register -M D:\mcarb_dir\arbiter1 -P ********
```

Note

When specifying the password in the -P option of the mc_arb command, for security reasons, you should be careful not to allow other users to access it.

Information

Use the mc_arb command with the -S option to specify automatic start and stop of the Mirroring Controller arbitration process. Refer to "2.13 Setting Automatic Start and Stop of the Mirroring Controller Arbitration Process" for details.

The Mirroring Controller arbitration process is registered as a Windows service using the service name specified in the service_name parameter of arbitration.conf in step 6.

You can execute the sc qc command to check the registration status.

2.3.2 Creating a User Exit for the Arbitration Server

The only user exit for the arbitration server is the fencing command.

The fencing command is a user command that is called by the Mirroring Controller arbitration process if Mirroring Controller performs arbitration processing and determines that a database server is unstable.

In the fencing command, the user implements a process that isolates a database server from a cluster system by, for example, stopping the target operating system or server. The fencing command that was created is to be specified for the parameter in the arbitration configuration file. Refer to "A.4.2 Arbitration Configuration File" for information on the parameters.

- Fencing the primary server during the switch
  - Prevent the Mirroring Controller management process on the primary server from communicating with the Mirroring Controller management process on the other server.
  - Prevent applications from connecting to the primary server instance.
- Fencing the standby server during disconnection
  - Prevent the Mirroring Controller management process on the standby server from communicating with the Mirroring Controller management process on the other server.
  - Prevent applications from connecting to the standby server instance.
  - Prevent the standby server from continuing streaming replication.

See

Refer to "Appendix C User Commands" for information on user exits.

2.3.3 Starting the Mirroring Controller Arbitration Process

This section explains how to start the Mirroring Controller arbitration process.

An operating system user who has logged in to the arbitration server can start the Mirroring Controller arbitration process by executing the mc_arb command in start mode.

Linux

```
Example)
```

```
$ mc_arb start -M /mcarb_dir/arbiter1
```

Windows

Example)

```
> mc_arb start -M D:\mcarb_dir\arbiter1
```

2.4 Setting Up the Primary Server

This section explains how to set up the primary server.

2.4.1 Setting Up Database Multiplexing Mode on the Primary Server

This section explains how to set up database multiplexing mode on the primary server.

In database multiplexing, the files that are required for operations are managed in the Mirroring Controller management directory.

There is one Mirroring Controller management directory for each instance.

Information

Do not place the Mirroring Controller management directory in a directory managed by Fujitsu Enterprise Postgres, otherwise it may be deleted by mistake with the directories managed by Fujitsu Enterprise Postgres, and an old version of files may be restored.

See

- Refer to "Preparing Directories for Resource Deployment" in the Installation and Setup Guide for Server for details on the directories that are managed by Fujitsu Enterprise Postgres.
- Refer to "mc_ctl" in Reference for information on the command.
- Refer to "Appendix A Parameters" for details on each parameter to be edited for the setup.

Perform the following procedure:

1. Log in to the primary server.
2. Create the Mirroring Controller management directory that will store the files required by database multiplexing.

   Use ASCII characters in the Mirroring Controller management directory.

   Additionally, grant "Write" permission to the instance administrator user for the Mirroring Controller management directory.
3. In the network configuration file (network.conf), define the network configuration that will link between the Mirroring Controller processes.

   Create the network.conf file in the Mirroring Controller management directory, based on the sample file.

   Sample file

   ```
   installDir\share\mc_network.conf.sample
   ```

   In network.conf, specify the IP address or host name and port number of the primary server and standby server, and define the network configuration that will link between the Mirroring Controller processes, and between Mirroring Controller processes and the Mirroring Controller arbitration process.

   Refer to "A.3 Network Configuration File" for details.

   A definition example is shown below.

   The content to be defined depends on the operation settings at the time a heartbeat abnormality is detected.

When automatic degradation by the arbitration server is selected

```
Example)
The IDs of the primary server and standby server are set to "server1" and "server2", and their
port numbers are set to "27540" and "27541". The ID of the server of the Mirroring Controller
arbitration process is set to "arbiter", and its port number is set to "27541".
```

```
server1 192.0.2.100,192.0.3.100 27540,27541 server
server2 192.0.2.110,192.0.3.110 27540,27541 server
arbiter 192.0.3.120 27541 arbiter
```

Ensure that the port numbers set for the primary server, standby server, and arbitration server do not conflict with other software. In addition, when the arbitration server is used for automatic degradation, use a network in which the arbitration network is not affected by a line failure in the admin network.

When the server type is "server", two IP addresses or host names, and two port numbers need to be specified in the following order:

- IP address or host name of the database server used as the admin network
- IP address or host name of the database server used as the arbitration network
- Port number of the database server used as the admin network
- Port number of the database server used as the arbitration network

If the server type is "arbiter", specify the IP address or host name set for the my_address parameter and the port number set for the port parameter in arbitration.conf of the arbitration server.

When using the admin network and arbitration network together, the following IP addresses or host names must be assigned the same values.

- IP address or host name of the database server used as the admin network
- IP address or host name of the database server used as the arbitration network

Example)
Here is an example where the server identifiers for the primary server and standby server are "server1" and "server2", with port numbers "27540" and "27541", and the server identifier for the Mirroring Controller arbitration process is "arbiter", with port number "27541".

```
server1 192.0.2.100,192.0.2.100 27540,27541 server
server2 192.0.2.110,192.0.2.110 27540,27541 server
arbiter 192.0.2.120 27541 arbiter
```

When operation other than automatic degradation by the arbitration server is selected

```
Example)
The IDs of the servers are set to "server1" and "server2", and their port numbers are set to
"27540".
```

```
server1 192.0.2.100 27540
server2 192.0.2.110 27540
```

Ensure that the port numbers for the primary and standby server do not conflict with other software.

Register the port number of the primary server in the services file, because there are programs, such as WebAdmin, that search an available port number using the services file.

Register any name as the service name.

4. Change the access permissions for the network.conf file.

   For network.conf, set read and write permissions for the instance administrator user only.

   If users other than the instance administrator user are granted access permissions, the mc_ctl command will not work. Accordingly, users other than the instance administrator user are prevented from operating Mirroring Controller.

   ```
   Example)
   The following is an execution example, in which the instance administrator user is granted full
   ```

access permissions as the owner when the operating system user name of the instance administrator user is "fsepuser". The following procedure applies when the user is logged in to the Windows server as "fsepuser":

```
> takeown /f network.conf
> icacls network.conf /reset
> icacls network.conf /inheritance:r
> icacls network.conf /grant fsepuser:F
```

5. Define the information related to Mirroring Controller monitoring and control in the *serverIdentifier*.conf file.

   Create the *serverIdentifier*.conf file in the Mirroring Controller management directory, based on the sample file.

   As the file name for the *serverIdentifier*.conf file, use the server identifier name that was specified in the network.conf file in step 3.

   Sample file

```
installDir\share\mc_server.conf.sample
```

   Set the parameters shown in the table below in the *serverIdentifier*.conf file.

   Refer to "A.4.1 Server Configuration File for the Database Servers" for information on the parameters and for other parameters.

Table 2.3 Parameters

Parameter	Content specified	Remarks
db_instance	'*dataStorageDestinationDir*'	Use ASCII characters, and specify "\\" as the path delimiter. Enclose the parameter value in single quotation marks (').
db_instance_service_name	'*registeredServiceNameOfFujitsuEnterprisePostgresInstance*'	Specify the registered service name of the Fujitsu Enterprise Postgres instance in the Windows service. Use ASCII characters, enclosed in single quotation marks (').
db_instance_password	'*passwordOfInstanceAdminUser*'	If password authentication is performed, specify this parameter in the settings used when Mirroring Controller connects to a database instance. Use ASCII characters, enclosed in single quotation marks ('). If the specified value of this parameter includes ' or \, write \' or \\, respectively.
enable_hash_in_password	on or off	Specify on to treat the # in the db_instance_password specification as a password character, or off to treat it as a comment. The default is "off".
mc_service_name	'*registeredServiceNameOfMirroringController*'	Specify the Mirroring Controller service name registered in the Windows service. Use ASCII characters excluding forward slash (/) and backslash (\) to specify this parameter. The service name is up to 124 bytes.
event_source	'*eventSourceName*'	Specify the event source name to be used to identify the Mirroring Controller message in the event log. Use ASCII characters to specify this parameter.

Parameter	Content specified	Remarks
		The maximum length of the event source name is 255 bytes. By using a similar event source name as the postgresql.conf file parameter, the Mirroring Controller output content can be referenced transparently, so log reference is easy.
remote_call_timeout	Admin communication timeout	Specify the timeout value (milliseconds) of the Mirroring Controller agent process for communication between servers. Specify a value that is less than the operation system TCP connection timeout. Also, when using the Mirroring Controller arbitrage process for arbitrage, fencing, and state transition commands, specify a value that is greater than the sum of the timeout values.
heartbeat_error_action	Operation when a heartbeat abnormality is detected using operating system or server heartbeat monitoring	arbitration: Perform automatic degradation using the arbitration server. command: Call a user exit to determine degradation, and perform automatic degradation if required. message: Notify messages. fallback: Perform automatic degradation unconditionally. Set the same value on the primary server and standby server.
heartbeat_interval	Interval time for abnormality monitoring during heartbeat monitoring of the operating system or server (milliseconds)	Abnormality monitoring of the operating system or server is performed at the interval (milliseconds) specified in heartbeat_interval. This parameter setting is used as the default for database process heartbeat monitoring, streaming replication abnormality monitoring, and disk abnormality monitoring. When setting the monitoring time, there are some considerations to take into account to optimize degradation using abnormality monitoring. Refer to "2.11.4.1 Tuning for Abnormality Monitoring of the Operating System or Server" for details.
heartbeat_timeout	Timeout for abnormality monitoring during heartbeat monitoring of the operating system or server (seconds)	
heartbeat_retry	Number of retries for abnormality monitoring during heartbeat monitoring of the operating system or server (number of times)	
fencing_command	'*fencingCmdFilePath*' [Setting example] fencing_command = 'c:\\mc\\fencing_dir\\execute_fencing.bat'	Specify the full path of the fencing command that fences a database server where an error is determined to have occurred. Enclose the path in single quotation marks ('). Any multibyte characters must use the same encoding as the operating system. This parameter must be specified when "command" is set for heartbeat_error_action.

Parameter	Content specified	Remarks
		Specify the path using less than 260 bytes.
fencing_command_timeout	Fencing command timeout (seconds)	If the command does not respond within the specified number of seconds, fencing is determined to have failed and a signal (SIGTERM) is sent to the fencing command execution process. Specify a value between 1 and 2147483647. The default is 20 seconds.
arbitration_timeout	Timeout for arbitration processing in the Mirroring Controller arbitration process (seconds)	The specified value must be at least equal to the heartbeat monitoring time of the operating system or server + fencing_command_timeout in the arbitration configuration file. If there is no response for at least the number of seconds specified, the primary server will not be switched and the standby server will not be disconnected. Therefore, perform degradation manually. Specify a value between 1 and 2147483647. This parameter does not need to be set for operation that does not use the arbitration server.
arbitration_command	'*ArbitrationCmdFilePath*' [Setting example] arbitration_command = 'c:\\mc\\arbitration_dir\\execute_arbitration_command.bat'	Specify the full path of the arbitration command to be executed when an abnormality is detected during heartbeat monitoring of the operating system or server. Enclose the path in single quotation marks ('). Any multibyte characters must use the same encoding as the operating system. This parameter must be specified when "command" is set for heartbeat_error_action. Specify the path using less than 260 bytes.
arbitration_command_timeout	Timeout for arbitration command (seconds)	If the command does not respond within the specified number of seconds, it is determined that execution of the arbitration command has failed and a signal (SIGTERM) is sent to the arbitration command execution process. Specify a value between 1 and 2147483647. This parameter can be specified only when "command" is set for heartbeat_error_action.

6. Change the access permissions for the *serverIdentifier*.conf file.

   For *serverIdentifier*.conf, set read and write permissions for the instance administrator user only. If users other than the instance administrator user are granted access permissions, the mc_ctl command will not work.

   ```
   Example)
   The following is an execution example, in which the instance administrator user is granted full
   access permissions when the operating system user name of the instance administrator user is
   "fsepuser". The following procedure applies when the user is logged in to the Windows server as
   "fsepuser":
   ```

```
> takeown /f serverIdentifier.conf
> icacls serverIdentifier.conf /reset
> icacls serverIdentifier.conf /inheritance:r
> icacls serverIdentifier.conf /grant fsepuser:F
```

7. Configure the Windows firewall.

   If the Windows firewall feature is to be enabled, you should enable the port number of Mirroring Controller that you specified in the network definition file in step 3. Refer to "E.2 Windows Firewall Settings" for details.

8. Register Mirroring Controller to the Windows service.

   Execute the mc_ctl command in the register mode.

   For the -P option of the mc_ctl command, specify the password of the operating system user who executes the command.

   Example)

```
> mc_ctl register -M D:\mcdir\inst1 -P ********
```

Note

When specifying the password in the -P option of the mc_ctl command, for security reasons, you should be careful not to allow other users to access it.

Information

You can use the mc_ctl command with the -S option to specify automatic start and stop of Mirroring Controller. Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

Using the service name specified in the mc_service_name parameter of *serverIdentifier*.conf in step 5, Mirroring Controller is registered to the Windows service.

You can execute the sc qc command to check the registration status.

2.4.2 Creating, Setting, and Registering the Primary Server Instance

This section explains how to create, set, and register the primary server instance.

Mirroring Controller supports instances that are registered in the Windows service.

See

- Refer to "Client Authentication" in the PostgreSQL Documentation for information on the pg_hba.conf file.
- Refer to "A.1 Parameters Set on the Primary Server" for information on the postgresql.conf file.
- Refer to "mc_ctl" in Reference for information on the command.

Perform the following procedure:

1. Refer to "Setup" in the Installation and Setup Guide for Server, and then perform the Fujitsu Enterprise Postgres setup and create the Fujitsu Enterprise Postgres instance.

   - Use ASCII characters in the data storage destination directory.
   - When registering an instance to the Windows service, perform the settings required to enable Mirroring Controller to start and stop the instance. Execute the pg_ctl command with the following specified for the register mode:
     - For the service name of the -N option, specify the name set for the db_instance_service_name parameter in the server definition file

- Specify "demand" for the -S option, so that the service does not start automatically on startup of the system

- Do not configure the Windows service of a multiplexed instance to perform automatic start, as it is started by Mirroring Controller.

Point

If degradation starts occurring due to an error during operations in database multiplexing mode, recovery is required for the standby server. There are some conditions to execute the pg_rewind command to recover the standby server. One of the conditions can be satisfied by enabling checksums when executing the initdb command. This is not mandatory. Refer to "4.1.1.1.3 Identify cause of error and perform recovery" for details.

2. When using transparent data encryption, configure the encryption settings for the storage data.

   If you want to use the key management system as a keystore, set the connection information for the key management system and declare the master encryption key.

   Refer to "Protecting Storage Data Using Transparent Data Encryption" or "Using Transparent Data Encryption with Key Management Systems as Keystores" in the Operation Guide for details, and then configure the settings.

3. Add the following entry to the pg_hba.conf file to authenticate connections from the standby server.

   Copy the file to the standby server later.

```
# TYPE    DATABASE        USER        ADDRESS                     METHOD
  host    replication     fsep        standbyServerAddress        authenticationMethod
  host    replication     fsep        primaryServerAddress        authenticationMethod
```

   For the primary and standby server addresses, specify the IP address that will connect to the log transfer network.

   Additionally, all servers can be used as the primary server or the standby server, so add entries for the addresses of all servers that comprise the database multiplexing system.

Point

Setting an authentication method other than trust authentication

If the primary server becomes the standby server, to perform automatic authentication of connections to the primary server, create a password file (%APPDATA%\postgresql\pgpass.conf), and then specify a password for the replication database. Accordingly, the instance administrator operating system user and the user registered in the database will be the same, so you can verify that the connection was not made by an unspecified user. Additionally, the password that was set beforehand will be used in the authentication, so that the connection will be automatic.

Information

If trust authentication is set, all OS users who can log in to the primary server will be able to connect, and if one of these is a malicious user, then that user can corrupt the standby server data, or cause the job system to fail, by sending an erroneous transaction log. Therefore, decide on the authentication method according to the security requirements of the system using database multiplexing mode.

Refer to "Authentication Methods" in the PostgreSQL Documentation for details on the authentication methods that can be set.

4. Configure this setting to enable the instance administrator user of the primary server to connect as a database application.

   This setting enables the connection to the instance using the user name of the instance administrator user, so that Mirroring Controller can monitor instance errors. Configure this setting to enable the connection to the postgres database.

   - If password authentication is used

     In the db_instance_password parameter of the *serverIdentifier*.conf file, specify the password for the instance administrator user. This password is used to connect to the database instance. If a password is not specified in the db_instance_password parameter,

the connection to the database instance from Mirroring Controller will fail, and it will not be possible to perform the process monitoring of the instance.

- If password authentication is not used

  There is no need to specify the password in the db_instance_password parameter.

  Even if the password for the instance administrator user is specified in the db_instance_password parameter, it will be ignored.

- If certificate authentication using SSL is used

  Specify connection parameters for SSL in the db_instance_ext_ pq_conninfo parameter and db_instance_ext_jdbc_conninfo parameter in the *serverIdentifier*.conf file. If the pasrameters are not specified, the connection to the database instance from Mirroring Controller will fail, and it will not be possible to perform the process monitoring of the instance. If certificate authentication using SSL is not performed, the parameters specification is not required.

  For information about the db_instance_ext_pq_conninfo and db_instance_ext_jdbc_conninfo parameters, refer to "A.4.1 Server Configuration File for the Database Servers".

An example of setting the authentication method is shown below.

```
# TYPE    DATABASE        USER        ADDRESS         METHOD
  host    postgres        fsep        127.0.0.1/32    authenticationMethod
```

Information

Mirroring Controller uses the PostgreSQL JDBC 4.2 driver to connect to the database instance. Therefore, for the authentication method, specify a method supported by the JDBC driver. If an authentication method not supported by the JDBC driver is specified, Mirroring Controller will fail to start. Refer to the PostgreSQL JDBC Driver Documentation for information on authentication methods supported by the JDBC driver.

5. To use database multiplexing mode, specify the parameters shown in the table below in the postgresql.conf file.

   The postgresql.conf file is copied when the standby server instance is created. Accordingly, set the required parameters in the standby server.

   To use database multiplexing mode, specify the parameters shown in the table below in the postgresql.conf file. After editing the postgresql.conf file, restart the instance.

Table 2.4 Parameters

Parameter	Content specified	Remarks
wal_level	replica or logical	Specify "logical" when logical decoding is also to be used.
max_wal_senders	2 or more	Specify "2" when building a Mirroring Controller cluster system. When additionally connecting asynchronous standby servers to the cluster system, add the number of simultaneous connections from these standby servers.
synchronous_standby_names	'*standbyServerName*'	Specify the name that will identify the standby server. Enclose the name in single quotation marks ('). Do not change this parameter while Mirroring Controller is running. Do not specify multiple names to this parameter as the Mirroring Controller can manage only one standby server.
synchronized_standby_slots	'*physicalReplicationSlotName*'	Specify this parameter if the primary server will be a logical replication publication. Setting this parameter ensures that the subscriber is updated after WAL is sent to the standby server. This allows logical replication to continue if the primary server fails and the standby server is promoted.

Parameter	Content specified	Remarks
		Do not change this parameter while the Mirroring Controller is running. Because the Mirroring Controller can manage only one standby server, do not specify multiple names for this parameter.
hot_standby	on	Specify whether queries can be run on the standby server.
wal_keep_size	WAL save size (megabytes)	If a delay exceeding the value set in this parameter occurs, the WAL segment required later by the primary server may be deleted. Additionally, if you stop a standby server (for maintenance, for example), consider the stop time and set a value that will not cause the WAL segment to be deleted. Refer to "Estimating Transaction Log Space Requirements" in the Installation and Setup Guide for Server for information on estimating the WAL save size.
wal_log_hints	on	When using the pg_rewind command to recover a standby server, specify this parameter or enable checksums when executing the initdb command.
wal_sender_timeout	Timeout (milliseconds)	Specify the time period after which it is determined that an error has occurred in the transaction log transfer on the primary server. By aligning this value with the value for the database process heartbeat monitoring time, you can unify the time after which it is determined that an error has occurred.
archive_mode	on	Specify the archive log mode.
archive_command	'cmd /c ""installDir\\bin\\pgx_walcopy.cmd" "%p" "backupDataStorageDestinationDir\\archived_wal\\%f"""	Specify the command and storage destination to save the transaction log.
backup_destination	Backup data storage destination directory	Specify the name of directory where to store the backup data. Set the permissions so that only the instance administrator user can access the specified directory. Specify the same full path on all servers, so that the backup data of other servers can be used to perform recovery.
max_connections	Number of simultaneous client connections to the instance + superuser_reserved_connections	The value specified is also used to restrict the number of connections from client applications and the number of connections for the management of instances. Refer to "When an Instance was Created with the initdb Command" in the Installation and Setup Guide for Server, and "Connections and Authentication" in the PostgreSQL Documentation, for details.
superuser_reserved_connections	Add the number of simultaneous executions of mc_ctl status (*1) + 2	Specify the number of connections reserved for connections from database superusers. Add the number of connections from Mirroring Controller processes. Also reflect the added value in the max_connections parameter.

Parameter	Content specified	Remarks
wal_receiver_timeout	Timeout (milliseconds)	Specify the time period after which it is determined that an error has occurred when the transaction log was received on the standby server. By aligning this value with the value for the heartbeat monitoring time of the database process, you can unify the time after which it is determined that an error has occurred.
restart_after_crash	off	If "on" is specified, or the default value is used for this parameter, behavior equivalent to restarting Fujitsu Enterprise Postgres, including crash recovery, will be performed when some server processes end abnormally. However, when database multiplexing monitoring is used, a failover will occur after an error is detected when some server processes end abnormally, and the restart of those server processes is forcibly stopped. Specify "off" to prevent behavior such as this from occurring for no apparent reason.
synchronous_commit	on or remote_apply	Specify up to what position WAL send is to be performed before transaction commit processing returns a normal termination response to a client. Set "on" or "remote_apply" to prevent data loss caused by operating system or server down immediately after a switch or switch.
recovery_target_timeline	latest	Specify "latest" so that the new standby server (original primary server) will follow the new primary server when a switch occurs. This parameter is required when the original primary server is incorporated as a new standby server after the primary server is switched.

*1: Number of simultaneous executions of the mc_ctl command in the status mode.

2.4.3 Starting Mirroring Controller on the Primary Server

This section explains how to start Mirroring Controller on the primary server.

When the arbitration server is used for automatic degradation, start the Mirroring Controller arbitration process on the arbitration server in advance.

1. Start the Mirroring Controller process.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

   ```
   > mc_ctl start -M D:\mcdir\inst1
   ```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   Example)

   ```
   > mc_ctl start -M D:\mcdir\inst1 -F
   ```

Information

- When the arbitration server is used for automatic degradation, the database server must connect to the arbitration server, and as a result, Mirroring Controller startup may take longer than when the arbitration server is not used.
- If the parameter for heartbeat monitoring of operating systems or servers set by the abitration server is greater than parameter for heartbeat monitoring of operating systems and servers of the Mirroring Controller, the Mirroring Controller may fail to start. In this case, check the contents of the message notification and review the parameters for heartbeat monitoring of operating systems or servers for the arbitration server or Mirroring Controller.
- If the heartbeat_error_action parameter in *serverIdentifier*.conf is set to "message", even if automatic switch/disconnection is enabled and Mirroring Controller is started, only message output is performed when a heartbeat abnormality is detected during heartbeat monitoring of operating systems and servers - switch/disconnection is not performed.
- Mirroring Controller startup usually fails if the standby server is mistakenly started as the primary server or if the old primary server is not recovered after the switch and is then mistakenly started as the primary server. However, if the admin network is disconnected, then startup does not fail, and both servers may become primary servers. Therefore ensure that the admin network is connected before starting Mirroring Controller.
- If the automatic switch/disconnection is enabled, do not edit synchronous_standby_names parameter and synchronized_standby_slots parameter for the Mirroring Controller monitoring target instance. If Mirroring Controller is switched after editing, data may be lost or SQL access may stop.

Point

- The mc_ctl command fails if the Mirroring Controller arbitration process has not been started on the arbitration server when the arbitration server is used for automatic degradation. However, if the Mirroring Controller arbitration process cannot be started in advance, it can be started by specifying the --async-connect-arbiter option in the mc_ctl command.
- After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

2. Obtain the backup.

   Use the pgx_dmpall command to collect the backup.

2.5 Setting Up the Standby Server

This section explains how to set up the standby server.

2.5.1 Setting Up Database Multiplexing Mode on the Standby Server

This section explains how to set up database multiplexing mode on the standby server.

In database multiplexing, the files that are required for operations are managed in the Mirroring Controller management directory.

There is one Mirroring Controller management directory for each instance.

Information

- Do not place the Mirroring Controller management directory in a directory managed by Fujitsu Enterprise Postgres, otherwise it may be deleted by mistake with the directories managed by Fujitsu Enterprise Postgres, and an old version of files may be restored.
- When creating a standby server for a large database, stop job system operations, specify a large value for the wal_keep_size parameter, or use replication slots.
  This is because WALs generated after the standby server is built using the pg_basebackup command, but before it is started, need to be retained. However, the number of WAL segments that can be retained is constrained by the wal_keep_size parameter.

Additionally, setting the wal_keep_size parameter requires consideration regarding stabilization of the database multiplexing mode (refer to "2.11.1 Tuning to Stabilize the Database Multiplexing Mode" for details).

See

- Refer to "Preparing Directories for Resource Deployment" in the Installation and Setup Guide for Server for details on the directories that are managed by Fujitsu Enterprise Postgres.
- Refer to "pg_basebackup" in "Reference" in the PostgreSQL Documentation for information on the pg_basebackup command.
- Refer to "mc_ctl" in Reference for information on the command.
- Refer to "Appendix A Parameters" for details on each parameter to be edited for the setup.
- Refer to "Replication Slots" in the PostgreSQL Documentation for information on replication slots.

Perform the following procedure:

1. Log in to the standby server.
2. Create the Mirroring Controller management directory that will store the files required by database multiplexing.

   Use ASCII characters in the Mirroring Controller management directory.

   Additionally, grant "Write" permission to the instance administrator user for the Mirroring Controller management directory.
3. Copy, and then deploy, the network.conf file of the primary server.

   Copy the network.conf file that was defined in the primary server setup, and deploy it to the Mirroring Controller management directory of the standby server.

   Register the port number of the standby server that was specified in the network.conf file in the services file, because there are programs, such as WebAdmin, that search an available port number using the services file.

   Register any name as the service name.
4. Change the access permissions for the network.conf file.

   Set read and write permissions for the instance administrator user only. If users other than the instance administrator user are granted access permissions, the mc_ctl command will not work. Accordingly, users other than the instance administrator user are prevented from operating Mirroring Controller.

   ```
   Example)
   The following is an execution example, in which the instance administrator user is granted full
   access permissions as the owner when the operating system user name of the instance administrator
   user is "fsepuser". The following procedure applies when the user is logged in to the Windows
   server as "fsepuser".
   ```

   ```
   > takeown /f network.conf
   > icacls network.conf /reset
   > icacls network.conf /inheritance:r
   > icacls network.conf /grant fsepuser:F
   ```
5. Copy, and then deploy, the *serverIdentifier*.conf file of the primary server.

   Copy the *serverIdentifier*.conf file that was defined in the primary server setup, and deploy it to the Mirroring Controller management directory of the standby server.

   ## Point

   If the primary server and standby server are to be built within the same server, change the following parameters in the *serverIdentifier*.conf file, ensuring that the names are not duplicated with those on the primary server:

   - db_instance_service_name (registered service name of the Fujitsu Enterprise Postgres instance)

- mc_service_name (registered service name of Mirroring Controller)
- event_source (event source name)

6. Change the access permissions for the *serverIdentifier*.conf file.

   Set read and write permissions for the instance administrator user only. If users other than the instance administrator user are granted access permissions, the mc_ctl command will not work.

   ```
   Example)
   The following is an execution example, in which the instance administrator user is granted full
   access permissions as the owner when the operating system user name of the instance administrator
   user is "fsepuser". The following procedure applies when the user is logged in to the Windows
   server as "fsepuser":
   ```

   ```
   > takeown /f serverIdentifier.conf
   > icacls serverIdentifier.conf /reset
   > icacls serverIdentifier.conf /inheritance:r
   > icacls serverIdentifier.conf /grant fsepuser:F
   ```

7. Configure the Windows firewall.

   If the Windows firewall feature is to be enabled, you should enable the port number of Mirroring Controller that you specified in the network definition file in step 3. Refer to "E.2 Windows Firewall Settings" for details.

8. Register Mirroring Controller to the Windows service.

   Execute the mc_ctl command in the register mode.

   For the -P option of the mc_ctl command, specify the password of the operating system user who executes the command.

   ```
   Example)
   ```

   ```
   > mc_ctl register -M D:\mcdir\inst1 -P ********
   ```

   Note

   When specifying the password in the -P option of the mc_ctl command, for security reasons, you should be careful not to allow other users to access it.

   Point

   You can use the mc_ctl command with the -S option to specify automatic start and stop of Mirroring Controller. Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

   Using the service name specified in the mc_service_name parameter of *serverIdentifier*.conf in step 5, Mirroring Controller is registered to the Windows service.

   You can execute the sc qc command to check the registration status.

2.5.2 Creating, Setting, and Registering the Standby Server Instance

This section explains how to create, set, and register the standby server instance.

Mirroring Controller supports instances that are registered in the Windows service.

See

- Refer to "Appendix A Parameters" for details on each parameter.

- Refer to "mc_ctl" in Reference for information on the command.

Perform the following procedure:

1. Prepare for setup.

   Refer to "Preparations for Setup" in the Installation and Setup Guide for Server for information on the preparatory tasks to be performed before creating an instance on the standby server.

   Point

   If the primary server and standby server are to be built within the same server, perform preparation to ensure that the event source names of Fujitsu Enterprise Postgres are not duplicated with that of the primary server.

2. When using transparent data encryption, configure the encryption settings for the storage data.

   Refer to "Protecting Storage Data Using Transparent Data Encryption" or "Using Transparent Data Encryption with Key Management Systems as Keystores" in the Operation Guide for details, and then configure the settings.

3. Execute the pg_basebackup command to create a copy of the primary server instance on the standby server.

   Example)

   ```
   > pg_basebackup -D D:\database\inst1 -X fetch --waldir=E:\transaction\inst1 --progress --verbose
   -R --dbname="application_name=standbyServerName" -h primaryServerIpAddress -p
   primaryServerPortNumber
   ```

   Point

   - Use the pg_basebackup command with the -R option to create a standby.signal file. If you do not create the standby.signal file, the Mirroring Controller cannot be started as a standby server.
   - If using a method that requires password authentication for connections to the primary server, you will need to ensure that authentication is performed automatically. If the -R option is specified for the pg_basebackup command and the password parameter is specified for the --dbname option, the pg_basebackup command will set the password in the primary_conninfo parameter in postgresql.auto.conf file, enabling connections to be performed automatically.

     If a password is not set in the primary_conninfo parameter in postgresql.auto.conf file, it will be necessary to create a password file (%APPDATA%postgresql\pgpass.conf), and then specify a password for the replication database.
   - The primary_conninfo parameter should not be set in the postgresql.conf file, but only in the postgresql.auto.conf file using the pg_basebackup command.
   - When executing the pg_basebackup command, consider the following for collection of transaction logs.
     - When "fetch" is specified for the -X option of the command

       Transaction logs are collected at the end of the backup, so it is necessary to ensure that transaction logs that occur during backup are not deleted from the primary server. Therefore, allow for a sufficient value for the wal_keep_size parameter in postgresql.conf.
     - When the -X option is omitted or "stream" is specified for the -X option of the command

       Transaction logs are streamed, so when Mirroring Controller is running on the primary server, the connection is changed to a synchronous standby server on detection of a streaming replication connection using this command. Therefore, if a job has started on the primary server, the primary server will be impacted, therefore execute this command after stopping only the Mirroring Controller process on the primary server.

   See

   Refer to "Hot Standby" in the PostgreSQL Documentation for information on the standby.signal file.

4. Set the parameters shown in the table below in the postgresql.conf file.

Table 2.5 Parameters

Parameter	Content specified	Remarks
synchronous_standby_names	'*primaryServerName*'	Required after switching the primary server and then changing the original primary server to the new standby server. Enclose the name in single quotation marks ('). Do not change this parameter while Mirroring Controller is running. Do not specify multiple names to this parameter as the Mirroring Controller can manage only one standby server.

5. Register an instance to the Windows service.

   Refer to "Creating an Instance" in the Installation and Setup Guide for Server for information on how to register an instance to the Windows service. Do not configure the Windows service of a multiplexed instance to perform automatic start, as it is started by Mirroring Controller. Note that you should execute the pg_ctl command with the following specified for the register mode to enable Mirroring Controller to start and stop an instance:

   - For the service name of the -N option, specify the name set for the db_instance_service_name parameter in the server definition file
   - Specify "demand" for the -S option, so that the service does not start automatically on startup of the system

Point

If the primary server and standby server are to be built within the same server, ensure that the registered service name of the Fujitsu Enterprise Postgres instance is not duplicated with that of the primary server.

2.5.3 Starting Mirroring Controller on the Standby Server

This section explains how to start Mirroring Controller on the standby server.

When the arbitration server is used for automatic degradation, start the Mirroring Controller arbitration process on the arbitration server in advance.

1. After ensuring that the Mirroring Controller process of the primary server has started, start Mirroring Controller on the standby server.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -f option specified. This action enables automatic switch/disconnection.

   If you start Mirroring Controller and the instance without specifying the -f option, automatic switch/disconnection will not be enabled. To enable both, start Mirroring Controller and then execute the mc_ctl command in enable-failover mode or restart Mirroring Controller with the -f option specified.

   ```
   Example)
   ```

   ```
   > mc_ctl start -M D:\mcdir\inst1
   ```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   ```
   Example)
   ```

   ```
   > mc_ctl start -M D:\mcdir\inst1 -F
   ```

2. Check the status of the Mirroring Controller process.

   As the instance administrator user, execute the mc_ctl command in status mode. Ensure that "mirroring status" is switchable.

Example)

```
> mc_ctl status -M D:\mcdir\inst1
```

Information

- When the arbitration server is used for automatic degradation, the time required for the database server to connect to the arbitration server is added on. Therefore, Mirroring Controller startup may take longer than when the arbitration server is not used.
- If the parameter for heartbeat monitoring of operating systems or servers set by the abitration server is greater than parameter for heartbeat monitoring of operating systems and servers of the Mirroring Controller, the Mirroring Controller may fail to start. In this case, check the contents of the message notification and review the parameters for heartbeat monitoring of operating systems or servers for the arbitration server or Mirroring Controller.
- If the heartbeat_error_action parameter in *serverIdentifier*.conf is set to "message", even if automatic switch/disconnection is enabled and Mirroring Controller is started, only message output is performed when a heartbeat abnormality is detected during heartbeat monitoring of operating systems and servers - switch/disconnection is not performed.
- Mirroring Controller startup usually fails if the standby server is mistakenly started as the primary server or if the old primary server is not recovered after the switch and is then mistakenly started as the primary server. However, if the admin network is disconnected, then startup does not fail, and both servers may become primary servers. Therefore, ensure that the admin network is connected before starting Mirroring Controller.
- If the automatic switch/disconnection is enabled, do not edit synchronous_standby_names parameter and synchronized_standby_slots parameter for the Mirroring Controller monitoring target instance. If Mirroring Controller is switched after editing, data may be lost or SQL access may stop.

Point

- The mc_ctl command fails if the Mirroring Controller arbitration process has not been started on the arbitration server when the arbitration server is used for automatic degradation. However, if the Mirroring Controller arbitration process cannot be started in advance, it can be started by specifying the --async-connect-arbiter option in the mc_ctl command.
- After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

2.6 Creating a User Exit for a Database Server

This section explains how to create a user exit for a database server.

The user command types explained below can be used as user exits. These commands are called by Mirroring Controller management processes.

The user can create user exits as required.

Specify the user commands that were created for the parameters in the server configuration file of the database server. Refer to "A.4.1 Server Configuration File for the Database Servers" for information on these parameters.

User command types

- Fencing command

  This user command performs fencing if Mirroring Controller performs arbitration processing and determines that a database server is unstable.

- Arbitration command

  This user command performs arbitration processing in lieu of the arbitration server when there is no arbitration server.

- State transition commands

  These user commands are called when Mirroring Controller performs state transition of a database server.
  It includes the following types:

  - Post-switch command

    This user command is called after a promotion from standby server to primary server.

  - Pre-detach command

    This user command is called before the standby server is disconnected from a cluster system.
    If the pre-detach command is specified on both the primary server and standby server, it is called first on the standby server and then on the primary server.

    If the settings are configured to forcibly stop the instance on the standby server when the standby server is disconnected, the pre-detach command is called on the standby server and then the instance on the standby server is stopped.

  - Post-attach command

    This user command is called after the standby server has been attached to a cluster system.
    If the post-attach command is specified on both the primary server and standby server, it is called first on the primary server and then on the standby server.

Point

When the arbitration server is used for automatic degradation and the requirements can be satisfied using the fencing command on the arbitration server only, the fencing command on the database server is not required. In addition, if the requirements can be satisfied using the fencing command on the database server only, create a fencing command on the arbitration server for termination processing only (without implementation).

Table 2.6 Availability of user commands, and database server calling the command

User command	Operation when a heartbeat abnormality is detected using operating system or server heartbeat monitoring				Database server calling the command	
	Message output	Automatic degradation by arbitration server	Automatic degradation by arbitration command	Unconditional automatic degradation	Primary server	Standby server
Fencing command	Y (*1)	Y (*2)	R	N	Y	Y
Arbitration command	N	N	R	N	Y	Y
Post-switch command	Y	Y	Y	Y	Y	N
Pre-detach command	Y	Y	Y	Y	Y	Y (*3)
Post-attach command	Y	Y	Y	Y	Y	Y (*3)

R: Required

Y: Can be used

N: Cannot be used

*1: Called only when the mc_ctl command is used to execute forced switching or forced disconnection.

*2: Creation of a fencing command on a database server is optional, but it must be created on the arbitration server.

*3: If message output or unconditional automatic degradation is selected, this command is called only from the primary server.

See

Refer to "Appendix C User Commands" for information on the interface for each user command.

2.7 Confirming the Streaming Replication Status

Before performing the setup of the database multiplexing mode, ensure that the prerequisite streaming replication feature has been set up correctly.

Perform the following procedure:

1. On the primary server, ensure that single-row searches can be performed using the pg_stat_replication statistics view.

   An example output of the psql command is shown below.

   ```
   Example)
   ```

   ```
   postgres=# select * from pg_stat_replication;
   -[ RECORD 1 ]----+------------------------------
   pid              | 10651
   usesysid         | 10
   usename          | fsep
   application_name | standby
   client_addr      | 192.0.2.210
   client_hostname  |
   client_port      | 55098

   ```

2. Confirm the search results of step 1.

   Ensure that the connection established with the intended standby server is in synchronous mode.

   Table 2.7 Items to be checked

Item	Required value
application_name	Value specified for synchronous_standby_names parameter in the postgresql.conf file of the primary server.
client_addr	IP address of the standby server.
state	"streaming".
sync_state	"sync".

See

- Refer to "The Statistics Collector" in "Server Administration" in the PostgreSQL Documentation for information on the pg_stat_replication statistics view.
- Note that the pg_stat_replication statistics view may change in the future.

2.8 Checking the Connection Status

This section explains how to check the connection status from a database server or the arbitration server.

2.8.1 Checking the Connection Status on a Database Server

This section explains how to use a database server to check the connection status of the Mirroring Controller arbitration process and the Mirroring Controller process on the primary server and standby server.

Perform the following procedure:

1. On the primary server and standby server, execute the mc_ctl command in status mode with the --arbiter option specified.

   Example)
   The mc_ctl command is executed with the --arbiter option specified, and the status is output.

```
> mc_ctl status --arbiter -M D:\mcdir\inst1

arbiter_id   host            status
--------------------------------------
arbiter      192.0.3.120     online
```

2. On the primary server and standby server, check the result displayed by executing the mc_ctl command in status mode in step 1.

   Items to be checked

   Check that the output status" is "online".

See

Refer to the Reference for information on the mc_ctl command.

2.8.2 Checking the Connection Status on the Arbitration Server

This section explains how to use the arbitration server to check the connection status of the Mirroring Controller arbitration process and the Mirroring Controller process on the primary server and standby server.

Perform the following procedure:

1. Execute the mc_arb command in status mode on the arbitration server.

   The example below executes the mc_arb command, and shows the status.

   Linux

   Example)

```
$ mc_arb status -M /mcarb_dir/arbiter1

server_id    host            status
--------------------------------------
server1      192.0.3.100     online
server2      192.0.3.110     online
```

   Windows

   Example)

```
> mc_arb status -M D:\mcarb_dir\arbiter1

server_id    host            status
--------------------------------------
```

```
server1      192.0.3.100     online
server2      192.0.3.110     online
```

2. Check the result displayed by executing the mc_arb command in step 1.

   Items to be checked

   Check that the output status is "online" on both lines.

See

Refer to the Reference for information on the mc_arb command.

2.9 Creating Applications

This section explains how to create applications using database multiplexing, and points that should be noted when you create the applications.

2.9.1 Application Connection Server Settings

If database multiplexing is used and a failover occurs, it will be necessary to switch the application connection server. Accordingly, use the application connection switch feature to create applications.

See

Refer to "Application Connection Switch Feature" in the Application Development Guide for details.

2.10 Checking the Behavior

To check if the environment setup was performed correctly, start the application and then check the behavior of the switch and rebuild.

2.11 Tuning

This section explains how to tune database multiplexing mode.

2.11.1 Tuning to Stabilize the Database Multiplexing Mode

When large amounts of data are updated, the write-to load for the database will become great, and the multiplexing state may become unstable.

Accordingly, by editing the parameters below in the postgresql.conf file, a stable multiplexing state can be maintained. Refer to "Estimating Transaction Log Space Requirements" in the Installation and Setup Guide for Server for information on transaction log space requirements.

Table 2.8 Parameters

Parameter	Content
wal_keep_size	Refer to "2.4.2 Creating, Setting, and Registering the Primary Server Instance" for details.
max_wal_size	The transaction log is written out according to the checkpoint trigger. If a transaction log with the capacity of the value specified in this parameter is generated, the checkpoint will be executed. If a large value is specified in this parameter, the time required for crash recovery will increase. If a small value is specified in this parameter, many checkpoints will be generated, which will affect the performance of the applications that connect to the primary server.

2.11.2 Tuning to Stabilize Queries on the Standby Server

Queries made using reference jobs on the standby server may be canceled by jobs executed on the primary server.

To reduce the possibility of a job being canceled, specify as large a value as possible for the max_standby_archive_delay parameter in the postgresql.conf file.

See

- Refer to "Handling Query Conflicts" in the PostgreSQL Documentation for details.
- Refer to "Standby Servers" in the PostgreSQL Documentation for details on the max_standby_archive_delay parameter.

2.11.3 Tuning to Stabilize Queries on the Standby Server (when Performing Frequent Updates on the Primary Server)

If jobs are updated on the primary server regularly and frequently, it will be easy for the query made by the reference job on the standby server to be canceled. In this case, edit the postgresql.conf file parameters shown in the table below.

Table 2.9 Parameters

Parameter	Description
hot_standby_feedback	When "on" is set, the deletion (vacuum) of the data area that was deleted or updated on the primary server is suppressed. Accordingly, the query on the standby server will not be canceled. (*1)

*1: Because the vacuum is delayed, the data storage destination disk space of the primary server comes under pressure.
Additionally, if there is conflict between accesses and queries executed on the standby server, transaction logs indicating this conflict will be transferred.
Accordingly, specify as large a value as possible for the max_standby_archive_delay parameter so that access conflicts do not occur.

See

Refer to "Standby Servers" in the PostgreSQL Documentation for details on the hot_standby_feedback parameter.

2.11.4 Tuning for Optimization of Degradation Using Abnormality Monitoring

Mirroring Controller uses a monitoring method that outputs an error if the timeout or number of retries is exceeded when accessing resources targeted for monitoring. Setting inappropriate values in these settings may lead to misdetection or a delay in automatic degradation, so you must design these values appropriately.

For example, the following type of issue occurs if the tuning related to abnormality monitoring is not performed appropriately.

- If the timeout is too short

  Results in redundant degradation and availability falls.

- If the timeout is too long

  It takes longer for automatic degradation to be performed even when an error affecting operational continuity occurs, potentially causing downtime.

You can optimize degrading operation by editing the values for the parameters in the server configuration file described below in accordance with the system. Refer to "A.4 Server Configuration File" for information on how to edit these parameters.

2.11.4.1 Tuning for Abnormality Monitoring of the Operating System or Server

Tuning for abnormal monitoring of the operating system or server depends on the operation when heartbeat abnormality is detected by the heartbeat monitoring of operating systems or servers.

See

Refer to "1.1.1 Monitoring Using Database Multiplexing Mode" for the operation when heartbeat abnormality is detected in the the heartbeat monitoring of operating systems or servers.

2.11.4.1.1 Tuning Abnormality Monitoring for Operations that Use an Arbitration Server for Automatic Degradation

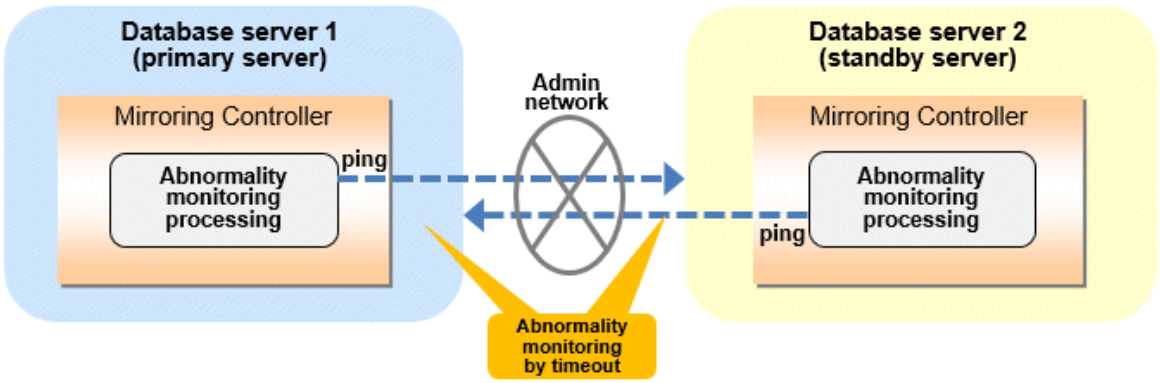
In an operation that use an arbitration server for automatic degradation, the database server is periodically monitored for abnormalities so that the Mirroring Controller arbitration process can immediately respond to an arbitration request from the Mirroring Controller.The automatic degradation using the arbitration server can optimize the time from error detection to automatic degradation of the operating systems or servers by editing the following parameters.

- Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server
- Parameters for the abnormality monitoring of the operating system or server in the arbitration configuration file
- Parameters for the arbitration processing and fencing

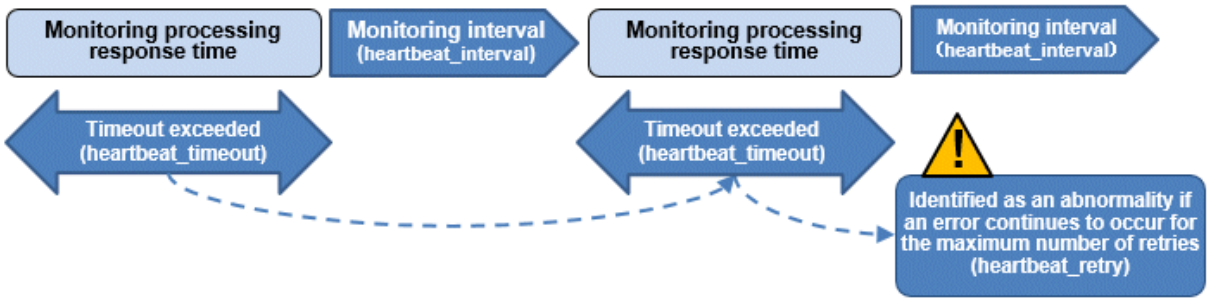
Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server

Table 2.10 Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server

Parameter	Description
Abnormality monitoring interval (heartbeat_interval)	Mirroring Controller is configured so that abnormality monitoring does not place a load on the system. This parameter does not normally need to be set. (The default is 800 milliseconds.)
Abnormality monitoring timeout (heartbeat_timeout)	Take into account the time during which a load is placed continuously on the server or admin network performance. For example, it is envisaged that this parameter will be used in situations such as when performing high-load batch jobs or when a large number of online jobs occur continuously and concurrently. (The default is 1 second.)
Abnormality monitoring retries (heartbeat_retry)	This parameter can be set when needing a safety value for situations in which the value specified for heartbeat_timeout is exceeded, for example, when using systems with fluctuating loads, however, this parameter does not normally need to be set. (The default is 2 times.)



Flow of abnormality monitoring by timeout



The expression for calculating the time required to detect an abnormality by Mirroring Controller is shown below.

```
Abnormality detection time of Mirroring Controller = ( heartbeat_timeout(seconds) +
heartbeat_interval(milliseconds) / 1000 ) x ( heartbeat_retry(number of times) + 1)
```

The abnormality detection time when the default value is used is shown below.

```
Abnormality detection time of Mirroring Controller = ( 1 + 800 / 1000 ) x ( 2 + 1 )
            = 5.4(seconds)
```

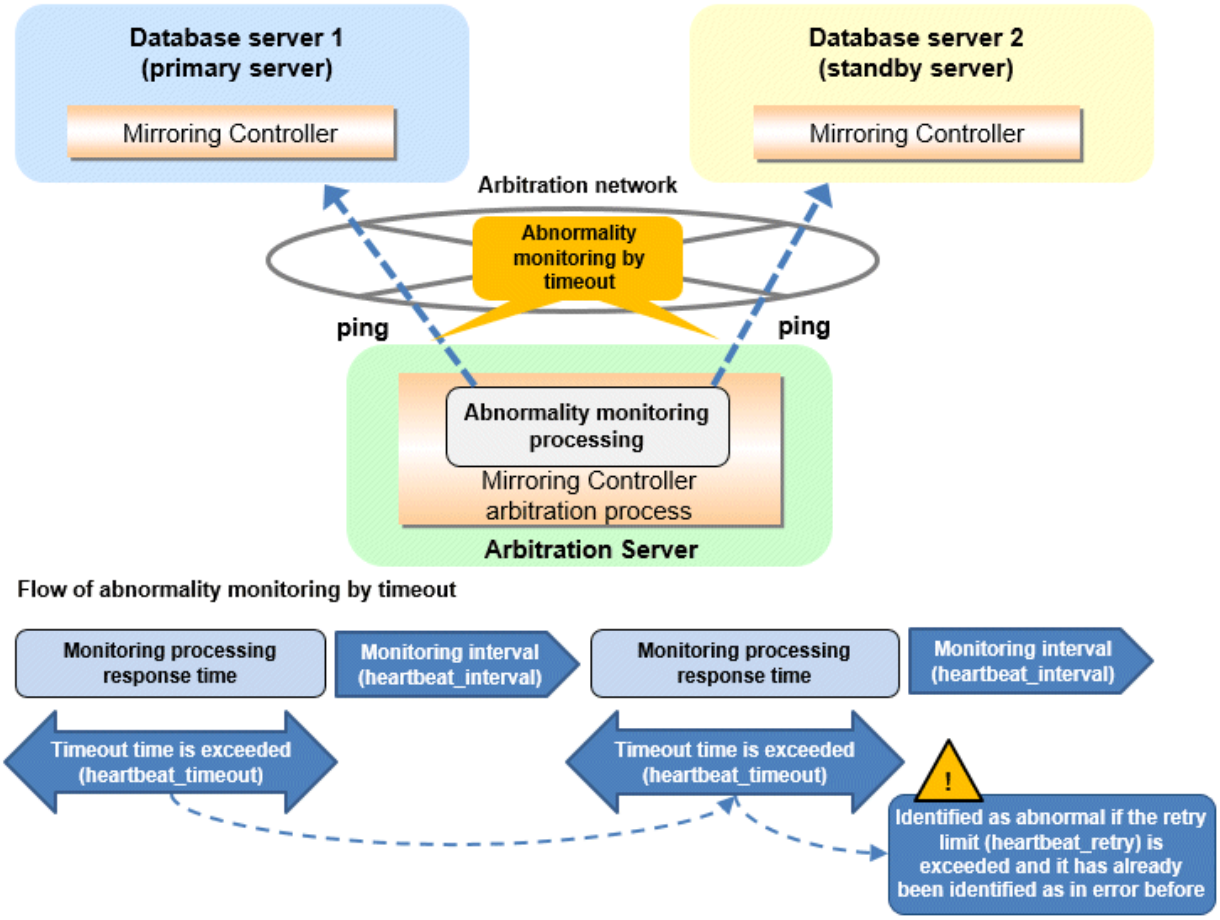
Parameters for the abnormality monitoring of the operating system or server in the arbitration configuration file

Table 2.11 Parameters for the abnormality monitoring of the operating system or server in the arbitration configuration file

Parameter	Description
Abnormality monitoring interval (heartbeat_interval)	Mirroring Controller arbitration process is configured so that abnormality monitoring does not place a load on the system. This parameter does not normally need to be set. (The default is the value set in heartbeat_interval in the server configuration file of the database server.) (milliseconds).
Abnormality monitoring timeout (heartbeat_timeout)	Take into account the time during which a load is placed continuously on the server and arbitration network capabilities. (The default is the value set in heartbeat_timeout in the server configuration file of the database server.) (seconds).
Abnormality monitoring retries (heartbeat_retry)	This parameter can be set when needing a safety value for situations in which the value specified for heartbeat_timeout is exceeded, for example, when using systems with fluctuating loads, however, this parameter does not normally need to be set. (The default is the value set in heartbeat_retry in the server configuration file of the database server.) (number of times)



The expression for calculating the time required to detect an abnormality by Mirroring Controller arbitration process is shown below.

```
Abnormality detection time of Mirroring Controller arbitration process = ( heartbeat_timeout(seconds)
+ heartbeat_interval(milliseconds) / 1000 ) x ( heartbeat_retry(number of times) + 1)
```

The abnormality detection time when the default value is used is shown below.

```
Abnormality detection time of Mirroring Controller arbitration process = ( 1 + 800 / 1000 ) x ( 2 + 1 )
            = 5.4(seconds)
```

Point

- The abnormality detection time of the operation for automatic degradation using the arbitration server can be calculated as follows.

```
Abnormality detection time = Max(Abnormality detection time by Mirroring Controller, Abnormality
detection time by Mirroring Controller arbitration process)
```

- If the heartbeat_interval is set in the arbitration configuration file, the relationship between the parameter for operating system or server abnormality monitoring specified in the server configuration file of the database server file and the heartbeat_interval of the arbitration configuration file must satisfy the following relational expression.

```
 Heartbeat_interval in the arbitration configuration file (milliseconds) / 1000 ) <
( heartbeat_timeout(seconds) + heartbeat_interval(milliseconds) / 1000 ) * heartbeat_retry(number
of times) + heartbeat_timeout(seconds)
```

Parameters for the arbitration processing and fencing

Table 2.12 Parameters for the arbitration processing and fencing

Parameter	Description
Arbitration processing timeout (arbitration_timeout in the server configuration file of the database server)	Take into account the time to perform arbitration processing on the Mirroring Controller arbitration process. The value must be greater than or equal to abnormality detection time of Mirroring Controller arbitration process + fencing_command_timeout in the arbitration configuration file (seconds).
Fencing timeout (fencing_command_timeout in the arbitration configuration file)	Take into account the time to execute the fencing command (seconds).

Information

If the fencing_command parameter is specified in the server configuration file of the database server, the fencing command is invoked on the database server if fencing is successful on the arbitration server. In that case, add the value of the fencing_command_timeout parameter in the server configuration file of the database server to the estimate.

Flow from the abnormality detection to the automatic degeneracy

When performing automatic degradation using the arbitration server, the flow from the abnormality detection in the operating system or server to the occurrence of automatic degeneracy and the parameters is shown below.

<table>
<tr><th>Flow from the abnormality detection to the automatic degeneracy</th><th>Description</th><th colspan="2">Parameter</th></tr>
<tr><td>(1) Abnormality detection</td><td>Mirroring Controller detect the database server operating system or server errors.</td><td colspan="2">Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server</td></tr>
<tr><td>(2) Arbitration request</td><td>Mirroring Controller that detect the operating system or server error asks the Arbitration Server to check the status of the other server's operating system or server.</td><td>-</td><td rowspan="3">arbitration_timeout in the server configuration file of the database server</td></tr>
<tr><td>(3) Arbitration processing</td><td>The Mirroring Controller arbitration process checks the status of the other server's operating system or server. However, if the result of the operating system or server abnormality monitoring by the arbitration server has been determined before the arbitration request from the Mirroring Controller of the database server, this process is not performed.</td><td>Parameters for the abnormality monitoring of the operating system or server in the arbitration configuration file</td></tr>
<tr><td>(4) Fencing</td><td>If the Mirroring Controller arbitration process determines that the other server is an abnomaly of the operating system or server, it fences the other server and isolates it from the cluster system. If the Mirroring Controller arbitration process determines that the operating system or server status is normal, this process and the (6) are not performed.</td><td>fencing_command_timeout in the arbitration configuration file</td></tr>
</table>

Flow from the abnormality detection to the automatic degeneracy	Description	Parameter
(5) Return of the arbitration results	Returns the results of the arbitration to the Mirroring Controller of the database server that requested the arbitration.	-
(6) Automatic degradation	The automatic degradation is performed. If fencing fails in (4), this procedure is not performed.	-

-: No associated parameters

Figure 2.1 When the Mirroring Controller on the primary server detects an operating system or server error

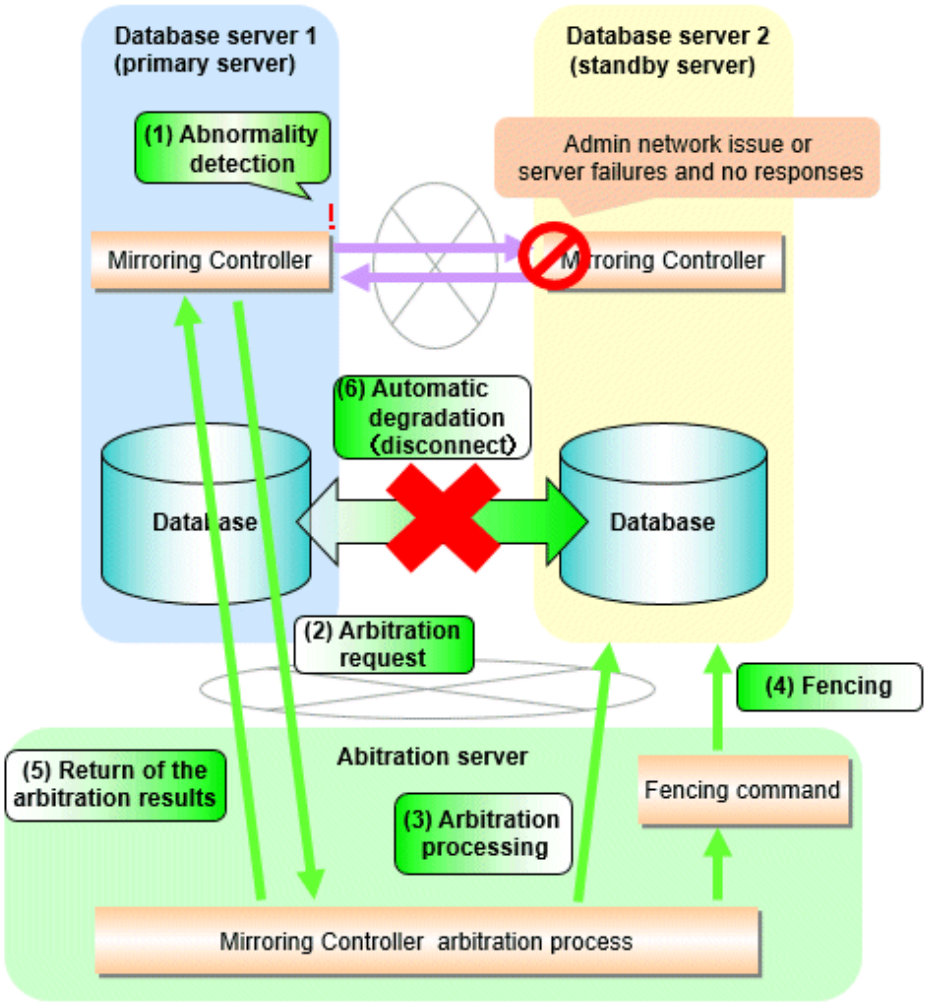

Figure 2.2 When the Mirroring Controller on the standby server detects an operating system or server error

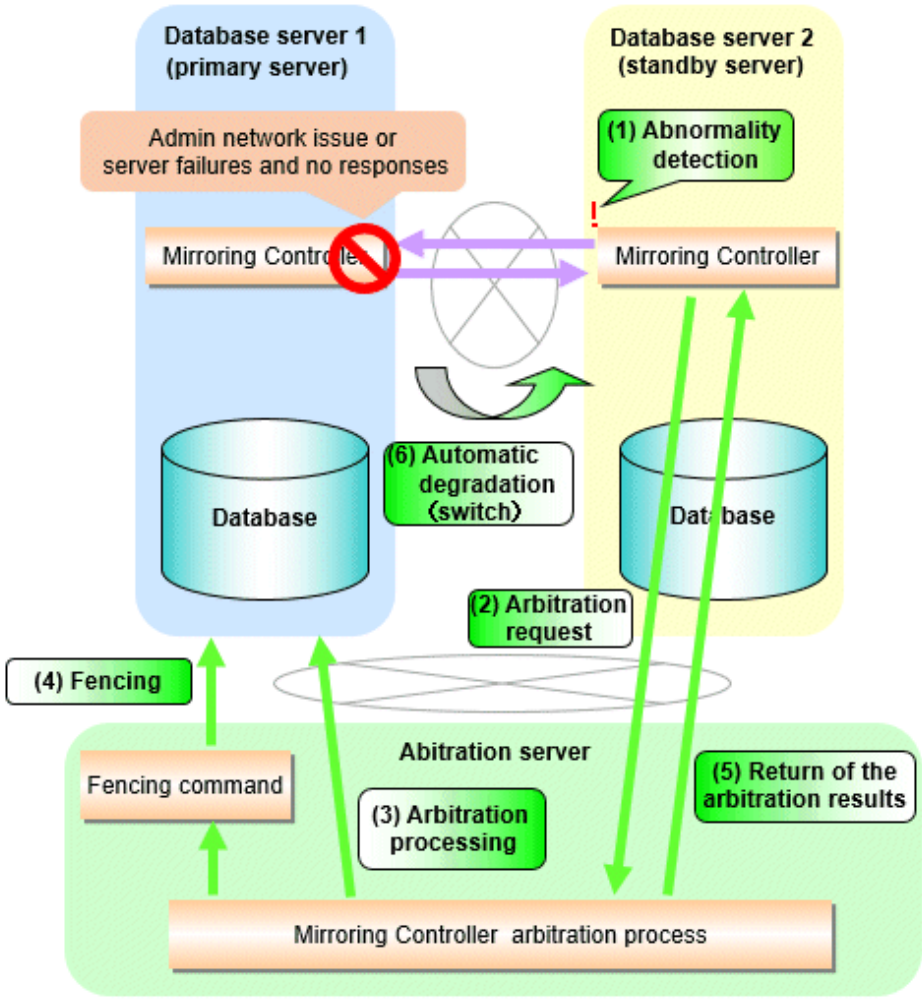

2.11.4.1.2 Tuning Abnormality Monitoring for Operations that Perform Automatic Degradation by Calling a User Exit that Determines Degradation

In an operation that perform automatic degradation by calling a user exit that determines degradation, you can optimize the time from operating system or server abnormality detection to automatic degradation by editing the operating system or server abnormality monitoring parameters and parameters related to arbitration processing and fencing in the server configuration file of the database server. Refer to "Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server" for information on the operating system or server abnormality monitoring parameters in the server configuration file of the database server.

Table 2.13 Parameters for the arbitration processing and fencing

Parameter	Description
Arbitration processing timeout (arbitration_command_timeout)	Take into account the time to execute the arbitration command(seconds).
Fencing timeout (fencing_command_timeout)	Take into account the time to execute the fencing command (seconds).

Flow from the abnormality detection to the automatic degeneracy

When performing automatic degradation by calling a user exit that determines degradation, the flow from the abnormality detection in the operating system or server to the occurrence of automatic degeneracy and the parameters is shown below.

Flow from the abnormality detection to the automatic degeneracy	Description	Parameter
(1) Abnormality detection	Mirroring Controller detect the database server operating system or server errors.	Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server
(2) Arbitration processing	An arbitration command is executed to check the status of the other server's operating system or server.	arbitration_command_timeout in the server configuration file of the database server
(3) Fencing	If the operating system or server status of the other server is abnomal in (2), it fences the other server and isolates it from the cluster system. If the operating system or server status of the other server is nomal in (2), this process and (4) are not executed.	fencing_command_timeout in the server configuration file of the database server
(4) Automatic degradation	The automatic degradation is performed. If fencing fails in (3), this procedure is not performed.	-

-: No associated parameters

Figure 2.3 When the Mirroring Controller on the primary server detects an operating system or server error

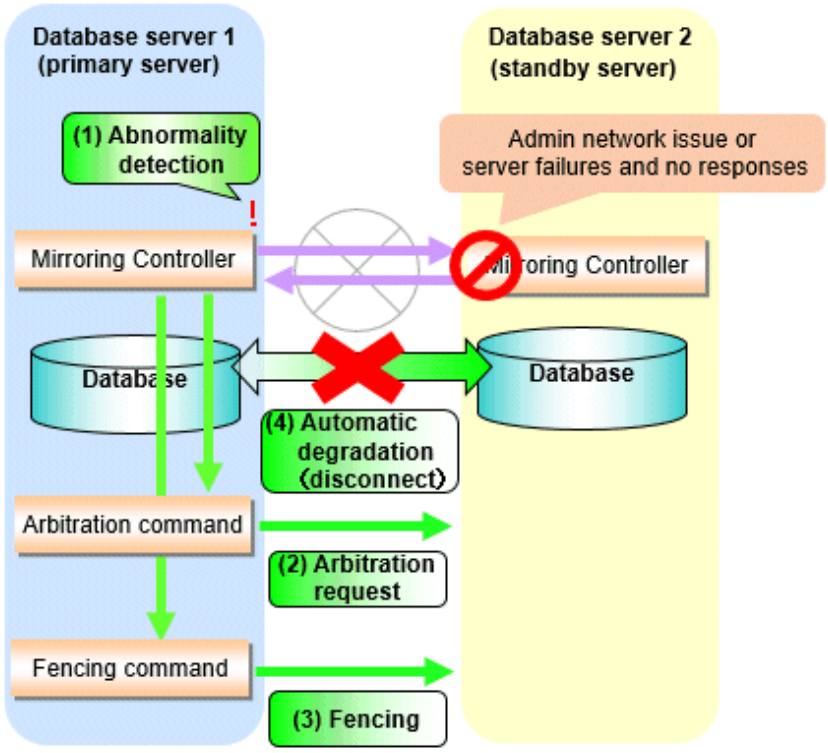

Figure 2.4 When the Mirroring Controller on the standby server detects an operating system or server error

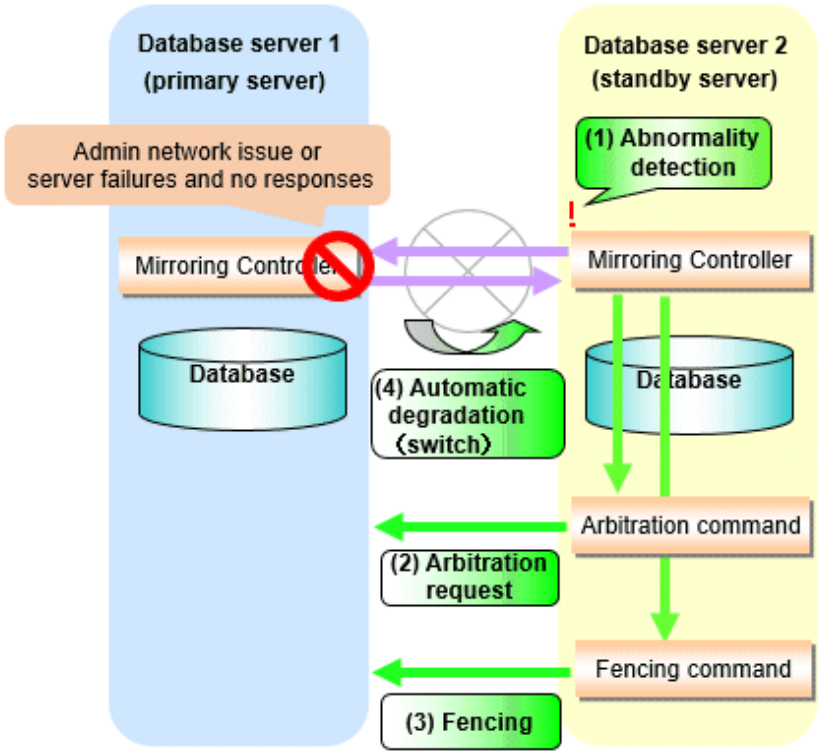


2.11.4.1.3 Tuning Abnormality Monitoring for Operations that Notify Messages

In an operation that notify messages, you can optimize the abnormality detection time by editing the operating system or server abnormality monitoring parameters in the server configuration file of the database server. Refer to "Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server" for information on the operating system or server abnormality monitoring parameters in the server configuration file of the database server. In addition, when the Mirroring Controller detects an error, it does not perform the arbitration processing, fencing, or automatic degradation, but only notification messages is performed.

2.11.4.1.4 Tuning Abnormality Monitoring for Operations that Perform Automatic Degenerate Unconditionally due to Heartbeat Abnormality

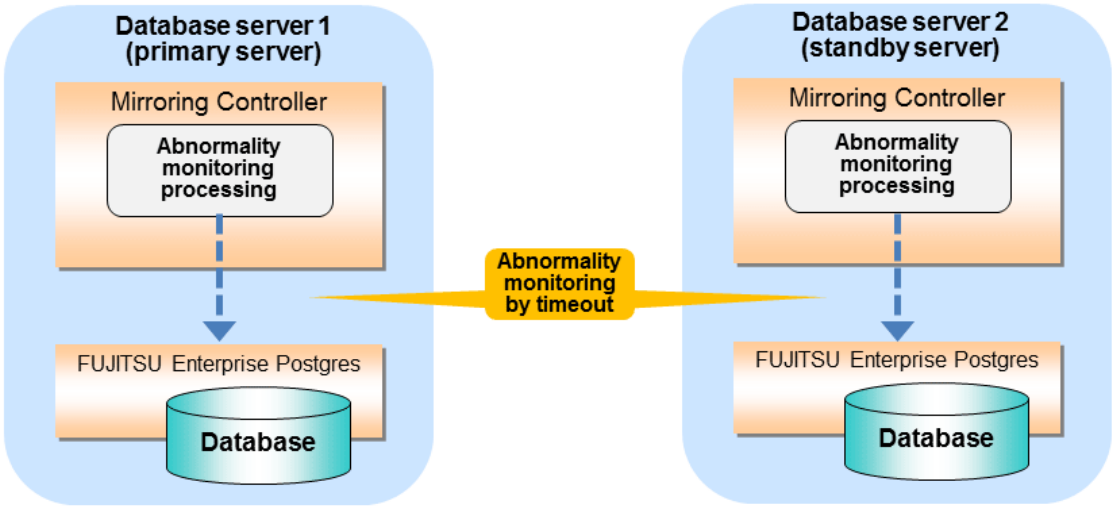
In an operation that perform automatic degenerate unconditionally due to heartbeat abnormality, you can optimize the time from operating system or server abnormality detection to automatic degradation by editing the operating system or server abnormality monitoring parameters in the server configuration file of the database server. Refer to "Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server" for information on the operating system or server abnormality monitoring parameters in the server configuration file of the database server. In addition, when the Mirroring Controller detects an error, it does not perform the arbitration processing, fencing, or automatic degradation, but only automatic degenerate unconditionally is performed. Refer to "Appendix D Notes on Performing Automatic Degradation Immediately after a Heartbeat Abnormality" for notes on the operation that perform automatic degenerate unconditionally due to heartbeat abnormality.

2.11.4.2 Tuning for Abnormality Monitoring of Darabase Processes

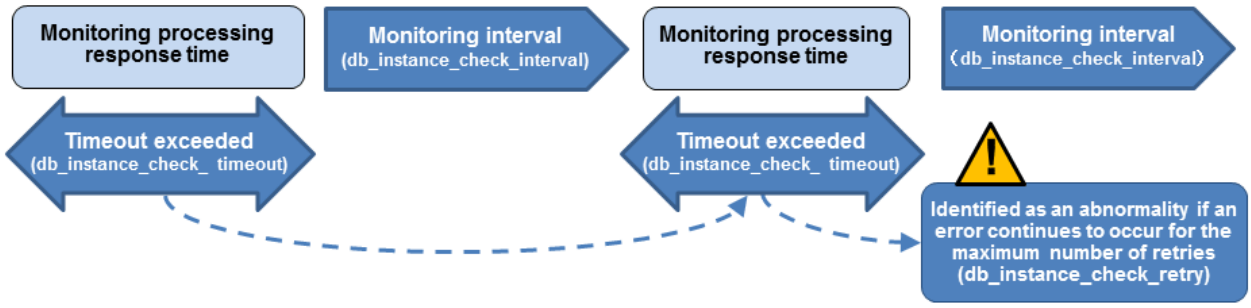
You can optimize database pocesses abnormality monitoring by editing the following parameters in the server configuration file of the database server.

Table 2.14 Parameters for abnormality monitoring of database processes

Parameter	Description
Abnormality monitoring interval (db_instance_check_interval)	Abnormality monitoring by Mirroring Controller is set so as not to place load on the system, but normally it does not need to be set. (The default is the value set in heartbeat_interval.) (milliseconds)
Timeout for abnormality monitoring of database processes (db_instance_check_timeout)	Take into account the time during which a load is placed continuously on the database. For example, it is envisaged that this parameter will be used in situations such as when performing high-load batch jobs or when a large number of online jobs occur continuously and concurrently. (The default is the value set in heartbeat_timeout.) (seconds)
Abnormality monitoring retries (db_instance_check_retry)	This parameter can be set when needing a safety value for situations in which the value specified for db_instance_check_timeout is exceeded, for example, when using systems with fluctuating loads, however, this parameter does not normally need to be set. (The default is the value set in heartbeat_retry.) (number of times)



Flow of abnormality monitoring by timeout



The expression for calculating the time required to detect an abnormality is shown below.

```
Abnormality detection time = ( db_instance_check_timeout(seconds) +
db_instance_check_interval(milliseconds) / 1000 ) x ( db_instance_check_retry(number of times) + 1 )
```

The abnormality detection time when the default value is used is shown below.

```
Abnormality detection time = ( 1 + 800 / 1000 ) x ( 2 + 1 )
            = 5.4(seconds)
```

Information

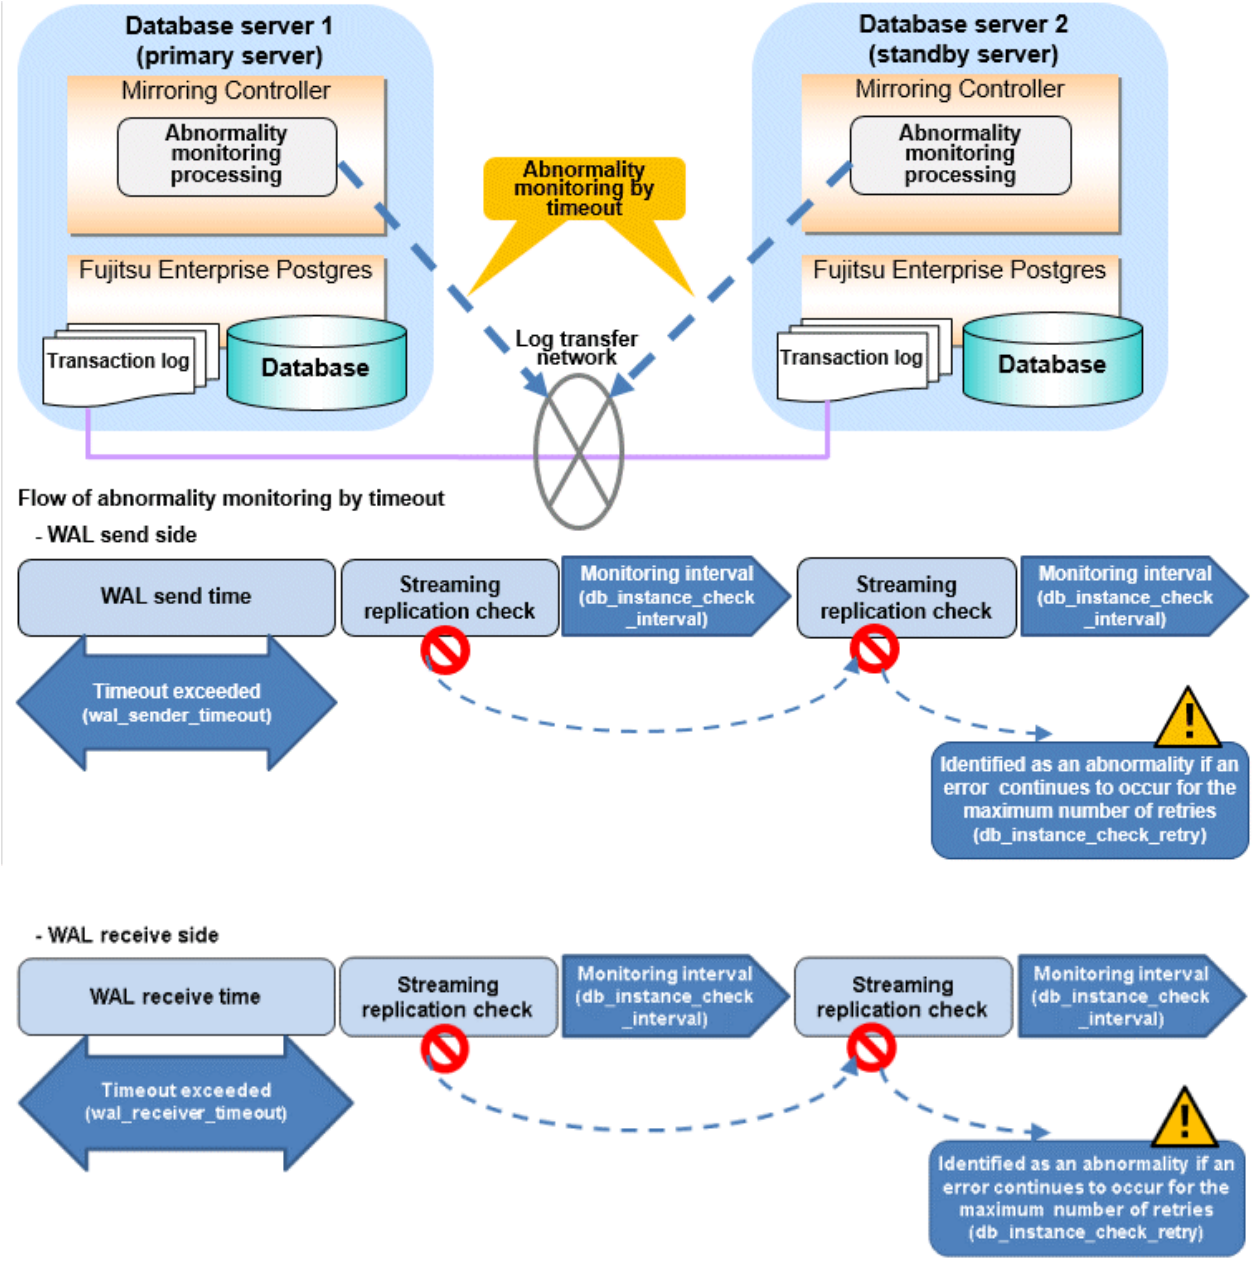
- If the db_instance_timeout_action parameter in *serverIdentifier*.conf is set to "message", and the db_instance_check_timeout parameter is set to a short value, a crash of the database process will be detected as "no response", and it may take time for automatic degradation to occur. Therefore, specify an appropriate timeout for db_instance_check_timeout.
- If a high load on the database and an event that prevents connection to an instance occur at the same time, it is judged as abnormal without retrying monitoring.

2.11.4.3 Tuning for Abnormality Monitoring of Streaming Replication

You can optimize streaming replication abnormality monitoring by editing the following parameters in the server configuration file of the database server.

Table 2.15 Parameters for abnormality monitoring of streaming replication

Parameter	Description
Abnormality monitoring interval (db_instance_check_interval)	Abnormality monitoring by Mirroring Controller is set so as not to place load on the system, but normally it does not need to be set. (The default is the value set in heartbeat_interval.) (milliseconds)
Abnormality monitoring retries (db_instance_check_retry)	This parameter can be set when needing a safety value, such as when it is anticipated that a temporary log transfer LAN error may occur, but it does not normally need to be set. (The default is the value set in heartbeat_retry.) (number of times)
Timeout for abnormality monitoring of streaming replication (wal_sender_timeout and wal_receiver_timeout in postgresql.conf)	Take into account the capacity and load of the log transfer network and the time during which a load is placed continuously on the database. For example, if there is a succession of data update jobs that generate a high WAL volume, you must configure the settings to avoid misdetection. (The default is 60 seconds.)



The expression for calculating the time required to detect an abnormality is shown below.

```
Abnormality detection time = ( wal_sender_timeout(seconds) +
db_instance_check_interval(milliseconds) / 1000 x ( disk_check_retry(number of times) + 1 ) )  Or,
            = ( wal_receiver_timeout(seconds) + db_instance_check_interval(milliseconds) / 1000 x
( disk_check_retry(number of times) + 1 ) )
```

The abnormality detection time when the default value is used is shown below.

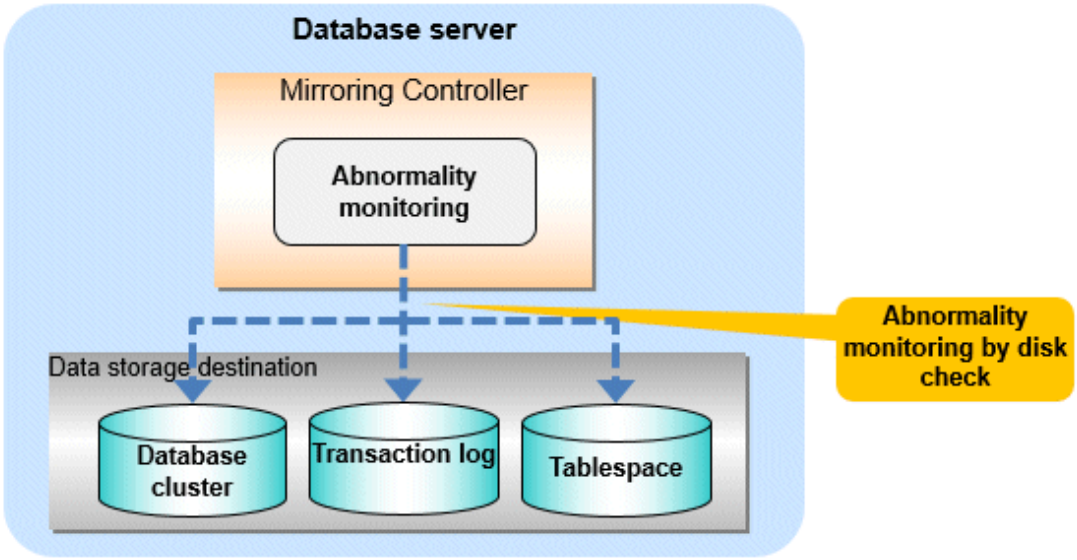
```
Abnormality detection time = 60 + (800 / 1000 x (2 + 1))
            = 62.4(seconds)
```

2.11.4.4 Tuning for Disk Abnormality Monitoring

You can optimize disk abnormality monitoring by editing the following parameters in the server configuration file of the database server.

Table 2.16 Parameters for disk abnormality monitoring

Parameter	Description
Abnormality monitoring interval (disk_check_interval)	Abnormality monitoring by Mirroring Controller is set so as not to place load on the system, but normally it does not need to be set. Set a value larger than the disk access time. (The default is the value set in heartbeat_interval.) (milliseconds)
Abnormality monitoring retries (disk_check_retry)	This parameter can be set when needing a safety value, such as when it is anticipated that a temporary disk input/output error may occur, but normally it does not need to be set. (The default is the value set in heartbeat_retry.) (number of times)
Abnormality monitoring timeout time (disk_check_timeout)	The time allowed from the start time of the next disk_check_interval after a disk error occurs until the error is determined to be due to timeout. (The default is 2147483.) (seconds). You can specify an integer between 0 and 2147483.
Upper limit on the number of threads used for abnormality monitoring (disk_check_max_threads)	Upper limit on the number of threads for disk monitoring. (The default is the number of processors available to the JVM.) You can specify an integer between 1 and 2147483647, but setting a value greater than the threads available on the machine may result in a system error. When you run the mc_ctl status command separately from the monitoring process, each mc_ctl status temporarily uses the same number of threads as the monitoring process. When setting disk_check_max_threads, consider the machine's thread limit, the number of tablespaces you plan to use, and the number of mc_ctl status commands that may be executed at the same time.



In disk error monitoring, a disk check is performed, and degradation is performed when an error is first detected within the error detection time or the time set in disk_check_timeout. However, in order to disconnect the standby server when disk_check_timeout detects an error on the standby server, shutdown_detached_synchronous_standby must be set to on.

The following shows how to calculate the abnormality detection time (the time until an error is determined).

```
Abnormality detection time = disk_check_interval (milliseconds) / 1000 x ( disk_check_retry(number of
times) + 1 )
```

The abnormality detection time when the default value is used is shown below.

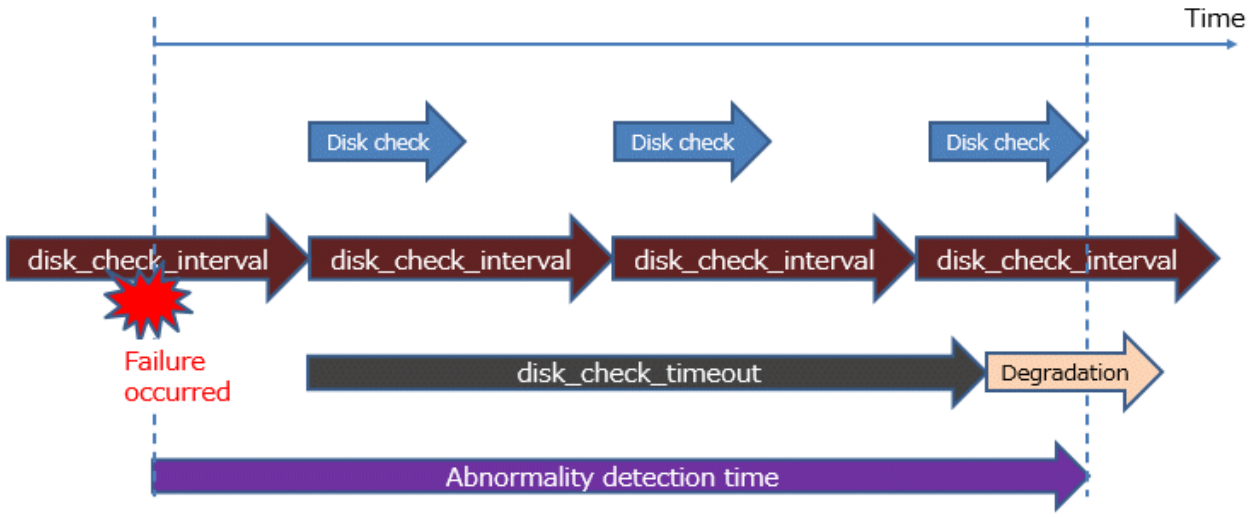
```
Abnormality detection time = 800 / 1000  x ( 2 + 1 )
            = 2.4(seconds)
```

An example of detecting disk abnormality monitoring is shown below.

Example 1)

One thread monitors one disk, set disk_check_retry = 2.

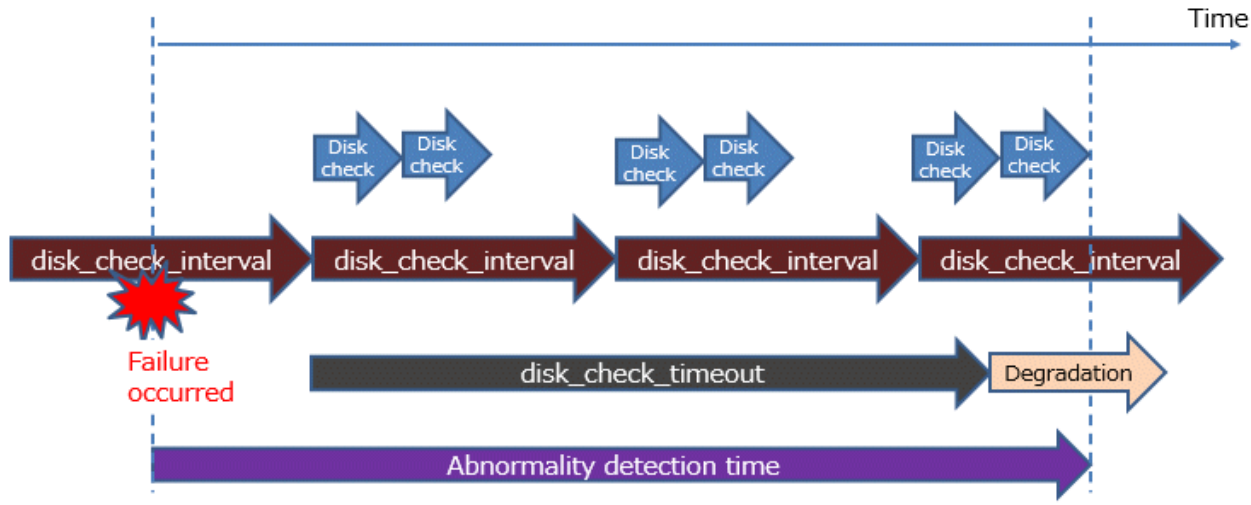
When the read or write cannot be completed within the disk access time because the response to the disk is slow.



Example 2)

One thread monitors two disks, set disk_check_retry = 2.

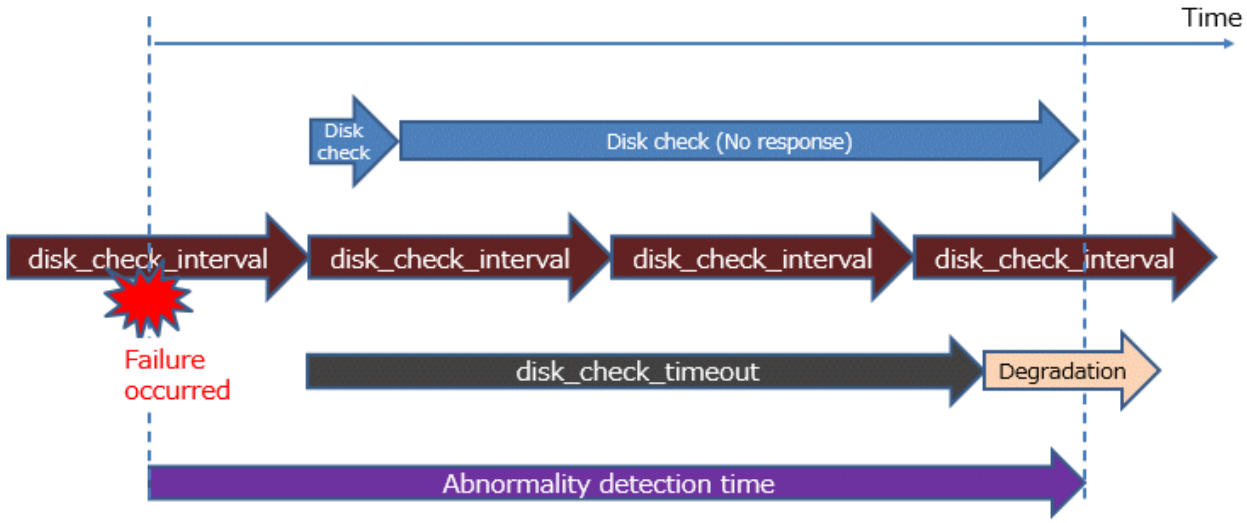
Due to the slow response to the disk, reading or writing to disk 1 could not be completed within the disk access time on the first and second attempts, but the reading or writing was successful on the third retry. All reads or writes to disk 2 fail within the disk access time.



Example 3)

One thread monitors two disks, set disk_check_retry = 2.

If disk 2 becomes unresponsive and monitoring results cannot be obtained within the timeout period.



Information

- The tuning described above impacts on the time taken from detection of a timeout until switching the primary server. Therefore, modify the values while taking into account the switch/disconnection time, using a design for which misdetection does not occur.
- Immediately selecting automatic degradation when a heartbeat abnormality occurs in operating system or server heartbeat monitoring risks causing split brain. Refer to "Appendix D Notes on Performing Automatic Degradation Immediately after a Heartbeat Abnormality" for details.
- Mirroring Controller uses connections to database instances and SQL access to monitor abnormality in some resources targeted for monitoring. The connection destination database names and connection user names used for abnormality monitoring conform to the parameters in the server configuration file. The application name is "mc_agent".

2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances

Multiplexed instances and Mirroring Controller can be started and stopped automatically in line with the starting and stopping of the operating system of the database server.

You can configure the Windows service to perform automatic start and stop of Mirroring Controller.

Setting automatic start and stop of a multiplexed instance

No settings are required for Mirroring Controller to start and stop an instance.

Do not configure the Windows service of a multiplexed instance to perform automatic start.

Configuring automatic start and stop for database multiplexing mode

Configuring during setup

When registering Mirroring Controller to the Windows service in "2.4.1 Setting Up Database Multiplexing Mode on the Primary Server" and "2.5.1 Setting Up Database Multiplexing Mode on the Standby Server", specify "auto" for the -S option of the register mode used with the mc_ctl command.

```
Example)
```

```
> mc_ctl register -M D:\mcdir\inst1 -P ******** -S auto
```

Changing the configuration after setup

Use the sc config command to change the configuration of the Windows service of Mirroring Controller.

Example)
The following is an example using the registered service name "Mirroring_Controller_inst1".

```
> sc config "Mirroring_Controller_inst1" start= auto
```

Point

When using an arbitration server to perform automatic degradation, if you are considering starting the Mirroring Controller process on the database server before starting the Mirroring Controller arbitration process on the arbitration server, specify the --async-connect-arbiter option in register mode and register it as a Windows service.

Information

Since Mirroring Controller is automatically started and stopped on each server in accordance with the startup and shutdown of the OS, to prevent unnecessary automatic switching or errors by Mirroring Controller, start it from the OS of the primary server and stop it from the OS of the standby server.

See

Refer to documentation such as Windows Help and Support for the sc command for information on how to configure the service.

Point

You can check the registration status in the Windows service window or by using the sc qc command.

2.13 Setting Automatic Start and Stop of the Mirroring Controller Arbitration Process

You can automatically start or stop the Mirroring Controller arbitration process when the operating system on the arbitration server is started or stopped.

Linux

Perform the following procedure:

1. Create a unit file.

   Copy the unit file sample stored in the directory below, and revise it to match the target instance.

   Sample file

   ```
   /installDir/share/mcarboi.service.sample
   ```

   Example)
   In the following example, the installation directory is "/opt/fsepv<x>assistant", and the identifier of the arbitration process is "arbiter1". Note that "<x>" indicates the product version.

   ```
   # cp /opt/fsepv<x>assistant/share/mcarboi.service.sample /usr/lib/systemd/system/
   mcarboi_arbiter1.service
   ```

   Revise the underlined portions of the options below in the unit file.

   Also, because starting the Mirroring Controller arbitration process requires time correction, opening the network environment, and other wait times, modify the unit that starts first in the After option of the unit file as appropriate.

Section	Option	Specified value	Description
Unit	Description	Fujitsu Enterprise Postgres Mirroring Controller Arbiter <*arbitrationProcessId*>	Specifies the feature overview. Specifies the identifier of the targeted arbitration process. (*1)
Service	ExecStart	/bin/bash -c '*installDir*/bin/mc_arb_std start *installDir mirroringControllerArbitrationProcessMgmtDir mc_arbOption*'	Command to be executed when the service is started. Specify the option you want to add when the mc_arb command (start mode) is executed without the -M option in the mc_arb option. Note that the content specified in this mc_arb option is carried over from the mc_arb_std command in "Specified value" to the mc_arb command.
	ExecStop	/bin/bash -c '*installDir*/bin/ mc_arb_std stop *installDir mirroringControllerArbitrationProcessMgmtDir mc_arbOption*'	Command to be executed when the service is stopped. Specify the option you want to add when the mc_arb command (stop mode) is executed without the -M option in the mc_arb option. Note that the content specified in this mc_arb option is carried over from the mc_arb_std command in "Specified value" to the mc_arb command.
	User	User	Specify the account of the operating system user.
	Group	Group	Specify the group to which the user belongs.

*1: The arbitration process identifier used here is a name for identifying the Mirroring Controller arbitration process.

The naming conventions for identifying the Mirroring Controller arbitration process are as follows:

- Up to 16 bytes
- The first character must be an ASCII alphabetic character
- The other characters must be ASCII alphanumeric characters

2. Enable automatic start and stop.

As the operating system superuser, use the systemctl command to enable automatic start and stop.

```
Example)
```

```
# systemctl enable mcarboi_arbiter1.service
```

Windows

You can configure the Windows service to perform automatic start and stop.

Configuring during setup

When registering the Mirroring Controller arbitration process as a Windows service in "2.3.1 Configuring the Arbitration Server", specify "auto" for the -S option of the register mode used with the mc_arb command.

Example)

```
> mc_arb register -M D:\mcdir\inst1 -P ******** -S auto
```

Changing the configuration after setup

Use the sc config command to change the configuration of the Windows service of the Mirroring Controller arbitration process.

Example)
The configuration of the registered service name "Mirroring_Controller_Arbiter1" is changed.

```
> sc config "Mirroring_Controller_Arbiter1" start= auto
```

See

Refer to sc command help for information on how to configure the service.

Information

You can check the registration status in the Windows service window or by using the sc qc command.

2.14 Backup Operation

This section explains the backup operation for database multiplexing mode.

2.14.1 Backing up Database Multiplexing Mode Information

When changing the Mirroring Controller settings, in addition to backing up the database, back up the configuration file in the Mirroring Controller management directory so that the Mirroring Controller settings are not lost.

When the arbitration server is used for automatic degradation, also back up the configuration file in the Mirroring Controller arbitration process management directory.

2.14.2 Database Backup Operation

Using database multiplexing mode is the same as obtaining the backup data on the standby server as a safeguard against a disk failure. Note that all server disks may be corrupted due to some cause.

As a safeguard against this type of case, execute the pgx_dmpall command on the primary server to create the backup data.

However, it is not definite as to which server runs as the primary server, so ensure that the pgx_dmpall command is executed periodically on all servers, so that the backup data will be obtained. For example, create a script to obtain the backup data, and set it in the operation management software.

Point

When the pgx_dmpall command is executed on the standby server, it will not match the statuses, however the error message shown below will be output and return the value "1".

If a script that ignores only this type of error is executed on all servers, the backup data of the primary server can be obtained.

Error message

```
ERROR:recovery is in progress (10095)
```

Information

- Consider the possibility that the server that runs as the primary server may be destroyed alongside the backup data, so it is recommended to promote another server to become the primary server, and then back up the data on the new primary server without waiting for the next scheduled backup.
- Specify the same backup directory name for the primary and standby servers. If different backup directory names are specified, and recovery is performed using the backup data of the other server, the recovery cannot be performed correctly.

See

- Period backups allow shorter recovery time and reduction in disk usage. Refer to "Backing Up the Database" in the Operation Guide for details on the backup operation.
- Refer to "Chapter 4 Action Required when an Error Occurs in Database Multiplexing Mode" for details on recovery based on the backup data that was obtained using the pgx_dmpall command.

Chapter 3 Operations in Database Multiplexing Mode

This chapter describes the periodic operations that are performed when running database multiplexing mode.

The periodic operations are the same as the operations on a single server.

See

Refer to "Periodic Operations" in the Operation Guide for information on the periodic operations.

3.1 Starting and Stopping the Mirroring Controller Arbitration Process

This section describes how to start and stop the Mirroring Controller arbitration process.

3.1.1 Starting the Mirroring Controller Arbitration Process

Linux

While the Mirroring Controller arbitration process is in a stopped state, execute the mc_arb command in start mode to start the Mirroring Controller arbitration process.

Example)

```
$ mc_arb start -M /mcarb_dir/arbiter1
```

Windows

The Mirroring Controller arbitration process can be started using one of the following options:

- Using the mc_arb command
- Starting the service on system startup

Using the mc_arb command

While the Mirroring Controller arbitration process is in a stopped state, execute the mc_arb command from the command prompt to start the Mirroring Controller arbitration process.

Example)

```
> mc_arb start -M D:\mcarb_dir\arbiter1
```

Starting the service on system startup

Specify automatic start when registering the Mirroring Controller arbitration process to the Windows service during setup of database multiplexing mode. Accordingly, the Mirroring Controller arbitration process service will start on startup of the operating system.

See

Refer to the Reference for information on how to specify the mc_arb command.

3.1.2 Stopping the Mirroring Controller Arbitration Process

Linux

While the Mirroring Controller arbitration process is running, execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

```
Example)

$ mc_arb stop -M /mcarb_dir/arbiter1
```

Windows

The Mirroring Controller arbitration process can be stopped using one of the following options:

- Using the mc_arb command
- Stopping the service

Using the mc_arb command

While the Mirroring Controller arbitration process is running, execute the mc_arb command in stop mode from the command prompt to stop the Mirroring Controller arbitration process.

```
Example)

> mc_arb stop -M D:\mcarb_dir\arbiter1
```

Stopping the service

Select [Administrative Tools], then [Services] to open the [Services] window, and then select the Mirroring Controller service and click the [Stop] menu.

The arbitration server will be forcibly stopped when the service is stopped.

See

Refer to the Reference for information on how to specify the mc_arb command.

Information

Before shutting down the operating system on the arbitration server, either stop the Mirroring Controller on the primary server or standby server or shut down the operating system on the primary server or standby server.

3.2 Starting and Stopping Mirroring Controller

When database multiplexing mode is used, use the mc_ctl command or Windows service to start and stop the instance and Mirroring Controller at the same time.

Do not start or stop the instance by itself.

3.2.1 Starting Mirroring Controller

Mirroring Controller can be started using one of the following.

Mirroring Controller must be started by a user with administrator privileges (user ID belonging to the Administrators group).

- Using the mc_ctl command
- Starting a service on system startup

Information

Mirroring Controller startup usually fails if the standby server is mistakenly started as the primary server or if the old primary server is not recovered after the switch and is then mistakenly started as the primary server. However, if the admin network is disconnected, then startup does not fail, and both servers may become primary servers. Therefore, ensure that the admin network is connected before starting Mirroring Controller.

Using the mc_ctl command

While Mirroring Controller is in a stopped state, execute the mc_ctl command from the command prompt to start the instance and Mirroring Controller.

Enabling automatic switch/disconnection

Execute the mc_ctl command in start mode.

Example)

```
> mc_ctl start -M D:\mcdir\inst1
```

Disabling automatic switch/disconnection

Execute the mc_ctl command in start mode with the -F option specified.

Example)

```
> mc_ctl start -M D:\mcdir\inst1 -F
```

Point

- To start the Mirroring Controller process only, execute the mc_ctl command in start mode with the --mc-only option specified.
- After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.
- When the arbitration server is used for automatic degradation, the Mirroring Controller process startup fails on the database server if the Mirroring Controller arbitration process has not been started on the arbitration server in advance. However, even if the Mirroring Controller arbitration process cannot be started in advance, the Mirroring Controller process can be started by specifying the --async-connect-arbiter option in the mc_ctl command.

See

Refer to the Command Reference for information on how to specify the mc_ctl command.

Starting a service on system startup

Specify automatic start when registering Mirroring Controller to the Windows service during setup of database multiplexing mode. Accordingly, the Mirroring Controller service will start on startup of the operating system.

See

Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for details.

3.2.2 Stopping Mirroring Controller

Mirroring Controller can be stopped using one of the following ways.

Mirroring Controller must be stopped by a user with administrator privileges (user ID belonging to the Administrators group).

- Using the mc_ctl command
- Stopping the service

Information

If you stop the Mirroring Controller by stopping the service, you must firstly exit all applications or programs that are using the instance that is to be stopped.

Using the mc_ctl command

While Mirroring Controller is running, execute the mc_ctl command from the command prompt in stop mode to stop Mirroring Controller.

Example)

```
> mc_ctl stop -M D:\mcdir\inst1
```

Point

To stop the Mirroring Controller process only, execute the mc_ctl command in stop mode with the --mc-only option specified.

See

Refer to the Command Reference for information on how to specify the mc_ctl command.

Stopping the service

Select [Administrative Tools], then [Services] to open the [Services] window, and then select the Mirroring Controller service and click the [Stop] menu.

Point

To prevent an unintended automatic switch, before shutting down the operating system on the primary server, you must stop the Mirroring Controller, or shut down the operating system on the standby server.

3.3 Checking the Database Multiplexing Mode Status

3.3.1 Checking the Status of the Database Server

This section describes how to check the status of the database server.

Check the multiplexed database status by executing the mc_ctl command in status mode.

Additionally, errors can be detected by monitoring the Mirroring Controller messages. If the status or messages are monitored periodically, you can react quickly following an automatic switch failure.

Checking the status of the multiplexing database

When the mc_ctl command is executed, the details of the multiplexing configuration, information about whether switch is possible following the error, and location and details of the error that caused the switch or disconnection are displayed.

After starting database multiplexing mode, execute the mc_ctl command in status mode to check the multiplexing status.

An example of the status displayed when the mc_ctl command is executed is shown below.

Example)

```
> mc_ctl status -M D:\mcdir\inst1

mirroring status
----------------
switchable
server_id  host_role       host            host_status  db_proc_status       disk_status
-------------------------------------------------------------------------------------------------
----
server1    primary         192.0.2.100     normal       normal                 normal
server2    standby         192.0.2.110     normal       normal                 normal
```

Checking the status of connection to the Mirroring Controller arbitration process

When the arbitration server is used for automatic degradation, the status of the connection to the Mirroring Controller arbitration process can be checked by specifying the --arbiter option. If the output status is "online", it indicates that an arbitration request can be made from the database server to the arbitration server. When the arbitration server is used for automatic degradation, regularly execute the command in status mode with the --arbiter option specified and check that the output status is "online".

Example)
The mc_ctl command is executed with the --arbiter option specified, and the status is output.

```
> mc_ctl status --arbiter -M D:\mcdir\inst1

arbiter_id   host            status
---------------------------------------
arbiter      192.0.3.120     online
```

Checking the status of data synchronization

Additionally, by referencing the pg_stat_replication statistics view on the primary server, the data synchronization status can be confirmed. However, when creating the monitoring program, note that the content of pg_stat_replication may be changed in the future.

The following example shows that the locations of the transaction log after it is sent and received (sent_lsn, replay_lsn) match, and that they are fully synchronized.

Example)

```
postgres=# select * from pg_stat_replication;
-[ RECORD 1 ]----+------------------------------
pid              | 10651
usesysid         | 10
usename          | fsep
application_name | standby
client_addr      | 192.0.2.210
client_hostname  |
client_port      | 55098
backend_start    | 2022-03-23 11:17:49.628793+09
backend_xmin     |
state            | streaming
sent_lsn         | 0/3000060
write_lsn        | 0/3000060
flush_lsn        | 0/3000060
replay_lsn       | 0/3000060
write_lag        |
flush_lag        |
replay_lag       |
sync_priority    | 1
sync_state       | sync
reply_time       | 2022-03-23 11:23:27.703366+09
```

See

- Refer to "mc_ctl" in Reference for information on the command.
- Refer to "Notes on Application Compatibility" in the Application Development Guide for information on retaining application compatibility.
- Refer to "The Statistics Collector" in "Server Administration" in the PostgreSQL Documentation for details on pg_stat_replication.

3.3.2 Checking the Status of the Arbitration Server

This section describes how to check the status of the arbitration server.

The status of the connection between the Mirroring Controller arbitration process and primary server/standby server can be checked by executing the mc_arb command in status mode.

The example below executes the mc_arb command, and shows the status.

Linux

Example)

```
$ mc_arb status -M /mcarb_dir/arbiter1

server_id    host            status
--------------------------------------
server1      192.0.3.100     online
server2      192.0.3.110     online
```

Windows

Example)

```
> mc_arb status -M D:\mcarb_dir\arbiter1

server_id    host            status
--------------------------------------
server1      192.0.3.100     online
server2      192.0.3.110     online
```

3.4 Manually Switching the Primary Server

The primary server cannot be switched automatically in the following case:

- If automatic switch/disconnection is disabled
- If output of messages is selected for heartbeat abnormalities during heartbeat monitoring of the operating system or server and the operating system/server crashes or becomes unresponsive

In this case, to manually switch the primary server, execute the mc_ctl command in switch mode on either the primary server or the standby server.

Example)

```
> mc_ctl switch -M D:\mcdir\inst1
```

Point

If automatic switch/disconnection is enabled, it is possible to perform switch of primary server at any time.

3.5 Manually Disconnecting the Standby Server

The procedure to perform disconnection of the standby server differs depending on whether the automatic switch/disconnection is enabled or disabled.

If automatic switch/disconnection is enabled

Execute the mc_ctl command in stop mode on the standby server.

Example)

```
> mc_ctl stop -M D:\mcdir\inst1
```

If automatic switch/disconnection is disabled

1. Execute the mc_ctl command in stop mode on the standby server.

   Example)

   ```
   > mc_ctl stop -M D:\mcdir\inst1
   ```

2. Comment out the synchronous_standby_names parameter in the postgresql.conf file on the primary server. If you have set the synchronized_standby_slots parameter, comment out the synchronized_standby_slots parameter as well.

3. Execute the pg_ctl command in reload mode on the primary server.

   Example)

   ```
   > pg_ctl reload -D D:\database\inst1
   ```

3.6 Action Required when a Heartbeat Abnormality is Detected

The message below is output when a heartbeat abnormality is detected during heartbeat monitoring of operating systems or servers:

```
detected an error on the monitored object "server(server identifier name)": no response:ping timeout
(MCA00019)
```

If the heartbeat_error_action parameter in *serverIdentifier*.conf is set to "message", even if automatic switch/disconnection is enabled and Mirroring Controller is started, automatic switch/disconnection is not performed when a heartbeat abnormality is detected. Therefore, user action will be necessary.

This section explains the action required when the heartbeat_error_action parameter is set to "message" and a heartbeat abnormality is detected.

1. Identify the cause of the heartbeat abnormality. The possible causes are below:

   - The remote operating system or server crashed or is unresponsive
   - An admin network issue occurred

2. Address the cause identified in step 1.

   - The remote operating system or server crashed or is unresponsive

     Manually perform switch or disconnection using the mc_ctl command.

   - An admin network issue occurred

     Refer to "Chapter 4 Action Required when an Error Occurs in Database Multiplexing Mode", and recover the database multiplexing system.

3.7 Monitoring Mirroring Controller Messages

The messages that are output by Mirroring Controller are output to both the database server and the arbitration server. If the automatic switch fails, for example, an important message related to the continuation of the operation may be output, so ensure that the system log messages are monitored.

If the arbitration server is used for automatic degradation, monitor messages on both the database server and the arbitration server.

Message output destination on the database server

Messages are output to the event log.

Message output destination on the arbitration server

Linux

Messages are output to the system log.

Windows

Messages are output to the event log.

Point

- To monitor message types considered to be important, an operating system setting must be configured beforehand. Refer to the operating system manuals, check if the message is of a message type that is monitored to be output to the system log, and configure the setting if required.
- If the heartbeat_error_action parameter in *serverIdentifier*.conf is set to "message", only message output is performed when a heartbeat abnormality is detected during heartbeat monitoring of operating systems and servers - automatic switch/disconnection is not performed. Therefore users need to monitor the messages. Refer to "3.6 Action Required when a Heartbeat Abnormality is Detected" for details.

Display format on the database server

```
eventSourceName[processId]: messageType: messageContent (messageNumber)
```

Specify the event source name in the event_source parameter of the serverIdentifier.*conf* file of the database server.

The message types output by Mirroring Controller, their severity, and their corresponding value in the event log are shown in the table below.

Table 3.1 Message type, severity, and corresponding value in the event log

Message type	Severity	Meaning	Event log
INFO	Information	Provides information that does not fall under LOG or NOTICE.	INFORMATION
LOG		Provides information recognized as a particularly important event in tracing the operation history. (Example: Automatic switch is complete)	
NOTICE	Notice	Outputs information that takes into account the user instructions within the program in response to an executed or automatically executed process.	
WARNING	Warning	Provides a warning, for example it will soon be impossible to maintain multiplexing capabilities.	WARNING
ERROR	Error	Reports that an error other than FATAL or PANIC has occurred.	ERROR
FATAL		Reports that an abnormality was detected in the multiplexed database systems requiring recovery of the system, and also the content and cause of the abnormality.	

Message type	Severity	Meaning	Event log
PANIC		Reports that an abnormality was detected in all multiplexed database systems requiring immediate recovery of the system, and also the content and cause of the abnormality.	

The message severity has the following meanings:

- Information

  Informational status. A message that was reported by the system is displayed. No action is required.

- Notice

  Informational status, but a message that should be noted is displayed. If necessary, take the actions described in the "Action" section of the message.

- Warning

  No error has occurred, but the user is requested to check, and take action. Take the actions described in the "Action" section of the message.

- Error

  An error has occurred. Take the actions described in the "Action" section of the message.

Display format on the arbitration server

Linux

```
programName[processId]: messageType: messageText (messageNumber)
```

Specify the program name in the syslog_ident parameter of the arbitration.conf file of the arbitration server.

Windows

```
eventSourceName[processId]: messageType: messageText (messageNumber)
```

Specify the event source name in the event_source parameter of the arbitration.conf file of the arbitration server.

The message types output by Mirroring Controller, their severity, and their corresponding value in the output destination log are shown in the table below.

Table 3.2 Message type, severity, and corresponding value in the output destination log

Message type	Severity	Meaning	System log (Linux)	Event log (Windows)
INFO	Information	Provides information not categorized as LOG or NOTICE.	INFO	INFORMATION
LOG		Provides information recognized as a particularly important event in tracing the operation history. (Example: Automatic switch is complete)		
NOTICE	Notice	Outputs information that takes into account the user instructions within the program in response to an executed or automatically executed process.	NOTICE	
WARNING	Warning	Provides a warning, for example it will soon be impossible to perform the arbitration process.	WARNING	WARNING
ERROR	Error	Reports that an error other than FATAL or PANIC has occurred.	ERROR	ERROR
FATAL		Reports that an abnormality was detected in the arbitration server requiring recovery of the system, and also the content and cause of the abnormality.	CRIT	

Message type	Severity	Meaning	System log (Linux)	Event log (Windows)
PANIC		Reports that an abnormality was detected in the arbitration server requiring immediate recovery of the system, and also the content and cause of the abnormality.	ALERT	

The message severity has the following meanings:

- Information

  Informational status. A message that was reported by the system is displayed. No action is required.

- Notice

  Informational status, but a message that should be noted is displayed. If necessary, take the actions described in the "Action" section of the message.

- Warning

  No error has occurred, but the user is requested to check, and take action. Take the actions described in the "Action" section of the message.

- Error

  An error has occurred. Take the actions described in the "Action" section of the message.

3.8 Server Maintenance

To perform maintenance tasks such as periodic server inspections and the application of updates for software products including the operating system, you must perform a planned stop of the server, and then perform the maintenance.

3.8.1 Rolling Updates

In database multiplexing mode, rolling updates, that perform the maintenance for the servers that comprise the cluster system, can be performed while jobs continue.

First, perform the maintenance for the standby server, and then switch the standby server to the primary server. Then, perform the maintenance for the original primary server that was switched to the standby server. This enables maintenance to be performed while jobs continue. Obtain a backup as soon as this task is complete.

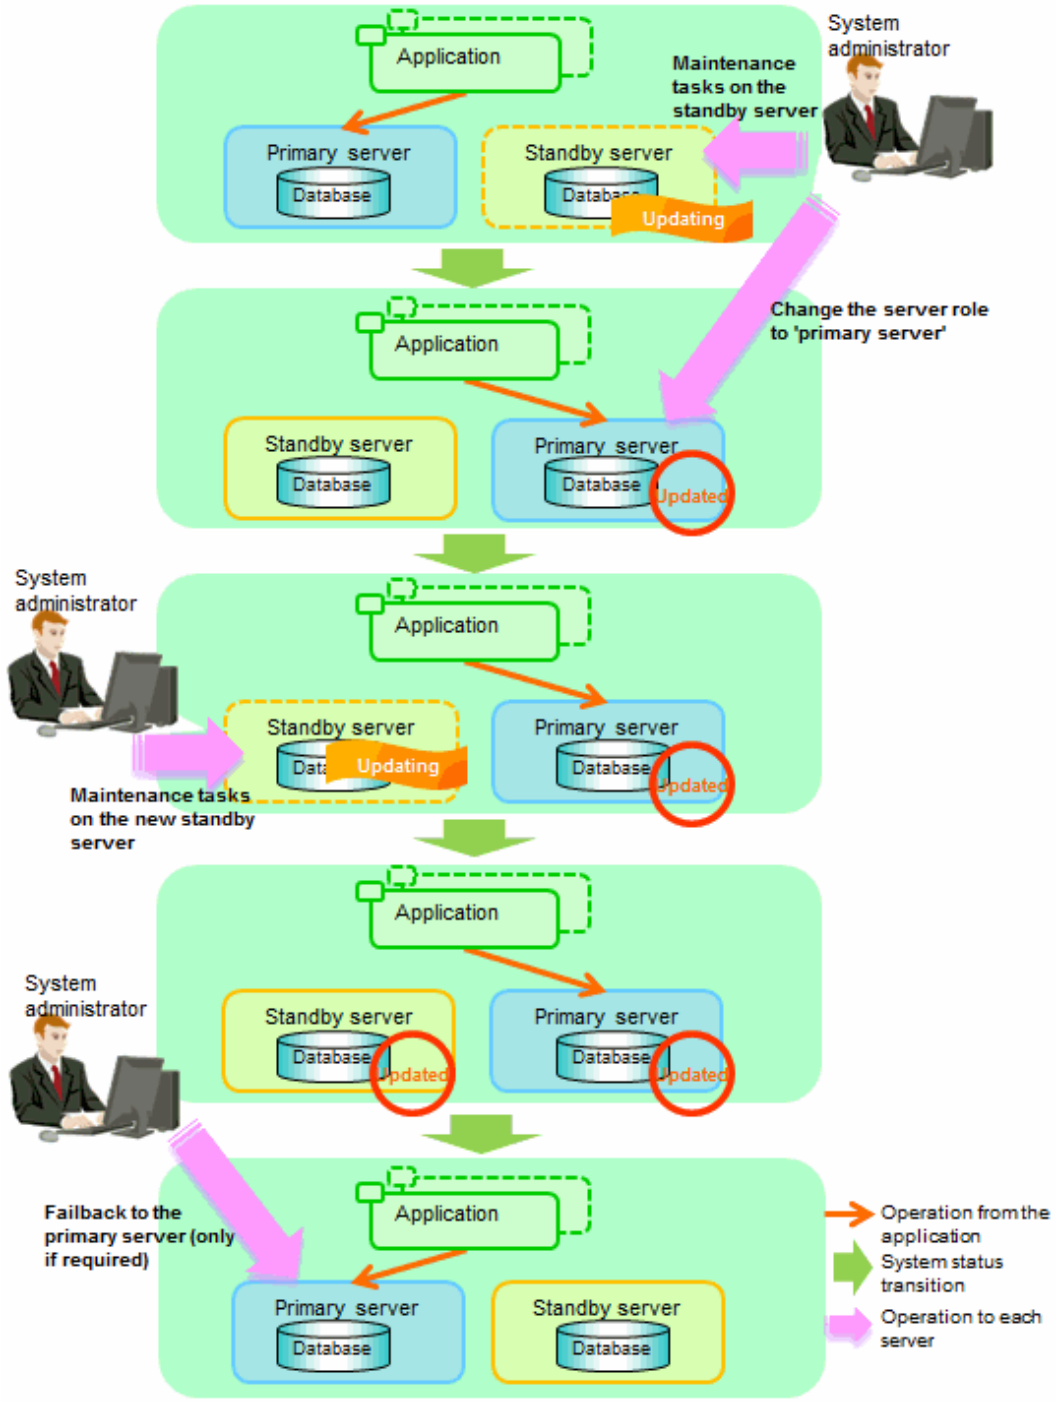
Note that arbitration server maintenance can be performed without affecting database server operation, so it is not necessary to consider rolling update.

See

If the downtime due to the maintenance of the standby server is expected to be long, refer to "Standby server downtime" in "3.9.1 Changes Required when the Standby Server is Stopped".

The flow of a rolling update is shown below.

Figure 3.1 Performing a Rolling Update



Perform the following procedure as shown in the above figure:

Standby server maintenance tasks

1. To perform the maintenance on the standby server, stop Mirroring Controller.

   Example)

   ```
   > mc_ctl stop -M D:\mcdir\inst1
   ```

2. Ensure that Mirroring Controller has completely stopped.

   If the multiplexed instances and Mirroring Controller have been configured on the standby server to start and stop automatically when the operating system of the database server is started or stopped, cancel the setting to start and stop automatically.

   ### See

   Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for information on how to configure the multiplexed instances and Mirroring Controller to start and stop automatically when the operating system of the database server start and stops.

   This task should be performed by the instance administrator user with administrator privileges.

   Use the sc config command to disable automatic start of multiplexed instances and Mirroring Controller from the Windows service.

   ```
   Example)
   The following is an example using the registered service name "Mirroring_Controller_inst1".
   ```

   ```
   > sc config "Mirroring_Controller_inst1" start= demand
   ```

   ### Information

   You can use the sc qc command to check the registration status.
   Refer to documentation such as Windows Help and Support for the sc command for information on registry content.

3. Perform maintenance tasks.

4. Create a copy of the primary server instance on the standby server.

   Execute the pg_basebackup command to create data in the standby server by synchronizing with the primary server.

   ```
   Example)
   ```

   ```
   > pg_basebackup -D D:\database\inst1 -X fetch --waldir=E:\transaction\inst1 --progress --verbose
   -R --dbname="application_name=standbyServerName" -h primaryServerHostName -p
   primaryServerPortNumber
   ```

   ### See

   The procedure for copying the primary server instance to the standby server is the same as the procedure for setting up the standby server.

   Refer to "2.5.2 Creating, Setting, and Registering the Standby Server Instance", and then perform the recovery.

5. Check the settings for automatic start and stop of the multiplexed instances and Mirroring Controller.

   If the multiplexed instances and Mirroring Controller were configured in step 2 to not start and stop automatically when the operating system of the database server starts and stops, then change the settings back. This step can be skipped if automatic start and stop are not required.

   This task should be performed by an instance administrator user with administrator privileges.

   Use the sc config command to enable automatic start of multiplexed instances and Mirroring Controller from the Windows service.

   ```
   Example)
   The following is an example using the registered service name "Mirroring_Controller_inst1".
   ```

   ```
   > sc config "Mirroring_Controller_inst1" start= auto
   ```

Information

You can use the sc qc command to check the registration status.
Refer to documentation such as Windows Help and Support for the sc command for information on registry content.

6. Start (rebuild) Mirroring Controller on the standby server.

   This operation is required when determining the maintenance tasks on the standby server.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

```
> mc_ctl start -M D:\mcdir\inst1
```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   Example)

```
> mc_ctl start -M D:\mcdir\inst1 -F
```

Point

After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

Switching to the primary server

To perform the maintenance on the primary server, execute the mc_ctl command in the switch mode on the primary server or the standby server.

Example)

```
> mc_ctl switch -M D:\mcdir\inst1
```

When the switch is complete, the synchronous_standby_names parameter and synchronized_standby_slots parameter in the postgresql.conf file of the new primary server will be commented as follows:

Example)

```
#synchronous_standby_names = 'primary'
#synchronized_standby_slots = 'slot'
```

New standby server maintenance tasks

1. Stop the Mirroring Controller.

   On the new standby server (the primary server before the switch), execute the mc_ctl command in stop mode.

   Example)

```
> mc_ctl stop -M D:\mcdir\inst1
```

2. Ensure that Mirroring Controller has completely stopped.

   If the multiplexed instances and Mirroring Controller have been configured on the new standby server to start and stop automatically when the operating system of the database server is started or stopped, cancel the setting to start and stop automatically now.

See

Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" for information on how to configure the multiplexed instances and Mirroring Controller to start and stop automatically when the operating system of the database server starts and stops.

This task should be performed by an instance administrator user with administrator privileges.

Use the sc config command to disable automatic start of multiplexed instances and Mirroring Controller from the Windows service.

```
Example)
The following is an example using the registered service name "Mirroring_Controller_inst1".
```

```
> sc config "Mirroring_Controller_inst1" start= demand
```

Information

You can use the sc qc command to check the registration status.
Refer to documentation such as Windows Help and Support for the sc command information on registry content.

3. Perform the maintenance on the new standby server that was stopped.

4. Create a copy of the new primary server instance on the new standby server.

   Execute the pg_basebackup command to create data in the new standby server by synchronizing with the new primary server.

   ```
   Example)
   ```

   ```
   > pg_basebackup -D D:\database\inst1 -X fetch --waldir=\transaction\inst1 --progress --verbose -
   R --dbname="application_name=standbyServerName" -h primaryServerHostName -p
   primaryServerPortNumber
   ```

   ### See

   The procedure for copying the primary server instance to the standby server is the same as the procedure for setting up the standby server.

   Refer to "2.5.2 Creating, Setting, and Registering the Standby Server Instance", and then perform the recovery.

5. Check the settings for automatic start and stop of the multiplexed instances and Mirroring Controller.

   If the multiplexed instances and Mirroring Controller were configured in step 2 to not start and stop automatically when the operating system of the database server starts and stops, then change the settings back. This step can be skipped if automatic start and stop are not required.

   This task should be performed by an instance administrator user with administrator privileges.

   Use the sc config command to enable automatic start of multiplexed instances and Mirroring Controller from the Windows service.

   ```
   Example)
   The following is an example using the registered service name "Mirroring_Controller_inst1".
   ```

   ```
   > sc config "Mirroring_Controller_inst1" start= auto
   ```

   ### Information

   You can use the sc qc command to check the registration status.
   Refer to the document such as Windows Help and Support for the sc command for information on registry content.

6. After the maintenance is complete, edit the following parameters in the postgresql.conf file of the standby server as required.

   Copying an instance results in the value of the synchronous_standby_names parameter becoming the specified value on the primary server. Therefore, correct it to the specified value on the standby server. If the parameter was commented out, then you must uncomment it.

7. If you are using a replication slot, create a communication replication slot on the primary server before rebuilding.

   Example)

```
> psql -h primaryServerHostName -p primaryServerPortNumber -d databaseName -c "SELECT * FROM
pg_create_physical_replication_slot('replicationSlotName')"
```

8. On the standby server, start (rebuild) Mirroring Controller.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

```
> mc_ctl start -M D:\mcdir\inst1
```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   Example)

```
> mc_ctl start -M D:\mcdir\inst1 -F
```

   Point

   After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

9. If you are using a replication slot, replication slot may remain on the standby server. Delete the replication slot on the standby server side as needed.

   Example)

```
> psql -h standbyServerHostName -p standbyServerPortNumber -d databaseName -c "SELECT * FROM
pg_drop_replication_slot('replicationSlotName')"
```

   Information

   If unused replication slots remain on the standby server, WAL files may not be deleted on the standby server.

Failback of the Primary Server

Revert the primary server and standby server to the original server configuration. Do this to execute the main job on the previous primary server. Refer to "4.1.1.3 Failback of the Primary Server" for details.

3.8.2 Stopping for Maintenance

Perform this procedure to stop all servers for periodic inspections, for example. On the server on which Mirroring Controller is running, execute the mc_ctl command in stop mode to stop the instance and Mirroring Controller.

After that, on the server where the Mirroring Controller arbitration process is running, execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

Stopping Mirroring Controller

Example)

```
> mc_ctl stop -M D:\mcdir\inst1 -a
```

Stopping the Mirroring Controller arbitration process

Linux

Example)

```
$ mc_arb stop -M /mcarb_dir/arbiter1
```

Windows

Example)

```
> mc_arb stop -M D:\mcarb_dir\arbiter1
```

3.8.3 Arbitration Server Maintenance

Arbitration server maintenance can be performed without affecting database server operation.

Follow the procedure below to perform arbitration server maintenance.

1. Execute the mc_arb command in stop mode to forcibly stop the Mirroring Controller arbitration process.

   Linux

   Example)

   ```
   $ mc_arb stop -M /mcarb_dir/arbiter1 -e
   ```

   Windows

   Example)

   ```
   > mc_arb stop -M D:\mcarb_dir\arbiter1 -e
   ```

2. Perform maintenance tasks.
3. Execute the mc_arb command in start mode to restart the Mirroring Controller arbitration process.

   Linux

   Example)

   ```
   $ mc_arb start -M /mcarb_dir/arbiter1
   ```

   Windows

   Example)

   ```
   > mc_arb start -M D:\mcarb_dir\arbiter1
   ```

4. Execute the mc_arb command in status mode to check that the arbitration server is connected to the database server.

   The example below executes the mc_arb command, and shows the status.

   Linux

   Example)

   ```
   $ mc_arb status -M /mcarb_dir/arbiter1
   ```

```
server_id    host            status
-------------------------------------
server1      192.0.3.100     online
server2      192.0.3.110     online
```

Windows

Example)

```
> mc_arb status -M D:\mcarb_dir\arbiter1

server_id    host            status
-------------------------------------
server1      192.0.3.100     online
server2      192.0.3.110     online
```

5. Check the command output.

   Items to be checked

   Check that the output status is "online" on both lines.

3.9 Changes in Operation

The following changes in operation may be required:

- Changes required when the standby server is stopped
- Changing from single server mode to database multiplexing mode
- Changing from database multiplexing mode to single server mode
- Changing to database multiplexing mode when the arbitration server is used for automatic degradation
- Changing parameters
- Uninstalling in the database multiplexing mode

3.9.1 Changes Required when the Standby Server is Stopped

Operation when the standby server is stopped

Before performing maintenance for the primary server instance when the standby server has been stopped, stop Mirroring Controller on the primary server, comment out the synchronous_standby_names parameter and synchronized_standby_slots parameter in the postgresql.conf file of the primary server, and then execute the pg_ctl command in reload mode.

If this operation is not performed, operations performed on the primary server for the instance will remain in a wait state.

See

Refer to "pg_ctl" in Reference for information on the command.

Information

The standby server must be rebuilt if the pending transaction log to be transferred to the standby server is lost when the standby server is started after the maintenance task is complete.

Take the action advised in the recovery operation that starts from "4.1.1.1.3 Identify cause of error and perform recovery" through to "4.1.1.2 Rebuild the Standby Server".

Standby server downtime

If you specified the synchronous_standby_names parameter of the postgresql.conf file and then the standby server instance is stopped, consider the points below.

- The wal_sender_timeout parameter in the postgresql.conf file

  If the standby server is stopped after the timeout time set in this parameter was exceeded, an error stating that the transaction log could not be received may be output to the primary server event log, and all transaction logs that should be transferred to the standby server are accumulated.

- The wal_keep_size parameter in the postgresql.conf file

  If a transaction log that exceeds the value set in this parameter was generated while the standby server was stopped, the transaction log may be deleted.

  Additionally, setting this parameter requires consideration regarding stabilization of the database multiplexing mode. Refer to "2.11.1 Tuning to Stabilize the Database Multiplexing Mode" for details.

3.9.2 Changing from Single Server Mode to Database Multiplexing Mode

The procedure for switching single server mode to database multiplexing mode for the purposes of high reliability and load distribution of the system is explained below.

This procedure is equivalent to the setup procedure explained in "Chapter 2 Setting Up Database Multiplexing Mode".

Point

If the data storage destination directory name is not comprised of ASCII characters

Stop the application job and then perform the following procedure to migrate to a directory with a name that uses only ASCII characters:

1. Stop the database instance on the primary server.
2. Change the name of the data storage destination directory to one that uses only ASCII characters.
   For example, do not perform operations that will cause the symbolic link contained in the data storage destination directory to become lost, such as moving data to another drive.

See

When encrypting the storage data, refer to "Database Multiplexing Mode" in the Operation Guide, and then perform the setup for encryption on the primary and standby servers.

1. Install on the arbitration server

   Perform this step only if the arbitration server is used for automatic degradation.

   Install the Server Assistant on the server where the Mirroring Controller arbitration process is started.

   Refer to "Installation" in the Installation and Setup Guide for Server Assistant for information on how to install the Server Assistant.

2. Install on the standby server

   Install Fujitsu Enterprise Postgres on the server to be started as the standby server.

   Refer to "Installation" in the Installation and Setup Guide for Server for information on how to install Fujitsu Enterprise Postgres.

   Use ASCII characters in the data storage destination directory.

3. Stop the application jobs

   Stop the application jobs to be connected to the primary server.

4. Change the primary server settings

   To allow connections from the server to be started as the standby server, configure the settings in step 2 and thereafter of "2.4.2 Creating, Setting, and Registering the Primary Server Instance" on the primary server.

5. Set up the arbitration server

   Refer to "2.3 Setting Up the Arbitration Server" for details.

   Perform this step only if the arbitration server is used for automatic degradation.

6. Set up database multiplexing mode on the primary server

   Refer to "2.4.1 Setting Up Database Multiplexing Mode on the Primary Server" for details.

7. Set up database multiplexing mode on the standby server

   Refer to "2.5.1 Setting Up Database Multiplexing Mode on the Standby Server" for details.

8. Create the standby server instance and start it

   Refer to "2.5.2 Creating, Setting, and Registering the Standby Server Instance" for details.

After the above steps are completed, refer to the remaining explanations in "Chapter 2 Setting Up Database Multiplexing Mode" and ensure that the required settings and operations are completed.

3.9.3 Changing from Database Multiplexing Mode to Single Server Mode

The procedure for stopping database multiplexing mode and changing to single server mode is explained below.

Some tasks must be performed on the database server, and others must be performed on the arbitration server.

The tasks on the arbitration server are required only if the arbitration server is used for automatic degradation.

Tasks on the database server

1. Determine the server for which the instance is to be stopped, and switch this server

   Determine the server that is to be excluded as the database multiplexing mode target, and for which the instance is to be stopped.

   If the server for which the instance is to be stopped is the primary server, execute the mc_ctl command in the switch mode to switch the standby server to the primary server.

   The standby server after the switch is complete will be the server for which the instance is to be stopped.

   If the server for which the instance is to be stopped is the standby server, there is no need to perform the switch operation.

   Example)

```
> mc_ctl switch -M D:\mcdir\inst1
```

2. Stop Mirroring Controller and the instance.

   On the server that was determined in step 1, execute the mc_ctl command in the stop mode to stop Mirroring Controller and the instance.

   Example)

```
> mc_ctl stop -M D:\mcdir\inst1
```

3. Unregister Mirroring Controller from the Windows service.

   Execute the mc_ctl command in unregister mode to unregister Mirroring Controller from the Windows service.

   Example)

```
> mc_ctl unregister -M D:\mcdir\inst1
```

4. Delete registries related to the event log

   If error logs are output to the event log in "2.2.1.2 Preparatory Tasks for the Output of Error Logs to the Event Log", delete the registered event source name for each instance.

   Example)

```
> regsvr32 /u /i:"Mirroring Controller inst1" "c:\Program Files\Fujitsu\fsepv<x>server64\lib
\mcevent.dll"
```

   Note that "<x>" indicates the product version.

5. Delete the file resources

   Delete the following file resources:

   - Data storage destination directory
   - Mirroring Controller management directory

     Example)

```
> rmdir /S /Q D:\database\inst1
> rmdir /S /Q D:\mcdir\inst1
```

See

Refer "Security-Related Notes" in the Operation Guide for information on deleting the data securely.

6. Stop the application jobs

   Stop the application jobs to be connected to the primary server.

7. Stop Mirroring Controller and the instance on the primary server

   Execute the mc_ctl command in stop mode on the primary server.

   Example)

```
> mc_ctl stop -M D:\mcdir\inst1
```

8. Unregister Mirroring Controller from the Windows service on the primary server

   Execute the mc_ctl command in unregister mode to unregister Mirroring Controller from the Windows service.

   Example)

```
> mc_ctl unregister -M D:\mcdir\inst1
```

9. Delete registries related to the event log on the primary server

   If error logs are output to the event log in "2.2.1.2 Preparatory Tasks for the Output of Error Logs to the Event Log", delete the registered event source name for each instance.

   Example)

```
> regsvr32 /u /i:"Mirroring Controller inst1" "c:\Program Files\Fujitsu\fsepv<x>server64\lib
\mcevent.dll"
```

   Note that "<x>" indicates the product version.

10. Delete the database multiplexing mode settings that were configured for the primary server instance.

    Reset the postgresql.conf file parameters to their values before the database multiplexing operation was set.

    Delete the file resources from the Mirroring Controller management directory.

If the backup operation was performed, delete the following resources:

- Mirroring Controller management directory backup data obtained in database multiplexing mode
- Instance backup data obtained in database multiplexing mode

Additionally, if the primary_conninfo parameter is set in the postgresql.auto.conf file, execute the ALTER SYSTEM RESET statement to delete the setting.

```
Example)
An example execution of the psql command is shown below.
```

```
postgres=# ALTER SYSTEM RESET primary_conninfo;
```

After these actions are performed, ensure that the backup data is collected when starting the single operation.

See

- Refer to "Security-Related Notes" in the Operation Guide for details on deleting the data securely.
- Refer to "2.14 Backup Operation" for details on the backup operation.
- Refer to "Appendix A Parameters" for details on the postgresql.conf file parameters.

Point

In the above procedure, if the postgresql.conf file of the single primary server can be changed by reloading the file, the operation mode can be changed without stopping the application job.

In that case, execute the mc_ctl command in stop mode with the --mc-only option specified to stop only Mirroring Controller in relation to stopping the primary server.

Tasks on the arbitration server

Linux

1. Execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

   ```
   Example)
   ```

   ```
   $ mc_arb stop -M /mcarb_dir/arbiter1
   ```

2. Delete the Mirroring Controller arbitration process management directory.

   ```
   Example)
   ```

   ```
   $ rm -rf /mcarb_dir/arbiter1
   ```

Windows

1. Execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

   ```
   Example)
   ```

   ```
   > mc_arb stop -M D:\mcarb_dir\arbiter1
   ```

2. Unregister the Mirroring Controller arbitration process from the Windows service.

   Execute the mc_arb command in unregister mode to unregister the Mirroring Controller arbitration process from the Windows service.

   ```
   Example)
   ```

```
> mc_arb unregister -M D:\mcarb_dir\arbiter1
```

3. Delete registrations related to the event log

   If error logs are output to the event log in "2.2.2.1 Preparing to Output Error Logs to the Event Log (Windows)", delete the registered event source name for each instance.

   Example)

```
> regsvr32 /u /i:"Mirroring Controller arbtier1" "c:\Program Files\Fujitsu
\fsepv<x>assistant64\lib\mcarbevent.dll"
```

   Note that "<*x*>" indicates the product version.

4. Delete the Mirroring Controller arbitration process management directory.

   Example)

```
> rmdir /S /Q D:\mcarb_dir\arbiter1
```

3.9.4 Changing to Database Multiplexing Mode when the Arbitration Server is Used for Automatic Degradation

This section provides the procedure to change to database multiplexing mode using the Mirroring Controller only on the database server when the arbitration server is used for automatic degradation.

Some tasks must be performed on the database server, and others must be performed on the arbitration server.

Tasks on the arbitration server

1. Set up the arbitration server.

   Refer to "2.3 Setting Up the Arbitration Server" for information on how to set up the arbitration server.

Tasks on the database server

1. On the server where Mirroring Controller is running, execute the mc_ctl command in stop mode to stop Mirroring Controller on the primary server and standby server.

   Example)

```
> mc_ctl stop -M D:\mcdir\inst1 -a --mc-only
```

2. Edit the network.conf file of the primary server and standby server to add the information of the arbitration server.

   Refer to "A.3 Network Configuration File" for details.

   The definition example of the network.conf file of the primary server is shown below:

   Example)

   The IDs of the primary server and standby server are set to "server1" and "server2", and their port numbers are set to "27540" and "27541". The ID of the server of the Mirroring Controller arbitration process is set to "arbiter", and its port number is set to "27541".

```
server1 192.0.2.100,192.0.3.100 27540,27541 server
server2 192.0.2.110,192.0.3.110 27540,27541 server
arbiter 192.0.3.120 27541 arbiter
```

Information

Ensure that the port numbers set for the primary server, standby server, and arbitration server do not conflict with other software. Also do not configure the same segment for the admin network and arbitration network.

Point

- If the server type is "server", two IP addresses or host names, and two port numbers need to be specified in the following order:
  - IP address or host name of the database server used as the admin network
  - IP address or host name of the database server used as the arbitration network
  - Port number of the database server used as the admin network
  - Port number of the database server used as the arbitration network
- If the server type is "arbiter", specify the IP address or host name set for the my_address parameter and the port number set for the port parameter in arbitration.conf.
- When using the admin network and arbitration network together, the following IP addresses or host names must be assigned the same values.
  - IP address or host name of the database server used as the admin network
  - IP address or host name of the database server used as the arbitration network

  Example)
  Here is an example where the server identifiers for the primary server and standby server are "server1" and "server2", with port numbers "27540" and "27541", and the server identifier for the Mirroring Controller arbitration process is "arbiter", with port number "27541".

```
server1 192.0.2.100,192.0.2.100 27540,27541 server
server2 192.0.2.110,192.0.2.110 27540,27541 server
arbiter 192.0.2.120 27541 arbiter
```

3. Edit the *serverIdentifier*.conf file of the primary server and standby server to add parameters required for the operation where the arbitration server is used for automatic degradation.

   Refer to "A.4.1 Server Configuration File for the Database Servers" for information on the parameters required when the arbitration server is used for automatic degradation.

4. On the primary server and standby server, execute the mc_ctl command in start mode to start the Mirroring Controller process.

   Example)

```
> mc_ctl start -M D:\mcdir\inst1 --mc-only
```

Common tasks

1. Check the connection status from the database server or arbitration server.

   Refer to "2.8 Checking the Connection Status" for details.

3.9.5 Changing Parameters

Stop Mirroring Controller before editing the Mirroring Controller server configuration file and network configuration file.

If the Mirroring Controller process crashes or becomes unresponsive, restart is performed automatically by the Mirroring Controller monitoring process, and the configuration file is reloaded. Therefore, if the configuration file was being edited, unintended behavior will occur.

3.9.6 Uninstalling in Database Multiplexing Mode

This section explains how to uninstall Fujitsu Enterprise Postgres on a server using database multiplexing mode.

Some tasks must be performed on the database server, and others must be performed on the arbitration server.

The tasks on the arbitration server are required only if the arbitration server is used for automatic degradation.

Tasks on the database server

1. Stop the multiplexed instances and Mirroring Controller

   Refer to "3.2 Starting and Stopping Mirroring Controller" for information on how to stop the instance.

2. Unregister Mirroring Controller from the Windows service

   Execute the mc_ctl command in unregister mode to unregister Mirroring Controller from the Windows service.

   ```
   Example)
   ```

   ```
   > mc_ctl unregister -M D:\mcdir\inst1
   ```

3. Delete registries related to the event log

   If messages are output to the event log, DLLs are registered in accordance with "2.2.1.2 Preparatory Tasks for the Output of Error Logs to the Event Log". Delete these registries so that no unnecessary issues occur.

   Ensure that you delete the DLLs before the uninstallation. If you perform the uninstallation without doing so, you may not be able to delete the DLLs at a later time.

   ```
   Example)
   The following is an example in which the DLL of a 64-bit product that is registered under the
   default event source name is deleted. Note that "<x>" indicates the product version.
   ```

   ```
   > regsvr32 /u "c:\Program Files\Fujitsu\fsepv<x>server64\lib\mcevent.dll"
   ```

   - Delete the registered DLL for each instance

     DLL registration is performed so that messages output to the event log are identified by each instance, and are output to any event source named by the user.

     Accordingly, it is necessary to delete the DLL registry for each instance. Delete the DLL registry for each event source name.

     ```
     Example)
     The following is an example in which the DLL of a 64-bit product that is registered under the
     event source name "Mirroring Controller inst1" is deleted. Note that "<x>" indicates the
     product version.
     ```

     ```
     > regsvr32 /u /i:"Mirroring Controller inst1" "c:\Program Files\Fujitsu\fsepv<x>server64\lib
     \mcevent.dll"
     ```

   - If installing multiple versions

     If the database multiplexing system you set up using the Fujitsu Enterprise Postgres package has been set to output error logs to the event log, use the DLL path name that you took note of previously as explained in "2.2.1.2 Preparatory Tasks for the Output of Error Logs to the Event Log" to reregister the default event source name.

4. Uninstall Fujitsu Enterprise Postgres

   Refer to "Uninstallation" in the Installation and Setup Guide for Server for information on how to uninstall Fujitsu Enterprise Postgres.

Tasks on the arbitration server

Refer to "Uninstallation" in the Installation and Setup Guide for Server Assistant, and uninstall the Server Assistant.

Chapter 4 Action Required when an Error Occurs in Database Multiplexing Mode

This chapter describes the action required if an error occurs in database multiplexing mode.

In database multiplexing mode, when an error is detected, the switch or disconnection of the standby server is performed automatically, so that only the primary server starts degrading. In this case, the recovery tasks will be required for the standby server on which the switch or disconnection was performed.

Other possible cases are as follows:

- When automatic switch fails
- When automatic disconnection fails
- When all servers or instances were stopped

4.1 Action Required when Server Degradation Occurs

If the server has started degrading, the recovery tasks will vary depending on whether the cause was the switch (failover or switchover), or the disconnection.

Execute the mc_ctl command in status mode, or refer to the event log, and check if the cause of the server to start degrading was the switch or the disconnection.

In the example below, the mc_ctl command is executed in status mode.

If a switch has occurred, "switched" (the switch is complete and the server is in a degrading state) is displayed for "mirroring status".

Example)

```
> mc_ctl status -M D:\mcdir\inst1
mirroring status
----------------
switched

   :
```

If a disconnection has occurred, "not-switchable" (disconnection was performed so the server cannot be switched) is displayed for "mirroring status".

Example)

```
> mc_ctl status -M D:\mcdir\inst1
mirroring status
----------------
not-switchable

  :
```

Information

If Mirroring Controller detects any errors on the server on which operations are continuing during recovery to database multiplexing mode from a degrading operation state, perform the procedure in "4.1.3 Addressing Errors During Degrading Operation", and then recover to database multiplexing mode.

4.1.1 Operations when the Server has Started Degrading after a Switch has Occurred

This section explains the operations when the server has started degrading after a switch has occurred.

Information

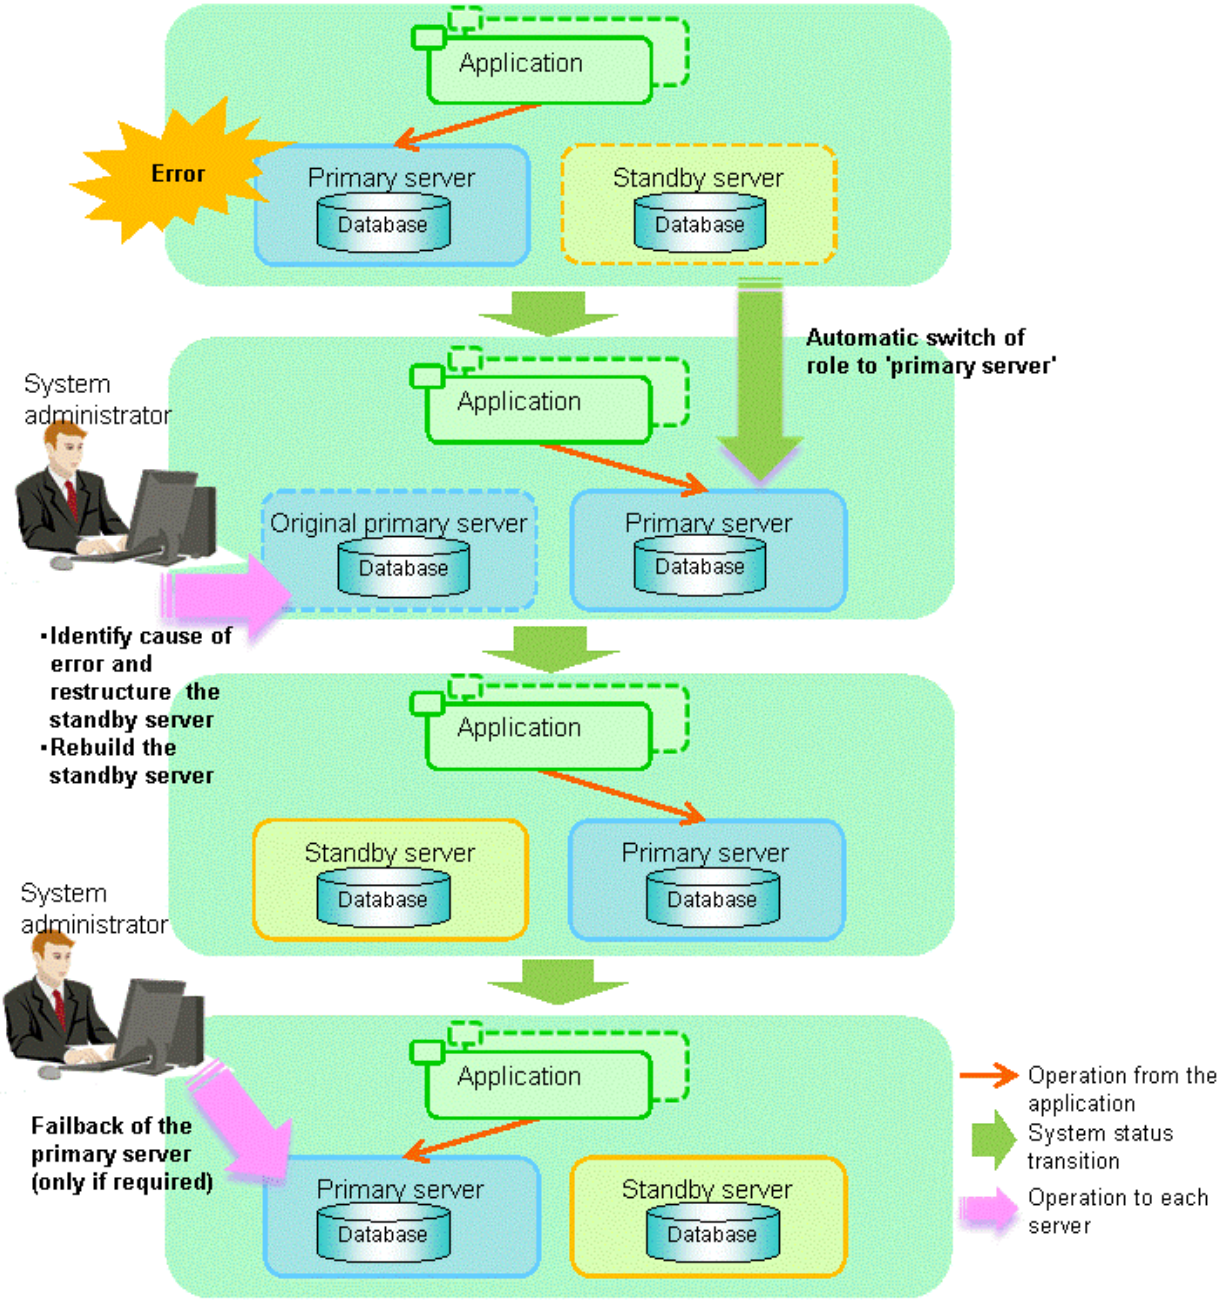
- After a switch has occurred as a result of an abnormality on the primary server, the database will not have a multiplexed configuration until the standby server is rebuilt. Remove the cause of the error as quickly as possible, and then rebuild the standby server.
- If the reference job was executed on the standby server, and the servers are switched because an error occurred on the primary server, the load is concentrated on the new primary server. Accordingly, pause the reference job on the original standby server, rebuild the original primary server as the new standby server, and then resume the reference job for the new standby server.
- If the instance on the new primary server is stopped before the original primary server where the error occurred is rebuilt as the new standby server, a split brain occurs at startup from the instance on the original primary server. Therefore, start the instance on the new primary server before rebuilding the standby server.

If the switch occurred and the server has started degrading, perform the following operations to recover the standby server and revert it to its original state:

- Identify Cause of Error and Restore the Standby Server
- Rebuild the Standby Server
- Failback of the Primary Server (only if required)

The flow of these operations is shown in the figure below.

Figure 4.1 Flow of operations



4.1.1.1 Identify Cause of Error and Restore the Standby Server

Perform the recovery according to the following procedure:

1. Stop Mirroring Controller
2. Recovery of the Mirroring Controller management directory
3. Identify cause of error and perform recovery

4.1.1.1.1 Stop Mirroring Controller

Execute the mc_ctl command in stop mode for the original primary server on which the error occurred.

```
Example)
```

```
> mc_ctl stop -M D:\mcdir\inst1
```

This also stops the instance that is required to perform the recovery.

Point

If the instance does not stop, refer to "Actions in Response to Failure to Stop an Instance" in the Operation Guide, and then stop the instance.

Then, specify the -e option in the above command to forcibly stop Mirroring Controller.

4.1.1.1.2 Recovery of the Mirroring Controller management directory

Copy the files in the Mirroring Controller management directory from the backup data, and then perform the recovery.

4.1.1.1.3 Identify cause of error and perform recovery

Refer to the event log of the primary server and the standby server to identify the cause of the error, and then perform recovery.

The following commands can be used to recover a standby server. Select depending on the recovery and the situation.

- pg_basebackup

  Creates a copy of all resources of the primary server instance.

- pg_rewind

  Creates a copy of only the updated files on the new primary server. For this reason, if this command is used to incorporate a new standby server, recovery time can be shortened. To use this command to build the original primary server as a new standby server, at least one of the following must be met:

  a. Checksums were enabled when an instance was created, or

  b. The wal_log_hints parameter of postgresql.conf was enabled when an instance was started.

  Additionally, full_page_writes must be enabled, which is its default value.

See

- Refer to "pg_basebackup" in "Reference" in the PostgreSQL Documentation for information on the pg_basebackup command.
- Refer to "pg_rewind" in "Reference" in the PostgreSQL Documentation for information on the pg_rewind command.

The example below executes the pg_rewind command to perform recovery by synchronizing data on the original primary server with the new primary server.

Information

If the pg_rewind command is executed immediately after promotion of the new primary server, the processing in steps 1 and 2 is required. If update-type SQL can be executed on the new primary server and checkpoint processing is executed after promotion, the processing in steps 1 and 2 will not be necessary.

1. Wait for the application of unapplied update transaction logs on the new primary server.

   Execute the SQL below on the new primary server, and wait until the result is false.

   ```
   # select pg_is_in_recovery();
   ```

   Example)

   ```
   > psql -h hostNameOfNewPrimaryServer -p portNumOfNewPrimaryServer -d dbName -c "select
   pg_is_in_recovery();"
   ```

Any database can be connected to.

2. Update the timeline ID.

   Execute checkpoint processing, and update the timeline ID.

```
> psql -h hostNameOfNewPrimaryServer -p portNumOfNewPrimaryServer -d dbName -c "checkpoint;"
```

   Any database can be connected to.

3. Create a copy of the new primary server instance in the original primary server (new standby server).

   Execute the pg_rewind command to synchronize the new standby server data with the new primary server.

   Example)

```
> pg_rewind -D D:\database\inst1 -R --source-server="user=userName host=newPrimaryServerHostName
port=newPrimaryServerPortNumber dbname=dbName application_name=newStandbyServerName"
```

Point

- Use the pg_rewind command with the -R option to create a standby.signal file. If you do not create the standby.signal file, the Mirroring Controller cannot be started as a standby server.
- If using a method that requires password authentication for connections to the primary server, you will need to ensure that authentication is performed automatically. If the -R option is specified for the pg_rewind command and the password parameter is specified for the --dbname option, the pg_rewind command will set the password in the primary_conninfo parameter in postgresql.auto.conf file, enabling connections to be performed automatically.

  If a password is not set in the primary_conninfo parameter in postgresql.auto.conf file, it will be necessary to create a password file (%APPDATA%postgresql\pgpass.conf), and then specify a password for the replication database.
- If you need to set a connection string other than host, port and application_name, include it in the setting of the primary_conninfo parameter.
- The primary_conninfo parameter should not be set in the postgresql.conf file, but only in the postgresql.auto.conf file using the pg_rewind command.

4. Specify parameters in the postgresql.conf file of the original primary server (new standby server).

   Set the parameters required for the standby server in postgresql.conf.

   Refer to "Table 2.5 Parameters" for information on the parameters to set in postgresql.conf.

Information

A new timeline is branched for the new primary server due to promotion, so 'latest' needs to be specified for the recovery_target_timeline parameter so that the old primary server (new standby server) follows the new primary server.

See

- Refer to "Hot Standby" in the PostgreSQL Documentation for details on the standby.signal file.
- Refer to "Setting Up a Standby Server" in the PostgreSQL Documentation for details on the primary_conninfo.

4.1.1.2 Rebuild the Standby Server

The starting of the recovered original primary server as the standby server is referred to as the "standby server rebuild".

Perform the following procedure:

1. If you are using a replication slot, create a communication replication slot on the primary server before rebuilding.

   Example)

   ```
   > psql -h primaryServerHostName -p primaryServerPortNumber -d databaseName -c "SELECT * FROM
   pg_create_physical_replication_slot('replicationSlotName')"
   ```

2. On the original primary server, start Mirroring Controller and the instance.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

   ```
   > mc_ctl start -M D:\mcdir\inst1
   ```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   Example)

   ```
   > mc_ctl start -M D:\mcdir\inst1 -F
   ```

   Point

   After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

3. If you are using a replication slot, replication slot may remain on the standby server. Delete the replication slot on the standby server side as needed.

   Example)

   ```
   > psql -h standbyServerHostName -p standbyServerPortNumber -d databaseName -c "SELECT * FROM
   pg_drop_replication_slot('replicationSlotName')"
   ```

   Information

   If unused replication slots remain on the standby server, WAL files may not be deleted on the standby server.

4.1.1.3 Failback of the Primary Server

To revert the primary server and standby server to the original server configuration after rebuilding the standby server, perform failback for the primary server.

Do this to execute the main job on the previous primary server.

Perform the following procedure:

1. Failback of the primary server

   Execute the mc_ctl command in switch mode on the primary server or the standby server.

   Example)

   ```
   > mc_ctl switch -M D:\mcdir\inst1
   ```

   After executing the mc_ctl command in switch mode, the status will be as follows:

   Example)

```
> mc_ctl status -M D:\mcdir\inst1
mirroring status
----------------
switched
server_id  host_role                  host        host_status   db_proc_status       disk_status
-------------------------------------------------------------------------------------------------
server1    primary                  192.0.2.100 normal        abnormal(postmaster) normal
server2    none(inactivated primary) 192.0.2.110 normal        abnormal(postmaster) normal
```

2. Stop the original primary server

   On the original primary server, execute the mc_ctl command in stop mode to stop Mirroring Controller and the instance.

   Example)

```
> mc_ctl stop -M D:\mcdir\inst1
```

3. Create a copy of the new primary server instance in the original primary server (new standby server)

   Execute the pg_basebackup command to create data in the new standby server by synchronizing with the new primary server.

   Example)

```
> pg_basebackup -D D:\database\inst1 -X fetch --waldir=E:\transaction\inst1 --progress --verbose
-R --dbname="application_name=standbyServerName" -h primaryServerHostName -p
primaryServerPortNumber
```

See

The procedure for copying the new primary server instance to the new standby server is the same as the procedure for setting up the new standby server.

Refer to "2.5.2 Creating, Setting, and Registering the Standby Server Instance", and then perform the recovery.

4. If you are using a replication slot, create a communication replication slot on the primary server before rebuilding.

   Example)

```
> psql -h primaryServerHostName -p primaryServerPortNumber -d databaseName -c "SELECT * FROM
pg_create_physical_replication_slot('replicationSlotName')"
```

5. Rebuild the standby server

   On the standby server, start Mirroring Controller and the instance.

   #### Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

```
> mc_ctl start -M D:\mcdir\inst1
```

   #### Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   Example)

```
> mc_ctl start -M D:\mcdir\inst1 -F
```

Point

After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

6. If you are using a replication slot, replication slot may remain on the standby server. Delete the replication slot on the standby server side as needed.

   Example)

```
> psql -h standbyServerHostName -p standbyServerPortNumber -d databaseName -c "SELECT * FROM
pg_drop_replication_slot('replicationSlotName')"
```

Information

If unused replication slots remain on the standby server, WAL files may not be deleted on the standby server.

4.1.2 Operations when the Server has Started Degrading after a Disconnection has Occurred

This section explains the operations when the server has started degrading after a disconnection has occurred.

Information

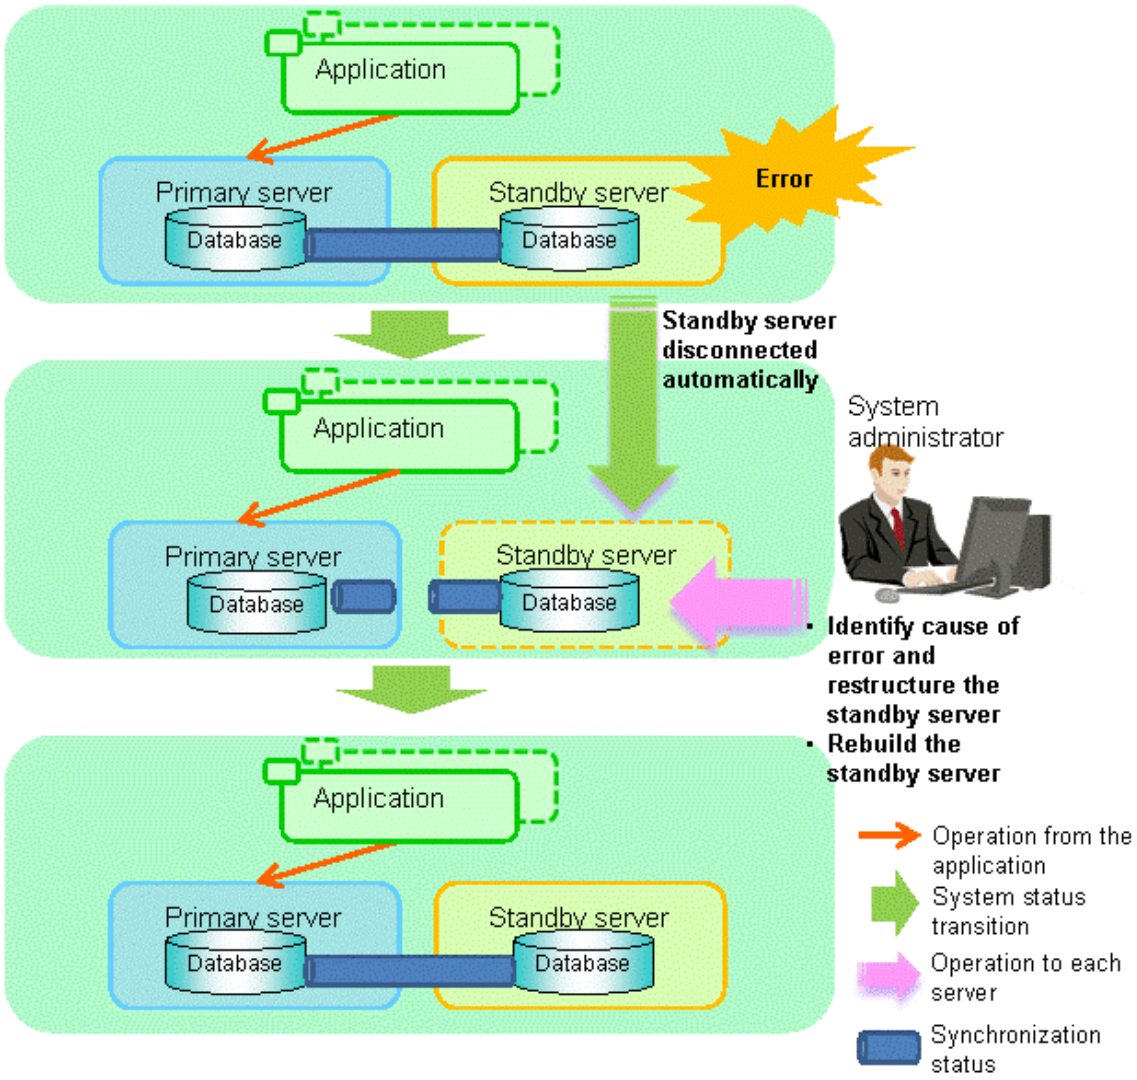
After a disconnection has occurred as a result of an abnormality on the standby server, the database will not have a multiplexed configuration until the standby server is rebuilt. Remove the cause of the error as quickly as possible, and then rebuild the standby server.

If the disconnection occurred and the server has started degrading, perform the following operations to recover the standby server and revert it to its original state:

- Identify Cause of Error and Restore the Standby Server
- Rebuild the Standby Server

The flow of these operations is shown in the figure below.

Figure 4.2 Flow of operations



4.1.2.1 Identify Cause of Error and Restore the Standby Server

Perform the recovery according to the following procedure:

1. Stop Mirroring Controller
2. Recovery of the Mirroring Controller management directory
3. Identify cause of error and perform recovery

4.1.2.1.1 Stop Mirroring Controller

Execute the mc_ctl command in stop mode for the standby server on which the error occurred.

Example)

```
> mc_ctl stop -M D:\mcdir\inst1
```

This also stops the instance that is required to perform the recovery.

Point

If the instance does not stop, refer to "Actions in Response to Failure to Stop an Instance" in the Operation Guide, and then stop the instance.

Then, specify the -e option in the above command to forcibly stop Mirroring Controller.

4.1.2.1.2 Recovery of the Mirroring Controller management directory

Copy the files in the Mirroring Controller management directory from the backup data, and then perform the recovery.

4.1.2.1.3 Identify cause of error and perform recovery

Refer to the event log of the primary server and the standby server to identify the cause of the error, and then perform recovery.

Execute the pg_basebackup command to perform recovery by synchronizing data in the primary server with the standby server.

```
Example)
```

```
> pg_basebackup -D D:\database\inst1 -X fetch --waldir=E:\transaction\inst1 --progress --verbose -R --
dbname="application_name=standbyServerName" -h primaryServerHostName -p primaryServerPortNumber
```

See

This recovery procedure is the same as the procedure for setting up the standby server.

Refer to "2.5.2 Creating, Setting, and Registering the Standby Server Instance", and then perform the recovery.

4.1.2.2 Rebuild the Standby Server

Start the Mirroring Controller and the instance of the standby server, and rebuild the standby server.

Enabling automatic switch/disconnection

As the instance administrator user, execute the mc_ctl command in start mode.

```
Example)
```

```
> mc_ctl start -M D:\mcdir\inst1
```

Disabling automatic switch/disconnection

As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

```
Example)
```

```
> mc_ctl start -M D:\mcdir\inst1 -F
```

Point

After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

4.1.3 Addressing Errors During Degrading Operation

This section explains how to address errors that may occur on the server on which operation is continuing during degrading operation triggered by a switch or disconnection.

If needing to recover from backup data

If it is necessary to recover the database using backup data due to data becoming corrupted from disk failure or user operation error, refer to the following for information on recovery to database multiplexing mode:

- Action Required when All Database Servers or Instances Stopped
- Recovering from an Incorrect User Operation

If a temporary error occurs

If a temporary error occurs, such as due to a high load on the server or insufficient system resources, remove the cause of the error and restart Mirroring Controller, and then refer to the following for details on recovery to database multiplexing mode:

- Operations when the Server has Started Degrading after a Switch has Occurred
- Operations when the Server has Started Degrading after a Disconnection has Occurred

See

Refer to "3.2.1 Starting Mirroring Controller" and "3.2.2 Stopping Mirroring Controller" for information on restarting Mirroring Controller.

4.2 Action Required when Automatic Switch Fails

If the system behavior is unstable, for example there are insufficient temporary system resources, the Mirroring Controller automatic switch may fail.

Perform the switch manually using one of the following methods:

- Refer to the procedures in "3.4 Manually Switching the Primary Server".
- In the standby server, execute the mc_ctl command in switch mode with the -force option specified to forcibly perform the switch.

  Example)

```
> mc_ctl switch -M D:\mcdir\inst1 --force
```

Point

- Even if connection cannot be established between database servers, it is possible to fence the primary server and forcibly switch by executing the mc_ctl command in switch mode with the --force option specified.
- The primary server is not fenced in the cases below, so stop Mirroring Controller and instances of the primary server database in advance:
  - The --no-fencing option is specified when performing forced switch.
  - The heartbeat_error_action parameter in *serverIdentifier*.conf is set to "message" and the fencing command is not configured to be used (the fencing_command parameter is omitted in *serverIdentifier*.conf).
  - The heartbeat_error_action parameter in *serverIdentifier*.conf is set to "fallback".

See

Recovery to database multiplexing mode

Refer to "4.1.1.2 Rebuild the Standby Server" and "4.1.1.3 Failback of the Primary Server" for information on recovery to database multiplexing mode.

4.3 Action Required when Automatic Disconnection Fails

If the system behavior is unstable, for example there are insufficient system resources such as available memory or free disk space, automatic disconnection using Mirroring Controller may not be possible.

Perform the disconnection manually using one of the following methods:

- Refer to the procedures in "3.5 Manually Disconnecting the Standby Server".
- In the primary server, execute the mc_ctl command in detach mode to perform forced disconnection.

  Example)

```
> mc_ctl detach -M D:\mcdir\inst1
```

Point

- Even if connection cannot be established between database servers, it is possible to fence the standby server and forcibly disconnect by executing the mc_ctl command in detach mode.
- In the cases below, stop Mirroring Controller and instances of the standby server database in advance so that the standby server is not fenced:
  - The --no-fencing option is specified when performing forced disconnection.
  - The heartbeat_error_action parameter in *serverIdentifier*.conf is set to "message" and the fencing command is not configured to be used (the fencing_command parameter is omitted in *serverIdentifier.conf*).
  - The heartbeat_error_action parameter in *serverIdentifier*.conf is set to "fallback".

See

Recovery to database multiplexing mode

Refer to "4.1.2.2 Rebuild the Standby Server" for information on recovery to database multiplexing mode.

4.4 Action Required when All Database Servers or Instances Stopped

This section explains what happens when all database servers or instances on the database server have stopped, so jobs cannot continue.

See

Recovery to database multiplexing mode

Refer to "4.1.1.2 Rebuild the Standby Server" and "4.1.1.3 Failback of the Primary Server" for information on recovery to database multiplexing mode.

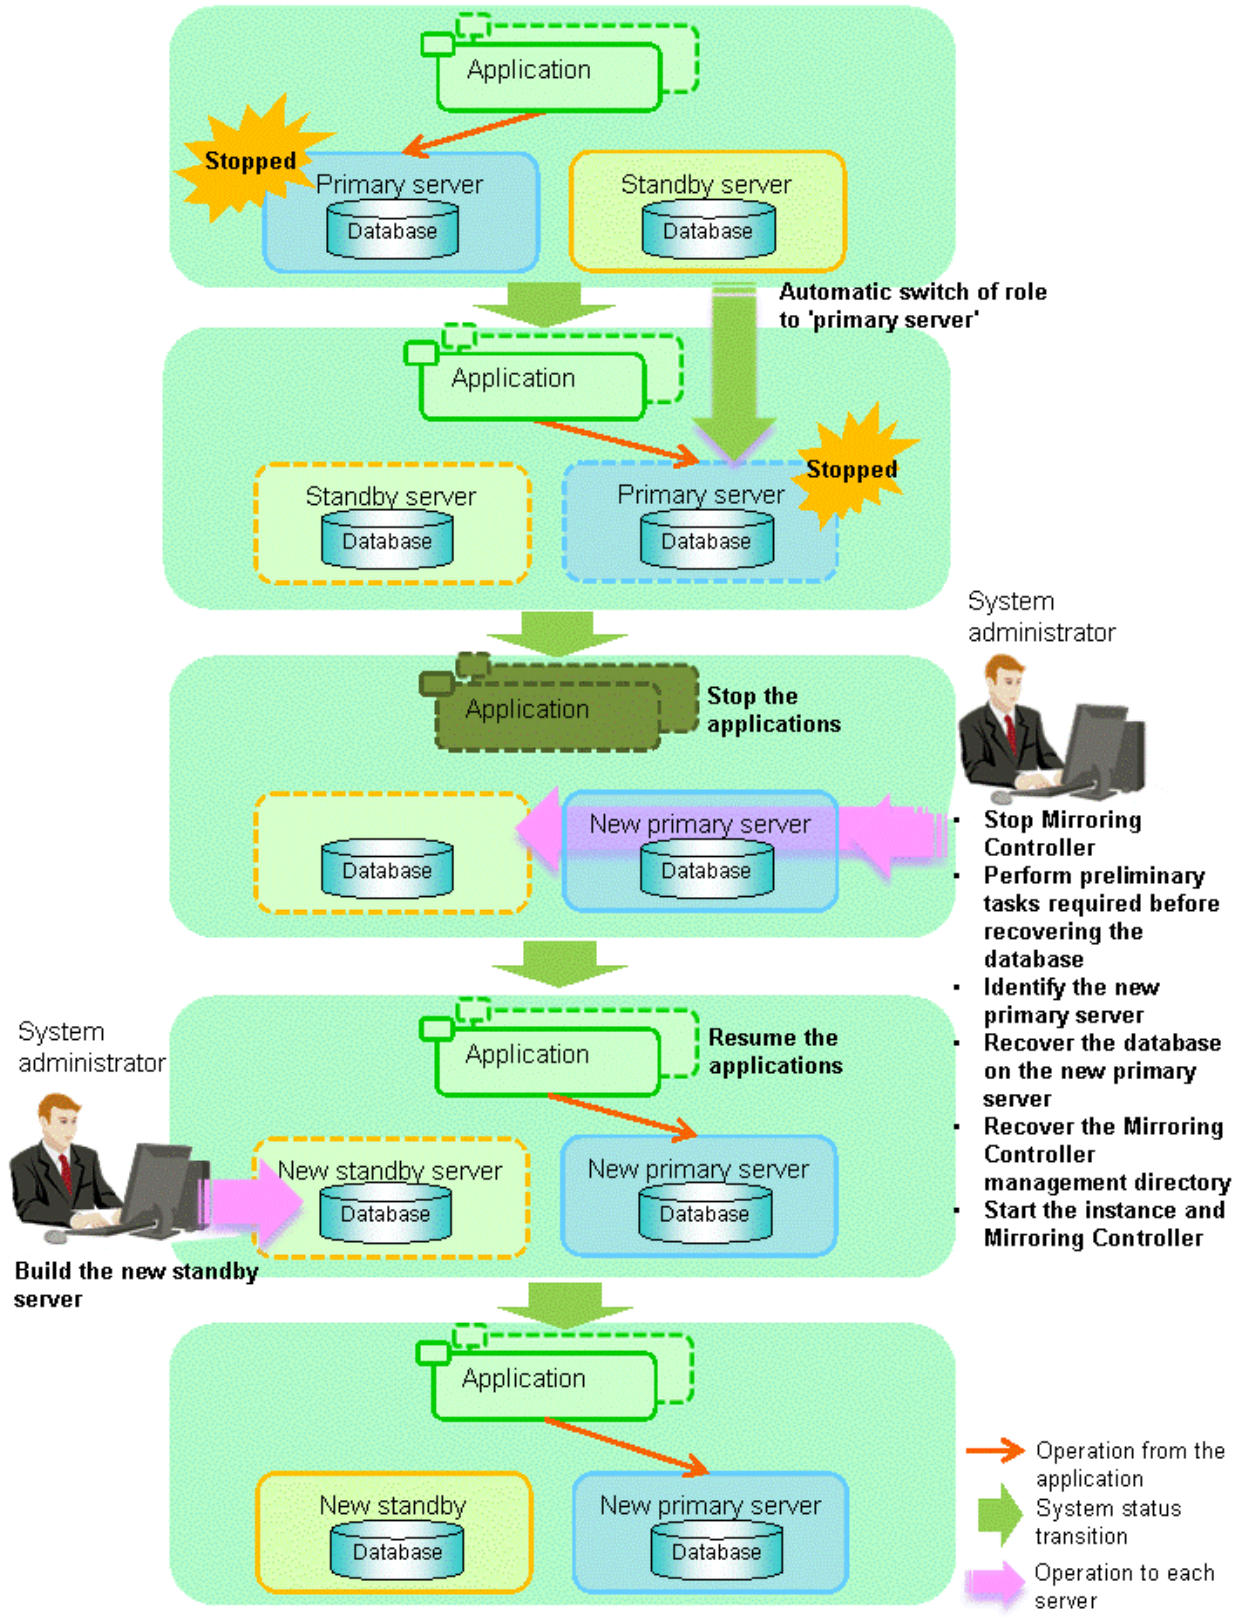
Overview of recovery operations

After recovering the database to the state immediately prior to the failure on a specific server comprising the database multiplexing system, restore the system.

In other words, after specifying the server on which the database is to be recovered and then recovering it as the new primary server, configure all other servers as new standby servers.

The flow of these recovery operations is shown in the figure below.

Figure 4.3 Flow of recovery operations



Perform the following procedure.

1. Stop applications

   Stop running applications.

2. Stop Mirroring Controller

   Execute the mc_ctl command in stop mode on all servers that comprise the database multiplexing system.

   Example)

```
> mc_ctl stop -M D:\mcdir\inst1
```

   Point

   Forcibly stop Mirroring Controller

   If Mirroring Controller does not stop, execute the mc_ctl command in stop mode with the -e option specified.

   Example)

```
> mc_ctl stop -M D:\mcdir\inst1 -e
```

3. Perform prerequisite tasks before recovering the database

   First, refer to "Actions when an Error Occurs" in the Operation Guide, and then identify the cause of the error and perform recovery of the disk on which the failure occurred, etc.

4. Identify the new primary server

   Perform the following operations on all servers comprising the database multiplexing system, and check the server containing the backup data that shows the latest date. This server will become the new primary server, on which the database is to be recovered.

   Example)
   In the example below, the pgx_rcvall command is executed with the -l option specified and the backup data that shows the latest date is identified.

```
> pgx_rcvall -l -D D:\database\inst1
Date                    Status          Dir
2013-07-01 13:30:40     COMPLETE        E:/backup/inst1/2013-07-01_13-30-40
```

5. Recover the database on the new primary server

   Recover the database using the recovery method that uses the pgx_rcvall command based on the backup data.

   a. Perform the following operations on all servers comprising the database multiplexing system, and check the server containing the archive log and mirrored transaction log that show the latest date.

      Example)
      In the example below, the archive log and mirrored transaction log that show the latest date are identified.

```
> dir /OD <backupDataStorageDir>\*_wal
```

   b. If the server containing the latest archive log and mirrored transaction log is different to the new primary server identified in step 4, all files and directories under the directory shown below are copied and written to the backup storage destination directory on the new primary server.

      Deployment destination directory of the archive log and mirrored transaction log

```
<backupDataStorageDir>\*_wal
```

   c. Execute the pgx_rcvall command on the new primary server, specifying the backup storage destination directory of the new primary server.

      Example)
      In the example below, the pgx_rcvall command is executed with the -B option specified.

```
> pgx_rcvall -B E:\backup\inst1 -D D:\database\inst1
```

See

Refer to "Actions when an Error Occurs" in the Operation Guide for information on the pgx_rcvall command.

6. Recover the Mirroring Controller management directory

   Copy the files in the Mirroring Controller management directory from the backup data on the new primary server, and then perform the recovery.

7. Start the instance and Mirroring Controller

   Start the instance and Mirroring Controller on the new primary server.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

```
> mc_ctl start -M D:\mcdir\inst1
```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   Example)

```
> mc_ctl start -M D:\mcdir\inst1 -F
```

   ### Point

   After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

8. Resume applications

   Resume execution of applications.

9. Build the new standby server

   Refer to "2.5 Setting Up the Standby Server" for information on building (setting up) a standby server from the primary server.

Point

It is not necessary to repeat steps that have already been performed, such as registering to Windows services.

4.5 Recovering from an Incorrect User Operation

This section describes how to recover an instance when data has been corrupted due to incorrect user operation.

For example, when data has been corrupted due to incorrect user operation, such as data being unintentionally changed or deleted by an application or command, it is necessary to restore the original data on the primary server and resynchronize with the standby server.

Use the following procedure to perform recovery.

1. Identify the primary server

   Execute the mc_ctl command in status mode on each server, and search for a server for which "primary" or "none(inactivated primary)" is displayed.

2. Stop the applications and commands that caused the incorrect operation to occur

   Stop applications and commands that are running on the primary server. This will minimize the impact caused by the incorrect data.

Also, if any applications used for reference by the standby server are running, stop them too.

3. Stop the instance and Mirroring Controller

   Stop the instance and Mirroring Controller on both the primary server and standby server.

   Example)

```
$ mc_ctl stop -a -M D:\mcdir\inst1
```

4. Recover the database on the primary server

   Recover the database using the recovery method in which the pgx_rcvall command uses the backup data to recover the database to a restore point prior to the time when the incorrect operation was performed.

   See

   Refer to "Recovering from an Incorrect User Operation" in the Operation Guide for information on using the pgx_rcvall command to recover the database to a restore point, and then perform only the database recovery procedure while the instance is in a stop state.

5. Start the instance and Mirroring Controller

   Start the instance and Mirroring Controller on the primary server.

   Enabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode.

   Example)

```
> mc_ctl start -M D:\mcdir\inst1
```

   Disabling automatic switch/disconnection

   As the instance administrator user, execute the mc_ctl command in start mode with the -F option specified.

   Example)

```
> mc_ctl start -M D:\mcdir\inst1 -F
```

   Point

   After Mirroring Controller is started, automatic switch/disconnection can be enabled or disabled using the enable-failover or disable-failover mode of the mc_ctl command.

6. Build the new standby server

   Refer to "2.5 Setting Up the Standby Server" for information on building (setting up) a standby server from the primary server.

   Point

   It is not necessary to repeat steps that have already been performed, such as registering to Windows services.

Chapter 5 Managing Mirroring Controller Using WebAdmin

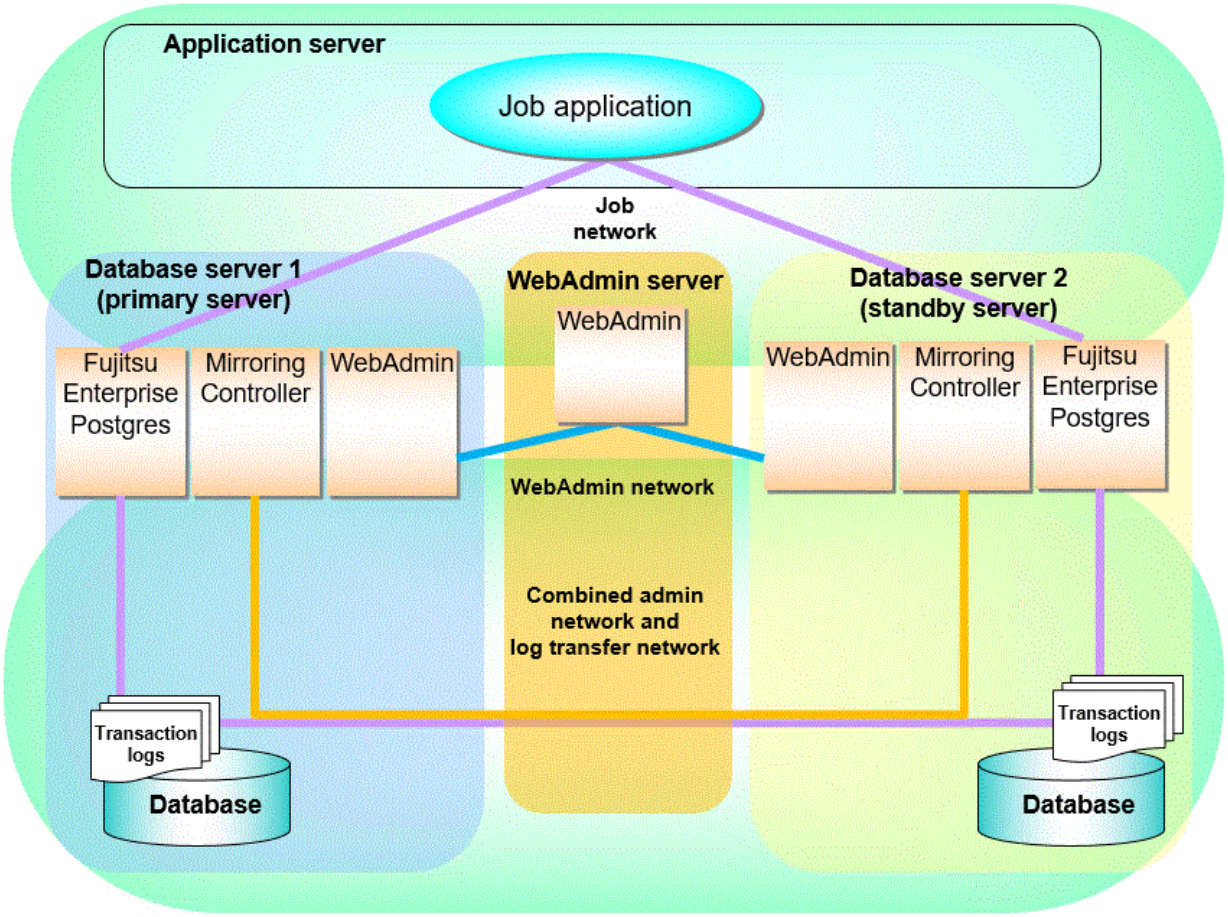
This chapter describes how to set up and manage Mirroring Controller in a streaming replication cluster using WebAdmin.

Mirroring Controller can be used to monitor a streaming replication cluster and perform automatic switching or disconnect synchronous replication when there is an error.

WebAdmin can be used to set up Mirroring Controller in an existing replication cluster. Mirroring Controller can be set up for either synchronous standby instances or asynchronous standby instances.

The configuration of the database multiplexing system built using WebAdmin is shown below:

Figure 5.1 Configuration of database multiplexing operation system using WebAdmin



Point

- If you set up the arbitration server using WebAdmin, install WebAdmin on the arbitration server.
- If Mirroring Controller is set up to the replication cluster using WebAdmin, the network with the host name (or IP address) specified in [Host name] will be used as the admin network and the log transfer network.
- To use a network other than the job network as the log transfer network, before building the replication cluster specify a host name other than the job network one in [Host name].

5.1 Mirroring Controller Setup

Perform the following procedure to set up Mirroring Controller in a streaming replication cluster.

1. In the [Instances] tab, select the standby instance on which Mirroring Controller needs to be set up.

2. Click .

3. Enter the information for the Mirroring Controller to be set up.

   - [Enable automatic switch over]: Toggles the automatic switch/disconnection functionality. Select "Yes". The default is "No".
   - [Mirroring Controller management directory]: Directory where the Mirroring Controller configuration files will be stored. When the [Mirroring Controller management directory] is entered, WebAdmin will search the Mirroring Controller configuration files in the entered directory based on the [Data storage path] of the corresponding DB instance. If Mirroring Controller configuration files are found, the Mirroring Controller fields will be auto filled.
   - [Mirroring Controller port]: Port number of Mirroring Controller. Note that if the Windows firewall feature is enabled, you must enable the port number of Mirroring Controller. Refer to "E.2 Windows Firewall Settings" for details.
   - [Heartbeat interval (milliseconds)]: Number of milliseconds between two consecutive heartbeat checks. The default is "800".
   - [Heartbeat timeout (seconds)]: Number of seconds for the heartbeat timeout. The default is "1".
   - [Heartbeat retry]: Number of retries for heartbeat monitoring, before failover occurs. The default is "2".
   - [Heartbeat error action]: Operation when a heartbeat abnormality is detected. The default is "Fallback".

     When using FUJITSU Enterprise Postgres 10 or 11 instance which was created with FUJITSU Enterprise Postgres WebAdmin 10 or 11, the mode in the [Heartbeat error action] for Mirroring Controller setup cannot be changed.

     When setting up Mirroring Controller for FUJITSU Enterprise Postgres 9.5 and 9.6 instances, the [Heartbeat error action] is not supported and therefore is not displayed.

   When the [Heartbeat error action] is set to "Arbitration", the following extra items are displayed:

   - [Arbitration network IP address]: IP address of the arbitration network.
   - [Mirroring Controller Arbitration port]: Port number of Mirroring Controller for communicating with the arbitration server.

   The [Arbitration server configuration] section is also displayed with the following items. The [Arbitration server configuration] will not be auto filled.

   - [Location]: Location of the arbitration server. "Local" or "Remote" can be selected depending on your configuration.

     If the arbitration server and WebAdmin server are located on the same server, you can select "Local" and the following items are displayed:

     - [Arbitration management directory]: Directory where the arbitration server configuration files will be stored.
     - [Arbitration server host or IP address]: Host name or IP address of the arbitration server.
     - [Arbitration process port]: Port number for the arbitration process.
     - [Fencing command]: Full path of the fencing command that fences a database server when an abnormality is detected.

     If "Remote" is set for the item, the items below are displayed in addition to the above items.

     - In the [Arbitration server configuration] section, [Operating system credential] is displayed where you can enter the following information. Operating system credential (User name, Password) should not contain hazardous characters. Refer to "Appendix F WebAdmin Disallow User Inputs Containing Hazardous Characters".

       [User name]: User name to access the arbitration server.

       [Password]: Password to access the arbitration server.

     - In the [Remote WebAdmin for Arbitration server] section, the following items are displayed:

       [Remote WebAdmin address]: IP address of the remote WebAdmin installed on the arbitration server.

       [Remote WebAdmin port]: Port number for the WebAdmin installed on the arbitration server.

   When the [Heartbeat error action] is set to "Command", the following extra items are displayed:

- [Arbitration command]: Full path of the arbitration command to be executed when an abnormality is detected.
- [Fencing command]: Full path of the fencing command that fences a database server when an abnormality is detected.

4. Click to set up Mirroring Controller.
5. Upon successful completion, Mirroring Controller will be started on master and standby instances.

After the Mirroring Controller has been set up, ([Edit Mirroring Controller] button) and ([Mirroring Controller Configuration] button) are available. These buttons are displayed only when FUJITSU Enterprise Postgres 10 or later instances are created with FUJITSU Enterprise Postgres WebAdmin 12 or later.

For FUJITSU Enterprise Postgres 9.5 and 9.6 instances, the [Heartbeat error action] will not be displayed.

When the [Heartbeat error action] is "Arbitration", the following information is displayed: whether the arbitration status is "online" or "offline", the arbitration server IP address and the arbitration process port.

5.2 Edit Mirroring Controller Setup

Settings made in "5.1 Mirroring Controller Setup" can be updated in either the master instance or a standby instance using WebAdmin.

Perform the following procedure to edit Mirroring Controller configuration:

1. In the [Instances] tab, select the instance for which the Mirroring Controller configuration is to be edited.
2. Click .
3. Enter the information for the Mirroring Controller to be updated. Refer to "5.1 Mirroring Controller Setup".
4. Click to update the Mirroring Controller.
5. Upon successful completion, Mirroring Controller will be started on master and standby instances.

Editing and saving the [Edit Mirroring Controller] page will reset all other settings that are not listed on this page to default values.

5.3 Mirroring Controller Configuration

The information related to Mirroring Controller monitoring and control (refer to "A.4.1 Server Configuration File for the Database Servers") and the information related to arbitration and control of the Mirroring Controller arbitration process (refer to "A.4.2 Arbitration Configuration File") can be set using WebAdmin. You can view and update the configuration on either the master instance or the standby instance.

Perform the following procedure:

1. In the [Instances] tab, select the instance for the Mirroring Controller configuration you want to view.
2. Click to view the Mirroring Controller configuration.
3. Click to show the editing page for the Mirroring Controller configuration. The Mirroring Controller configurations defined during [Mirroring Controller Setup] are read-only on this page. Refer to "5.1 Mirroring Controller Setup".

   Additionally, refer to the "Appendix A Parameters" for information about the settings and the corresponding parameter names.

   The items common to all [Heartbeat error action] are:

   - Target DB
   - Core file path
   - Remote call timeout (milliseconds)
   - Agent alive timeout (seconds)
   - DB instance check interval (milliseconds)
   - DB instance check timeout (seconds)

- DB instance check retry
- DB instance timeout action
- Disk check interval (milliseconds)
- Disk check retry
- Tablespace directory error action
- Post-switch command
- Post-promote command
  (Post-promote command is replaced in FUJITSU Enterprise Postgres 12. The Post-promote command is still valid and will be displayed when it is used in the server configuration file of Mirroring Controller.)
- Post-attach command
- Pre-detach command
- State transition command timeout (seconds)
- Check synchronous standby names validation

When the [Heartbeat error action] is set to "Arbitration", the following extra items are displayed:

- Arbitration timeout (seconds)
- Arbiter alive interval (milliseconds)
- Arbiter alive retry
- Arbiter alive timeout (seconds)
- Arbiter connect interval (milliseconds)
- Arbiter connect timeout (seconds)
- Fencing command
- Fencing command timeout (seconds)
- Shutdown detached synchronous standby

When the [Heartbeat error action] is set to "Arbitration", the [Arbitration server configuration] section is displayed with the following items:

- Core file path
- Fencing command timeout (seconds)
- Heartbeat interval (milliseconds)
- Heartbeat timeout (seconds)
- Heartbeat retry

When the [Heartbeat error action] is set to "Command", the following extra items are available:

- Fencing command timeout (seconds)
- Arbitration command timeout (seconds)
- Shutdown detached synchronous standby

When the [Heartbeat error action] is set to "Message", the following extra items are available:

- Fencing command
- Fencing command timeout (seconds)

In addition, the following configurations are provided:

- DB instance JDBC connection SSL parameters
- DB instance libpq connection SSL parameters

4. Click to update the Mirroring Controller configurations.

5.4 Stopping Mirroring Controller

Mirroring Controller can be stopped either in master instance or in standby instance using WebAdmin.

Perform the following procedure to stop Mirroring Controller.

1. In the [Instances] tab, select the instance where to stop Mirroring Controller.
2. Click .
3. In the confirmation dialog box, click [Yes].

Mirroring Controller will be stopped on the selected instance. The Mirroring Controller status will be updated, and a confirmation message entry will be displayed in the [Message] section.

5.5 Starting Mirroring Controller

Mirroring Controller can be started either in master instance or in standby instance using WebAdmin.

Perform the following procedure to start Mirroring Controller.

1. In the [Instances] tab, select the instance where to start Mirroring Controller.
2. Click .
3. In the confirmation dialog box, select the desired failover mode, and then click [Yes].

Mirroring Controller will be started on the selected instance. The Mirroring Controller status will be updated, and a confirmation message entry will be displayed in the [Message] section.

5.6 Disabling Failover Mode

Disabling failover mode in Mirroring Controller disables automatic switch/disconnection between master and standby instances.

Perform the following procedure to disable failover mode.

1. In the [Instances] tab, select the instance.
2. Click .
3. In the confirmation dialog box, click [Yes].

Failover mode will be disabled in Mirroring Controller. The Mirroring Controller status will be updated and a confirmation message entry will be displayed in the [Message] section.

5.7 Enabling Failover Mode

Enabling failover mode in Mirroring Controller enables automatic switch/disconnection between master and standby instances.

Perform the following procedure to enable failover.

1. In the [Instances] tab, select the instance.

2. Click .

3. In the confirmation dialog box, click [Yes].

Failover mode will be enabled in Mirroring Controller. The Mirroring Controller status will be updated and a confirmation message entry will be displayed in the [Message] section.

5.8 Deleting Mirroring Controller Setup

Deleting Mirroring Controller setup removes its setup from master and standby instances.

1. In the [Instances] tab, select the instance.

2. Click .

3. In the confirmation dialog box, click [Yes].

Mirroring Controller setup will be removed from the cluster. The cluster status will be updated and a confirmation message entry will be displayed in the [Message] section.

For the instances in FUJITSU Enterprise Postgres 12 or later, WebAdmin does not delete the Mirroring Controller management directory and the configuration files.

5.9 Status Update after Failover

When Mirroring Controller performs a failover, standby instance will be promoted to standalone instance. The Mirroring Controller setup will be removed from both standby and master instances.

The following scenario describes one of the ways in which failover can be triggered, and the results achieved by the use of Mirroring Controller in WebAdmin.

1. In the [Instances] tab, select the master instance "inst1".

2. Click .

3. In the confirmation dialog box, the warning "This instance is being monitored by Mirroring Controller. Stopping the instance may result in cluster failover." is displayed.

4. Choose the stop mode and click [Yes].

   In the server, the following takes place:

   a. The master instance is stopped.

   b. Failover is triggered in Mirroring Controller.

   c. The Mirroring Controller setup is removed from both master and standby instances

   d. Standby instance is promoted to standalone.

5. When the instance is refreshed in WebAdmin, the latest status of the instances will be displayed.

Information

When failover is performed, the Mirroring Controller setup is removed from both master and standby instances. Therefore, to manage the Mirroring Controller using WebAdmin again, create the standby instance and set up Mirroring Controller.

Refer to "Creating a Standby Instance" in the Operation Guide for details.

Refer to "5.1 Mirroring Controller Setup" for details.

5.10 Action Required when an Error Occurs in the Combined Admin Network and Log Transfer Network

Communication errors may temporarily occur in the network used as the admin network and log transfer network due to reasons such as high load on the server or insufficient system resources. Because of this, there is a risk of causing a split-brain situation by mistake even though the server has no issues.

Split brain is a phenomenon in which both servers temporarily operate as primary servers, causing data updates to be performed on both servers.

Point

The admin network is important because Mirroring Controllers use it to confirm the status of each server.

The log transfer network is also important to maintain the data freshness.

Therefore, use network configurations resistant to faults for these networks by using the network redundancy channel bonding feature provided by the operating system or network driver vendor.

How to detect split brain using WebAdmin

If the conditions below are met, split brain may occur. Refer to "Split-brain detection method" and "How to recover from a split-brain" in "Appendix D Notes on Performing Automatic Degradation Immediately after a Heartbeat Abnormality" and take the actions described.

1. A standby instance is selected in the [Instances] tab, and
2. "Standalone" is displayed in [Instance type], and
3. A master instance is selected in the [Instances] tab, and
4. "Standalone" is displayed in [Instance type].

5.11 Performing Automatic Degradation Using the Arbitration Server

If database multiplexing is performed using WebAdmin, it is also possible to perform automatic degradation using the arbitration server. In such cases, it is necessary to perform tasks on the database server and the arbitration server after setting up Mirroring Controller in WebAdmin.

Tasks on the arbitration server

Perform setup of the arbitration server using Mirroring Controller commands.

1. Set up the arbitration server.

   Refer to "2.3 Setting Up the Arbitration Server" in "Chapter 2 Setting Up Database Multiplexing Mode" for information on how to set up the arbitration server.

Tasks on the database server

Change some of the settings after setting up Mirroring Controller in WebAdmin.

1. Set up Mirroring Controller in WebAdmin.

   Refer to "5.1 Mirroring Controller Setup" for details.

2. Use WebAdmin to stop Mirroring Controller on the master and standby instances.

   Refer to "5.4 Stopping Mirroring Controller" for details.

3. Edit the network configuration file of the master and standby instances, and add the arbitration server information.

   The network configuration file is network.conf, which exists in the Mirroring Controller management directory specified during Mirroring Controller setup. Refer to "A.3 Network Configuration File" for details.

   A definition example of network.conf is shown below.

   ```
   Example:
   The port number of the database server to be used as the arbitration network is set to "27541".
   The ID of the server of the Mirroring Controller arbitration process is set to "arbiter", and its
   port number is set to "27541".
   ```

   ```
   dbsvm27500 192.0.2.100,192.0.3.100 27540,27541 server
   dbsvs27500 192.0.2.110,192.0.3.110 27540,27541 server
   arbiter 192.0.3.120 27541 arbiter
   ```

   Information

   Ensure that the port numbers set for the database server and the arbitration server do not conflict with other software. In addition, do not configure the same segment for the admin network and the arbitration network.

   Point

   - If the server type is "server", two IP addresses or host names, and two port numbers need to be specified in the following order:
     - IP address or host name of the database server used as the admin network
     - IP address or host name of the database server used as the arbitration network
     - Port number of the database server used as the admin network
     - Port number of the database server used as the arbitration network
   - If the server type is "arbiter", specify the IP address or host name set for the my_address parameter and the port number set for the port parameter in arbitration.conf of the arbitration server.
   - When using the admin network and arbitration network together, the following IP addresses or host names must be assigned the same values.
     - IP address or host name of the database server used as the admin network
     - IP address or host name of the database server used as the arbitration network

     Example)
     Here is an example where the server identifiers for the primary server and standby server are "server1" and "server2", with port numbers "27540" and "27541", and the server identifier for the Mirroring Controller arbitration process is "arbiter", with port number "27541".

     ```
     server1 192.0.2.100,192.0.2.100 27540,27541 server
     server2 192.0.2.110,192.0.2.110 27540,27541 server
     arbiter 192.0.2.120 27541 arbiter
     ```

4. Edit the server configuration file of the master and standby instances, and add the parameters required for automatic degradation using the arbitration server.

   The server configuration file is *instanceName*.conf or *instancePort*.conf, which exists in the Mirroring Controller management directory specified during Mirroring Controller setup.

   To perform automatic degradation using the arbitration server, set the heartbeat_error_action parameter to "arbitration".

   Refer to "A.4.1 Server Configuration File for the Database Servers" for information on other parameters.

5. Use WebAdmin to start Mirroring Controller on the master and standby instances.

   Refer to "5.5 Starting Mirroring Controller" for details.

Common tasks

1. Use the Mirroring Controller command to check the connection status from the database server or the arbitration server.

   Refer to "2.8 Checking the Connection Status" for information on how to check the connection status.

Appendix A Parameters

This appendix describes the configuration files and parameters required by the database multiplexing mode.

See

Refer to "Server Configuration" in the PostgreSQL Documentation for information on the postgresql.conf file.

A.1 Parameters Set on the Primary Server

The content for the parameters set in the postgresql.conf file of the primary server is shown in the table below.

Table A.1 postgresql.conf file

Parameter	Value set	Explanation
wal_level	replica or logical	Specify the output level for the transaction log. Specify "logical" when logical decoding is also to be used.
max_wal_senders	2 or more	Specify "2" when building a Mirroring Controller cluster system. When additionally connecting asynchronous standby servers to the cluster system, add the number of simultaneous connections from these standby servers.
synchronous_standby_names	'*standbyServerName*'	Use single quotation marks (') to enclose the name that will identify the standby server. Any name can be specified. Do not change this parameter while Mirroring Controller is running. Do not specify multiple names to this parameter as the Mirroring Controller can manage only one standby server.
synchronized_standby_slots	'*physicalReplicationSlotName*'	Specify this parameter if the primary server will be a logical replication publication. Setting this parameter ensures that the subscriber is updated after WAL is sent to the standby server. This allows logical replication to continue if the primary server fails and the standby server is promoted. Do not change this parameter while the Mirroring Controller is running. Because the Mirroring Controller can manage only one standby server, do not specify multiple names for this parameter.
hot_standby	on	Specify whether queries can be run on the standby server.
wal_keep_size	WAL save size (megabytes)	If a delay exceeding the value set in this parameter occurs, the WAL segment required later by the primary server may be deleted. Additionally, if you stop a standby server (for maintenance, for example), consider the stop time and set a value that will not cause the WAL segment to be deleted. Refer to "Estimating Transaction Log Space Requirements" in the Installation and Setup Guide for Server for information on estimating the WAL save size.

Parameter	Value set	Explanation
wal_log_hints	on	When using the pg_rewind command to recover a standby server, specify this parameter or enable checksums when executing the initdb command.
wal_sender_timeout	Timeout (milliseconds)	Specify the time period after which it is determined that the receiver process (walreceiver) of the transaction log is in an abnormal state on the primary server. The specified value must be larger than the value set for the wal_receiver_status_interval parameter set in the postgresql.conf file of the standby server. By aligning this value with the value for the database process heartbeat monitoring time, you can unify the time after which it is determined that an error has occurred.
wal_receiver_timeout	Timeout (milliseconds)	Specify the time period after which it is determined that an error has occurred when the transaction log was received on the standby server. By aligning this value with the value for the database process heartbeat monitoring time, you can unify the time after which it is determined that an error has occurred.
archive_mode	on	Specify the archive log mode.
archive_command	'cmd /c ""installDir\\bin\ \pgx_walcopy.cmd" "%p" "backupDataStorageDestinationDir \\archived_wal\\%f"""	Specify the command and storage destination to save the transaction log.
backup_destination	Backup data storage destination directory	Specify the name of directory where to store the backup data. Set the permissions so that only the instance administrator user can access the specified directory. Specify the same full path on all servers, so that the backup data of other servers can be used to perform recovery.
listen_addresses	Primary server IP address, host name, or "*"	Specify the IP address or host name of the primary server. Specify the IP address or corresponding host name that will be used to connect to the log transfer network. The content specified is also used to allow connections from client applications. To receive the connection and the transaction log from any client or standby server, specify "*". Refer to "Connections and Authentication" in the PostgreSQL Documentation for details.
max_connections	Number of simultaneous client connections to the instance + superuser_reserved_connections value	The value specified is also used to restrict the number of connections from client applications and the number of connections for the management of instances. Refer to "When an Instance was Created with the initdb Command" in the Installation and Setup Guide for Server, and "Connections and Authentication" in the PostgreSQL Documentation, for details.
superuser_reserved_connections	Add the number of simultaneous executions of mc_ctl status (*1) + 2	Specify the number of connections reserved for connections from database superusers.

Parameter	Value set	Explanation
		Add the number of connections from Mirroring Controller processes. Also reflect the added value in the max_connections parameter.
restart_after_crash	off	If "on" is specified, or the default value is used for this parameter, behavior equivalent to restarting Fujitsu Enterprise Postgres, including crash recovery, will be performed when some server processes end abnormally. However, when database multiplexing monitoring is used, a failover will occur after an error is detected when some server processes end abnormally, and the restart of those server processes is forcibly stopped. Specify "off" to prevent behavior such as this from occurring for no apparent reason.
synchronous_commit	on or remote_apply	Specify up to what position WAL send is to be performed before transaction commit processing returns a normal termination response to a client. Set "on" or "remote_apply" to prevent data loss caused by operating system or server down immediately after a switch or switch.
recovery_target_timeline	latest	Specify "latest" so that the new standby server (original primary server) will follow the new primary server when a switch occurs. This parameter is required when the original primary server is incorporated as a new standby server after the primary server is switched.

*1: Number of simultaneous executions of the mc_ctl command in the status mode.

A.2 Parameters Set on the Standby Server

This section explains the content of the file and parameters set on the standby server. After editing postgresql.conf file, start the instance.

The content for the parameters specified in postgresql.conf file is shown in the table below.

Table A.2 postgresql.conf file

Parameter	Value set	Explanation
wal_level	replica or logical	Specify the output level for the transaction log. Specify "logical" when logical decoding is also to be used.
max_wal_senders	2 or more	Specify "2" when building a Mirroring Controller cluster system. When additionally connecting asynchronous standby servers to the cluster system, add the number of simultaneous connections from these standby servers.
synchronous_standby_names	'*primaryServerName*'	Use single quotation marks (') to enclose the name that will identify the primary server. Any name can be specified. This name will be required to rebuild the original primary server as the new standby server after the primary server was switched.

Parameter	Value set	Explanation
		Do not change this parameter while Mirroring Controller is running. Do not specify multiple names to this parameter as the Mirroring Controller can manage only one standby server.
hot_standby	on	Specify whether queries can be run on the standby server. Specify this to execute reference type jobs on the standby server.
wal_keep_size	WAL save size (megabytes)	If a delay exceeding the value set in this parameter occurs, the WAL segment required later by the primary server may be deleted. Additionally, if you stop a standby server (for maintenance, for example), consider the stop time and set a value that will not cause the WAL segment to be deleted. Refer to "Estimating Transaction Log Space Requirements" in the Installation and Setup Guide for Server for information on estimating the WAL save size.
wal_log_hints	on	When using the pg_rewind command to recover a standby server, specify this parameter or enable checksums when executing the initdb command.
wal_sender_timeout	Timeout (milliseconds)	Specify the time period after which it is determined that the receiver process (walreceiver) of the transaction log is in an abnormal state on the primary server. The specified value must be larger than the value set for the wal_receiver_status_interval parameter set in the postgresql.conf file of the standby server. By aligning this value with the value for the database process heartbeat monitoring time, you can unify the time after which it is determined that an error has occurred.
wal_receiver_timeout	Timeout (milliseconds)	Specify the time period after which it is determined that an error has occurred when the transaction log was received on the standby server. By aligning this value with the value for the database process heartbeat monitoring time, you can unify the time after which it is determined that an error has occurred.
backup_destination	Backup data storage destination directory	Specify the name of the backup data storage directory. Set the permissions so that only the instance administrator user can access the specified directory. Specify the same full path on all servers so that the backup data of other servers can be used to perform recovery.
archive_mode	on	Specify the archive log mode.
archive_command	'cmd /c ""installDir\\bin\ \pgx_walcopy.cmd" "%p"	Specify the command and storage destination to save the transaction log.

Parameter	Value set	Explanation
	"backupDataStorageDestinationDir\\archived_wal\\%f"''	
listen_addresses	Standby server IP address, host name, or "*"	Specify the IP address or host name of the standby server. Specify the IP address or corresponding host name that will be used to connect to the log transfer network. The content specified is also used to allow connections from client applications. To receive the connection and the transaction log from any client or standby server, specify "*". Refer to "Connections and Authentication" in the PostgreSQL Documentation for details.
max_connections	Number of simultaneous client connections to the instance + superuser_reserved_connections value	The value specified is also used to restrict the number of connections from client applications and the number of connections for the management of instances. Refer to "When an Instance was Created with the initdb Command" in the Installation and Setup Guide for Server, and "Connections and Authentication" in the PostgreSQL Documentation, for details.
superuser_reserved_connections	Add the number of simultaneous executions of mc_ctl status (*1) + 2	Specify the number of connections reserved for connections from database superusers. Add the number of connections from Mirroring Controller processes. Also reflect the added value in the max_connections parameter.
restart_after_crash	off	If "on" is specified, or the default value is used for this parameter, behavior equivalent to restarting Fujitsu Enterprise Postgres, including crash recovery, will be performed when some server processes end abnormally. However, when database multiplexing monitoring is used, a failover will occur after an error is detected when some server processes end abnormally, and the restart of those server processes is forcibly stopped. Specify "off" to prevent behavior such as this from occurring for no apparent reason.
synchronous_commit	on or remote_apply	Specify up to what position WAL send is to be performed before transaction commit processing returns a normal termination response to a client. Set "on" or "remote_apply" to prevent data loss caused by operating system or server down immediately after a switch or switch.
primary_conninfo	'*streamingReplicationConnectionDestinationInfo*'	Use single quotation marks (') to enclose the connection destination information of the streaming replication. The default value of this parameter is automatically set to postgresql.auto.conf in the procedure to run pg_basebackup for instance setup.
recovery_target_timeline	latest	Specify "latest" so that the new standby server (original primary server) will follow the new primary server when a switch occurs.

Parameter	Value set	Explanation
		This parameter is required when the original primary server is incorporated as a new standby server after the primary server is switched.

A.3 Network Configuration File

This section explains the network configuration file (network.conf) to be defined individually for the database servers and the arbitration server. Define the same content on the primary server and standby server.

For database multiplexing mode, define the network configuration for the following in network.conf.

- Integration between Mirroring Controller processes
- Integration between a Mirroring Controller process and the Mirroring Controller arbitration process

Items to be defined in network.conf

Format:

```
serverIdentifier hostName[,hostName] portNum[,portNum] [serverType]
Or,
serverIdentifier ipAddr[,ipAddr] portNum[,portNum] [serverType]
```

Specify the server identifier, IP address or host name, port number, and server type, using a space as the delimiter.

The items are explained in the table below.

Table A.3 network.conf file

Item	Description
serverIdentifier	Specify any identifier for the server. The maximum length is 64 bytes. Use ASCII characters excluding spaces and number signs (#) to specify this parameter.
ipAddrOrHostName	Specify the IP address or its corresponding host name that will connect to the admin network that performs communication between the database servers, and to the arbitration network that performs communication between a database server and the arbitration server. When specifying two IP addresses or host names delimited by a comma, do not insert a space after the comma. Use ASCII characters excluding spaces to specify the host name.
portNum	A port number cannot be specified if it exceeds the range 0 to 65535. Ensure that the port number does not conflict with other software. Do not specify an ephemeral port that may temporarily be assigned by another program. Note that the value specified in this parameter must also be set in the services file. When specifying two port numbers delimited by a comma, do not insert a space after the comma.
serverType	Specify "server" for a database server ("server" can be omitted), or "arbiter" for the arbitration server.

Content to be defined on the database servers

This section explains the network.conf content to be defined on the database servers.

The content to be defined depends on the operation settings at the time a heartbeat abnormality is detected.

When automatic degradation by the arbitration server is selected

- Specify definitions related to the admin network and arbitration network.
- Specify the IP address or host name and port number according to the server type (database server or arbitration server) as shown in the table below.

Server type	IP address or host name		Port number	
	First	Second	First	Second
server	IP address or host name used as the admin network	IP address or host name used as the arbitration network (*1)	Port number used as the admin network	Port number used as the arbitration network (*1)
arbiter	IP address or host name of the arbitration server Specify the same value as that specified in the my_address parameter of arbitration.conf on the arbitration server.	Not required	Port number on the arbitration server Specify the same value as that specified in the port parameter of arbitration.conf on the arbitration server.	Not required

*1: This value can be omitted from definitions not related to the local server. If it is omitted, network.conf must be created on both the primary server and standby server.

Example)

IPv4

```
server1 192.0.2.100,192.0.3.100 27540,27541 server
server2 192.0.2.110,192.0.3.110 27540,27541 server
arbiter 192.0.3.120 27541 arbiter
```

IPv6

```
server1 2001:258:8404:1217:250:56ff:fea7:559f,2001:258:8404:1217:250:56ff:fea8:559f
27540,27541 server
server2 2001:258:8404:1217:250:56ff:fea7:55a0,2001:258:8404:1217:250:56ff:fea8:55a0
27540,27541 server
arbiter 2001:258:8404:1217:250:56ff:fea8:55a0 27541 arbiter
```

When operation other than automatic degradation by the arbitration server is selected

- Specify definitions related to the admin network.
- Define the same content on the primary server and standby server.
- Define lines for database servers only.
- Specify only one IP address or host name and port number.

IP address or host name		Port number	
First	Second	First	Second
IP address or host name to be used as the admin network	Not required	Port number used as the admin network	Not required

Example)

The literal space represents a space.

IPv4

```
server1 192.0.2.100 27540
server2 192.0.2.110 27540
```

IPv6

```
server1 2001:258:8404:1217:250:56ff:fea7:559f 27540
server2 2001:258:8404:1217:250:56ff:fea7:55a0 27540
```

Content to be defined on the arbitration server

This section explains the network.conf content to be defined on the arbitration server.

- Specify definitions related to the arbitration network.
- Define lines for database servers only.
- For the IP address or host name, specify the same value as the second IP address or host name specified in the database server line in network.conf of the database server.
- For the port number, specify the same value as the second port number specified in the database server line in network.conf of the database server.

Example)

The literal space represents a space.

IPv4

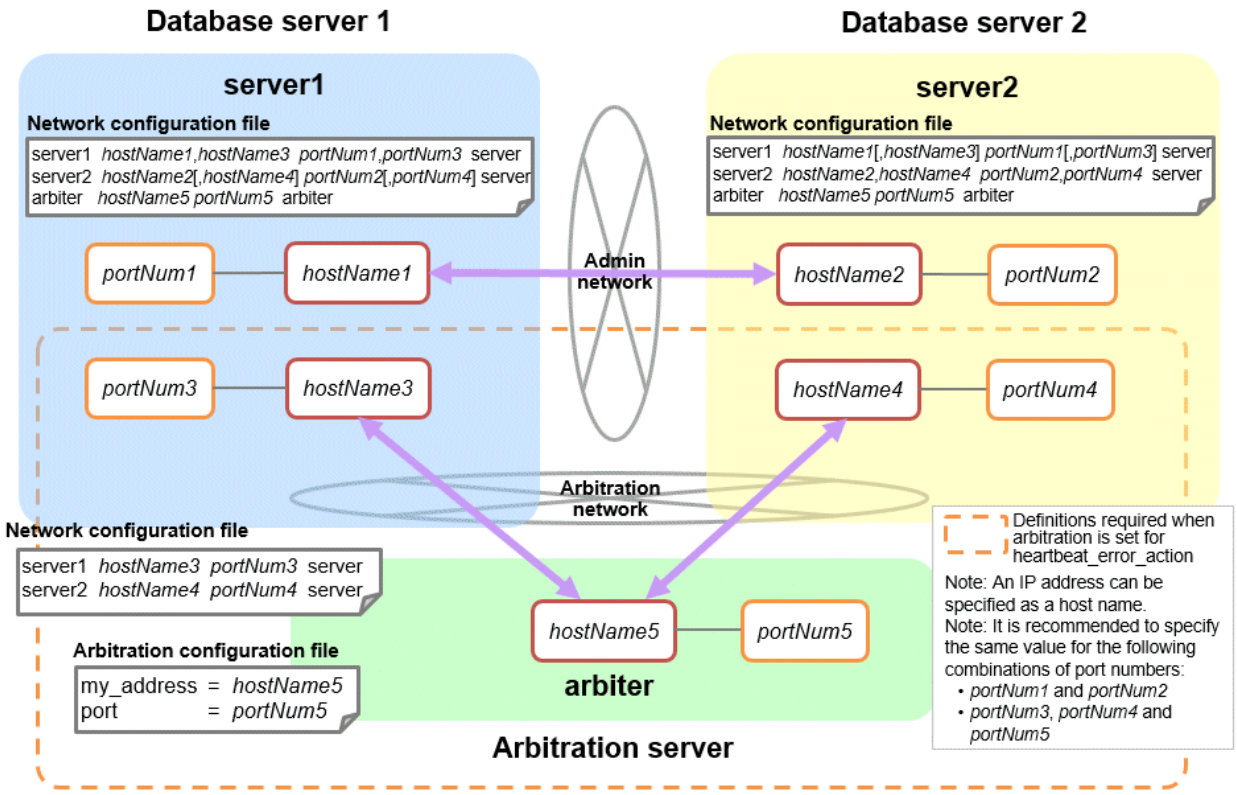
```
server1 192.0.3.100 27541
server2 192.0.3.110 27541
```

IPv6

```
server1 2001:258:8404:1217:250:56ff:fea8:559f 27541
server2 2001:258:8404:1217:250:56ff:fea8:55a0 27541
```

Relationship between network-related definitions

Refer to the diagram below for the relationship between the host names and IP addresses or port numbers specified in the network configuration file (network.conf) and arbitration configuration file (arbitration.conf).



A.4 Server Configuration File

A.4.1 Server Configuration File for the Database Servers

Define the information related to Mirroring Controller monitoring and control in the serverIdentifier.conf file. The maximum length of the server identifier is 64 bytes. Use ASCII characters excluding spaces to specify this parameter.

If the primary server and standby server environments are different, define content that is different, according to the environment.

Table A.4 serverIdentifier.conf file

Parameter	Value set	Explanation
db_instance	*'dataStorageDestinationDir'* [Example] db_instance = 'D:\\database1\\inst1'	Use halfwidth single quotation marks (') to enclose the data storage destination directory that will identify the monitoring target instance. Use ASCII characters. Specify \\ as file separator.
target_db	postgres or template1	Specify the name of the database to be connected to the database instance. The default is "postgres".
db_instance_username	'*usernameToConnectToDbInstance*'	Specify the username to connect to the database instance. Use ASCII characters to specify this parameter. Specify this parameter if the database administrator user is different from the operating system user who starts Mirroring Controller. Enclose the username of the database superuser in single quotation marks ('). The maximum length of the username is 63 bytes.

Parameter	Value set	Explanation
		The default is the operating system user who starts Mirroring Controller.
db_instance_password	'*passwordOfInstanceAdminUser*'	Specify the password used when Mirroring Controller connects to a database instance, enclosed in single quotation marks ('). Use ASCII characters to specify this parameter. If password authentication is performed, you must specify this parameter in the settings used when Mirroring Controller connects to a database instance. If you specify this parameter when password authentication is not performed, the parameter will be ignored. If the specified value of this parameter includes ' or \, write \' or \\, respectively.
enable_hash_in_password	on or off	Specify on to treat the # in the db_instance_password specification as a password character, or off to treat it as a comment. The default is "off".
core_file_path	*'coreFileOutputDir'*	Specify the directory to which the core file is to be output, enclosed in single quotation marks ('). Use ASCII characters. Specify \\ as file separator. If this parameter is omitted, it will be assumed that the Mirroring Controller management directory was specified.
db_instance_service_name	'*registeredServiceNameOfFujitsuEnterprisePostgresInstance*'	Specify the registered service name of the Fujitsu Enterprise Postgres instance in the Windows service. Use ASCII characters to specify this parameter, enclosed in single quotation marks (').
mc_service_name	'*registeredServiceNameOfMirroringController*'	Specify the Mirroring Controller service name registered in the Windows service. Use ASCII characters excluding forward slash (/) and backslash (\) to specify this parameter, enclosed in single quotation marks ('). The maximum length of the service name is 124 bytes. The default is 'MirroringControllerOpen'.
event_source(*1)	'*eventSourceName*'	Specify the event source name to be used to identify the Mirroring Controller message in the event log, enclosed in single quotation marks ('). Use ASCII characters to specify this parameter. The maximum length of the event source name is 255 bytes. The default is 'MirroringControllerOpen'.
remote_call_timeout	Admin communication timeout	Specify the timeout value (milliseconds) of the Mirroring Controller agent process for communication between servers. Specify a value between 0 and 2147483647 to be less than the operation system TCP connection timeout (*2).

Parameter	Value set	Explanation
		In addition, when using the Mirroring Controller arbitrage process, fencing commands, and state transition commands, specify a value that is greater than the sum of the timeout values (*3). The value 0 indicates that there is no timeout limit. The default is 70000 milliseconds (70 seconds).
agent_alive_timeout	Timeout for Mirroring Controller process heartbeat monitoring (seconds)	If there is no response for at least the number of seconds specified, the Mirroring Controller process is restarted. Specify 0 or a value between 2 and 2147483647. The value 0 indicates that there is no timeout limit. The default is 0 seconds.
heartbeat_error_action	Operation when a heartbeat abnormality is detected using operating system or server heartbeat monitoring	arbitration: Perform automatic degradation using the arbitration server. command: Call a user exit to determine degradation, and perform automatic degradation if required. message: Notify messages. fallback: Perform automatic degradation unconditionally. The default is "arbitration". Set the same value on the primary server and standby server.
heartbeat_interval	Interval time for abnormality monitoring during heartbeat monitoring of the operating system or server (milliseconds)	Abnormality monitoring of the operating system or server is performed at the interval specified in heartbeat_interval. If an error is detected, operation will conform to the value specified for heartbeat_error_action. If "arbitration" is specified in heartbeat_error_action, the error detection time during monitoring of the operating system or server becomes longer than when the arbitration server is not used, by up to the value specified for arbitration_timeout. Specify a value between 1 and 2147483647. The specified value is used as the default for db_instance_check_interval and disk_check_interval. The default is 800 milliseconds.
heartbeat_timeout	Timeout for abnormality monitoring during heartbeat monitoring of the operating system or server (seconds)	If there is no response for at least the number of seconds specified, it will be assumed that an error has occurred that requires the primary server to be switched, or the standby server to be disconnected. If an error is detected, operation will conform to the value specified for heartbeat_error_action. If "arbitration" is specified in heartbeat_error_action, the error detection time during monitoring of the operating system or server becomes longer than when the arbitration server is not used, by up to the value specified for arbitration_timeout. Specify a value between 1 and 2147483647. The specified value is used as the default for db_instance_check_timeout. The default is 1 second.

Parameter	Value set	Explanation
heartbeat_retry	Number of retries for abnormality monitoring during heartbeat monitoring of the operating system or server (number of times)	Specify the number of retries to be performed when an error has been detected that requires the primary server to be switched, or the standby server to be disconnected. If an error is detected in succession more than the specified number of times, switch or disconnection will be performed. If an error is detected, operation will conform to the value specified for heartbeat_error_action. If "arbitration" is specified in heartbeat_error_action, the error detection time during monitoring of the operating system or server becomes longer than when the arbitration server is not used, by up to the value specified for arbitration_timeout. Specify a value between 0 and 2147483647. The specified value is used as the default for db_instance_check_retry and disk_check_retry. The default is 2 times.
db_instance_check_interval	Database process heartbeat monitoring interval (milliseconds)	Heartbeat monitoring of the database process is performed at the interval specified in db_instance_check_interval. This parameter setting is also used for abnormality monitoring of streaming replication. Specify a value between 1 and 2147483647. The default is the value set for heartbeat_interval.
db_instance_check_timeout	Database process heartbeat monitoring timeout (seconds)	If there is no response for at least the number of seconds specified, it will be assumed that an error has occurred that requires the primary server to be switched, or the standby server to be disconnected. Specify a value between 1 and 2147483647. The default is the value set for heartbeat_timeout.
db_instance_check_retry	Number of retries for database process heartbeat monitoring (number of times)	Specify the number of retries to be performed when an error has been detected that requires the primary server to be switched, or the standby server to be disconnected. If an error is detected in succession more than the specified number of times, switch or disconnection will be performed. However, if it detects that the database process is down, it will immediately switch or disconnect regardless of the setting of this parameter. This parameter setting is also used for abnormality monitoring of streaming replication. Specify a value between 0 and 2147483647. The default number of retries is the value set for heartbeat_retry.
db_instance_timeout_action	none, message, or failover	Specify the behavior for no-response monitoring of the instance. none: Do not perform no-response monitoring. message: Notify messages if an error is detected during no-response monitoring. failover: Perform automatic degradation if an error is detected during no-response monitoring.

Parameter	Value set	Explanation
		The default is "failover".
disk_check_interval	Interval time for disk abnormality monitoring (milliseconds)	Abnormality monitoring of disk failure is performed at the interval (milliseconds) specified in disk_check_interval. If the file cannot be created, it will be assumed that an error has occurred that requires the primary server to be switched, or the standby server to be disconnected. Specify a value between 1 and 2147483647. Set a value larger than the disk access time. The default is the value set for heartbeat_interval.
disk_check_retry	Number of retries for disk abnormality monitoring (number of times)	Specify the number of retries to be performed when an error has been detected that requires the primary server to be switched, or the standby server to be disconnected. If an error is detected in succession more than the specified number of times, switch or disconnection will be performed. Specify a value between 0 and 2147483647. The default number of retries is the value set for heartbeat_retry.
disk_check_timeout	Abnormality monitoring timeout time (seconds)	The time allowed from the start time of the next disk_check_interval after a disk error occurs until the error is determined to be due to timeout. To disconnect the standby server when a disk error due to this timeout is detected on the standby server, set shutdown_detached_synchronous_standby to on. The default is 2147483. Specify an integer between 0 and 2147483.
disk_check_max_threads	Upper limit on the number of threads used for abnormality monitoring	Upper limit on the number of threads for disk monitoring. The default is the number of processors available to the JVM) Specify an integer between 1 and 2147483647, but setting a value greater than the threads available on the machine may result in a system error. When you run the mc_ctl status command separately from the monitoring process, each mc_ctl status temporarily uses the same number of threads as the monitoring process. When setting disk_check_max_threads, consider the machine's thread limit, the number of table spaces you plan to use, and the number of mc_ctl status commands that may be executed at the same time.
tablespace_directory_error_action	message or failover	Specify the behavior to be implemented if an error is detected in the tablespace storage directory. message: Notify messages. failover: Perform automatic degradation. The default is "failover".
arbiter_alive_interval	Interval time for monitoring connection to the Mirroring Controller arbitration process (milliseconds)	A heartbeat is sent to the Mirroring Controller arbitration process at the specified interval. Specify a value between 1 and 2147483647.

Parameter	Value set	Explanation
		The default is 16000 milliseconds. This parameter does not need to be set for operation that does not use the arbitration server.
arbiter_alive_timeout	Timeout for monitoring connection to the Mirroring Controller arbitration process (seconds)	If the heartbeat does not respond within the specified number of seconds, the Mirroring Controller arbitration process is determined to have been disconnected, a message is output, and reconnection is attempted. Specify a value between 1 and 2147483647. The default is 20 seconds. This parameter does not need to be set for operation that does not use the arbitration server.
arbiter_alive_retry	Number of retries for monitoring connection to the Mirroring Controller arbitration process (number of times)	Specify the number of heartbeat retries to be performed if an error is detected in the heartbeat to the Mirroring Controller arbitration process. If the heartbeat does not respond within the specified number of retries, the Mirroring Controller arbitration process is determined to have been disconnected. Specify a value between 0 and 2147483647. The default is 0 times. This parameter does not need to be set for operation that does not use the arbitration server.
arbiter_connect_interval	Attempt interval for connection to the Mirroring Controller arbitration process (milliseconds)	Reconnection is attempted at the specified interval if connection fails at startup of the Mirroring Controller process or if the Mirroring Controller arbitration process is disconnected. Specify a value between 1 and 2147483647. The default is 16000 milliseconds. This parameter does not need to be set for operation that does not use the arbitration server.
arbiter_connect_timeout	Timeout for connection to the Mirroring Controller arbitration process (seconds)	If reconnection at startup of the Mirroring Controller process or after disconnection of the Mirroring Controller arbitration process does not succeed within the specified number of seconds, connection to the Mirroring Controller arbitration process is determined to have failed and reconnection is attempted. Specify a value between 1 and 2147483647. The default is 20 seconds. This parameter does not need to be set for operation that does not use the arbitration server.
fencing_command	'*fencingCmdFilePath*' [Setting example] fencing_command = 'c:\\mc\ \fencing_dir\\execute_fencing.bat'	Specify the full path of the fencing command that fences a database server where an error is determined to have occurred. Specify \\ as file separator. Enclose the path in single quotation marks ('). Specify the path using less than 260 bytes.

Parameter	Value set	Explanation
		Any multibyte characters must use the same encoding as the operating system. This parameter must be specified when "command" is set for heartbeat_error_action.
fencing_command_timeout	Fencing command timeout (seconds)	If the command does not respond within the specified number of seconds, fencing is determined to have failed and a signal (SIGTERM) is sent to the fencing command execution process. Specify a value between 1 and 2147483647. The default is 20 seconds.
arbitration_timeout	Arbitration processing timeout in the Mirroring Controller arbitration process (seconds)	The specified value must be at least equal to the value of fencing_command_timeout in the arbitration configuration file, which is the heartbeat monitoring time of the operating system or server. If there is no response for at least the number of seconds specified, the primary server will not be switched and the standby server will not be disconnected. Therefore, perform degradation manually. If the heartbeat_interval, heartbeat_timeout, and heartbeat_retry values are specified in arbitration.conf for the arbitration server, use the arbitration server values to design arbitration_timeout. Specify a value between 1 and 2147483647. The default is 30 seconds. This parameter does not need to be set for operation that does not use the arbitration server.
arbitration_command	'*arbitrationCmdFilePath*' [Setting example] arbitration_command = 'c:\\mc\ \arbitration_dir\ \execute_arbitration_command.bat'	Specify the full path of the arbitration command to be executed when an abnormality is detected by heartbeat monitoring of the operating system or server. Specify \\ as file separator. Enclose the path in single quotation marks ('). Any multibyte characters must use the same encoding as the operating system. Specify the path using less than 260 bytes. This parameter must be specified when "command" is set for heartbeat_error_action.
arbitration_command_timeout	Arbitration command timeout (seconds)	If the arbitration command does not respond within the specified number of seconds, it is determined that execution of the arbitration command has failed and a signal (SIGTERM) is sent to the arbitration command execution process. Specify a value between 1 and 2147483647. The default is 30 seconds. This parameter can be specified only when "command" is set for heartbeat_error_action.
shutdown_detached_synchronous_standby	on or off	Specify whether to forcibly stop the instance on the standby server when the standby server is disconnected.

Parameter	Value set	Explanation
		on: Stop the instance. off: Do not stop the instance. If "on" is specified and the pre-detach command was created, the pre-detach command is executed and then the instance is stopped. The default is "off".
post_switch_command	'*postSwtchCmdFilePath*' [Setting example] post_switch_command = 'c:\\mc\ \status_change\ \execute_post_switch.bat'	Specify the full path of the command to be called by Mirroring Controller after a new primary server is promoted during a failover of the primary server. Specify \\ as file separator. Enclose the path in single quotation marks ('). Specify the path using less than 260 bytes.
post_attach_command	'*postAttachCmdFilePath*' [Setting example] post_attach_command = 'c:\\mc\ \status_change\ \execute_post_attach.bat'	Specify the full path of the command to be called by Mirroring Controller after the standby server is attached to the cluster system. Specify \\ as file separator. Enclose the path in single quotation marks ('). Specify the path using less than 260 bytes.
pre_detach_command	'*preDetachCmdFilePath*' [Setting example] pre_detach_command = 'c:\\mc\ \status_change\ \execute_pre_detach.bat'	Specify the full path of the command to be called by Mirroring Controller before the standby server is disconnected from the cluster system. Specify \\ as file separator. Enclose the path in single quotation marks ('). Specify the path using less than 260 bytes.
status_change_command_timeout	State transition command timeout (seconds)	Specify the timeout value of the post-switch command, post-attach command, and pre-detach command. If the command does not respond within the specified number of seconds, a signal (SIGTERM) is sent to the execution process of the status change command. Specify a timeout between 1 and 2147483647. The default is 20 seconds.
enable_promote_on_os_and_admin_network_error	on or off	If on is specified, if a admin network error occurs and replication is further lost, the system will ask the arbitration server to verify that the primary server and databases are running, and if they are down, promote the standby server. The default is "off".
startup_process_check_timeout	Timeout period for error monitoring in startup process monitoring (seconds)	If this parameter is not specified, startup process monitoring is disabled. If this parameter is specified, startup process monitoring is enabled, and a startup process anomaly is considered to occur if pending WAL has not been applied in the specified number of seconds or more. This parameter takes effect when running as a standby server.

Parameter	Value set	Explanation
		The startup process monitor checks for WAL application at intervals specified by db_instance_check_interval. This delays detection of unresponsive conditions by up to db_instance_check_interval. Set shutdown_detached_synchronous_standby to on to automatically shutdown and disconnect the standby server when an error is detected. Note that depending on the server parameter settings, WAL application on the standby server might be delayed, so set the monitoring time. For example, the max_standby_streaming_delay and recovery_min_apply_delay parameters delay WAL application. Set the monitoring time parameters so that the startup process is not falsely detected as not responding due to the effect of these parameter settings. Specify a number between 1 and 2147483647.
check_synchronous_standby_names_validation	on or off	Specify whether Mirroring Controller is to periodically check during operations whether the synchronous_standby_names parameter in postgresql.conf was changed by an incorrect user operation. However, it is not recommended to enable this parameter, because performing this check causes Mirroring Controller to use the CPU of the database server redundantly and execute SQL statements at high frequency. This parameter is compatible with operations in FUJITSU Enterprise Postgres 9.6 or earlier. The default is "off".
db_instance_ext_pq_conninfo	*'libpqConnectionSSLParmToConnectToDbinstance'*	Specify, in key-value form, the connection parameter for libpq that Mirroring Controller adds when connecting to a database. The connection parametersyou can specify are those related to SSL. Use ASCII characters to specify this parameter. If you want to validate the server certificate using the destination host name, such as specifying sslmode=verify-full as the connection parameter, specify the host name in the Common Name of the server certificate in the sslservercertcn connection parameter. For information about the sslservercertcn connection parameter, refer to "Using the C Library (libpq)" in "Application Connection Switch Feature" in the Application Development Guide. The connection parameter specified in this parameter must also be specified in the db_instance_ext_jdbc_conninfo. Specify \\ as file separator.
db_instance_ext_jdbc_conninfo	*'JDBCConnectionSSLParmToConnectToDbinstance'*	Specify, in URI form, the connection parameter for JDBC that Mirroring Controller adds when connecting to a database. The connection parametersyou can specify are those related to SSL. Use ASCII characters to specify this parameter. If you want to validate the server certificate using the destination host name, such as specifying sslmode=verify-

Parameter	Value set	Explanation
		full as the connection parameter, specify the host name in the Common Name of the server certificate in the sslservercertcn connection parameter. For information about the sslservercertcn connection parameter, refer to "Using the JDBC Driver" in "Application Connection Switch Feature" in the Application Development Guide. The connection parameter specified in this parameter must also be specified in the db_instance_ext_pq_conninfo. Specify \\ as file separator.

*1: By using an event source name that is similar to the specified event_source parameter of the postgresql.conf file, the Mirroring Controller output content can be referenced transparently, so log reference is easy.

*2: The operating system TCP connection timeout period is determined by the TCP global parameters initial RTO and maximum SYN retransmits. The remote_call_timeout parameter must be set to a value that is shorter than the timeout period for the operating system TCP connection timeout, so change either parameter as necessary.

*3: In management communications, arbitrage processing, fencing commands, and state transition commands may be executed in succession by the Mirroring Controller arbitrage process. Therefore, the value specified for the remote_call_timeout parameter must be greater than the sum of these timeout values. Depending on the value specified for the heartbeat_error_action parameter, set the remote_call_timeout parameter using the following formula.

- arbitration: (arbitration_timeout + fencing_command_timeout + status_change_command_timeout) * 1000
- command: (fencing_command_timeout + status_change_command_timeout) * 1000
- message: (fencing_command_timeout + status_change_command_timeout) * 1000
- fallback: (status_change_command_timeout) * 1000

Because other internal processing may be performed in the management communication, set the value obtained by multiplying the calculation result of the above equation by the safety factor (about 1.2).

Also, for the fencing_command_timeout parameter, use the value of the parameter in the database server's server definition file, not in the arbitration definition file.

The availability of some parameters depends on the value set for the heartbeat_error_action parameter that sets the operation to be performed if heartbeat monitoring of the operating system or server detects a heartbeat abnormality.

Table A.5 Parameter availability depending on the value set for the heartbeat_error_action parameter

Parameter	Value set			
	arbitration	command	message	fallback
arbiter_alive_interval	Y	N	N	N
arbiter_alive_timeout	Y	N	N	N
arbiter_alive_retry	Y	N	N	N
arbiter_connect_interval	Y	N	N	N
arbiter_connect_timeout	Y	N	N	N
arbitration_timeout	Y	N	N	N
arbitration_command	N	R	N	N
arbitration_command_timeout	N	Y	N	N
fencing_command	Y	R	Y	N
fencing_command_timeout	Y	Y	Y	N
shutdown_detached_synchronous_standby	Y	Y	N	N

R: Required

Y: Can be specified

N: Cannot be specified

A.4.2 Arbitration Configuration File

In arbitration.conf, define the information related to arbitration and control of the Mirroring Controller arbitration process.

Linux

Table A.6 arbitration.conf file (Linux)

Parameter	Value set	Description
port	Port number of the Mirroring Controller arbitration process	The specified value must not exceed the range 0 to 65535. Ensure that the port number does not conflict with other software. Do not specify an ephemeral port that may temporarily be assigned by another program. For the port number of the arbitration server to be specified in network.conf on the database server, specify the same value as the port number specified in this parameter.
my_address	'*ipAddrOrHostNameThatAcceptsConnectionFromMirroringControllerProcessOnDbServer*' [Setting example] my_address = '192.0.3.120'	For the IP address or host name of the arbitration server to be specified in network.conf on the database server, specify the same value as the IP address or host name specified in this parameter. IPv4 and IPv6 addresses can be specified. Specify the IP address or host name, enclosed in single quotation marks (').
core_file_path	'*coreFileOutputDir*'	Specify the directory to which the core file is to be output, enclosed in single quotation marks ('). Use ASCII characters to specify this parameter. If this parameter is omitted, it will be assumed that the Mirroring Controller arbitration process management directory was specified.
syslog_facility	Specify LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, LOCAL5, LOCAL6, or LOCAL7.	When the import of logs to the syslog is enabled, the value of this parameter will be used for "facility" of the syslog. The default is "LOCAL0".
syslog_ident	'*programName*'	Specify using single quotation marks (') to enclose the program name used to identify the Mirroring Controller arbitration process message in the system log. Use ASCII characters excluding spaces to specify this parameter. The default is 'MirroringControllerArbiter'.
fencing_command	'*fencingCmdFilePath*' [Setting example] fencing_command = '/arbiter/fencing_dir/execute_fencing.sh'	Specify the full path of the fencing command that fences a database server where an error is determined to have occurred. Enclose the path in single quotation marks ('). Specify the path using less than 1024 bytes.
fencing_command_timeout	Fencing command timeout (seconds)	If the command does not respond within the specified number of seconds, fencing is determined to have failed and a signal (SIGTERM) is sent to the fencing command execution process.

Parameter	Value set	Description
		Specify a value between 1 and 2147483647. The default is 20 seconds.
heartbeat_interval(*1)	Interval time for heartbeat monitoring of the operating system or server (milliseconds)	The heartbeat monitoring of the database server is checked at the specified interval and arbitration is performed. Specify a value between 1 and 2147483647. The default is the value specified in *serverIdentifier*.conf of the database server. Specify this parameter to perform optimization taking into account differences in the line load to the admin network and the reduction in the time it takes to degrade.
heartbeat_timeout	Timeout for heartbeat monitoring of the operating system or server (seconds)	If there is no response for at least the number of seconds specified, it will be assumed that an error has occurred that requires the primary server or standby server to be fenced. Specify a value between 1 and 2147483647. The default is the value specified in *serverIdentifier*.conf of the database server. Specify this parameter to perform optimization taking into account differences in the line load to the admin network and the reduction in the time it takes to degrade.
heartbeat_retry	Number of retries for heartbeat monitoring of the operating system or server (number of times)	Specify the number of retries to be performed when an error has been detected that requires the primary server or standby server to be fenced. If an error is detected in succession more than the specified number of times, fencing will be performed. Specify a value between 0 and 2147483647. The default is the value specified in *serverIdentifier*.conf of the database server. Specify this parameter to perform optimization taking into account differences in the line load to the admin network and the reduction in the time it takes to degrade.

*1:Refer to "2.11.4 Tuning for Optimization of Degradation Using Abnormality Monitoring" for information on the tuning parameters for operating system or server abnormality monitoring when using an arbitration server.

Windows

Table A.7 arbitration.conf file (Windows)

Parameter	Value set	Description
port	Port number of the Mirroring Controller arbitration process	The specified value must not exceed the range 0 to 65535. Ensure that the port number does not conflict with other software. Do not specify an ephemeral port that may temporarily be assigned by another program.

Parameter	Value set	Description
		For the port number of the arbitration server to be specified in network.conf on the database server, specify the same value as the port number specified in this parameter.
my_address	'*ipAddrOrHostNameThatAcceptsConnectionFromMirroringControllerProcessOnDbServer*' [Setting example] my_address = '192.0.3.120'	For the IP address or host name of the arbitration server to be specified in network.conf on the database server, specify the same value as the IP address or host name specified in this parameter. IPv4 and IPv6 addresses can be specified. Specify the IP address or host name, enclosed in single quotation marks (').
core_file_path	'*coreFileOutputDir*'	Specify the directory to which the core file is to be output, enclosed in single quotation marks ('). Use ASCII characters. Specify \\ as file separator. If this parameter is omitted, it will be assumed that the Mirroring Controller arbitration process management directory was specified.
service_name	'*registeredServiceNameOfMirroringControllerArbitrationProcess*'	Specify the Mirroring Controller arbitration process service name to be registered as a Windows service, enclosed in single quotation marks ('). Use ASCII characters excluding forward slash (/) and backslash (\) to specify this parameter. The service name is up to 124 bytes. The default is 'MirroringControllerArbiter'.
event_source	*'eventSourceName'*	Specify the event source name to be used to identify the Mirroring Controller arbitration process message in the event log, enclosed in single quotation marks ('). Use ASCII characters to specify this parameter. The maximum length of the event source name is 255 bytes. The default is 'MirroringControllerArbiter'.
fencing_command	'*fencingCmdFilePath*' [Setting example] fencing_command = 'c:\\arbiter\ \fencing_dir\\execute_fencing.bat'	Specify the full path of the fencing command that fences a database server where an error is determined to have occurred. Specify \\ as file separator. Enclose the path in single quotation marks ('). Specify the path using less than 260 bytes. Any multibyte characters must use the same encoding as the operating system.
fencing_command_timeout	Fencing command timeout (seconds)	If the command does not respond within the specified number of seconds, fencing is determined to have failed and a signal (SIGTERM) is sent to the fencing command execution process. Specify a value between 1 and 2147483647. The default is 20 seconds.

Parameter	Value set	Description
heartbeat_interval(*1)	Interval time for heartbeat monitoring of the operating system or server (milliseconds)	The heartbeat monitoring of the database server is checked at the specified interval and arbitration is performed. Specify a value between 1 and 2147483647. The default is the value specified in *serverIdentifier*.conf of the database server. Specify this parameter to perform optimization taking into account differences in the line load to the admin network and the reduction in the time it takes to degrade.
heartbeat_timeout	Timeout for heartbeat monitoring of the operating system or server (seconds)	If there is no response for at least the number of seconds specified, it will be assumed that an error has occurred that requires the primary server or standby server to be fenced. Specify a value between 1 and 2147483647. The default is the value specified in *serverIdentifier*.conf of the database server. Specify this parameter to perform optimization taking into account differences in the line load to the admin network and the reduction in the time it takes to degrade.
heartbeat_retry	Number of retries for heartbeat monitoring of the operating system or server (number of times)	Specify the number of retries to be performed when an error has been detected that requires the primary server or standby server to be fenced. If an error is detected in succession more than the specified number of times, fencing will be performed. Specify a value between 0 and 2147483647. The default is the value specified in *serverIdentifier*.conf of the database server. Specify this parameter to perform optimization taking into account differences in the line load to the admin network and the reduction in the time it takes to degrade.

*1:Refer to "2.11.4 Tuning for Optimization of Degradation Using Abnormality Monitoring" for information on the tuning parameters for operating system or server abnormality monitoring when using an arbitration server.

Appendix B Supplementary Information on Building the Primary Server and Standby Server on the Same Server

The primary server and standby server can be pseudo-configured on the same server for system testing, for example. Out of consideration for performance and reliability, do not use this type of configuration for any other purposes. For this reason, do not use this type of configuration in a production environment.

Note that the setup and operations is the same as if the primary and standby servers are built on different servers.

This appendix provides supplementary information explaining how to configure the primary server and standby server on the same server.

Information

Even if automatic degradation by an arbitration server is set when the primary server and standby server are configured on the same server, there will be no effect of it.

B.1 Backup Data Storage Destination Directory

It is not a problem if the same backup data storage destination directory is used on the primary server and standby server.

B.2 Registering Service Names and Event Source Names in the Windows Service

Ensure that the following names of resources to be registered on the operating system by Fujitsu Enterprise Postgres and Mirroring Controller are not duplicated between the primary server and standby server:

- Service name registered in the Windows service
- Event source name

B.3 How to Execute the mc_ctl Command

When executing the mc_ctl command, specify the server identifier in the --local-server option in order to identify the operation destination server.

Below is an example of starting Mirroring Controller of the server "server1" defined in the network.conf file. For mc_ctl command operations using another mode, also specify the --local-server option.

Define two server identifiers for the same IP address with different port numbers in the network.conf file.

```
Example)
```

```
server1 192.0.2.100 27540
server2 192.0.2.100 27541
```

Ensure that the port numbers of both primary server and standby server do not conflict with any other software.

Enabling automatic switch/disconnection

Start Mirroring Controller of the server "server1":

```
Example)
```

```
> mc_ctl start -M D:\mcdir\inst1 --local-server server1
```

Stop Mirroring Controller of the server "server1":

Example)

```
> mc_ctl stop -M D:\mcdir\inst1 --local-server server1
```

Disabling automatic switch/disconnection

Start Mirroring Controller of the server "server1":

Example)

```
> mc_ctl start -M D:\mcdir\inst1 -F --local-server server1
```

Stop Mirroring Controller of the server "server1":

Example)

```
> mc_ctl stop -M D:\mcdir\inst1 --local-server server1
```

Point

To specify the mc_ctl command with register mode, for registering to the Windows service, and the mc_ctl command with unregister mode, for unregistering from the Windows service, add the --local-server option.

Appendix C User Commands

This appendix describes three categories of commands:

- Fencing command
- Arbitration command
- State transition commands

This appendix describes each category of user command.

C.1 Fencing Command

Format

The syntax for calling the fencing command from the Mirroring Controller process or the Mirroring Controller arbitration process is described below.

Fencing command of the database server

```
fencingCmd executionMode mcDegradationOper cmdServerId targetServerId primarycenter
```

Fencing command of the arbitration server

```
fencingCmd executionMode mcDegradationOper targetServerId
```

Input

Fencing command of the database server

Execution mode

monitor: Detect issues via automatic monitoring of the Mirroring Controller process

command: Mirroring Controller command execution (switch mode or detach mode of the mc_ctl command)

Degradation operation to be performed by Mirroring Controller

switch: Switch

detach: Disconnect

cmdServerId

ID of the database server that called the command

targetServerId

ID of the database server to be fenced

primarycenter

Fixed value

Fencing command of the arbitration server

Execution mode

monitor: Detect issues via automatic monitoring of the Mirroring Controller process

command: Mirroring Controller command execution (switch mode or detach mode of the mc_ctl command)

Degradation operation to be performed by Mirroring Controller

switch: Switch

detach: Disconnect

targetServerId

ID of the database server to be fenced

Output

Return value

0: Mirroring Controller will continue the degradation process.

Other than 0: Mirroring Controller will cancel the degradation process.

Description

Identifies the database server targeted for fencing based on the input server identifier, and implements the process that isolates it from the cluster system.

Notes

- The command is executed by the operating system user who started Mirroring Controller or the Mirroring Controller arbitration process. Therefore, if the command is to be executed by a specific operating system user, change the executing user of the command accordingly.
- The operating system user who started Mirroring Controller or the Mirroring Controller arbitration process must have execution privileges to the command. Otherwise, the degradation process will be canceled.
- From a security point of view, set the access privileges as necessary so that the fencing command is not overwritten and unauthorized operations are not performed by unintended operating system users.
- If the fencing command returns a value other than 0, Mirroring Controller will cancel the degradation process, so it is necessary for the user to check the status of the server, and switch or disconnect it manually.
- Before executing the fencing command, check if the server is already fenced, to avoid the command terminating abnormally.
- If the command times out, Mirroring Controller will stop the command, output an error message, and cancel the degradation process.

Information

The fencing command can be implemented by simply stopping the operating system or server. For example, if stopping the power for the database server, it is possible to use a utility to control the hardware control board in environments equipped with boards compatible with IPMI hardware standard.

If power operations via IPMI are not available in a cloud environment, check and manage the state of the VM using CLI commands or APIs provided by the cloud service. For details on the cloud service's CLI commands or APIs, refer to the manual of each cloud service.

Linux

Below is a sample script of a fencing command that powers off the database server using the IPMI tool.

```
Sample shell script
```

```
/installDir/share/mcarb_execute_fencing.sh.sample
```

Below is a sample script of a fencing command to stop the power of the database server using the CLI command of the cloud service.

```
Sample shell script for Amazon Web Services
```

```
/installDir/share/mcarb_execute_fencing.sh.aws.sample
```

```
Sample shell script for Microsoft Azure
```

```
/installDir/share/mcarb_execute_fencing.sh.az.sample
```

Windows

Below is a sample script of a fencing command that powers off the database server using IPMIUTIL.

```
Sample shell script
```

```
installDir\share\mcarb_execute_fencing.bat.sample
```

Below is a sample script of a fencing command to stop the power of the database server using the CLI command of the cloud service.

Sample shell script for Amazon Web Services

```
installDir\share\mcarb_execute_fencing.bat.aws.sample
```

Sample shell script for Microsoft Azure

```
installDir\share\mcarb_execute_fencing.bat.az.sample
```

C.2 Arbitration Command

Format

The syntax for calling the arbitration command from the Mirroring Controller process is described below.

```
arbitrationCmd cmdServerId targetServerId primarycenter
```

Input

cmdServerId

ID of the database server that called the command

targetServerId

ID of the database server to arbitrate

primarycenter

Fixed value

Output

Return value

0: The database server to arbitrate has an issue, and Mirroring Controller will continue the degradation process.

Other than 0: The database server to arbitrate is normal, and Mirroring Controller will cancel the degradation process.

Description

Identifies the database server to arbitrate based on the input server identifier, and checks the status of the server.

Notes

- The command is executed by the operating system user who started Mirroring Controller.
- The operating system user who started Mirroring Controller must have execution privileges to the command. Otherwise, the command will not be called, and the degradation process will be canceled.
- If the command times out, Mirroring Controller will stop the command, output an error message, and cancel the degradation process.

Information

One way to implement an arbitration command is to check the server status using the OS's ping command. It is recommended to execute the ping command on a network separate from the admin network to accurately check the server status. Adjust the following parameters of the sample script according to your environment, considering factors such as business load, network line load, and reduction of degradation time.

Parameter	Description
HEARTBEAT_TIMEOUT	Timeout duration for OS/server health monitoring (seconds) If there is no response for more than the specified number of seconds, it is considered that an abnormality has occurred that requires fencing of the primary server or standby server.

Parameter	Description
	Consider the time during which continuous load is applied to the server or arbitration network capabilities. For example, when executing high-load batch operations or when high-concurrency online operations occur continuously.
RETRY_COUNT	Retry count for monitoring the life and death of OS/servers (count) Specify the number of retries when an anomaly is detected. Fencing will be performed if an anomaly is detected consecutively for the specified number of times + 1 or more.
RETRY_INTERVAL	Interval time for monitoring the life and death of OS/servers (seconds) Monitoring the life and death of the database server at the specified interval.

Linux

Below is a sample script for the arbitration command.

Sample shell script

```
/installDir/share/mc_execute_arbitration_command.sh.sample
```

Windows

Below is a sample script for the arbitration command.

Sample shell script

```
installDir\share\mc_execute_arbitration_command.bat.sample
```

C.3 State Transition Commands

State transition commands include the three types of user commands below. Any of the commands can be implemented by Mirroring Controller in conjunction with database server status transitions.

- Post-switch command
- Pre-detach command
- Post-attach command

C.3.1 Post-switch Command

Format

The syntax for calling the post-switch command from the Mirroring Controller process is described below.

```
postswitchCmd serverIdentifier primarycenter
```

Input

serverIdentifier

ID of the database server (new primary server) that was switched

primarycenter

Fixed value

Output

Return value

None

Notes

- The command is executed by the operating system user who started Mirroring Controller.
- The operating system user who started Mirroring Controller must have execution privileges to the command. Otherwise, the command will not be called.
- If the command times out, Mirroring Controller will stop the command, output an error message, and cancel the process.

C.3.2 Pre-detach Command

Format

The syntax for calling the pre-detach command from the Mirroring Controller process is described below.

```
predetachCmd cmdServerId serverRole targetServerId primarycenter
```

Input

cmdServerId

ID of the database server that called the command

Server role

Role of the database server that called the command

primary: Primary

standby: Standby

targetServerId

ID of the standby server to be disconnected from the cluster system

primarycenter

Fixed value

Output

Return value

None

Notes

- The command is executed by the operating system user who started Mirroring Controller.
- The operating system user who started Mirroring Controller must have execution privileges to the command. Otherwise, the command will not be called, however, Mirroring Controller will output an error message and continue the process.
- If the command times out, Mirroring Controller will stop the command, output an error message, and cancel the process.

C.3.3 Post-attach Command

Format

The syntax for calling the post-attach command from the Mirroring Controller process is described below.

```
postattachCmd cmdServerId serverRole targetServerId primarycenter
```

Input

cmdServerId

ID of the database server that called the command

Server role

Role of the database server that called the command

primary: Primary

standby: Standby

targetServerId

ID of the standby server to be attached to the cluster system

primarycenter

Fixed value

Output

Return value

None

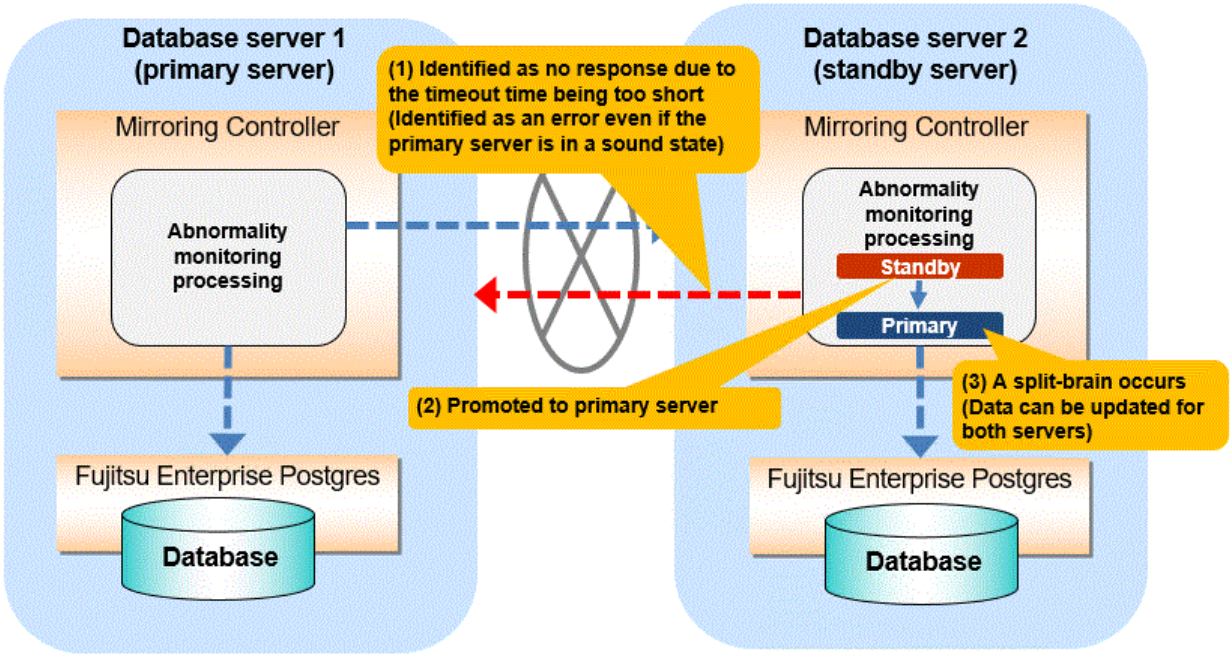
Notes

- The command is executed by the operating system user who started Mirroring Controller.
- The operating system user who started Mirroring Controller must have execution privileges to the command. Otherwise, the command will not be called.
- If the command times out, Mirroring Controller will stop the command, output an error message, and cancel the process.

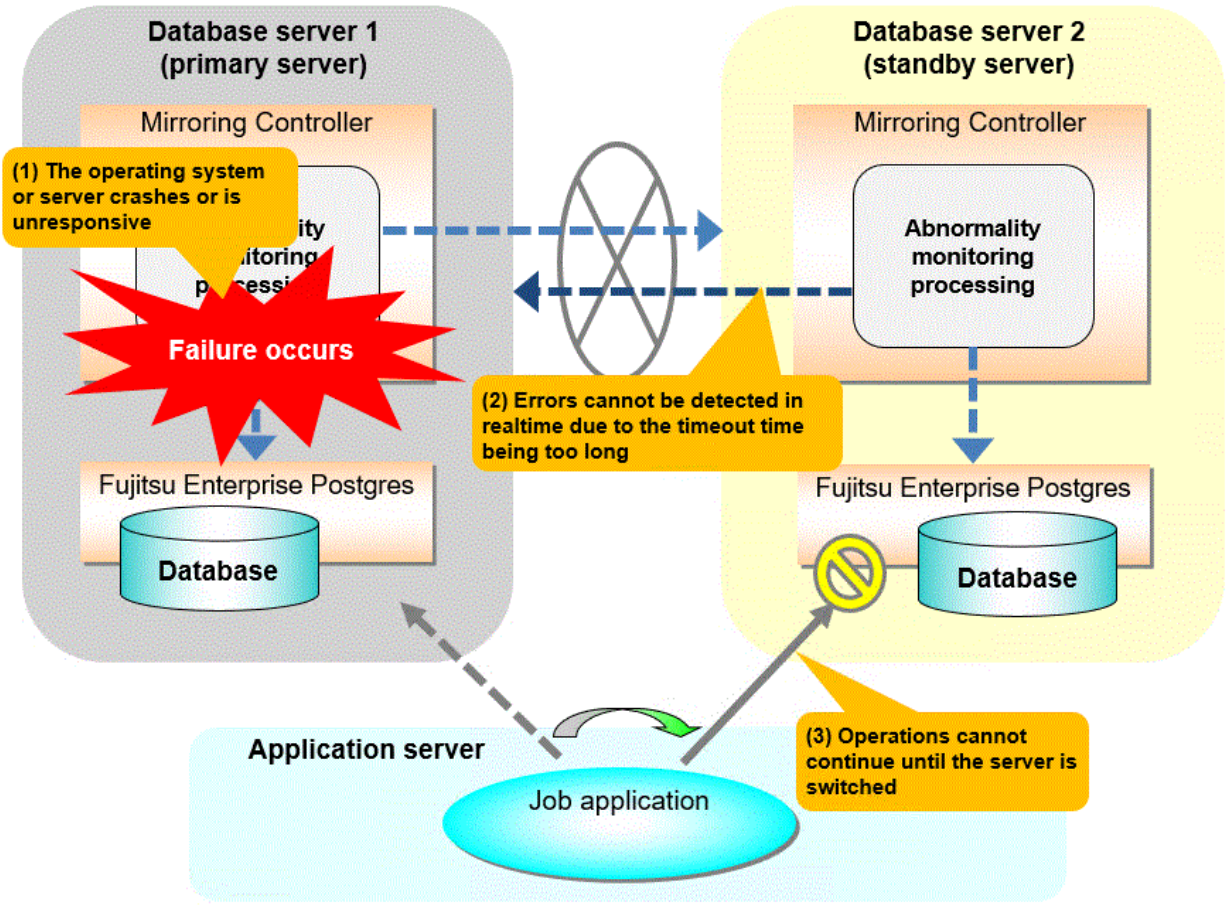
Appendix D Notes on Performing Automatic Degradation Immediately after a Heartbeat Abnormality

The type of issue below occurs if automatic degradation is performed unconditionally after an issue is detected during heartbeat monitoring of an operating system or server, and heartbeat monitoring was not properly tuned.

- **If the timeout time is too short**



● If the timeout time is too long



Notes on monitoring when the operating system or server crashes or is unresponsive

As illustrated in the diagram above, timeout is used to monitor whether the operating system or server crashes or is unresponsive. Therefore, if tuning has not been performed correctly, there is a risk of a split-brain mistakenly occurring even if the server is in a sound state.

Split-brain is a phenomenon in which both servers temporarily operate as primary servers, causing data updates to be performed on both servers.

Split-brain detection method

It can be confirmed that split-brain occurs under the following conditions:

1. When the mc_ctl command is executed in status mode on both servers, the "host_role" of both servers is output as "primary", and
2. The following message is output to the system log of one of the servers:

```
promotion processing completed (MCA00062)
```

How to recover from a split-brain

Use the procedure described below. Note that the new primary server is the server that was confirmed in step 2 of the aforementioned detection method.

1. Stop all applications that are running on the old and new primary servers.
2. Investigate and recover the database.
   Investigate the update results that have not been reflected to the new primary server from the database of the old primary server, and apply to the new primary server as necessary.
3. Stop the old primary server instance and the Mirroring Controller.
4. Resume the applications that were stopped in step 1.

5. Recover the old primary server.
   While referring to "2.5 Setting Up the Standby Server", build (set up) the old primary server as the new standby server, from the new primary server.

Notes on monitoring by restarting the OS

The heartbeat monitoring of the database server uses the OS ping command. Therefore, if the timeout period is too long and the OS restarts, an error might not be detected. This can result in a business shutdown without automatic switchover even though the primary server is down. There are several ways to avoid this situation:

- Refer to "Parameters for the abnormality monitoring of the operating system or server in the server configuration file of the database server" and perform tuning so that the timeout time is shorter than the time required to restart the OS.
- Refer to "2.12 Setting Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" to set automatic startup of Mirroring Controller.

Appendix E Supplementary Procedure on Configuring for Operation in Database Multiplexing Mode

This appendix explains a supplementary procedure on the configuration required for operation in database multiplexing mode.

E.1 Security Policy Settings

This section explains how to configure the security settings to enable an operating system user account designated as an instance administrator user to log on as a service.

1. Displaying the [Local Security Policy] window

   In Windows, select [Administrative Tools], and then click [Local Security Policy].

2. Setting up security

   1. In the [Local Security Policy] window, select [Security Settings], select [Local Policies], and then click [User Rights Assignment].
   2. Under [Policy] in the [User Rights Assignment] window, double-click [Log on as a service].
   3. In the [Log on as a service Properties] window, set the following:
      a. Select the [Local Security Setting] tab.
      b. On the [Local Security Setting] tab, click [Add User or Group].
      c. In the [Select Users or Groups] window, enter the operating system user account of the instance administrator user in [Enter the object names to select].
      d. Click [OK].
   4. In the [Log on as a service Properties] window, click [OK].
   5. From the [Local Security Policy] tree, click [Local Policies], and then double-click [Security Options].
   6. Scroll down and double-click [User Account Control: Behavior of the elevation prompt for administrators in Admin Approval Mode].
   7. From the drop-down menu, select the "Elevate without prompting" in the [Local Security Setting] tab.
   8. Click [OK].

E.2 Windows Firewall Settings

This section explains how to enable the port number used by Mirroring Controller, if the Windows firewall feature is enabled.

Windows Server(R) 2016:

1. In the [Windows Firewall] window, click [Advanced settings] on the left side of the window.
2. In the [Windows Firewall with Advanced Security] window, click [Inbound Rules] on the left side of the window.
3. Click [New Rule] on the right side of the window.
4. In the [New Inbound Rule Wizard] window, select [Port], and then click [Next].
5. Select [TCP] and [Specific local ports], then specify the port number defined in the network definition file, and then click [Next].
6. Select [Allow the connection], and then click [Next].
7. Select the profiles for which this rule applies, and then click [Next].
8. In [Name], specify the desired name, and then click [Finish].
9. In the [Windows Firewall with Advanced Security] window, check if the added rule is enabled under [Inbound Rules] in the center of the window.

Other than above:

1. In the [Windows Defender Firewall] window, click [Advanced settings] on the left side of the window.
2. In the [Windows Defender Firewall with Advanced Security] window, click [Inbound Rules] on the left side of the window.
3. Click [New Rule] on the right side of the window.
4. In the [New Inbound Rule Wizard] window, select [Port], and then click [Next].
5. Select [TCP] and [Specific local ports], then specify the port number defined in the network definition file, and then click [Next].
6. Select [Allow the connection], and then click [Next].
7. Select the profiles for which this rule applies, and then click [Next].
8. In [Name], specify the desired name, and then click [Finish].
9. In the [Windows Defender Firewall with Advanced Security] window, check if the added rule is enabled under [Inbound Rules] in the center of the window.

Appendix F WebAdmin Disallow User Inputs Containing Hazardous Characters

WebAdmin considers the following as hazardous characters, which are not allowed in user inputs.

```
| (pipe sign)

& (ampersand sign)

; (semicolon sign)

$ (dollar sign)

% (percent sign)

@ (at sign)

' (single apostrophe)

" (quotation mark)

\' (backslash-escaped apostrophe)

\" (backslash-escaped quotation mark)

<> (triangular parenthesis)

() (parenthesis)

+ (plus sign)

CR (Carriage return, ASCII 0x0d)

LF (Line feed, ASCII 0x0a)

, (comma sign)

\ (backslash)
```

Appendix G Collecting Failure Investigation Data

For information on collecting failure investigation data, refer to the following.

Using a database server to collect data

"Collecting Failure Investigation Data" in the Installation and Setup Guide for Server

Using an arbitration server to collect data

"Collecting Failure Investigation Data" in the Installation and Setup Guide for Server Assistant

PRIMECLUSTER

Linux

J2UL-3061-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document explains the items required to operate Fujitsu Enterprise Postgres on a cluster system that uses PRIMECLUSTER.

Intended readers

This document is aimed at people who install and operate Fujitsu Enterprise Postgres on a cluster system that uses PRIMECLUSTER. Readers of this document are also assumed to have general knowledge of:

- PRIMECLUSTER
- PostgreSQL
- SQL
- Linux

Structure of this document

This document is structured as follows:

Chapter 1 Overview of Failover Operation

Provides an overview of failover operation.

Chapter 2 Setting Up Failover Operation

Explains how to set up failover operation.

Chapter 3 Failover Operation

Explains the procedures involved in failover operation.

Chapter 4 Procedures Required after a Failover Error

Explains the procedures required after an abnormality occurs during failover operation.

Appendix A Creating Resources and Creating/Modifying Cluster Applications

Explains how to create and modify cluster applications that include Fujitsu Enterprise Postgres resources.

Appendix B Command Reference

Explains for details in command.

Appendix C Failover Operation in Streaming Replication

Explains failover operations in streaming replication.

Appendix D Single-Node Cluster Operation

Explains single-node cluster operation.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Chapter 1 Overview of Failover Operation

This chapter provides an overview of failover operation in Fujitsu Enterprise Postgres.

Information

In addition to failover operation, you can configure single-node cluster operation, which is one of the operating modes of a cluster system, as a development environment. For more information, refer to "Appendix D Single-Node Cluster Operation".

1.1 Definition of Failover Operation

When an abnormality occurs on any of the multiple server devices that make up the cluster system (hereafter referred to as "nodes"), the failover feature transfers a job operating on such a node to another one. Failover can reduce the time for which jobs are stopped when an abnormality occurs, and allows jobs to continue while the node on which the abnormality occurred is recovered.

In Fujitsu Enterprise Postgres, failover can be integrated with PRIMECLUSTER. In such a configuration, the shared disk (GDS) provided by PRIMECLUSTER is used. A server in the cluster system receives the application processing, acting as the active server (active node).

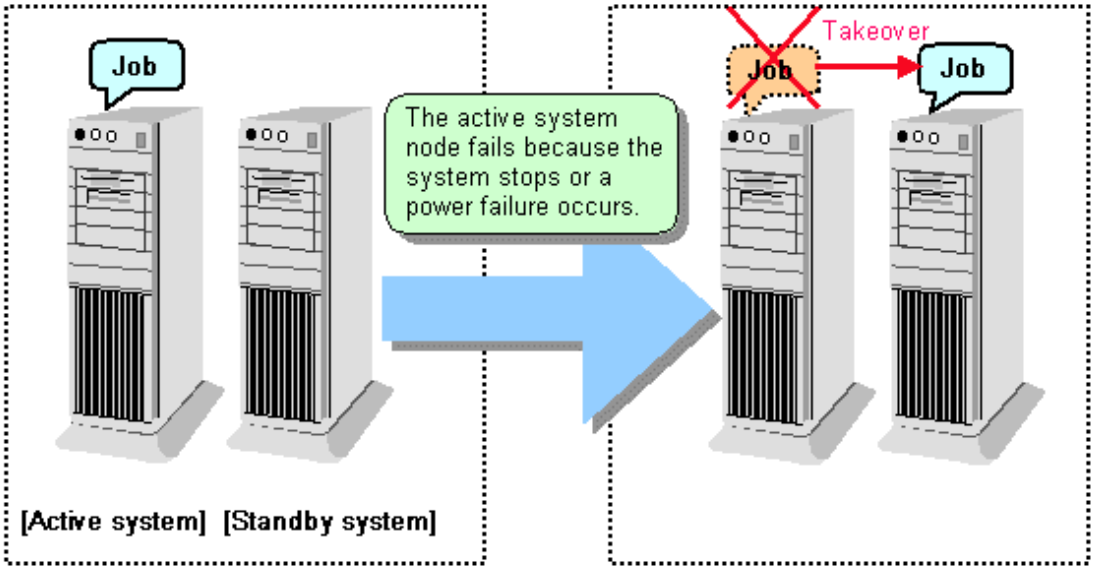
For example, if the active node fails, another server (standby node) inherits the shared disk content and becomes the active node. Using the PRIMECLUSTER feature, the applications to be run on the active node for the database can also be linked with the database and switched. Therefore, jobs can be continued even during recovery of a node where an abnormality has occurred. There is also no need to send the updated content of the database on the active node to the standby node, so the processing performance will be the same as that of a non-cluster system.

Information

- When failover operation is integrated with PRIMECLUSTER, the disk is not referenced by the standby node, and therefore failover operation cannot be used for load distribution.
- Streaming replication, which enables load balancing, can be combined with failover operations. For details, see "Appendix C Failover Operation in Streaming Replication".
- When failover operation is integrated with PRIMECLUSTER, failover operation cannot be performed concurrently with database multiplexing.

Hereinafter, failover operation integrated with PRIMECLUSTER is referred to as "failover operation".

Figure 1.1 Concept of failover



Feature of failover operation

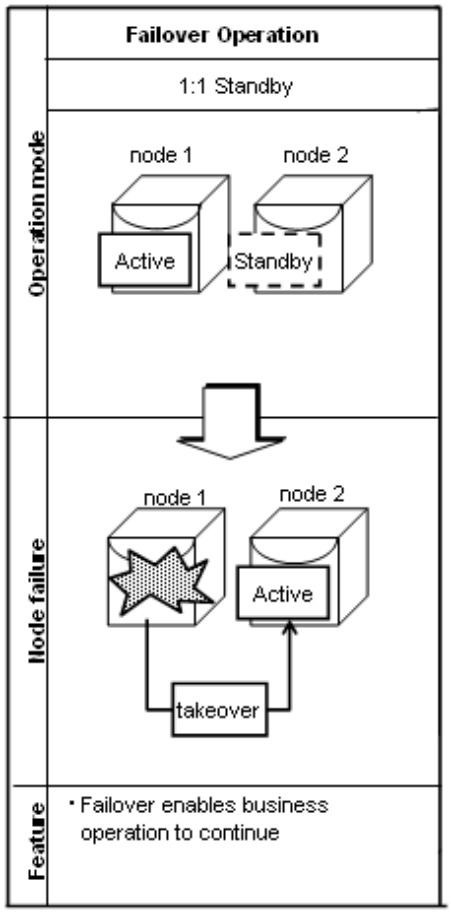
Failover operation supports the standby feature.

When an abnormality occurs on a node, the standby feature starts the instance that is the standby system at the time of the switch, and transfers the job to it.

Operation mode of failover operation

The operation mode supported in failover operation is 1:1 standby.

1:1 standby is a mode in which one active system or standby system operates on one node. Because failover allows jobs to continue when an abnormality occurs in the active system, this mode allows highly reliable systems to be constructed.



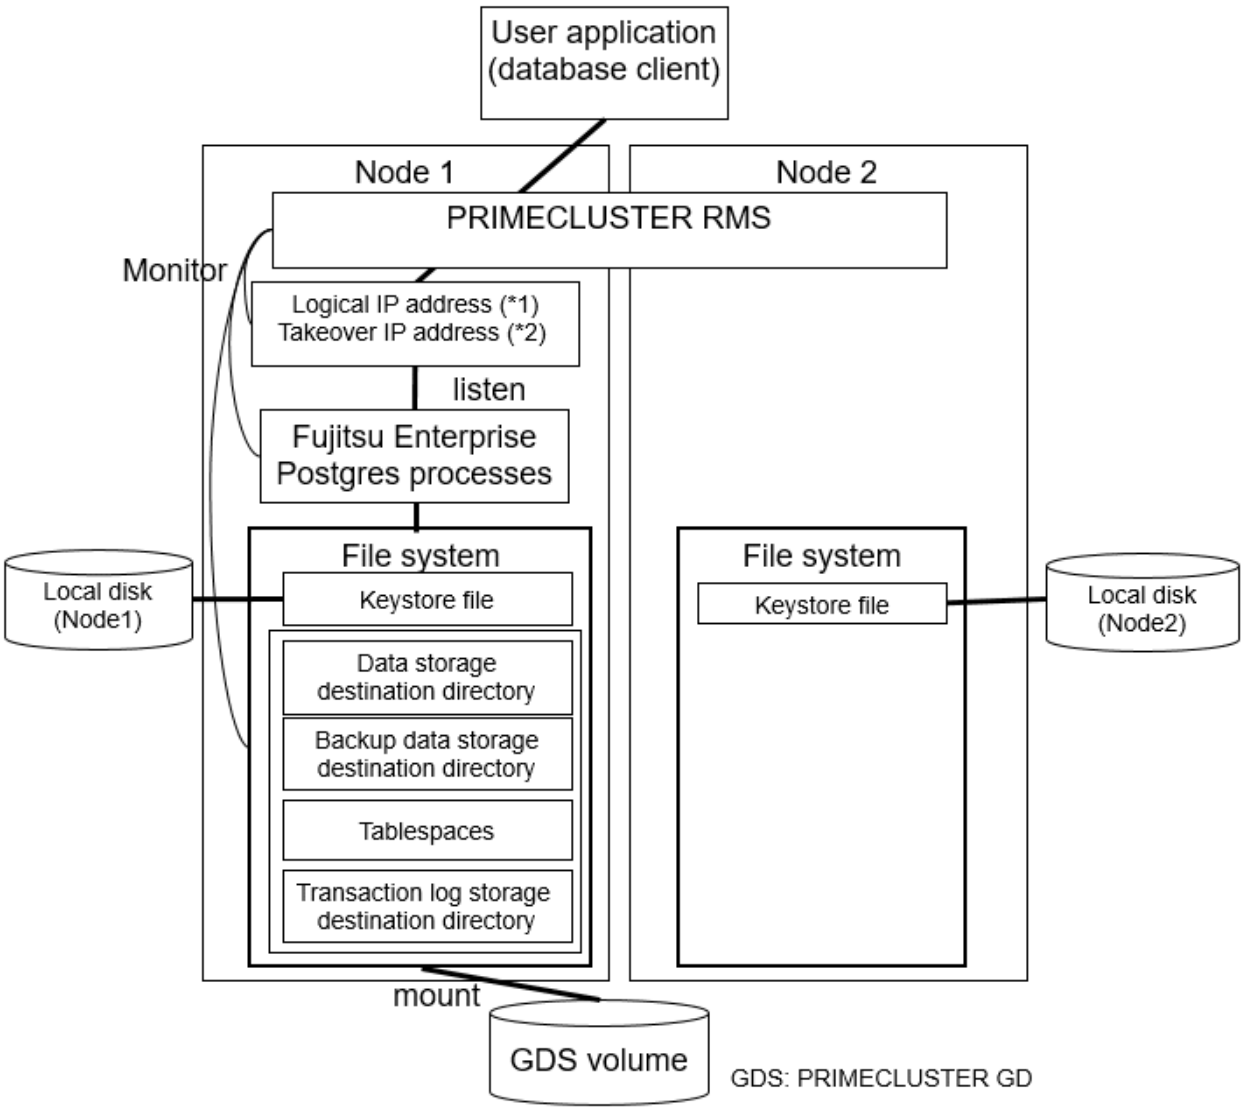
1.2 System Configuration of Failover Operation

In the illustration below, the file system is on a GDS volume (shared disk), mounted on node 1 only.

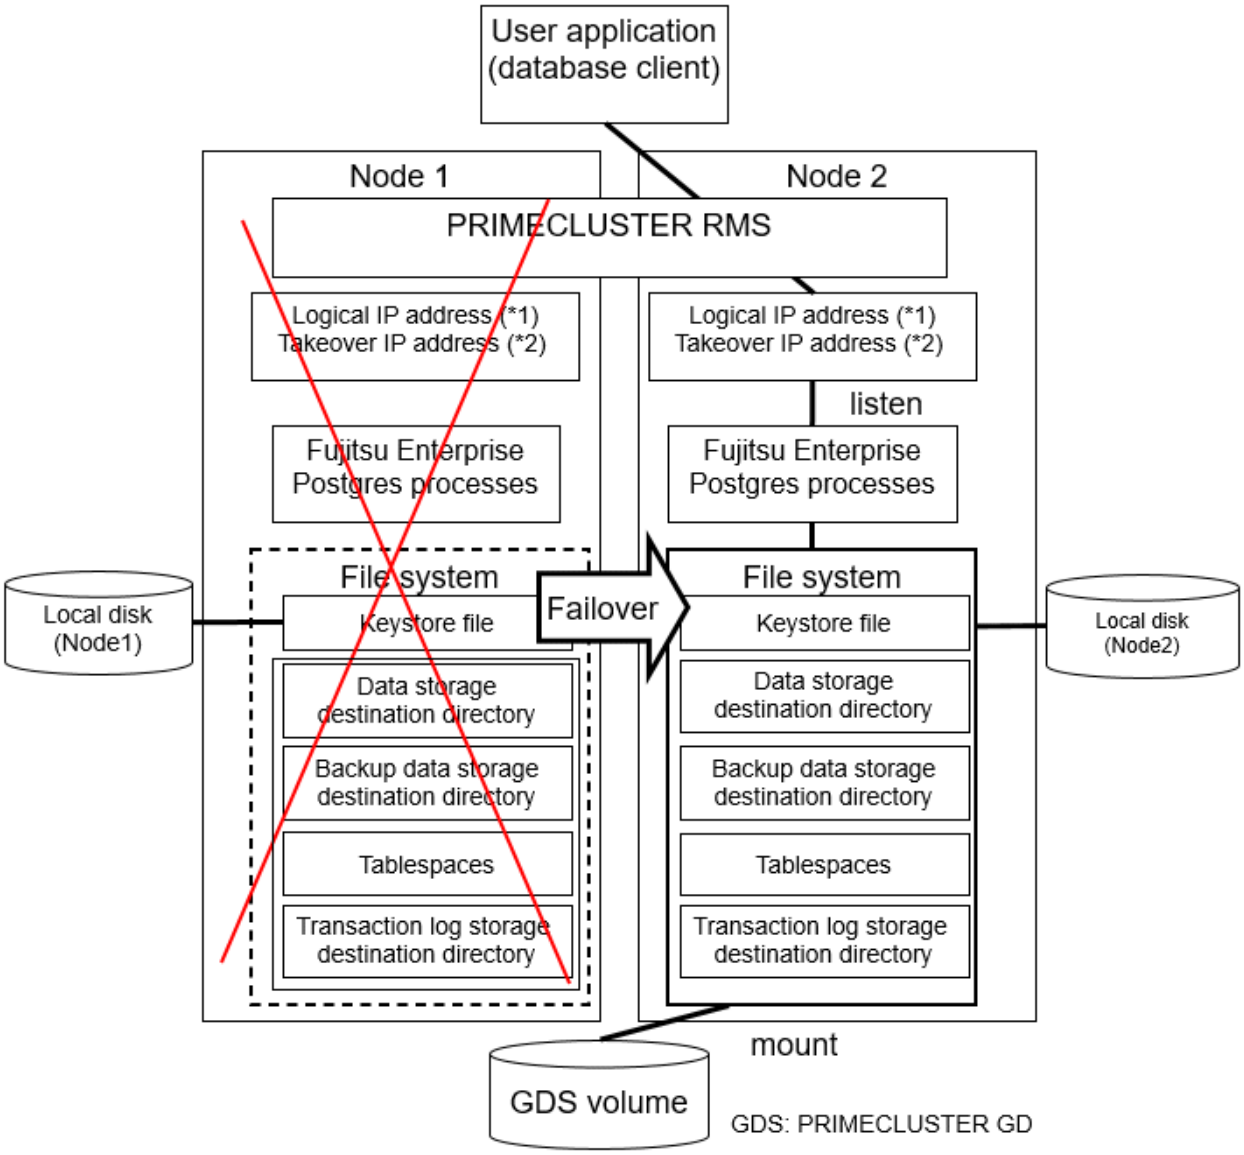
The following Fujitsu Enterprise Postgres resources are located in this file system:

- Data storage destination directory
- Tablespaces
- Backup data storage destination directory
- Transaction log storage destination directory

A Fujitsu Enterprise Postgres process waits for connections of user applications that access the database, on a logical IP address activated on node 1 only or on a takeover IP address.



When an error is detected on node 1, PRIMECLUSTER mounts the file system on node 2, and activates the logical IP address or the takeover IP address on it. The Fujitsu Enterprise Postgres process is also started on node 2. Since the logical IP address or the takeover IP address remains unchanged, the user application can access Fujitsu Enterprise Postgres process on node 2 simply by re-establishing the database connection.



*1: The function of PRIMECLUSTER GLS (Global Link Services)
*2: The function of PRIMECLUSTER Taking over network resource

Chapter 2 Setting Up Failover Operation

Use the procedure in the table below to perform setup:

Step	Work item		Reference
	Active system	Standby system	
1	Installing PRIMECLUSTER and Fujitsu Enterprise Postgres		2.1 Installing PRIMECLUSTER and Fujitsu Enterprise Postgres
2	Configuring PRIMECLUSTER		2.2 Configuring PRIMECLUSTER
3	Creating a GDS volume (*1)		2.3 Creating a GDS Volume
4	Creating a file system (*1)		2.4 Creating a File System
5	Creating a user for the operating system to start Fujitsu Enterprise Postgres		2.5 Creating an Operating System User to Start Fujitsu Enterprise Postgres
6	Mounting the file system		2.6 Mounting the File System
7	Creating a database cluster(*1)		2.7 Creating a Database Cluster
8	Registering resource information for the Fujitsu Enterprise Postgres database cluster		2.8 Registering Resource Information for the Fujitsu Enterprise Postgres Database Cluster
9	Configuring storage data protection using transparent data encryption (*1)		2.9 Configuring Storage Data Protection Using Transparent Data Encryption
10	Unmounting the file system		2.10 Unmounting the File System
11	Creating a cluster application		2.11 Creating a Cluster Application
12	Application development		2.12 Application Development
13	Checking operation		2.13 Checking Operation

*1: Some settings and operations must also be performed on the standby node. Refer to the relevant sections for details.

Note: GDS: PRIMECLUSTER GD

The sections that follow explain each step.

2.1 Installing PRIMECLUSTER and Fujitsu Enterprise Postgres

Refer to the manual for each product, and then install each product.

- Refer to the PRIMECLUSTER Installation and Administration Guide for information on how to install PRIMECLUSTER.
- Refer to the Installation and Setup Guide for Server for information on how to install Fujitsu Enterprise Postgres.

2.2 Configuring PRIMECLUSTER

Configure the initial settings for the cluster.

If using PRIMECLUSTER GL (hereafter referred to as "GLS"), configure the GLS settings.

Refer to the PRIMECLUSTER Installation and Administration Guide for information on steps required before setup.

2.3 Creating a GDS Volume

Create a GDS volume.

Each of the following Fujitsu Enterprise Postgres resources must be located in a file system on a GDS volume:

- Data storage destination directory
- Tablespaces
- Backup data storage destination directory
- Transaction log storage destination directory

Considerations when deploying resources

- Store data storage destination directories or tablespaces and backup data storage destination directories for these in different GDS classes to guard against file system corruption and the MONITORONLY attribute settings at the time of the Gds resource and Fsystem resource creation.
- It is also recommended that database storage destination directories and transaction log storage destination directories be placed in different groups or different single disks, so that the I/O load is distributed.

Considerations when mount directory

- Create a directory for each resource on each node. Ensure that the directories to be mounted have the same path on all nodes.

- Refer to the PRIMECLUSTER Installation and Administration Guide for information on GDS volume creation.
- Refer to "Preparing Directories to Deploy Resources" in the Installation and Setup Guide for Server for information on how to create directories.

2.4 Creating a File System

Create a file system.

See

- Refer to the PRIMECLUSTER Installation and Administration Guide for information on how to create a file system on a GDS volume.

2.4.1 Creating a File System

Use the operating system or file system command to create a file system on the GDS volume.

Example)

The example below creates a file system using ext4.

```
# mkfs -t ext4 /dev/sfdsk/class0001/dsk/volume0001
```

2.4.2 Editing Configuration Files

Edit /etc/fstab and /etc/fstab.pcl on each node.

- /etc/fstab

  Comment out each line below by prepending it with "#".

```
#/dev/sfdsk/class0001/dsk/volume0001 /mnt/swdsk1 ext4 noauto 0 0
#/dev/sfdsk/class0001/dsk/volume0002 /mnt/swdsk2 ext4 noauto 0 0
```

- /etc/fstab.pcl

  Copy the entries above, and then replace "#" in each line with "#RMS#", as follows:

```
#RMS#/dev/sfdsk/class0001/dsk/volume0001 /mnt/swdsk1 ext4 noauto 0 0
#RMS#/dev/sfdsk/class0001/dsk/volume0002 /mnt/swdsk2 ext4 noauto 0 0
```

2.4.3 Checking

Start the GDS volume, and ensure that each file system can be mounted on each node.

```
# mount -t ext4 /dev/sfdsk/class0001/dsk/volume0001 /mnt/swdsk1
# mount -t ext4 /dev/sfdsk/class0001/dsk/volume0002 /mnt/swdsk2
# umount /mnt/swdsk1
# umount /mnt/swdsk2
```

2.5 Creating an Operating System User to Start Fujitsu Enterprise Postgres

Create an operating system user (an OS user that will become the instance administrator) who is to start Fujitsu Enterprise Postgres.

Ensure that the name, UID, and GID of the operating system user (an OS user that will become the instance administrator) who is to start Fujitsu Enterprise Postgres match on all nodes that make up the cluster system.

2.6 Mounting the File System

1. Start the GDS volume if it has not already started.
2. Mount all file systems containing the resources required to create database clusters, such as for the data storage destination directory, as shown below:

```
# mount -t ext4 /dev/sfdsk/class0001/dsk/volume0001 /mnt/swdsk1
```

Information

It is not possible to use a directory mounted by NFS (Network File System) when using WebAdmin.

2.7 Creating a Database Cluster

1. Create the database cluster.

   a. Set environment variables.

      To execute the Fujitsu Enterprise Postgres commands, you must configure the environment variables on each node.

   b. Create a database cluster.

      Use the initdb command to create a database cluster.

   c. Edit postgresql.conf.

      Specify "off" for the restart_after_crash parameter in postgresql.conf.
      If "on" is specified, or the default value is used for the restart_after_crash parameter, behaviors equivalent to restarting the Fujitsu Enterprise Postgres, including crash recovery, will be performed when some server processes go down. When linking with PRIMECLUSTER, however, a failover will occur after an error is detected as soon as some server processes go down, and server processes restarting will be forced to stop. This is to inhibit complex behaviors such as processes being canceled in the middle of restarting for no particular meaningful purpose.
      Since postgresql.conf is stored in the data directory, it becomes a common configuration file for each node in the shared disk. Therefore, it must be taken into account that the path set for postgresql.conf must be valid for the Fujitsu Enterprise Postgres server processes started on each node. For example, if a local directory is specified in the core_directory parameter, that local directory must have been created on all nodes.

   d. Edit the /etc/services file.

      The value specified for the port parameter in postgresql.conf needs to be set in the /etc/services files on all nodes.

   e. Sets the password.

      If the configuration requires password authentication, create a .pgpass file in the home directory of the operating system user who is to start Fujitsu Enterprise Postgres, and then specify a password for the template1 database as this is required. This will be used when PRIMECLUSTER checks the operation of the Fujitsu Enterprise Postgres database server. If authentication fails, a fault will be assumed to have occurred in the database server.

2. Check starting, connection, and stopping at each node. The procedure is as follows.

   Point

   When monitoring Fujitsu Enterprise Postgres from PRIMECLUSTER, the name of the application that connects to instances is "pgx_wch_svprocess".
   Queries are issued to monitor the Fujitsu Enterprise Postgres from PRIMECLUSTER.

   a. Check the starting, connection, and stopping at node 1.

      Use the pg_ctl command to start and stop the node.

      For connection, execute the following to ensure that connections can be made without entering a password:

      ```
      su - OsUser
      psql -d template1 -p portNum [ -U dbUser]
      ```

      OsUser: Operating system user to start the Fujitsu Enterprise Postgres
      portNum: Port number specified when the database cluster was created
      dbUser: Database superuser

If the database superuser is specified at the time of executing the initdb command, or if the database superuser has been changed after the initdb command was executed, specify the user for the -U option. If the database superuser is not specified or changed, omit this.

b. Unmount all file systems containing the resources required to create database clusters (such as the data storage destination directory) on node 1, and stop the GDS volume.

c. Start the GDS volume on node 2, and mount all file systems containing the resources required to create database clusters (such as the data storage destination directory).

d. Check starting, connection, and stopping at node 2.

   Perform the same check as step 1.

e. Unmount all file systems containing the resources required to create database clusters (such as the data storage destination directory) on node 2, and stop the GDS volume.

f. Start the GDS volume on node 1, and mount all file systems containing the resources required to create database clusters (such as the data storage destination directory).

See

- Refer to "Using the initdb Command" of "Creating an Instance" in the Installation and Setup Guide for Server" for information on how to create a database cluster.
- Refer to "The Password File" in "Client Interfaces" in the PostgreSQL Documentation for information on files for which passwords are set.

2.8 Registering Resource Information for the Fujitsu Enterprise Postgres Database Cluster

Use the pgx_pclrsc command to register the database cluster in PRIMECLUSTER - the following is the simplest execution example: The database cluster does not need to be started when executing the command. Refer to the "B.1 pgx_pclrsc" for information on the pgx_pclrsc command.

```
# pgx_pclrsc -a -c databaseClusterName -u OsUser -D pgData -w workDir -n memberNodes
```

Item	Explanation
databaseClusterName	Specify the Fujitsu Enterprise Postgres database cluster name. The database cluster name is case-sensitive. The database cluster name must be as follows: - Up to 16 bytes, and - The first byte must be an ASCII letter, and - The other bytes must be ASCII alphanumeric characters, or underscores (_).
OsUser	Specify the operating system user (an OS user that will become the instance administrator) who can start the Fujitsu Enterprise Postgres database server.
pgData	Specify the absolute path of the data storage destination directory specified during database cluster creation.
workDir	Specify the directory for storing the temporary files required for Fujitsu Enterprise Postgres resource

Item	Explanation
	monitoring and state transition, and for storing the trace logs required in case of problems. If a parent directory that does not exist is specified, create the directory. The newly created directory path assumes the *OsUser* specified with the -u option as the owner, and 0700 as the privilege Required directory size is twice the size that is specified in the --trace-max-file-size option. If the default value is specified in the --trace-max-file-size option, 10240 KB x 2 is required for the directory size.
memberNodes	Specify the names of all nodes that make up the cluster system. Use a comma (,) to separate each node name. Suffix each cluster node name with the literal "RMS". Specification example: -n node1RMS,node2RMS

Other than the above, the following options can be specified:

Option	Explanation
--db-user=name	Specify the Fujitsu Enterprise Postgres database superuser. The user specified in the -u option is the default.
--response-timeout=seconds	In cluster operations, queries are regularly issued to the server to perform error detection and state monitoring. Specify a timeout time for queries issued for the heartbeat monitoring of the Fujitsu Enterprise Postgres database server. For queries, "SELECT 1" for the database "template1" is used. If 0 is specified, queries will not time out. The default is 0.
--timeout-retry-count=count	Specify the upper limit for the number of retries when queries for monitoring time out. The default is 6 times.
--trace-max-file-size	Specify the maximum size of the trace file. The default is 10240 KB.
--watch-interval=seconds	Specify the monitoring interval (the interval with which the queries are issued to the server) for a monitoring program to monitor the Fujitsu Enterprise Postgres database server. The default is 3 seconds.

2.9 Configuring Storage Data Protection Using Transparent Data Encryption

If using transparent data encryption, refer to "Protecting Storage Data Using Transparent Data Encryption" in the Operation Guide to configure it. Take note on the following when configuring it:

For file-based keystores

Location of the keystore file

Do not specify a shared disk for the keystore_location parameter in postgresql.conf. Instead, specify a local directory with the same path on all nodes that comprise the cluster application.

If a shared disk is specified, startup from the cluster application will fail. This is because the keystore.aks file, which is generated when automatic opening of the keystore is enabled, is obfuscated so that it can only be read on the node where it was generated, and therefore it cannot be shared across the shared disk.

Distribution of the keystore file

The master encryption key settings must be common across all nodes. For this reason, configure the master encryption key settings on one node, and then copy the keystore file to each node. Also, if the master encryption key or passphrase is changed, you must also copy the keystore file to each node.

Enabling automatic opening of the keystore

Automatic opening of the keystore must be enabled in all nodes that comprise the cluster application. Note that, when enabling the automatic opening of the keystore, only the directory in which the keystore file is stored will be referenced, therefore tasks such as starting and stopping the GDS volume are not required.

If it is not enabled, then startup from the cluster application will fail. This is because the startup process will not finish, since it waits for the manual input of the passphrase that opens the keystore.

Using a key management system

Arrangement of connection information file for key management system

The file describing the key management system connection information specified in the tde_kms.kms_conninfo_file parameter of the postgresql.conf file and the files referenced by that file, such as certificates, can be placed on a shared disk. However, the obfuscated credential file used to enable automatic keystore opening should be stored in a file on a local disk with the same path on all nodes that make up the cluster application.

Enable auto open keystore

Be sure to enable automatic keystore opening. Enable automatic keystore opening on all nodes that make up the cluster application. Note that you do not need to start or stop the GDS volume, because enabling automatic keystore opening refers only to the directory where the obfuscated credential file resides.

If you have not enabled automatic keystore opening, startup from the cluster application fails. because it waits for a manual pass phrase to be entered to open the keystore at startup, and does not terminate startup.

Changing credentials for key management systems

If the credentials for the key management system change, use the pgx_open_keystore function on the primary server to change the credentials. Repeat the procedure for enabling automatic keystore opening on the standby server.

2.10 Unmounting the File System

1. Stop the database cluster.
2. Unmount all file systems containing the resources required to create database clusters (such as the data storage destination directory).

```
# umount /mnt/swdsk1
```

3. Stop the GDS volume.

2.11 Creating a Cluster Application

Refer to "Appendix A Creating Resources and Creating/Modifying Cluster Applications".

2.12 Application Development

This section explains points to consider when creating applications during cluster operations.

2.12.1 Precautions when Developing Applications

To specify the IP address specified by the application, specify the IP address specified when creating the Gls resource or creating the takeover network resource. When state transition occurred, the operation can continue only by re-execute without changing the application.

Refer to "A.1.5 Creating Gls or Takeover Network Resources" for details.

2.12.2 Corrective Action with Application when State Transition Occurs

When accessing from an application running on another node such as an application server, the following describes the error information to be returned when an abnormality or the like occurs in the node where Fujitsu Enterprise Postgres operates, and the actions.

JDBC driver

State		Error information(*1)	Action
Node failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	57P01 08006	After the switch is complete, reestablish the connection, or re-execute the application.
	Accessed during node/system failure	08001	
Switch to the standby node	Switched during access	57P01 08006	
	Accessed during switch	08001	

*1: Return value of the getSQLState() of SQLException.

ODBC driver

State		Error information(*1)	Action
Node failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	57P01 08S01	After the switch is complete, reestablish the connection, or re-execute the application.
	Accessed during node/system failure	08001	
Switch to the standby node	Switched during access	57P01 08S01	
	Accessed during switch	08001	

*1: Return value of SQLSTATE.

.NET Data Provider

State		Error information	Action
Node failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	57P01 (*1) Empty string (*1) NullReferenceException is generated.	After the switch is complete, reestablish the connection, or re-execute the application.
	Accessed during node/ system failure	Empty string (*1)	
Switch to the standby node	Switched during access	57P01 (*1) Empty string (*1) NullReferenceException is generated.	
	Accessed during switch	Empty string (*1)	

*1: This is the return value of the PostgresException attribute SqlState.

C library(libpq)

State		Error information	Action
Node failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	PGRES_FATAL_ERROR(*1) 57P01(*2) NULL(*2)	After the switch is complete, reestablish the connection, or re-execute the application.
	Accessed during node/system failure	CONNECTION_BAD(*3)	
Switch to the standby node	Switched during access	PGRES_FATAL_ERROR(*1) 57P01(*2) NULL(*2)	
	Accessed during switch	CONNECTION_BAD(*3)	

*1: Return value of PQresultStatus().

*2: Return value of PQresultErrorField() PG_DIAG_SQLSTATE.

*3: Return value of PQstatus().

Embedded SQL in C

State		Error information(*1)	Action
Node failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	57P01 57P02 YE000 26000 40001	After the switch is complete, reestablish the connection, or re-execute the application.

State		Error information(*1)	Action
	Accessed during node/system failure	08001	
Switch to the standby node	Switched during access	57P01 57P02 YE000 26000 40001	
	Accessed during switch	08001	

*1: Return value of SQLSTATE

Embedded SQL in COBOL

State		Error information(*1)	Action
Node failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	57P01 57P02 YE000 26000 40001	After the switch is complete, reestablish the connection, or re-execute the application.
	Accessed during node/system failure	08001	
Switch to the standby node	Switched during access	57P01 57P02 YE000 26000 40001	
	Accessed during switch	08001	

*1: Return value of SQLSTATE.

2.13 Checking Operation

To ensure that the environment settings have been configured correctly, start, switch, and stop from Web-Based Admin View, and check the behavior.

To do a failover test, follow the procedure below.

1. Stop the Fujitsu Enterprise Postgres server processes by pg_ctl command with immediate mode.

   Example)

   ```
   # pg_ctl stop -m immediate
   ```

2. Check whether switching was done correctly.

Information

Fujitsu Enterprise Postgres uses the su(1) command to periodically monitor its resources.

Therefore, in a RHEL environment, after a cluster system is built, operating system messages relating to the su(1) command will be periodically output to /var/log/messages during cluster system operation.

Refer to the relevant manual of your operating system for information on how to control these messages.

Chapter 3 Failover Operation

This chapter explains the procedures involved in failover operation.

3.1 Adding Tablespaces

This section explains how to add tablespaces to a new file system.

This procedure is not required when you are adding tablespaces to an existing file system.

Perform the following steps when using a new shared disk class:

- Stop RMS on all nodes.
- Perform setup as described from "2.3 Creating a GDS Volume" to "2.4 Creating a File System".
- Modify the cluster application (refer to "A.2 Modifying Cluster Applications" for details).

Perform the following steps when using a new shared disk class:

- Stop RMS on all nodes.
- Perform the setup as described in "2.4 Creating a File System".

  If a new GDS volume is to be used, the GDS volume must be created in advance.
- Modify the cluster application (refer to "A.2 Modifying Cluster Applications" for details).

3.2 Modifying Database Cluster Resources

This section explains the following operations:

- Displaying database cluster resource information
- Modifying database cluster resource content
- Deleting a database cluster resource

Each operation is performed with the pgx_pclrsc command. Refer to "B.1 pgx_pclrsc" for information on the pgx_pclrsc command.

Displaying database cluster resource information

Execute the pgx_pclrsc command as shown below (note that if -c is not specified, the command lists all registered database cluster names):

```
# pgx_pclrsc -p -c databaseClusterName
```

Modifying database cluster resource content

If you are modifying resource content, first delete the Fujitsu Enterprise Postgres resource from the cluster application, and then re-register it. This is the simplest example

1. Stop RMS.
2. Execute the pgx_pclrsc command to remove it:

   ```
   # pgx_pclrsc -d -c databaseClusterName
   ```
3. Execute the pgx_pclrsc command to re-register:

   ```
   # pgx_pclrsc -a -c databaseClusterName -u OsUser -D pgData -w workDir -n memberNodes
   ```

Deleting a database cluster resource

1. Stop RMS.
2. Delete the Fujitsu Enterprise Postgres resource from the cluster application.

3. Execute the pgx_pclrsc command as shown below:

```
# pgx_pclrsc -d -c databaseClusterName
```

4. The directory specified in the -w option of the pgx_pclrsc command during registration will not be deleted. Use operating system commands to delete it if necessary.

3.3 Operations under Normal Circumstances

Starting and stopping

For cluster operations, perform starting and stopping from the cluster application. If starting and stopping are performed by using the pg_ctl command or WebAdmin during failover operation, the cluster application will misjudge that services have gone down, resulting in unexpected behaviors.

Information

Issuing a query to monitor Fujitsu Enterprise Postgres from PRIMECLUSTER.

If a query is issued during startup or shutdown, the following message may be printed, but this is not a problem.

```
FATAL:  Database system is in the process of starting
```

```
FATAL:  Database system is shutting down
```

Switching

There are two ways to switch between the active node and the standby node, as shown below.

Under normal circumstances, switch using mutual switch. In an emergency, for example when there is no response from the active node, perform forced switch. Forced switch should only be used in emergency scenarios because the differences in Fujitsu Enterprise Postgres stop modes when the active node is offline will cause the statistics to be initialized, and the load will increase as crash recovery is performed after the switch.

- Mutual switch

  Refer to "3.5.2.4 Mutual Switch".

  Fujitsu Enterprise Postgres is stopped with the "fast" mode of the pg_ctl command.

- Forced switch

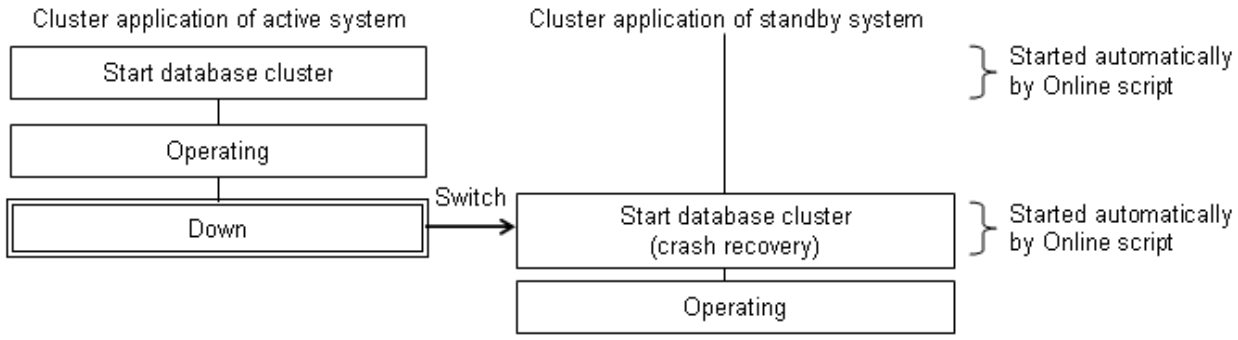
  Right-click the cluster application object, and select [Switch] from the menu. From the switchable nodes displayed in the drop-down menu, select a target node, and switch the cluster application to that node.

  Fujitsu Enterprise Postgres is stopped with the "immediate" mode of the pg_ctl command.

3.4 Operation at State Transition

The workflow for operation at state transition is shown below.

The start operation during failover operation will be performed automatically by the Online script.



Non-transferrable feature

- All transactions being processed by the cluster application on the active system will be rolled back.
- The statistics Fujitsu Enterprise Postgres has collected will be initialized.

  The statistics will be initialized in any of the following cases. Refer to the notes outlined in "Starting and Stopping an Instance" in the Operation Guide for details.

  - When the node goes down because of a kernel panic, for example
  - When forced switch is performed

    Statistics are initialized because the "immediate" mode of the pg_ctl command is used to stop Fujitsu Enterprise Postgres.

    Refer to "3.3 Operations under Normal Circumstances" for details.
  - When an error occurs in the cluster application resources

    Statistics are initialized because the "immediate" mode of the pg_ctl command is used to stop Fujitsu Enterprise Postgres to perform an immediate switch.

Errors during state transition

If an error occurs in a Fujitsu Enterprise Postgres script during cluster application state transition, the following message will be displayed in the switchlog of Cluster Admin (the registered database cluster name will be displayed in the inst1 part shown below):

```
2017-05-14 11:08:22.060:(DET, 3): ERROR: FAULT REASON: Resource <Fsep_inst1> transitioned to a
Faulted state due to a script failure.
```

To display the switchlog, select [Tools] >> [View switchlog] in the [Cluster Admin] window.

If the resource displayed in the error message is a Fujitsu Enterprise Postgres resource name, a message indicating the cause will be output either before the message above or to the system log.

3.5 Maintenance Tasks

When you need to perform tasks such as configuration changes, patch application, and hardware parts replacement that may require restarting, there are two ways of node maintenance. Performing maintenance on both nodes by stopping both active and standby nodes, and performing maintenance on one node at a time by leaving the active node running to perform maintenance on the standby node first, and then switch the active node to perform maintenance on the other node. In this section, the former is referred to as simultaneous stopped node maintenance, whereas the latter is referred to as mutual switch maintenance.

Refer to the tasks outlined below in either "Figure 3.1 Workflow for simultaneous stopped node maintenance" or "Figure 3.2 Workflow for mutual switch maintenance", and perform your maintenance tasks accordingly.

Figure 3.1 Workflow for simultaneous stopped node maintenance

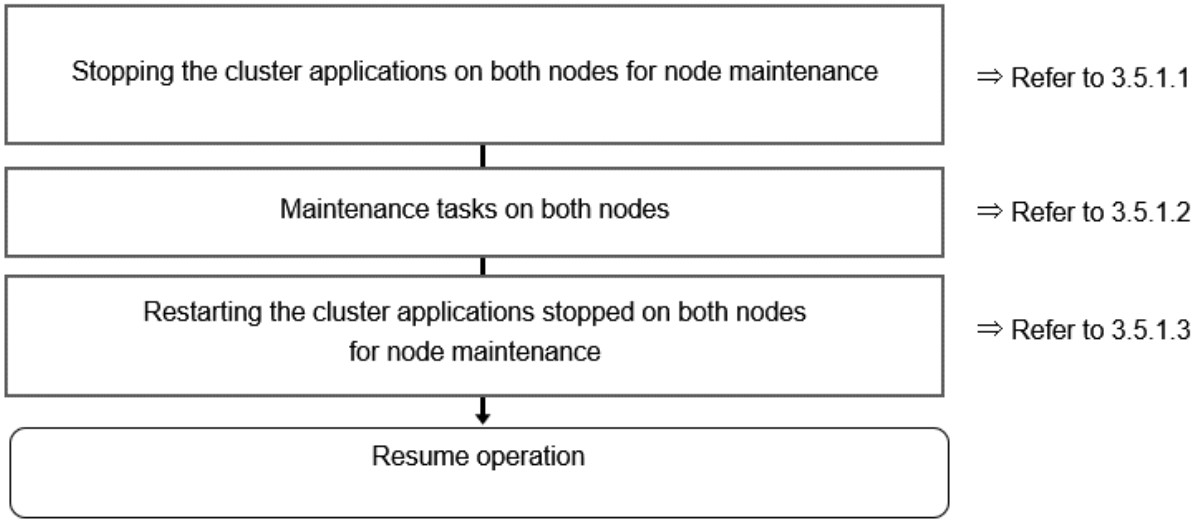


Figure 3.2 Workflow for mutual switch maintenance

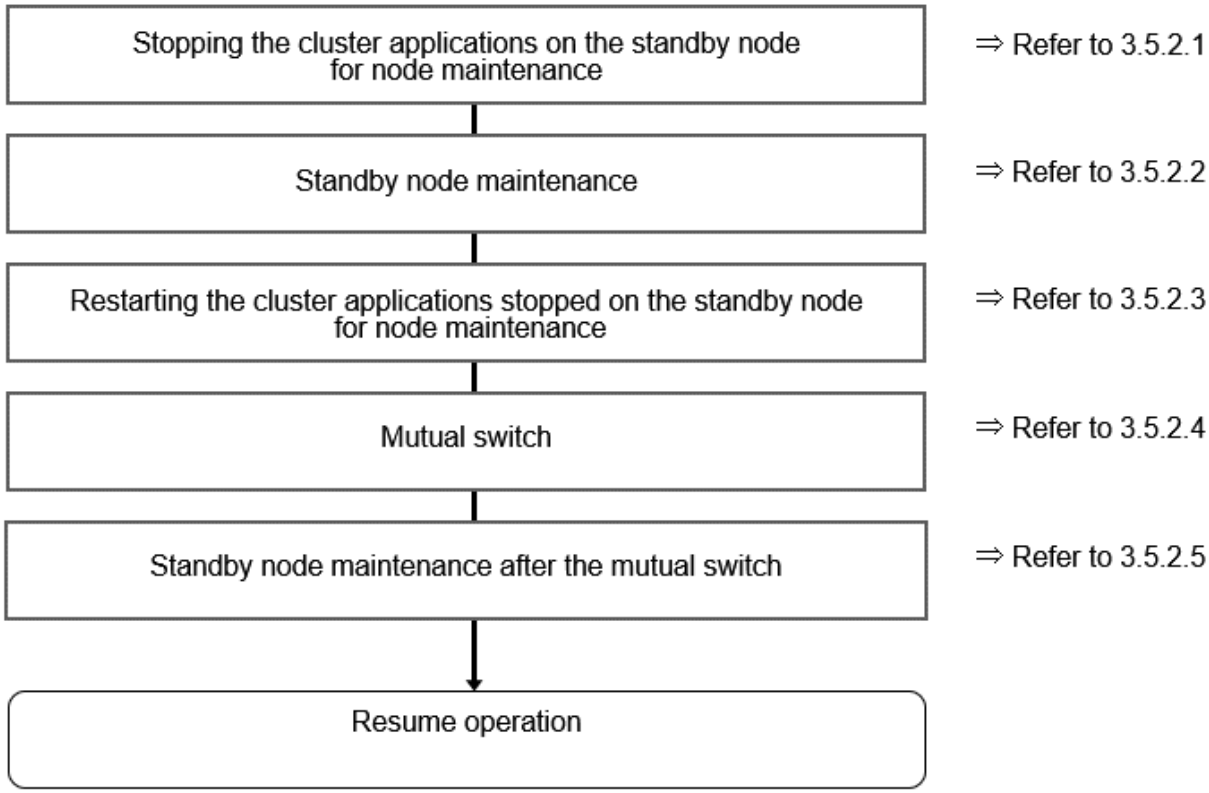


3.5.1 Simultaneous Stopped Node Maintenance

This section explains the procedure to perform maintenance on both active and standby nodes simultaneously.

3.5.1.1 Stopping the Cluster Applications on Both Nodes for Node Maintenance

Follow the steps shown below to stop the cluster application on the active and standby nodes:

1. Start the [Cluster Admin] window.

2. Stop the cluster application.

   On the RMS tree in the [Cluster Admin] window, right-click the standby cluster application to be stopped, and select [Offline] from the pop-up menu to stop it.
   Stop the cluster application on both the active and standby nodes.

3. Stop RMS.

   On the RMS tree in the [Cluster Admin] window, right-click the system node where the cluster application to be stopped exists, and select [Shutdown RMS] from the pop-up menu to stop RMS. To perform maintenance without stopping RMS, execute the hvutil -m on command to change the cluster application to maintenance mode.
   By stopping RMS, all cluster applications on the system node where RMS is stopped will stop. When you have multiple cluster applications configured, ensure that stopping all other cluster applications will not cause any problems, before stopping RMS.

Information

If applying the Fujitsu Enterprise Postgres update patches, RMS on the node (onto which the patches are applied) must be stopped. This is because the Fujitsu Enterprise Postgres monitoring process that runs when linked with PRIMECLUSTER must be stopped.

3.5.1.2 Maintenance Tasks on Both Nodes

Perform maintenance tasks such as configuration changes, patch application, hardware and parts replacement that may require restarting.

3.5.1.3 Restarting the Cluster Applications Stopped on Both Nodes for Node Maintenance

Follow the steps shown below to restart the cluster application on the active and standby nodes.

1. Start the [Cluster Admin] window.
2. If RMS has not been started, select [Tools] >> [Start RMS] in the [Cluster Admin] window, and select the node to be started and click [Ok].

   Note that if the cluster applications were stopped for node maintenance using the hvutil -m on command, execute the hvutil -m off command instead of starting RMS.

3. Start the cluster application.

   On the RMS tree in the [Cluster Admin] window, right-click the standby cluster application, and from the pop-up menu, if you are starting the node as the active node, select [Online], or if you are starting it as the standby node, select [Standby]. If the state is [Fault], then select [Clear fault].

   This operation is not required if the cluster application has been configured to start automatically when RMS is started.

3.5.2 Mutual Switch Maintenance

This section explains the procedure to perform maintenance on the standby node while running the active node at the same time.

3.5.2.1 Stopping the Cluster Applications on the Standby Node for Node Maintenance

Follow the steps shown below to stop the cluster application on the standby node only:

Ensure that the steps up to step 3 have been completed properly before performing the maintenance tasks. If the active node goes down at the point when steps 1 and 2 have been completed, Fujitsu Enterprise Postgres will be started on the supposedly stopped standby node, and it becomes the active node instead. As a result, this will compete with the maintenance tasks and unexpected behavior may occur.

1. Edit the /opt/SMAW/SMAWRrms/bin/hvenv.local file, and add "export HV_RCSTART=0".

   If the hvenv.local file does not exist, then create it.

```
# vi /opt/SMAW/SMAWRrms/bin/hvenv.local
Add export HV_RCSTART=0
```

2. On the RMS tree in the [Cluster Admin] window, right-click the cluster application on the standby node to be stopped, and select [Offline] from the pop-up menu to stop it.

3. On the RMS tree in the [Cluster Admin] window, right-click the system node (where the cluster application on the standby node that was stopped exists), and select [Shutdown RMS]. At this stage, select [Stop all Apps] as the option, and stop RMS.
   By stopping RMS, all cluster applications on the system node where RMS is stopped will stop. When you have multiple cluster applications configured, ensure that stopping all other cluster applications will not cause any problems, before stopping RMS.

Information

If applying the Fujitsu Enterprise Postgres update patches, RMS on the node (onto which the patches are applied) must be stopped. This is because the Fujitsu Enterprise Postgres monitoring process that runs when linked with PRIMECLUSTER must be stopped.

3.5.2.2 Standby Node Maintenance

Perform maintenance tasks such as patch application and hardware parts replacement.

3.5.2.3 Restarting the Cluster Applications Stopped on the Standby Node for Node Maintenance

Follow the steps shown below to restart the cluster application on the standby node only (that was stopped for maintenance):

1. Edit the /opt/SMAW/SMAWRrms/bin/hvenv.local file, and delete "export HV_RCSTART=0".

```
# vi /opt/SMAW/SMAWRrms/bin/hvenv.local
Delete export HV_RCSTART=0
```

2. Select [Tools]-[Start RMS] in the [Cluster Admin] window, and select the node to be started and click [Ok].

3. On the RMS tree in the [Cluster Admin] window, right-click the cluster application to be started as the standby node, and select [Standby] from the pop-up menu to start it. If the state is [Fault], then select [Clear fault].

3.5.2.4 Mutual Switch

To perform mutual switch between the active and standby nodes, perform the steps shown below:

1. Select and right-click the cluster application on the active node, and select [Offline] from the pop-up menu to stop it.

2. Select and right-click the cluster application on the standby node, and select [Online] from the pop-up menu to start it.

3. Select and right-click the cluster application that was previously on the active node, and select [Standby] from the pop-up menu to start it as standby.

3.5.2.5 Standby Node Maintenance after the Mutual Switch

To perform maintenance tasks on the new standby node after mutual switch, perform the steps from "3.5.2.1 Stopping the Cluster Applications on the Standby Node for Node Maintenance" to "3.5.2.3 Restarting the Cluster Applications Stopped on the Standby Node for Node Maintenance".

Chapter 4 Procedures Required after a Failover Error

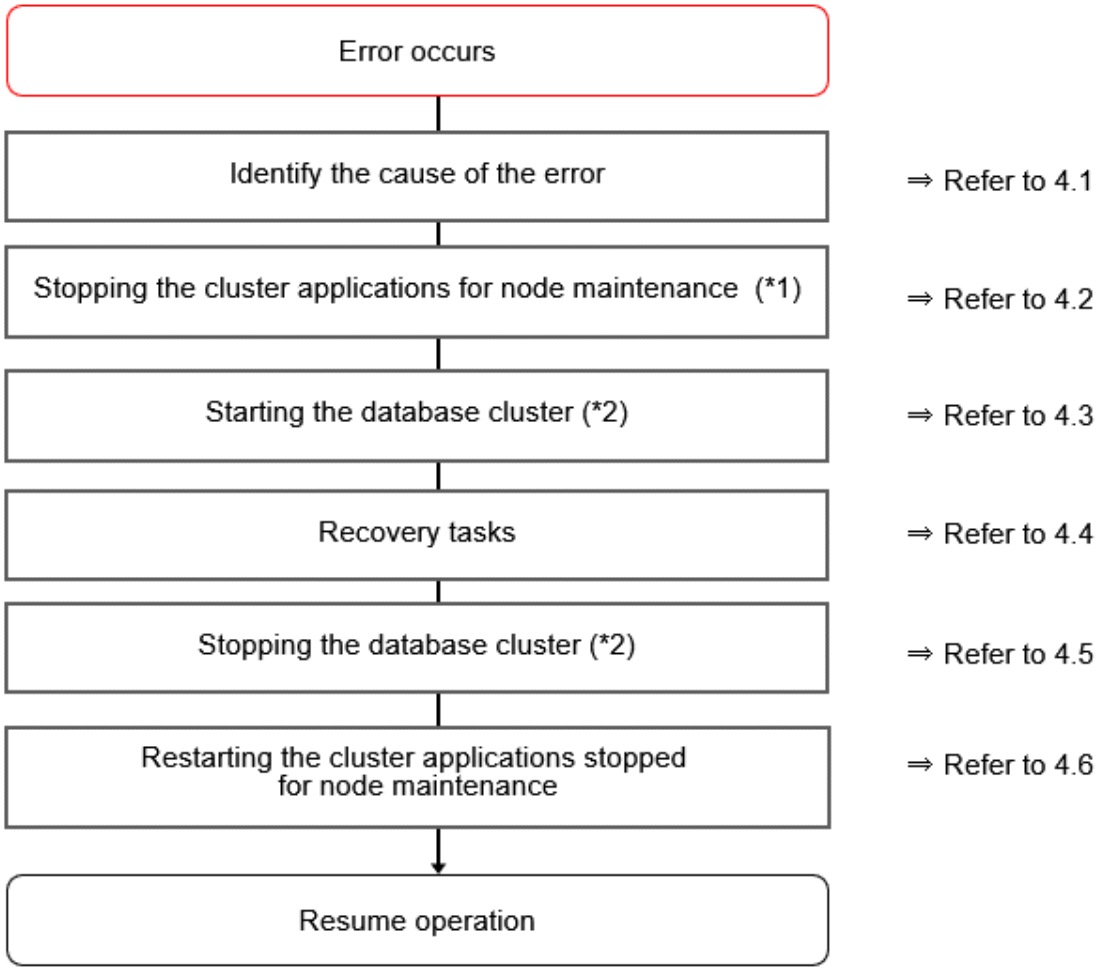
This chapter explains how to perform recovery when an abnormality occurs during failover operation.

When an error occurs during failover operation, refer to the system log to identify the cause and stop the RMS to perform recovery, separately from the RMS management. Normal operations can be resumed by restarting the RMS once the recovery is completed.

Note that the database cluster may be started or stopped without using cluster applications when performing recovery.

Refer to the tasks outlined below in "Figure 4.1 Operation flow when a failover error occurs", and perform recovery.

Figure 4.1 Operation flow when a failover error occurs



*1) If the machine is already stopped when the error occurred, this step is not necessary.

*2) Depending on the recovery tasks, start or stop the database cluster as required.

4.1 Identifying the Cause of an Error

When an error occurs during failover operation, refer to the system log to identify the cause. When cluster applications fail to start, refer to the server.log file to identify the cause.

The server.log file is a file created under the directory specified in the -w option when executing the pgx_pclrsc command. This file has almost the same content as the file specified in the -l option when executing the pg_ctl command to start the database cluster, and errors that are not output to the system log are output to these files, including startup errors.

4.2 Stopping the Cluster Applications for Node Maintenance

When an error occurs during failover operation, stop the RMS to perform recovery, separately from the RMS management. Refer to "3.5 Maintenance Tasks" for information on how to stop cluster applications for node maintenance.

Note that this task is not required in cases such as when the RMS is stopped because the machine is stopped due to an error.

4.3 Starting the Database Cluster

To perform recovery when an error occurs, it is necessary to start the database cluster without using cluster applications.

Follow the procedure below to start the database cluster if required.

Check if the database cluster needs to be started by referring to the recovery tasks written in "Actions When an Error Occurs" in the Operation Guide.

1. Start the GDS volume.
2. Mount the necessary file systems such as those where the data storage destination directory is placed.
3. Start the database cluster by using the pg_ctl command. Refer to "Using Server Commands" in "Starting an Instance and Creating a Database" in the Operation Guide for information on how to start the database cluster.

4.4 Recovery Tasks

Refer to "Actions When an Error Occurs" in the Operation Guide for information on how to perform recovery. If there are two ways available to perform recovery; using WebAdmin or commands, use commands.

4.5 Stopping the Database Cluster

If a database cluster is started, stop the database cluster.

1. Stop the database cluster using the pg_ctl command. Refer to "Using Server Commands" in "Starting an Instance and Creating a Database" in the Operation Guide" for information on how to stop the database cluster.
2. Unmount the file systems such as those where the data storage destination directory is placed.
3. Stop the GDS volume.

4.6 Restarting the Cluster Applications Stopped for Node Maintenance

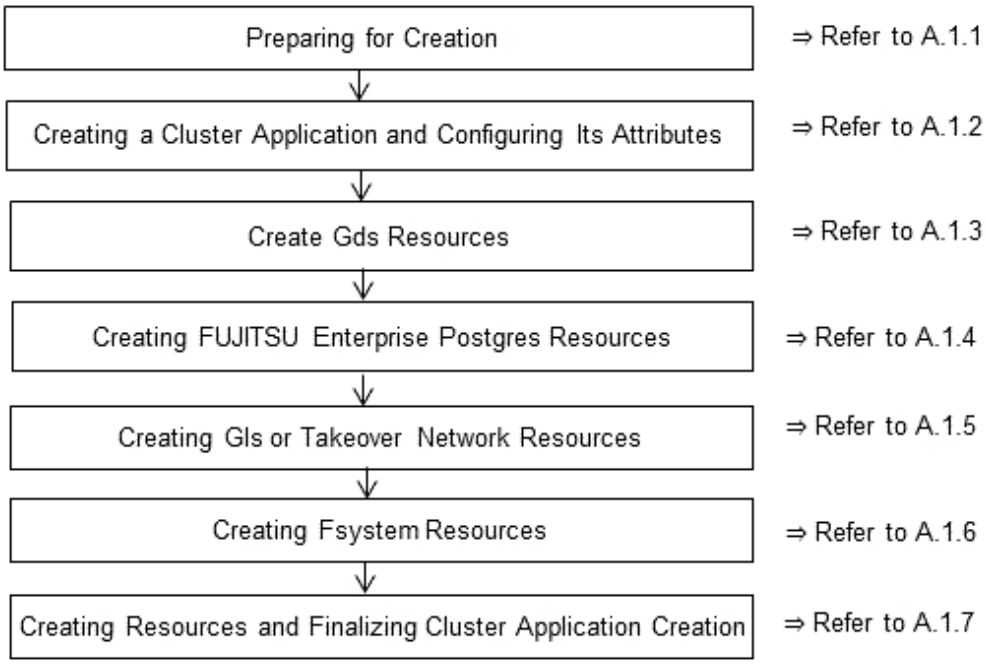
Refer to "3.5 Maintenance Tasks" to restart the cluster applications stopped for node maintenance.

Appendix A Creating Resources and Creating/Modifying Cluster Applications

This appendix explains how to create and modify cluster applications that include Fujitsu Enterprise Postgres resources in PRIMECLUSTER.

A.1 Creating Resources and Cluster Applications

Use the following procedure to create resources and a cluster application:



A.1.1 Preparing for Creation

1. Execute the hvgdsetup command for all shared disk classes to be used by all file systems to be registered in the cluster application.

```
# /opt/SMAW/SMAWRrms/bin/hvgdsetup -a class0001
```

2. From the Web-Based Admin View, stop RMS on all nodes.

3. Execute the hvw command.

```
# /opt/SMAW/SMAWRrms/bin/hvw
```

See

Refer to the PRIMECLUSTER Installation and Administration Guide for information on the hvgdsetup command.

A.1.2 Creating a Cluster Application and Configuring Its Attributes

1. Select [Application-Create].

```
pcl-vm13: Main configuration menu, current configuration: config
No RMS active in the cluster
 1) HELP                                10) Configuration-Remove
```

```
 2) QUIT                                11) Configuration-Freeze
 3) Application-Create                  12) Configuration-Thaw
 4) Application-Edit                    13) Configuration-Edit-Global-Settings
 5) Application-Remove                  14) Configuration-Consistency-Report
 6) Application-Clone                   15) Configuration-ScriptExecution
 7) Configuration-Generate              16) RMS-CreateMachine
 8) Configuration-Activate              17) RMS-RemoveMachine
 9) Configuration-Copy
Choose an action: 3
```

2. Select [STANDBY].

```
Creation: Application type selection menu:
1) HELP                                 7) SCALABLE
2) QUIT                                 8) STANDBY
3) RETURN
4) OPTIONS
5) DEMO
6) GENERIC
Application Type: 8
```

3. Select [Machines+Basics].

```
Settings of turnkey wizard "STANDBY" (APP1:not yet consistent)
1) HELP                                 4) REMOVE+EXIT
2) NO-SAVE+EXIT                         5) ApplicationName=APP1
3) SAVE+EXIT                            6) Machines+Basics(-)
Choose the setting to process: 6
```

Information

Although ApplicationName can be set to any name within the range of constraints of PRIMECLUSTER, do not set it to the database cluster name specified when registering a database cluster to PRIMECLUSTER using the pgx_pclrsc command. If the same name is set, RMS will fail to start.

4. Select [AdditionalMachine].

```
Machines+Basics (app1:consistent)
 1) HELP                                14) (AutoStartUp=no)
 2) -                                   15) (AutoSwitchOver=No)
 3) SAVE+EXIT                           16) (PreserveState=no)
 4) REMOVE+EXIT                         17) (PersistentFault=0)
 5) AdditionalMachine                   18) (ShutdownPriority=)
 6) AdditionalConsole                   19) (OnlinePriority=)
 7) Machines[0]=pcl-vm13RMS             20) (StandbyTransitions=)
 8) (PreCheckScript=)                   21) (LicenseToKill=no)
 9) (PreOnlineScript=)                  22) (AutoBreak=yes)
10) (PostOnlineScript=)                 23) (AutoBreakMaintMode=no)
11) (PreOfflineScript=)                 24) (HaltFlag=no)
12) (OfflineDoneScript=)                25) (PartialCluster=0)
13) (FaultScript=)                      26) (ScriptTimeout=)
Choose the setting to process: 5
```

5. Select a standby node.

```
1) HELP
2) RETURN
3) pcl-vm13RMS
4) pcl-vm14RMS
Choose a machine for this application: 4
```

6. Ensure that all nodes that make up the cluster application are displayed in [Machines]. Note that the item displayed in Machines[0] needs to be the active node, and Machines[1] to be the standby node. If these are not set correctly, modify the setting.

```
Machines+Basics (app1:consistent)
 1) HELP                                15) (AutoStartUp=no)
 2) -                                   16) (AutoSwitchOver=No)
 3) SAVE+EXIT                           17) (PreserveState=no)
 4) REMOVE+EXIT                         18) (PersistentFault=0)
 5) AdditionalMachine                   19) (ShutdownPriority=)
 6) AdditionalConsole                   20) (OnlinePriority=)
 7) Machines[0]=pcl-vm13RMS             21) (StandbyTransitions=)
 8) Machines[1]=pcl-vm14RMS             22) (LicenseToKill=no)
 9) (PreCheckScript=)                   23) (AutoBreak=yes)
10) (PreOnlineScript=)                  24) (AutoBreakMaintMode=no)
11) (PostOnlineScript=)                 25) (HaltFlag=no)
12) (PreOfflineScript=)                 26) (PartialCluster=0)
13) (OfflineDoneScript=)                27) (ScriptTimeout=)
14) (FaultScript=)
Choose the setting to process:
```

7. Configure attributes for cluster applications from step 8.

   Refer to the PRIMECLUSTER Installation and Administration Guide for information on the attributes for cluster applications.

   Configure the attributes as shown below:

Attribute	Value
AutoStartUp (Automatically starts cluster applications when the RMS is started.)	Yes
AutoSwitchOver (Automatically switches nodes when a fault occurs in cluster applications.)	- HostFailure - ResourceFailure - ShutDown
PersistentFault (Selects whether to keep the Faulted state of the cluster application after restarting the RMS.) (*1)	0 or 1
OnlinePriority (Selects whether to use the same online nodes as those used before all clusters were restarted or follow the configured order for nodes, when all clusters were restarted.) (*2)	0 or 1
StandbyTransitions (Timing to perform standby state transition.)	- ClearFaultRequest - StartUp - SwitchRequest
HaltFlag (Selects whether to terminate the node forcibly when another error occurs during the Fault process.)	Yes

*1: If 0 is specified, the Faulted state is automatically canceled when the RMS is started. If 1 is specified, the Faulted state is kept.

*2: If 0 is specified, cluster applications will become Online in accordance with the node setting order when all clusters are restarted. If 1 is specified, cluster applications will become Online on nodes where the cluster applications were Online before the restart.

8. Select [AutoStartUp].

```
Machines+Basics (app1:consistent)
 1) HELP                              15) (AutoStartUp=no)

A.1.5 Creating Gls or Takeover Network Resources

Create Gls or takeover network resources to use takeover network resources. This section provides an example for configuring Gl resources.

- Refer to the PRIMECLUSTER Installation and Administration Guide for information on creating takeover network resources.
- Refer to the PRIMECLUSTER Installation and Administration Guide for information on creating Gl resources.

1. Select [Gls:Global-Link-Services].

```
Settings of turnkey wizard "STANDBY" (APP1:consistent)
 1) HELP                               10) Enterprise-Postgres(Fsep_APP1)
 2) -                                  11) Symfoware(-)
 3) SAVE+EXIT                          12) Procedure:SystemState3(-)
 4) -                                  13) Procedure:SystemState2(-)
 5) ApplicationName=APP1               14) Gls:Global-Link-Services(-)
 6) Machines+Basics(app1)              15) IpAddresses(-)
 7) CommandLines(-)                    16) LocalFileSystems(-)
 8) Procedure:Application(-)           17) Gds:Global-Disk-Services(Gds_APP1)
 9) Procedure:BasicApplication(-)
Choose the setting to process:14
```

2. Select [AdditionalTakeoverIpaddress].

```
Gls (Gls_APP1:not yet consistent)
1) HELP                                4) REMOVE+EXIT
2) -                                   5) AdditionalTakeoverIpaddress
3) SAVE+EXIT                           6) (Timeout=60)
Choose the setting to process: 5
```

3. Select a takeover IP.

```

 6) Application-Clone                 15) Configuration-ScriptExecution
 7) Configuration-Generate            16) RMS-CreateMachine
 8) Configuration-Activate            17) RMS-RemoveMachine
 9) Configuration-Copy
Choose an action: 8
```

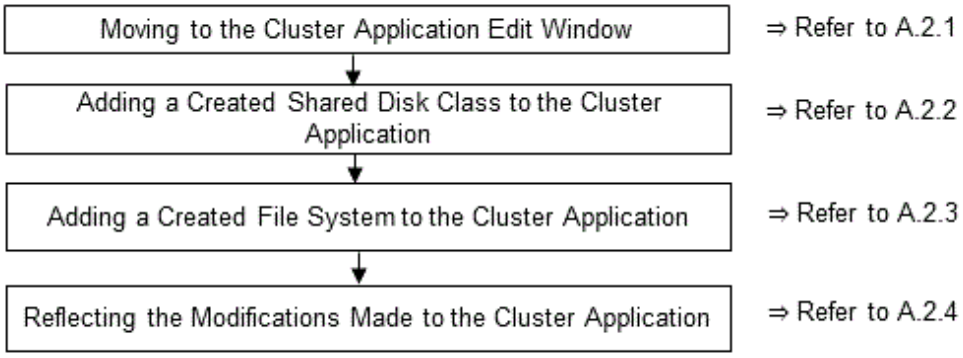
3. Select [QUIT].

```
pcl-vm13: Main configuration menu, current configuration: config
No RMS active in the cluster
 1) HELP                              10) Configuration-Remove
 2) QUIT                              11) Configuration-Freeze
 3) Application-Create                12) Configuration-Thaw
 4) Application-Edit                  13) Configuration-Edit-Global-Settings
 5) Application-Remove                14) Configuration-Consistency-Report
 6) Application-Clone                 15) Configuration-ScriptExecution
 7) Configuration-Generate            16) RMS-CreateMachine
 8) Configuration-Activate            17) RMS-RemoveMachine
 9) Configuration-Copy
Choose an action: 2
```

A.2 Modifying Cluster Applications

Follow the steps shown below to add a new file system to a cluster application. Refer to the PRIMECLUSTER Installation and Administration Guide for information on other modifications on cluster applications. Stop the RMS on all nodes when modifying cluster applications.



A.2.1 Moving to the Cluster Application Edit Window

1. Execute the hvw command.

```
# /opt/SMAW/SMAWRrms/bin/hvw
```

2. Select [Application-Edit].

```
pcl-vm13: Main configuration menu, current configuration: config
No RMS active in the cluster
 1) HELP                              10) Configuration-Remove
 2) QUIT                              11) Configuration-Freeze
 3) Application-Create                12) Configuration-Thaw
 4) Application-Edit                  13) Configuration-Edit-Global-Settings
 5) Application-Remove                14) Configuration-Consistency-Report
 6) Application-Clone                 15) Configuration-ScriptExecution
```

```
 7) Configuration-Generate              16) RMS-CreateMachine
 8) Configuration-Activate              17) RMS-RemoveMachine
 9) Configuration-Copy
Choose an action: 4
```

3. Select the user application to be used.

```
Edit: Application selection menu (restricted):
1) HELP
2) QUIT
3) RETURN
4) OPTIONS
5) APP1
Application Name: 5
```

A.2.2 Adding a Created Shared Disk Class to the Cluster Application

1. Select [Gds:Global-Disk-Services].

```
Settings of turnkey wizard "STANDBY" (APP1:consistent)
 1) HELP                                10) Enterprise-Postgres(Fsep_APP1)
 2) READONLY                            11) Symfoware(-)
 3) SAVE+EXIT                           12) Procedure:SystemState3(-)
 4) -                                   13) Procedure:SystemState2(-)
 5) ApplicationName=APP1                14) Gls:Global-Link-Services(Gls_APP1)

Appendix B Command Reference

This appendix explains for details in command.

B.1 pgx_pclrsc

Name

pgx_pclrsc -- Register, unregister, or display Fujitsu Enterprise Postgres database cluster with PRIMECLUSTER as resource of PRIMECLUSTER.

Synopsis

```
pgx_pclrsc  -a  -c  name  -u  osuser  -D directory -w directory
          {-n nodes  | -s} [options...]
pgx_pclrsc -d -c name
pgx_pclrsc -p [-c name]
```

Description

pgx_pclrsc is an utility for registering or unregistering Fujitsu Enterprise Postgres database cluster with PRIMECLUSTER, or displaying settings of Fujitsu Enterprise Postgres database cluster registered with PRIMECLUSTER. Execute the command on a member node of the cluster. Only the super user(root) can execute this command.

Options

-a
--add

Register the specified database cluster with PRIMECLUSTER. If the specified database cluster has already been registered with PRIMECLUSTER, then terminate abnormally.

-c *name*
--db-cluster-name=*name*

Specify database cluster name. name is case-sensitive, and must be within 16 bytes, and an initial letter must be ascii alphabet, and following letters must be ascii alphabet or ascii digit or underscore(_).

-d
--delete

Unregister the specified database cluster from PRIMECLUSTER.

-D directory
--pgdata=*directory*

Specify an absolute path of data directory.

--db-user=*name*

Specify a database super user. Default is the user specified with '-u'.

-n nodes
--member-nodes=*nodes*

Specify names of all member nodes of the cluster. Specfity a cluster node name with uffix "RMS" to the name. Separate names with comma(,). (e.g. -n node1RMS,node2RMS)

-p
--print

Print a list of database clusters registered with PRIMECLUSTER. If -c option is specified, then print settings of the database cluster.

--response-timeout=*seconds*

Specify timeout of the query for health check. It's used with a count specified with '--timeout-retry-num'. The query is "SELECT 1" to the database "template1". If '0', wait infinitely. (default: '0')

-s
--single-node

Specify this option for single-node cluster operation. You cannot specify this option with the -n option.

--timeout-retry-count=*count*

Specify a limit count of retrying query when timeout is occurred. If retry counter is over the limit, then PRIMECLUSTER considers status of the database server as FAULT. If a query doesn't timeout once, retry counter is reset. (default: '6')

--trace-max-file-size=*size*

Specify max size(KB) of trace file. (default: '10240')

-u osuser
--os-user=*osuser*

Specify an OS user who can start/stop Fujitsu Enterprise Postgres database server.

-w directory
--work-dir=*directory*

Specify a directory for temporary data and trace files. It's used for starting, stopping or checking Fujitsu Enterprise Postgres database server. If the directory doesn't exist, then create it. Owner of the directory created by the command is set to the user specified with '-u'. Permission of the directory created by the command is set to 0700.

--watch-interval=*seconds*

Specify an interval. It's used for the amount of time between health checks. (default: '3')

Diagnostics

0 : On success

otherwise : On error

Notes

Before unregistering a resource, stop RMS of PRIMECLUSTER.

Example

The following is the simplest example of resource registration in standby operation.

```
# pgx_pclrsc -a -c inst1 -u postgres -D /mnt/swdsk1/pgdata -w /var/tmp/work -n node1RMS,node2RMS
```

The following is the simplest example of resource registration in a single-node cluster operation.

```
# pgx_pclrsc -a -c inst1 -u postgres -D /mnt/swdsk1/pgdata -w /var/tmp/work -s
```

Appendix C Failover Operation in Streaming Replication

By combining streaming replication and failover operation, continuity of database operations can be ensured.

The following are additional notes on streaming replication when failover operation is applied to the primary server, standby server, or both.

Information

In this appendix, a group of nodes or a single server connected by streaming replication is referred to as a "primary server" or "standby server. When a specific node is explicitly indicated, it is expressed as “primary server's operational node ” or simply as“ standby server ” in the case of a single server.

C.1 Possible Cluster Operation

For failover operation of primary server

Same as "1.1 Definition of Failover Operation"

For failover operation of standby server

As with the primary server, for example, if the operational system goes down, the standby system takes over the contents of the shared disk and becomes the operational system, and can continue as a standby server. Also, applications (reference operations) that you want to run on the active system of the database can be switched in conjunction with the database. Cascaded standby operation, in which replication from one standby server to another is performed, is also possible.

C.2 Overview of Failover Operation

C.2.1 Supported Operational Forms and System Configurations

The following failover operation and system configurations are supported

Operational form of streaming replication

Failover operation is available for the following servers configured for streaming replication.

- Primary server for asynchronous replication only
- Standby server for asynchronous replication
- Cascaded standby server (cascaded replication configuration)

Information

- As the reason why the synchronous replication isn't supported, if the communication path between servers is disconnected or the standby server goes down, log transfer from the primary server to the standby server will not be possible, and operations running on the primary server instance will stop. Therefore, to ensure business continuity on the primary server, synchronous replication is not supported. However, in an environment where synchronous replication is performed between servers where neither the replication source nor the replication destination is a failover operation, there is no problem in adding a server with failover operation as an additional asynchronous standby server.
- Servers that perform failover operation cannot be monitored by database multiplexing.
- Please refer to the "PostgreSQL Documentation" for information on how to set up and use streaming replication. This section describes the key points for combining streaming replication with failover operations.
- The connection status of streaming replication is not monitored by PRIMECLUSTER.
  Even if streaming replication is disconnected, database operations can continue on the standby server. However, if the disconnection

is prolonged, the database will not be up-to-date, so please monitor the connection status and make decisions to continue operations as necessary.

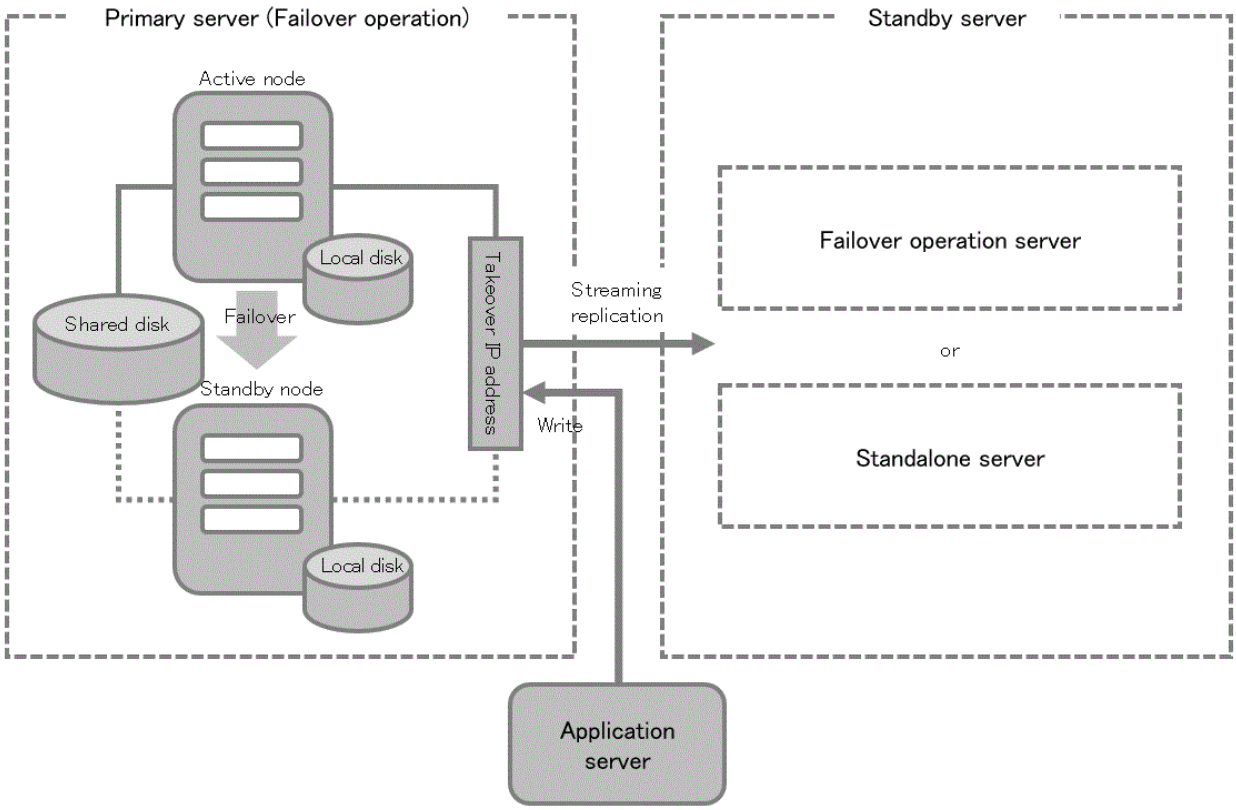
Failover operation functions and operational forms

Failover operation on the primary or standby server supports 1:1 operational standby as well as standby functionality. Cluster applications are also created on a per-primary or per-standby server basis.

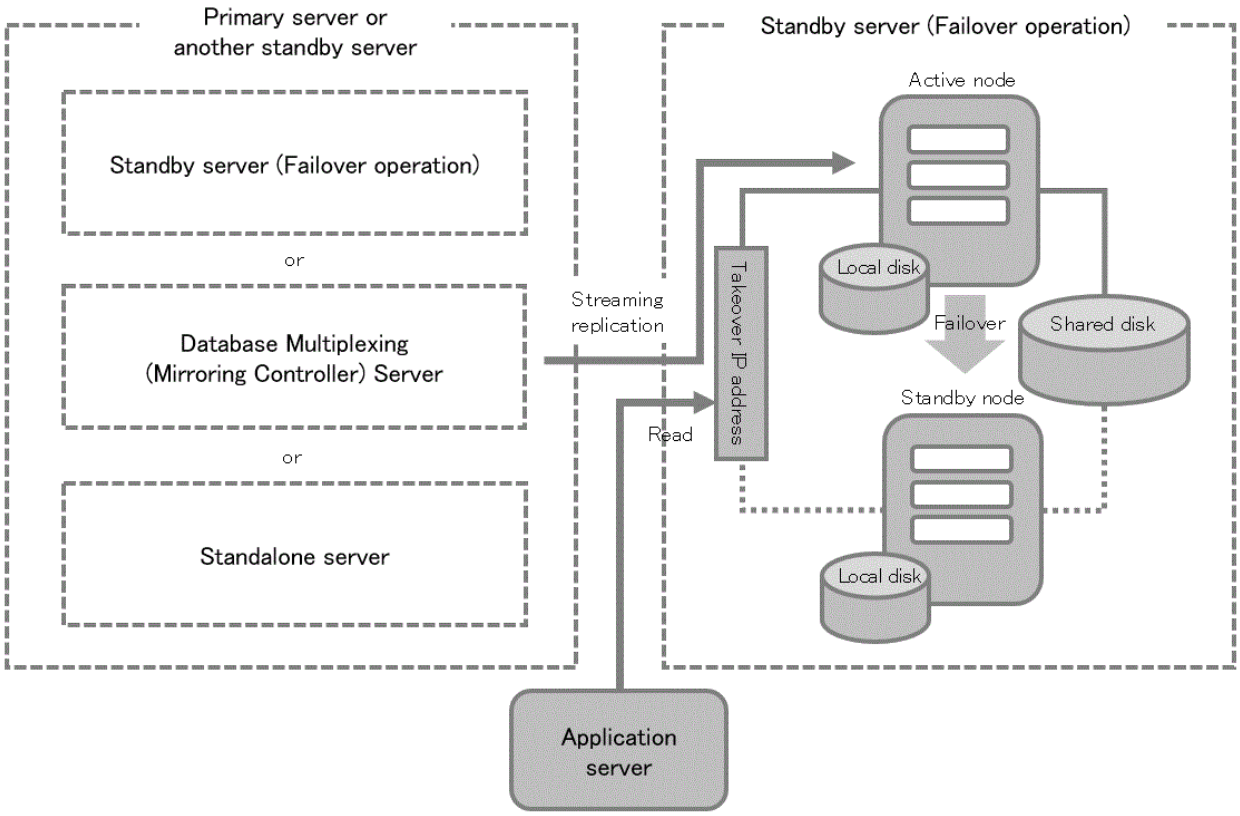
System configuration for failover operation

The following figure shows the configuration for failover operation of the primary or standby server. The primary or standby server has a file system on a shared disk that is mounted only on the active system node.

- Configuration diagram for failover operation of the primary server



- Configuration diagram for failover operation of standby server



Point

The network for connections from user applications accessing the database (business network) and the network for streaming replication connections from the standby server (log transfer network) can be located on different networks.

Enterprise Postgres resources and locations

The resources and locations of Fujitsu Enterprise Postgres on the standby and primary servers are the same as in "1.2 System Configuration of Failover Operation".

Point

The directory for storing backup data on the standby server is not required if the standby server is not promoted to the primary server.

See

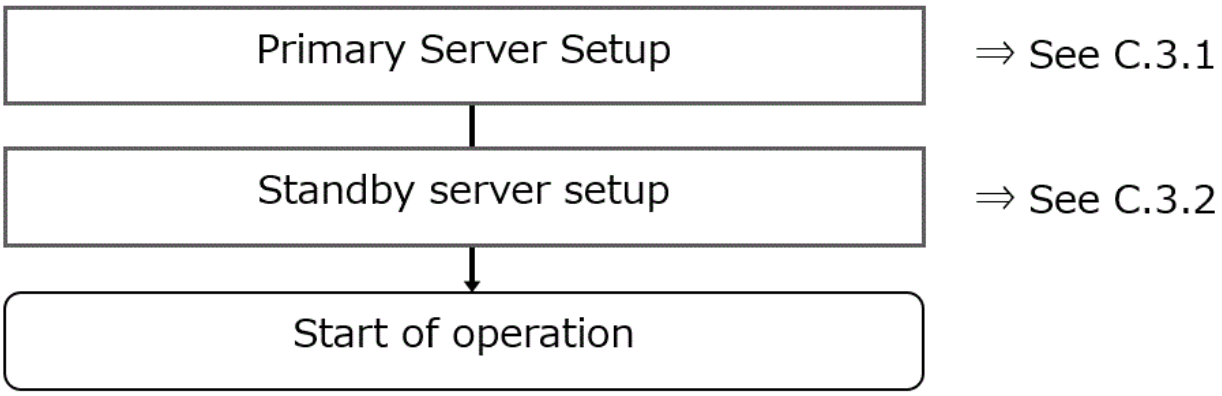
See "HA Cluster without Database Multiplexing Operation" in the Operations Guide for keystore file placement.

C.3 Set up failover operation

Follow the steps below for setup.

This procedure is described for failover operation on both the primary and standby servers.

If you want to perform the failover operation only one of the servers, please refer to the "PostgreSQL Documentation" and Fujitsu Enterprise Postgres manual for the server that will not be failovering. For the server that will perform failover operation, refer to the setup procedure for the appropriate server.



C.3.1 Primary Server Setup

Set up the primary server by referring to " Chapter 2 Setting Up Failover Operation"

However, additional precautions and steps are required in "2.2 Configuring PRIMECLUSTER", "2.7 Creating a Database Cluster" and "2.11 Creating a Cluster Application" have additional precautions and required steps.

Notes on GLS settings

Regarding the GLS settings performed in "2.2 Configuring PRIMECLUSTER", if the business network and log transfer network are separate networks, GLS settings are required for both networks.

Point

When a communication path set in the GLS is registered to a cluster, the default setting is to switch clusters in the event of a transmission path failure. While this is a desirable setting for the business network, the default setting for the log transfer network is not essential for business continuity and may result in unnecessary switching.

To avoid this problem, it is recommended that the GLS be configured not to switch clusters in the event of a transmission path failure for the log transfer network.

If the setting is not to switch over in the event of a transmission path failure in the log transfer network, operations will continue with streaming replication suspended in the event of a failure in all active log transfer network. To resume streaming replication, it is necessary to identify the abnormalities and take manual measures (e.g., switching clusters, repairing failed routes, etc.).

See

Please refer to the GLS manual for information on how to set up the cluster switching not to be performed in the event of a transmission path failure.

Additional steps when creating a database cluster

The following additional steps are required for "2.7 Creating a Database Cluster".

- Configuration of pg_hba.conf file
- Configuration of postgresql.conf file

Configuration of pg_hba.conf file

Add the following entry to the pg_hba.conf file to authenticate connections from the standby server

```
# TYPE    DATABASE        USER          ADDRESS                                  METHOD
  host    replication     User name     Standby server address                  Authentication
method
```

For user name, specify the user name to connect from the standby server. Also, for Standby server address, specify the IP address to connect to the log transfer network.

The above example is for only one standby server. Please add entries for all servers you may connect as standby servers.

Point

When setting an authentication method other than trust authentication

When connecting from the standby server as the instance administrator user, create a .pgpass file in the instance administrator user's home directory to specify the password to the replication database for automatic authentication when connecting to the primary server. This will verify that the instance administrator user's OS user and the user registered in the database are the same, and that the connection was not made by an unspecified user. In addition, the pre-defined password is used for authentication to automatically connect.

Information

We do not recommend configuring trust authentication. If trust authentication is set, all OS users who can log in to the primary server will be able to connect, and if one of these is a malicious user, then that user can corrupt the standby server data, or cause the job system to fail, by sending an erroneous transaction log. Therefore, decide on the authentication method according to the security requirements of the system using streaming replication operation.

Refer to "Authentication Methods" in the PostgreSQL Documentation for details on the authentication methods that can be set.

Configuring of postgresql.conf file

Specify the following parameters in the postgresql.conf file for streaming replication. postgresql.conf file is duplicated when the standby server instance is created. Therefore, also set the parameters required on the standby server.

Table C.1 Parameters to be set

Parameter	Contents of Designation	remarks
wal_level	replica or logical	Specify "logical" if logical decoding is also used.
max_wal_senders	Number of standby servers + 1	Specify the number of standby servers (n) + 1.
hot_standby	on	Specify this to perform reference-based operations on the standby server.
wal_keep_size	WAL storage size (megabytes)	If a delay exceeding the value set in this parameter occurs, the WAL segment required later by the primary server may be deleted. Additionally, if you stop a standby server (for maintenance, for example), consider the stop time and set a value that will not cause the WAL segment to be deleted. Refer to "Estimating Transaction Log Space Requirements" in the

Parameter	Contents of Designation	remarks
		Installation and Setup Guide for Server for information on estimating the WAL save size.
wal_sender_timeout	Timeout time (milliseconds)	Specify the time to determine that an error has occurred in the transfer of transaction logs on the primary server side. By specifying this parameter, log transfer to the standby server can be resumed even if the standby server temporarily stops due to failover, etc.
wal_receiver_timeout	Timeout time (milliseconds)	Specify the time to determine that an error has occurred in receiving transaction logs on the standby server side. By specifying this parameter, log reception from the primary server can be resumed even if the primary server temporarily stops due to failover, etc.

Point

Replication slots can be used instead of the wal_keep_size parameter to prevent deletion of old WAL segments. See "Replication Slots" in the "PostgreSQL Documentation" for details on replication slots.

See

- For more information on the pg_hba.conf file, see "Client Authentication" in "PostgreSQL Documentation".
- For more information on the postgresql.conf file, see "Server Configuration" in the "PostgreSQL Documentation".

Additional steps when creating a cluster application

The following additional steps are required for "2.11 Creating a Cluster Application".

If the business network that accepts connections from applications and the log transfer network that accepts replication connections for log transferring are Gls resources on separate networks, both the business network and the log transfer network Gls resources must be Register them as cluster application resources.

C.3.2 Standby Server Setup

Follow the steps below for setup.

The procedure is almost the same as in "Chapter 2 Setting Up Failover Operation" but some of the steps are different.

In this section, the word primary server is used as the replication source server. If you are building a cascaded standby environment, please read primary server as upstream server.

Procedure	Work item		See
	Active system	standby system	
1	Installing PRIMECLUSTER and Fujitsu Enterprise Postgres		"2.1 Installing PRIMECLUSTER and Fujitsu Enterprise Postgres"
2	Configuring PRIMECLUSTER		"2.2 Configuring PRIMECLUSTER".
3	Creating a GDS Volume (*1)		"2.3 Creating a GDS Volume" Note: It is not mandatory to create a directory for storing backup data.
4	Creating a file system (*1)		"2.4 Creating a File System"
5	Creating a user for the operating system to start Fujitsu Enterprise Postgres		"2.5 Creating an Operating System User to Start Fujitsu Enterprise Postgres"
6	Mounting the file system		"2.6 Mounting the File System"
7	Creating a Database cluster (*1)		"Creating a Database Cluster"
8	Registering resource information for the Fujitsu Enterprise Postgres database cluster		"2.8 Registering Resource Information for the Fujitsu Enterprise Postgres Database Cluster".
9	Configuring storage data protection using transparent data encryption (*1)		"Creating a Database Cluster"
10	Unmounting the file system		"2.10 Unmounting the File System"
11	Creating a cluster application		"2.11 Creating a Cluster Application"
12	Application development		"2.12 Application Development"
13	Checking operation		"Operation check"

*1: Some settings and operations must also be performed on the standby node. Please refer to the reference for details.

Creating a Database Cluster

Refer to "2.7 Creating a Database Cluster" for a setup that takes into account the following

1. Add configuration for standby server to primary server

   Add the configuration items for the standby server to the database cluster configuration file created on the primary server.

   Configure the pg_hba.conf file on the primary server

   Add the following entry to the pg_hba.conf file to authenticate connections from the standby server

```
# TYPE    DATABASE        USER          ADDRESS                                 METHOD
  host    replication     username Active node address of the standby server
authentication method
  host    replication     username Standby node address of the standby server
authentication method
```

User name is the name of the user connecting from the standby server.

When stating the address of the standby server, set it to allow connections from the IP address of the respective node, rather than from the takeover IP address.

Point

When setting an authentication method other than trust authentication

When connecting from the standby server as the instance administrator user, create a .pgpass file in the instance administrator user's home directory to specify the password to the replication database for automatic authentication when connecting to the primary server. This will verify that the instance administrator user's OS user and the user registered in the database are the same, and that the connection was not made by an unspecified user. In addition, the pre-defined password is used for authentication to automatically connect.

Information

We do not recommend configuring trust authentication. If trust authentication is set, all OS users who can log in to the primary server will be able to connect, and if one of these is a malicious user, then that

user can corrupt the standby server data, or cause the job system to fail, by sending an erroneous transaction log. Therefore, decide on the authentication method according to the security requirements of the system using streaming replication operation.

Refer to "Authentication Methods" in the PostgreSQL Documentation for details on the authentication methods that can be set.

Configure the postgresql.conf file on the primary server

Specify the following parameters in the postgresql.conf file for streaming replication. postgresql.conf file is replicated when the standby server instance is created. Therefore, set the necessary parameters in the primary server's postgresql.conf file before replicating it to the standby server. No additional configuration is required if you have already set up the same information when setting up the primary server.

Table C.2 Parameters to be set

Parameter	Contents of Designation	remarks
wal_level	replica or logical	Specify "logical" if logical decoding is also used.
max_wal_senders	Number of standby servers + 1	Specify the number of standby servers (n) + 1.
hot_standby	on	This setting must be on regardless of whether or not reference work is performed on the standby server, because the monitoring process by PRIMECLUSTER will connect to the standby server. If this setting is off, PRIMECLUSTER will erroneously assume that PostgreSQL has stopped.
wal_keep_size	WAL storage size (megabytes)	If a delay exceeding the value set in this parameter occurs, the WAL segment required later by the primary server may be deleted. Additionally, if you stop a standby server (for

Parameter	Contents of Designation	remarks
		maintenance, for example), consider the stop time and set a value that will not cause the WAL segment to be deleted. Refer to "Estimating Transaction Log Space Requirements" in the Installation and Setup Guide for Server for information on estimating the WAL save size.
wal_sender_timeout	Timeout time (milliseconds)	Specify the time to determine that an error has occurred in the transfer of transaction logs on the primary server side. By specifying this parameter, log transfer to the standby server can be resumed even if the standby server temporarily stops due to failover, etc.
wal_receiver_timeout	Timeout time (milliseconds)	Specify the time to determine that an error has occurred in receiving transaction logs on the standby server side. By specifying this parameter, log reception from the primary server can be resumed even if the primary server temporarily stops due to failover, etc.

Point

Replication slots can be used instead of the wal_keep_size parameter to prevent deletion of old WAL segments. See "Replication Slots" in the "PostgreSQL Documentation" for details on replication slots.

2. Creating a Database Cluster

   To create a database cluster on the standby server, run the pg_basebackup command to create a duplicate instance of the primary server.

   Example)

```
$ pg_basebackup -D <data storage destination directory of standby server> -X fetch --
waldir=<transaction log directory> --progress --verbose -R --
dbname='application_name=<application name>' -h <takeover IP address of primary server> -p <port
number of primary server>
```

Information

- Use the pg_basebackup command with the -R option to create a standby.signal file. If you do not create the standby.signal file, the server cannot start as a standby server.
- If using a method that requires password authentication for connections to the primary server, you will need to ensure that authentication is performed automatically. If the -R option is specified for the pg_basebackup command and the password parameter is specified for the --dbname option, the pg_basebackup command will set the password in the primary_conninfo parameter in postgresql.auto.conf file, enabling connections to be performed automatically.

If a password is not set in the primary_conninfo parameter in postgresql.auto.conf file, it will be necessary to create a .pgpass file in the home directory of the instance administrator user, and specify a password for the replication database.

- The primary_conninfo parameter should not be set in the postgresql.conf file, but only in the postgresql.auto.conf file using the pg_basebackup command.
- When executing the pg_basebackup command, consider the following for collection of transaction logs.
  - When "fetch" is specified for the -X option of the command
    Transaction logs are collected at the end of the backup, so it is necessary to ensure that transaction logs that occur during backup are not deleted from the primary server. Therefore, allow for a sufficient value for the wal_keep_size parameter in postgresql.conf.

See

- For more information on the pg_basebackup command, see "pg_basebackup" in the "Reference" section of the PostgreSQL Documentation.
- For more information on the standby.signal file, see "Hot Standby" in the PostgreSQL Documentation.

3. Setting up transparent data encryption to protect stored data

   Refer to "2.9 Configuring Storage Data Protection Using Transparent Data Encryption" and consider the following in your setup

   - Keystore file location
     Specify a local directory with the same path on the active and standby nodes.
   - Keystore File Distribution
     Copy the keystore files on the active node of the primary server to both active node and standby node of the standby server.
   - Enable auto-open keystore
     Please enable in both active node and standby node of the standby server.

4. Check each node for startup, connection, and shutdown.

Operation check

Refer to "2.13 Checking Operation" Before doing so, however, make sure that streaming replication is set up correctly.

Follow the steps below.

1. On the primary server, verify that the connection status from the standby server can be retrieved by the statistics view pg_stat_replication.

   Example)

   The following is an example of output when the psql command is used.

```
postgres=# select * from pg_stat_replication;
-[ RECORD 1 ]----+------------------------------
pid              | 321621
usesysid         | 10
usename          | fsep
application_name | standby
client_addr      | 192.0.2.210
client_hostname  |
client_port      | 27500
backend_start    | 2022-12-01 19:12:53.145639+09
backend_xmin     |
state            | streaming
sent_lsn         | 0/3000060
write_lsn        | 0/3000060
flush_lsn        | 0/3000060
replay_lsn       | 0/3000060
write_lag        |
```

```
flush_lag        |
replay_lag       |
sync_priority    | 0
sync_state       | async
reply_time       | 2022-12-01 19:13:11.194744+09
```

2. Check the search results in step 1.

   Verify that a connection in asynchronous mode has been established with the intended standby server.

   Table C.3 Items to be checked

item	Confirmation details
application_name	The application name must indicate the standby server.
client_addr	It must be the IP address of the active node of the standby server.
state	streaming
sync_state	async

Information

Streaming replication status is not monitored by PRIMECLUSTER. If you need to monitor streaming replication, please create and run a monitoring program referring to this section.

C.4 Failover Operation

This section describes operations that require special attention related to streaming replication operations when performing "Chapter 3 Failover Operation".

operation		special remarks
3.1 Adding Tablespaces		If you are adding a new file system in an environment where both the primary and standby servers are in failover operation, you must add the required GDS volumes or file systems on both the primary and standby servers before executing the CREATE TABLESPACE statement.
3.2 Modifying Database Cluster Resources		-
3.3 Operations under Normal Circumstances		-
3.4 Operation at State Transition		If the active system of the primary server in failover operation goes down, the standby system will automatically start up as the primary server. When promoting the standby server to the primary server, make sure that both nodes of primary server are down before promoting it. Otherwise, the primary server and the standby server may both be ready to execute update statements.
3.5 Maintenance Tasks	3.5.1 Simultaneous Stopped Node Maintenance	When performing the simultaneous stopped node maintenance on the standby server and continuing operations on the primary server, please estimate the WAL segment taking into account the maintenance outage time.
	3.5.2 Mutual Switch Maintenance	There are no precautions in the mutual switch maintenance procedure. However, when starting maintenance work, start with the standby server.

C.5 Procedures Required after a Failover Error

C.5.1 In Case of Primary Server Error

Refer to "Chapter 4 Procedures Required after a Failover Error" for information on recovering as the primary server when the primary server has an error.

However, if it is necessary to rebuild the standby server as well, such as by restoring an instance of the primary server from backup data, refer to "C.5.2 In Case of an Error on the Standby Server" to rebuild the standby server.

After the standby server has been promoted to the new primary server, prepare for recovery by referring to "Chapter 4 Procedures Required after a Failover Error" when the former primary server that became abnormal is incorporated as a standby server and restored. However, instead of the steps from "4.3 Starting the Database Cluster" to "4.6 Restarting the Cluster Applications Stopped for Node Maintenance" please follow the steps below.

The following two commands can be used to recover standby servers. Select the one that best suits your situation and the content of the restoration.

- pg_basebackup

  Creates a copy of all resources of the primary server instance.

  Refer to "C.5.2 In Case of an Error on the Standby Server" for the rebuilding procedure.

- pg_rewind

  Creates a copy of only the updated files on the new primary server. For this reason, if this command is used to incorporate a new standby server, recovery time can be shortened. To use this command to build the original primary server as a new standby server, at least one of the following must be met:

  a. Checksums were enabled when an instance was created, or

  b. The wal_log_hints parameter of postgresql.conf was enabled when an instance was started.

  Additionally, full_page_writes must be enabled, which is its default value.

  The following is an example of running the pg_rewind command to synchronize and recover data from the old primary server with the new primary server.

  If pg_rewind is executed immediately after the new primary server is promoted, steps 3 and 4 are required. If the new primary server is able to execute the SQL to write and the checkpoint process is executed after the promotion, steps 3 and 4 are not necessary.

  1. Start an instance of the old primary server
     Use the pg_ctl command to start the old primary server instance.

     Example)

     ```
     $ pg_ctl start -D <data storage destination directory>
     ```

  2. Stopping an instance of the old primary server
     Stop the old primary server instance using the pg_ctl command.

     Example)

     ```
     $ pg_ctl stop -D <data storage destination directory>
     ```

  3. Wait for unapplied update transaction log to be applied on new primary server
     Execute the following SQL on the new primary server and wait until the result is false.

     ```
     select pg_is_in_recovery();
     ```

     Example)

     ```
     $ psql -h <hostname of new primary server> -p <port number of new primary server> -d <database
     name> -c "select pg_is_in_recovery();"
     ```

     Any database can be connected.

4. Update Timeline ID
   Execute a checkpoint process to update the timeline ID.

```
$ psql -h <hostname of new primary server> -p <port number of new primary server> -d <database
name> -c "checkpoint;"
```

   Any database can be connected.

5. Create a duplicate instance of the new primary server on the old primary server (new standby server)

   Run the pg_rewind command to create the data on the new standby server in sync with the new primary server.

   Example)

```
$ pg_rewind -D <data storage destination directory of old primary server> -R --source-
server='user=<username> host=<hostname of new primary server> port=<port number of new
primary server> dbname=<database name>'
```

Information

- Use the pg_rewind command with the -R option to create a standby.signal file. If you do not create the standby.signal file, the server cannot start as a standby server.
- If using a method that requires password authentication for connections to the primary server, you will need to ensure that authentication is performed automatically. If the -R option is specified for the pg_rewind command and the password parameter is specified for the --dbname option, the pg_rewind command will set the password in the primary_conninfo parameter in postgresql.auto.conf file, enabling connections to be performed automatically.
- If a password is not set in the primary_conninfo parameter in postgresql.auto.conf file, it will be necessary to create a .pgpass file in the home directory of the instance administrator user, and specify a password for the replication database.
- If you need to set a connection string other than host, port and application_name, include it in the setting of the primary_conninfo parameter.

See

- For more information on the standby.signal file, see "Hot Standby" in the PostgreSQL Documentation.
- For more information on primary_conninfo, see "Setting Up a Standby Server" in the PostgreSQL Documentation. Setting Up a Standby Server" in the "PostgreSQL Documentation".

6. Set parameters in postgresql.conf file on old primary server (new standby server)
   Set the necessary parameters for the new standby server in the postgresql.conf file.
   The parameters to be set in the postgresql.conf file should be set with reference to "Creating a Database Cluster".

Information

Since the new primary server is branched to a new timeline by promotion, the 'latest' must be specified in the recovery_target_timeline parameter for the old primary server (new standby server) to follow the new primary server.

7. Resource Release
   Unmount the mounted file system, including the file system where the directory for data storage is located. Then, stop the GDS volume.
8. Cancellation of maintenance suspension
   Refer to "3.5 Maintenance Tasks" to cancel the maintenance suspension.
9. Operation check
   Refer to "Operation check" to check the operation.

See

- For more information on the pg_basebackup command, see "pg_basebackup" in the "Reference" section of the PostgreSQL Documentation.
- For more information on the pg_rewind command, see "pg_rewind in the "Reference" section of the "PostgreSQL Documentation".

C.5.2 In Case of an Error on the Standby Server

The following is a description of what to do in the event of a standby server malfunction.

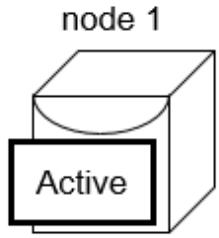
1. Identification of the cause of the abnormality
   Identify the cause of the abnormality by referring to "4.1 Identifying the Cause of an Error"
   In case of an anomaly that requires rebuilding the standby server, refer to the following procedures. In other cases, refer to "Chapter 4 Procedures Required after a Failover Error".
2. Stop RMS on standby server, remove cluster applications and resources
   Stop RMS and then remove cluster applications and resources.
3. Rebuild standby server
   Refer to "C.3.2 Standby Server Setup" to perform the re-setup.

Appendix D Single-Node Cluster Operation

This chapter explains single-node cluster operation.

D.1 Overview of Single-Node Cluster Operation

This mode of operation is used in a cluster system consisting of one node.



The Fujitsu Enterprise Postgres database cluster registered in the PRIMECLUSTER resource can be added as an Enterprise Postgres resource to a cluster application operating in a single-node cluster.

You can start and stop an instance of Fujitsu Enterprise Postgres as one of the resources of a cluster application. Resource monitoring also detects resource failures, such as server process down or no response. However, Enterprise Postgres resources do not automatically restart and recover from resource failures.

Use single-node cluster operations only in development environments for creating and testing applications, and not in production environments where reliability is required.

Information

Operation and handling in the event of an error are the same as when the standby node is excluded from failover operation, but failover and mutual switching maintenance that require the standby node are not possible.

D.2 Setting Up Single-Node Cluster Operation

The following table describes the differences from the "Active system" in "Chapter 2 Setting Up Failover Operation".

Step	Work item	Difference
1	Installing PRIMECLUSTER and Fujitsu Enterprise Postgres	-
2	Configuring PRIMECLUSTER	-
3	Creating a GDS volume	-
4	Creating a file system	-
5	Creating a user for the operating system to start Fujitsu Enterprise Postgres	-
6	Mounting the file system	-
7	Creating a database cluster	-
8	Registering resource information for the Fujitsu Enterprise Postgres database cluster	This is described in "D.2.1".
9	Configuring storage data protection using transparent data encryption	-
10	Unmounting the file system	
11	Creating a cluster application	This is described in "D.2.2".

Step	Work item	Difference
12	Application development	-
13	Checking operation	-

Note that you can build an environment without using the Gds resources, Gls resources, and Fsystem resources. Perform the setup as necessary.

D.2.1 Register the database cluster as a resource in PRIMECLUSTER

The pgx_pclrsc command registers a database cluster on a node that will operate in a single-node cluster.

For single-node cluster operation, specify the -s option without specifying the node name with the -n option. Refer to "B.1 pgx_pclrsc" for more information on the pgx_pclrsc command.

```
# pgx_pclrsc -a -c DatabaseClusterName -u OsUser -D PgData -w WorkDir -s
```

D.2.2 Creating Resources and Cluster Applications

Some of the information in "Appendix A Creating Resources and Creating/Modifying Cluster Applications" needs to be considered.

Adding a Standby Node

In "A.1.2 Creating a Cluster Application and Configuring Its Attributes", the standby node is not added from the "Machines+Basics" window.

Cluster Application Attributes

In "A.1.2 Creating a Cluster Application and Configuring Its Attributes", consider the values in the table for the following attributes:

Attribute	Value
AutoSwitchOver (Automatically switches nodes when a fault occurs in cluster applications.)	Do not set a value. (RMS Wizard displays "No")
OnlinePriority (Selects whether to use the same online nodes as those used before all clusters were restarted or follow the configured order for nodes, when all clusters were restarted.)	Do not set a value.
HaltFlag (Selects whether to terminate the node forcibly when another error occurs during the Fault process.)	Set "No".
ShutdownPriority (Determines the priority of forcing the subcluster to shut down in the event of an interconnect failure.)	Do not set a value.

Creating Gds Resources

In "A.1.3 Creating Gds Resources", since the cluster resource list is not displayed, select "FREECHOICE" and enter the class name of the GDS you created.

Connection Manager User's Guide

Windows/Linux

J2UL-3065-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document describes the Connection Manager features of Fujitsu Enterprise Postgres.

Intended readers

This document is aimed at people who use the Connection Manager features.

Readers of this document are also assumed to have general knowledge of:

- Fujitsu Enterprise Postgres
- PostgreSQL
- Linux
- Windows
- Network

Structure of this document

This document is structured as follows:

Chapter 1 Connection Manager Features

Explains the features and Mechanisms of the Connection Manager.

Chapter 2 Setting Up

Explains setting up the Connection Manager.

Chapter 3 Using from an Application

Explains how to use the Connection Manager from an application.

Appendix A System Views

Explains the system view of Connection Manager.

Export restrictions

If this document is to be exported or provided overseas, confirm legal requirements for the Foreign Exchange and Foreign Trade Act as well as other laws and regulations, including U.S. Export Administration Regulations, and follow the required procedures.

Index 22

Chapter 1 Connection Manager Features

The Connection Manager provides the following features:

Heartbeat monitoring feature

Detects kernel panics between the server running the client and the server running the PostgreSQL instance(hereinafter referred to as instance), physical server failures, and inter-server network link downs, and notifies the client or instance. The client is notified as an error event through the SQL connection, and the instance will be notified in the form of a force collection of SQL connections with clients that are out of service.

Transparent connection support feature

When an application wants to connect to an instance of an attribute in a set of instances configured for replication, it can connect to that instance without being aware of which server it is running on.

Load balancing and read connection redistribution feature

With load balancing, if selection is possible, connections can be made to the server accepting the fewest connections. To use this feature, specify "leastconn" for the loadbalance parameter in conmgr.conf.

Using read connection redistribution, when a standby server is promoted, Connection Manager disconnects existing connections, allowing the promoted server to focus on the workload of the newly added primary server. To use this feature, specify "auto_disconnect" for the on_promote_action parameter in conmgr.conf. Only connections using Connection Manager are disconnected, and the disconnection occurs when a new query is executed.

Additionally, when the number of connections between standby servers becomes uneven, existing connections can be disconnected. This gives applications an opportunity to reconnect, thereby balancing the number of connections. For example, this can handle changes in the number of connections due to the addition or removal of standby servers, or the suspension of specific operations. To use this feature, set standby_reconnect_threshold parameter and standby_reconnect_ratio_target parameter. Only non-update connections using Connection Manager are disconnected, and the disconnection occurs when a new query is executed.

Load balancing and read connection redistribution feature is available in cluster systems using Patroni.

Initial data synchronization waiting feature for standby servers

You can exclude standby servers that are not synchronized with the primary server on a transaction-by-transaction basis from the connection destination candidates. This prevents applications from connecting to unsynchronized standby servers, ensuring data consistency. To use this feature, set the wait_streaming_replica_state parameter in conmgr.conf to "on".

Initial data synchronization waiting feature for standby servers is available in cluster systems using Patroni.

Information

The available client drivers for Connection Manager are libpq (C language library), ECPG (embedded SQL in C), ECOBPG (embedded SQL in COBOL), JDBC driver, ODBC driver, Python language package (psycopg) and Go language.

Each function is described below.

1.1 Heartbeat Monitoring Feature

Describes the Connection Manager's heartbeat monitoring feature.

Note

The Connection Manager does not monitor for delays, such as CPU busy occurring in the postmaster process or in the backend processes to which the application connects directly, or for no response, such as due to a software bugs. It also does not

monitor application downtime or unresponsiveness. To detect these, use various timeout features provided by PostgreSQL or the client drivers.

1.1.1 Difference from TCP keepalive

A peer of TCP connections cannot automatically detect a link down or server down.

There are two main methods to detect it. One is the operating system (Not all operating systems support it) TCP keepalive feature, and the other is the keepalive-equivalent timeout function implemented at the application layer. Connection Manager's heartbeat monitoring capabilities are categorized as the latter.

The operating system TCP keepalive feature has the following disadvantages, but the Connection Manager's heartbeat monitoring feature does not:

- The keepalive does not work when the TCP layer cannot receive an acknowledgement (ACK) and retransmits the packet repeatedly. This means that it is not possible to detect a down (For example, if a network goes down,) before sending some data and receiving ACK from the other side. There is also a parameter to interrupt retransmissions, which is not supported by some operating systems. The Connection Manager's heartbeat monitoring feature does not have this disadvantage because it is timeout monitoring at the application layer.
- The periodic packets for keepalive are sent per-TCP socket. If a instance accepts too many (For example, a few thousand clients) SQL connections, the load on the instance side cannot be ignored. The Connection Manager's heartbeat monitoring feature greatly reduces the load by allowing packets to be sent to the instance on a per-server basis on which the client runs.

1.1.2 Mechanism of Heartbeat Monitoring Feature

On the client side, the user must start one monitoring process using the cm_ctl command for the set of the instances to be monitored. This process, called the "conmgr process", can only be started by a user who is not an administrator (e.g. superuser(root) on Linux), or by a user who does not have Windows administrator privileges. An instance set is a collection of one or more instances that make up replication. One configuration file (conmgr.conf) for each conmgr process is used to set the information about the set of the instances being monitored and the parameters for monitoring.

On the server side, by installing PostgreSQL's EXTENSION that is called "watchdog", the postmaster will start two processes as background workers at instance startup.

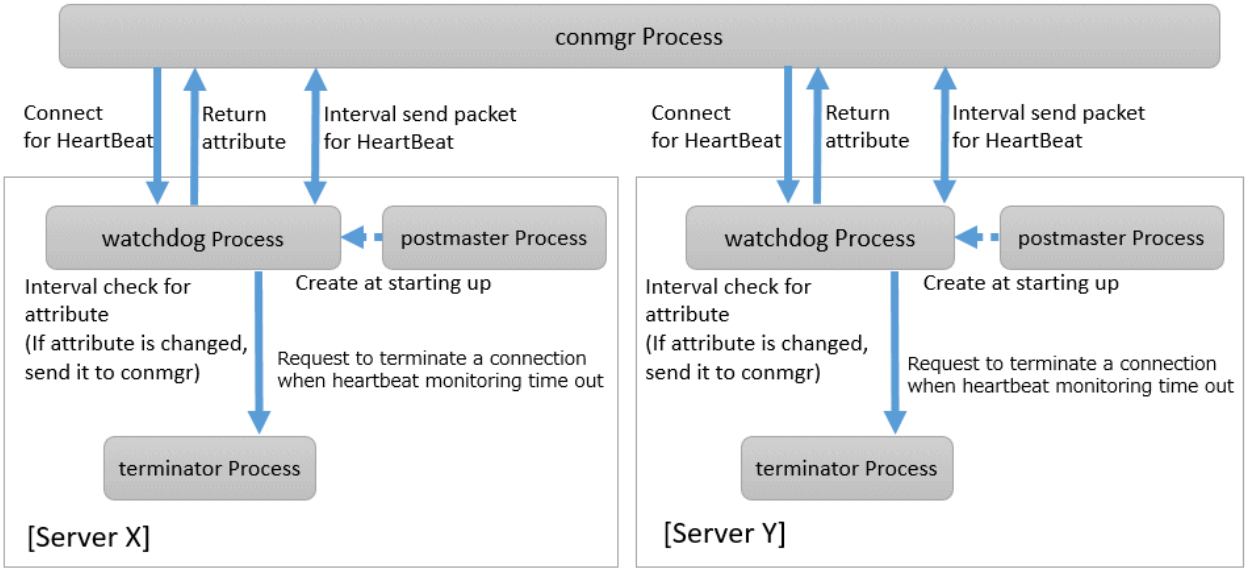
One is the process for sending and receiving packets to and from the conmgr process for heartbeat monitoring. It is called "watchdog process". The other is the process for forcibly terminating SQL connections of the clients for which the watchdog process detects a failure on heartbeat monitorting. It is called "terminator process". SQL connections that do not use Connection Manager is also terminated, because the terminator process terminates them by IP address as key.

System Configuration Notes

For replication, it is recommended that the instance that connects to the upstream instance of replication and the conmgr process that regards the upstream instance as an instance to be monitored for heartbeart (specified in backend_host parameter or backend_hostaddr parameter that is a configuration parameter of conmgr process) be not placed on the same server. This is because if the conmgr process stops normally or abnormally, the terminator process in the upstream instance will also kill the replication connection. The replication connection will reconnect automatically even if it is forcibly disconnected, so replication will continue without any problems. However, this can be a problem when the replication load is high or on systems that are sensitive to replication delays.

Note that the replication connection have different monitoring feature than the Connection Manager, so there is no need to monitor the Connection Manager for heartbeat. Refer to PostgreSQL documentation for details.

The process relationship is as follows:



See

Refer to "cm_ctl" in the Reference for information on cm_ctl command.

1.2 Transparent Connection Support Feature

The features similar to Connection Manager's transparent connection support feature can be found in PostgreSQL's libpq and other client drivers.

Using libpq as an example, the connection parameter to use that feature is target_session_attrs parameter. If this parameter is used not through Connection Manager, libpq will attempt to find the required instance by connecting sequentially to all instances of the set of instance requested by the host parameter or hostaddr parameter. In the worst case, libpq may find the promoted primary at the connection to the last instance of instance set. This means that you cannot predict how long it will take to complete the switch.

However, when conmbined with the Connection Manager, the conmgr process obtains its attributes via the watchdog process from all servers in a set of servers in advance, so that the connections to that server can be initiated as soon as the application requests it.

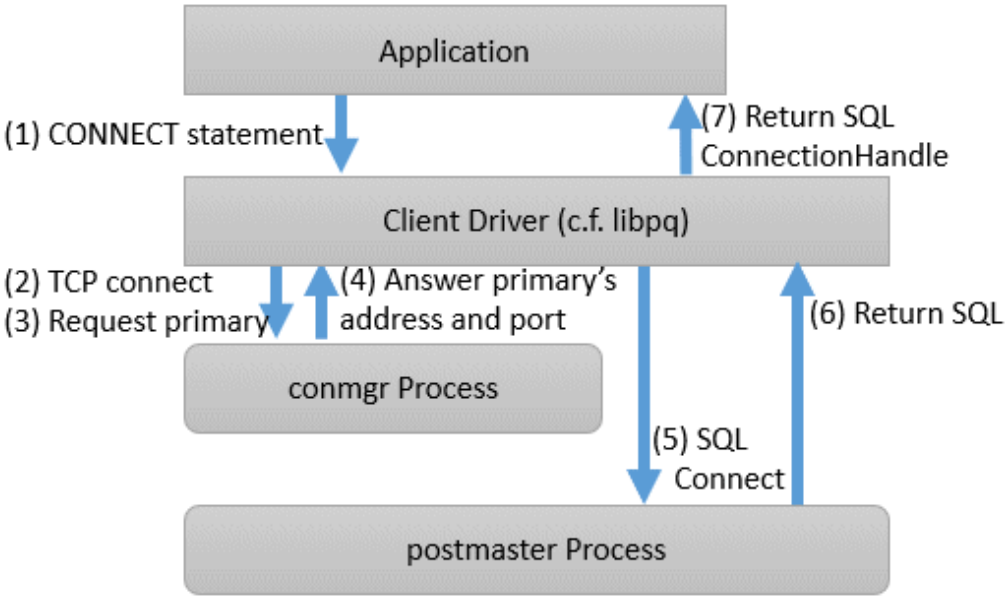
1.2.1 Mechanism of Connections using Transparent Connection Support Feature

A connection using this mechanism actually consists of two steps, but from the perspective of the application, it looks like a single SQL connection. In the application's connection string, specify the IP address or host name (In most cases it is "localhost") and port number where the conmgr process listens, and target_session_attrs parameter. You do not need to explicitly state that the connection is to the conmgr process. This is because the client driver can automatically determine whether the connection is to a instance or a conmgr process.

In the first phase of the connection, the client driver receives a connection request from the application and connects to the location specified in the connection string. Initially, it uses the protocol PostgreSQL requests, and if it learns in the middle that the connection is to a conmgr process, it asks the conmgr process for the IP address and port number that the instance with the attributes specified in the connection parameter target_session_attrs is listening for. If the destination is a backend process rather than a conmgr process, the connection process completes immediately and continues to send and receive data for normal SQL execution. The first stage of processing falls within the scope of timeout monitoring for SQL connection processing by each client driver. For example, the connection_timeout parameter of libpq.

In the second phase of the connection, the client driver connects to the instance using the IP address and port number from the conmgr process.Thereafter, the client driver and the instance directly send and receive the data for SQL execution. This ensures that the Connection Manager does not affect the performance of the SQL execution.

When the client driver is waiting to receive data after the second stage is completed, it monitors the reception of data to the two sockets obtained at each stage of the connection. This allows the client driver to know when, for example, the conmgr process notifies the client of a network link down.



Chapter 2 Setting Up

Describes setting up the Connection Manager.

2.1 Setting Up the Client Side

On the client side, configure settings for the conmgr process.

2.1.1 Setup Preparation Tasks

Describes the preparatory tasks to perform before you set up the conmgr process.

2.1.1.1 Security Policy Settings

In order for the Windows service to start and stop the conmgr process, Connection Manager requires a security setting that allows the OS user account that is to start the conmgr process to log on as a service.

Describes how to set up security so that you can log on as a service.

1. Displaying the [Local Security Policy] window

   In Windows, select [Administrative Tools], and then click [Local Security Policy].

2. Setting up security

   1. In the [Local Security Policy] window, select [Security Settings], select [Local Policies], and then click [User Rights Assignment].
   2. Under [Policy] in the [User Rights Assignment] window, double-click [Log on as a service].
   3. In the [Log on as a service Properties] window, set the following:

      a. Select the [Local Security Setting] tab.

      b. On the [Local Security Setting] tab, click [Add User or Group].

      c. In the [Select Users or Groups] window, enter the operating system user account of the instance administrator user in [Enter the object names to select].

      d. Click [OK].

   4. In the [Log on as a service Properties] window, click [OK].

2.1.1.2 Preparing for Output to the Event Log

Describes how to prepare for outputting error logs to the event log.

Note

If you have not registered the event source name, the content of the message output to the event log might be incomplete.

Register this default event source name before using the cm_ctl command because the event log may be output with a default event source name of "conmgr".

The following is an example of registering a DLL for a 64 bit product as the event source name "conmgr".

```
> regsvr32 /n /i:"conmgr" "c:\Program Files\Fujitsu\fsepv<x>client64\lib\pgevent.dll"
```

For a multi-version installation

If Fujitsu Enterprise Postgres is already installed on the same machine, note the path to the registered DLLs by searching for the following key in the Registry Editor. Then, register a new DLL with the default event source name.

The DLL path is used to re-register the default event source name during removing setup.

```
conmgr
```

2.1.2 Creating a Directory for the conmgr Process

You need one conmgr process for each set of instances that you want to configure for replication. Assign a dedicated directory to each conmgr process. This directory must assign read, execute, and write permissions for the user who starts the conmgr process.

This directory is specified when you run the cm_ctl command, which starts and stops the conmgr process. To specify a directory in the cm_ctl command, set it in the environment variable CMDATA or specify it in the -D option.

See

Refer to "cm_ctl" in the Reference for information on cm_ctl.

2.1.3 Configuring conmgr.conf

Place the configuration file conmgr.conf in the directory for the conmgr process.

Syntax for conmgr.conf

- In conmgr.conf, after the symbol(#) are considered comments.
- The parameter name = value" is a set of settings and must be written on one line.
- Set the value in a format that matches the type of each parameter. The types and formats are:
  - integer: Numeric type. Express as a sequence of numbers in decimal number.
  - string: String type. You can also include spaces by enclosing them in quotation marks('). If you include quotation marks, escape them.
  - enum: Enumeration type. Possible values are determined.

Parameters to Set

port (integer)

Specify the port number on which the conmgr process listens for connections from the applications.

The value must be greater than or equal to 1 and less than or equal to 65535. The default is 27546. You must restart conmgr process for this parameter change to take effect.

backend_host* (string)

Specify the host name or IP address of the instance.

You can also use IPv6 address. If you specify the IP address directly, you can save time by using backend_hostaddr parameter. If backend_host parameter and backend_hostaddr parameter are both specified, backend_hostaddr parameter is used. You must restart conmgr process for this parameter change to take effect.

To distinguish multiple instances, append a zero-based number immediately after the parameter name, such as backend_host0, backend_host1,... This number is called the instance number. A parameter identified by the same instance number configures the settings of a single instance. If you want to exclude some instances from your replication configuration, you can simply remove the settings for that instance.

Note

Refer to "System Configuration Notes" in "1.1.2 Mechanism of Heartbeat Monitoring Feature" for details.

Note

If the primary is not included in the instances configured in conmgr.conf, use the -W option when starting Connection Manager with the cm_ctl command. Without the -W option, the cm_ctl command will not return until the primary connection is complete.

For example, if two instances are listening on "host name:host0, port number:5432" and "host name:host1, port number: 2345", write as follows.

```
backend_host0='host0'
backend_port0=5432
backend_host1='host1'
backend_port1=2345
```

You can also mix different instance number settings:

```
backend_host0='host0'
backend_host1='host1'
backend_port0=5432
backend_port1=2345
```

It does not matter if the instance number is missing as in the following (instance number 1):

```
backend_host0='host0'
backend_host2='host2'
backend_port0=5432
backend_port2=2345
```

If the host name is omitted, as in instance number 1 below, an error will occur when loading the configuration file.

```
backend_host0='host0'
backend_host2='host2'
backend_port0=5432
backend_port1=5555
backend_port2=2345
```

backend_hostaddr*(string)

Same as backend_host parameter except no name resolution is used.

backend_port* (integer)

Specify the port number the postmaster of the instance will listen on.

The value must be greater than or equal to 1 and less than or equal to 65535. The default is 27500. Append the instance number as you would for backend_host parameter. You must restart conmgr process for this parameter change to take effect.

watchdog_port* (integer)

Specify the port number on which the watchdog process listens.

The conmgr process connects to this port, but the user application does not. you must set it to the same value as watchdog.port parameter in postgresql.conf. The value must be greater than or equal to 1 and less than or equal to 65535. The default is 27545. Append the instance number as you would for backend_host parameter. You must restart conmgr process for this parameter change to take effect.

heartbeat_interval (integer)

Specify the interval at which heartbeat packets are sent for heartbeat monitoring.

Used in conjunction with heartbeat_timeout parameter. Connection Manager heartbeat monitoring always continues to send packets periodically from both ends of the connection. If a packet is not received from the other side within a certain period of time, the link is considered down.

Note that this method is different from TCP keepalive. TCP keepalive send a keepalive packet only when there is a certain amount of inactivity (idle), and expects to receive an ACK for that packet. If TCP keepalive does not receive an ACK, it repeats this a specified number of times and then assumes that the link is down.

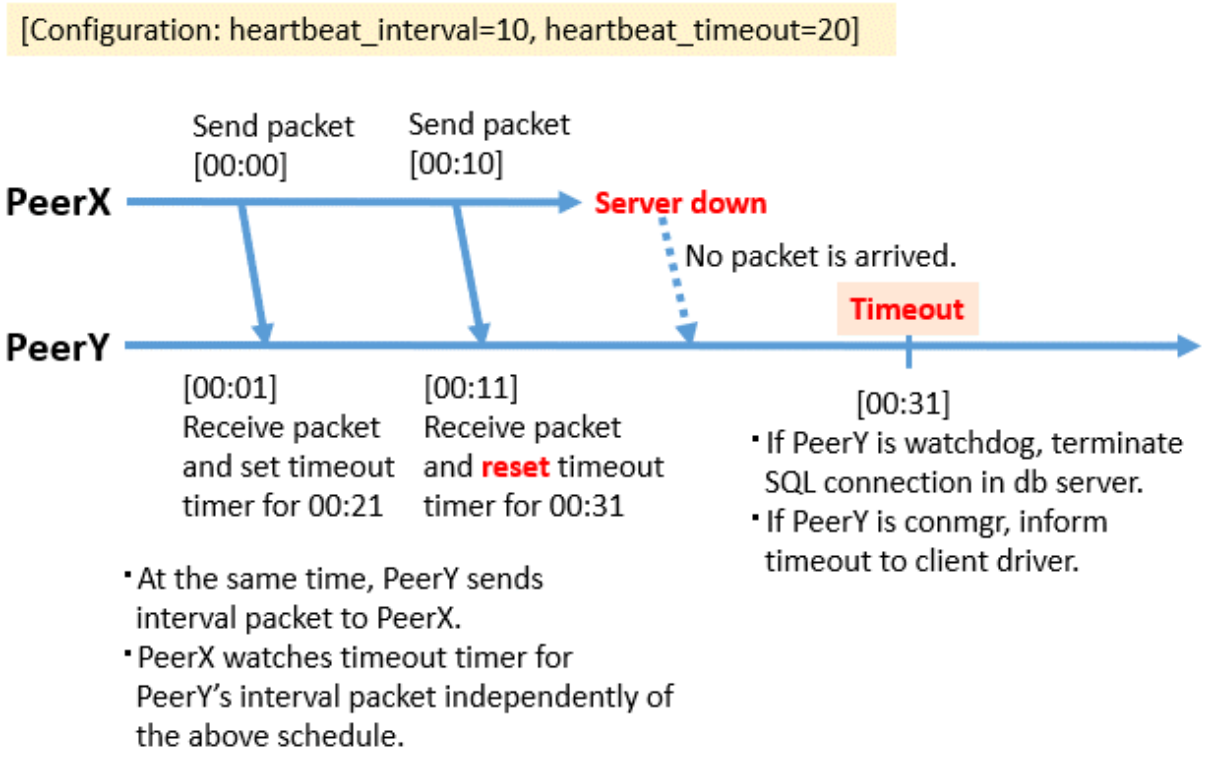
The heartbeat_interval parameter and heartbeat_timeout parameter are propagated from the conmgr process to the watchdog process, and also apply to the interval between the transmissions of heartbeat packets from the watchdog process. If a watchdog process is connected from both a conmgr process with a heartbeat_interval parameter of 3 seconds and a conmgr process with a heartbeat_interval of 5 seconds, it sends heartbeat packets every 3 seconds to the former process and every 5 seconds to the latter process. The unit is seconds. Specify a value equal to or more than 1 second. The default is 10 seconds. You must restart conmgr process for this parameter change to take effect.

heartbeat_timeout (integer)

If a heartbeat packet for heartbeat monitoring cannot be received for more than the time specified by this parameter, an error is assumed to have occurred and the application is notified of the error.

This parameter should be decide of heartbeat_interval parameter as the basis. No error is occured when the configuration file is loaded, but is always considered abnormal by heartbeat monitoring if it is at least not greater than heartbeat_interval parameter. The unit is seconds. Specify a value equal to or more than 1 second. The default is 20 seconds. You must restart conmgr process for this parameter change to take effect.

Refer to the following figure for the relationship between the heartbeat_interval parameter and heartbeat_timeout parameter settings and the heartbeat timeout.



heartbeat_connect_interval (integer)

Specify the interval between attempts to establish heartbeat monitoring again after detecting an abnormality.

This parameter is useful when only the database server is started, but not the instance. In such a situation, the TCP connection fails immediately, and retries cannot be attempted without an interval. If you specify an excessively long value, you may delay noticing the start of the instance. If a connection attempt fails for a long time, it will attempt the next connection after the time specified by heartbeat_connect_interval parameter has elapsed. The unit is seconds. Specify a value equal to or more than 1 second. The default is 1 second. You must restart conmgr for this parameter change to take effect.

heartbeat_connect_timeout (integer)

Specify the connection timeout for establishing heartbeat monitoring.

The connection includes the time it takes to send the TCP connection and the first heartbeat packet to the watchdog process and receive a reply from the watchdog process. This parameter is particularly needed when the other server is down or the network is disconnected. This is because TCP connections are attempted over a long period of time, depending on the operating system configuration, and the connection takes a long time to fail. The unit is seconds. Specify a value equal to or more than 1 second. The default is 10 seconds. You must restart conmgr process for this parameter change to take effect.

log_destination (string)

Specify the destination of the message.

You can specify multiple destinations. Use commas to separate multiple entries and enclose all in single quotation marks.

L

"stderr" and "syslog" can be specified. The default is to print only to stderr. You must restart conmgr process for this parameter change to take effect.

W

"stderr" and "eventlog" can be specified. The default is to print only to stderr. You must restart conmgr process for this parameter change to take effect.

L

syslog_facility (enum)

Specify the syslog facility.

Valid only if log_destination parameter includes "syslog".

LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, LOCAL5, LOCAL6, or LOCAL7 can be specified. The default is "LOCAL0". You must restart conmgr process for this parameter change to take effect.

L

syslog_ident (string)

Specify the program name used to identify the output from the conmgr process.

The default is "conmgr". You must restart conmgr process for this parameter change to take effect.

W

event_source (string)

Specify the event source name used to identify the output from the conmgr process.

The default is "conmgr". You must restart conmgr process for this parameter change to take effect.

log_min_messages (enum)

Specifies the level of messages to output.

It can be DEBUG, INFO, NOTICE, WARNING, ERROR, LOG, FATAL, or PANIC. Messages below the specified level are not output. The default is "WARNING". You must restart conmgr process for this parameter change to take effect.

max_connections (integer)

Specifies the maximum number of simultaneous connections to the conmgr process.

If there are more than this maximum number of client connections, it forces the connection to be closed without sending an error message to the client.

The conmgr process also outputs this fact at level “LOG” to the destination specified by log_destination. Specify a value equal to or more than 0.

If 0 is specified, there is no limit. The default is 0. You must restart conmgr process for this parameter change to take effect.

L

Note

The maximum number of file descriptors that can be opened simultaneously (You can check it with -n of the ulimit command.) imposed on a conmgr process by the OS user limit should be greater than the value derived from the following equation:. Otherwise, the conmgr process will abort if the user limit is violated.

```
9 + Number of database instances specified in conmgr.conf x 2  + max_connections
specified in conmgr.conf
```

loadbalance (string)

Specify the algorithm used for the load balancing feature as "roundrobin" or "leastconn".

When a connection request is received, the server to connect to is determined as follows:

roundrobin: It simply determines the connection destination according to the order of the server list defined in conmgr.conf.

leastconn: When a choice is available, it connects to the server that accepts the fewest connections.

The default is "roundrobin". You must restart conmgr process for this parameter change to take effect.

wait_streaming_replica_state (boolean)

Specify whether to exclude from connection candidates standby servers that are not synchronized with the primary server on a transaction-by-transaction basis.

If on is specified, it will be excluded from the connection destination. The default is off. You must restart conmgr process for this parameter change to take effect.

on_promote_action (string)

The following specifies the notification behavior to applications from the conmgr process when a standby server is promoted, using the read connection redistribution feature.

auto_disconnect: Notifying the message and disconnecting the connection.

none: Nothing works.

The default is "none". You must restart conmgr process for this parameter change to take effect.

standby_reconnect_threshold (integer)

With the read connection redistribution feature, you can specify a threshold for the number of connections to balance the total number of connections across all standby servers, including active ones, when a standby server recovers. Specify the average number of connections expected on a standby server.

When a server recovers, if the number of connections on an active server exceeds the specified value, a message may be sent to the application and the connection may be disconnected. In such cases, the acceptable range for imbalance will follow the value specified in the standby_reconnect_balance_ratio_target parameter.

If this parameter is omitted or set to 0, the read connection redistribution feature will not be enabled, and the application's connections will be maintained as they are.

The default is 0. You must restart conmgr process for this parameter change to take effect.

standby_reconnect_balance_ratio_target (floating point)

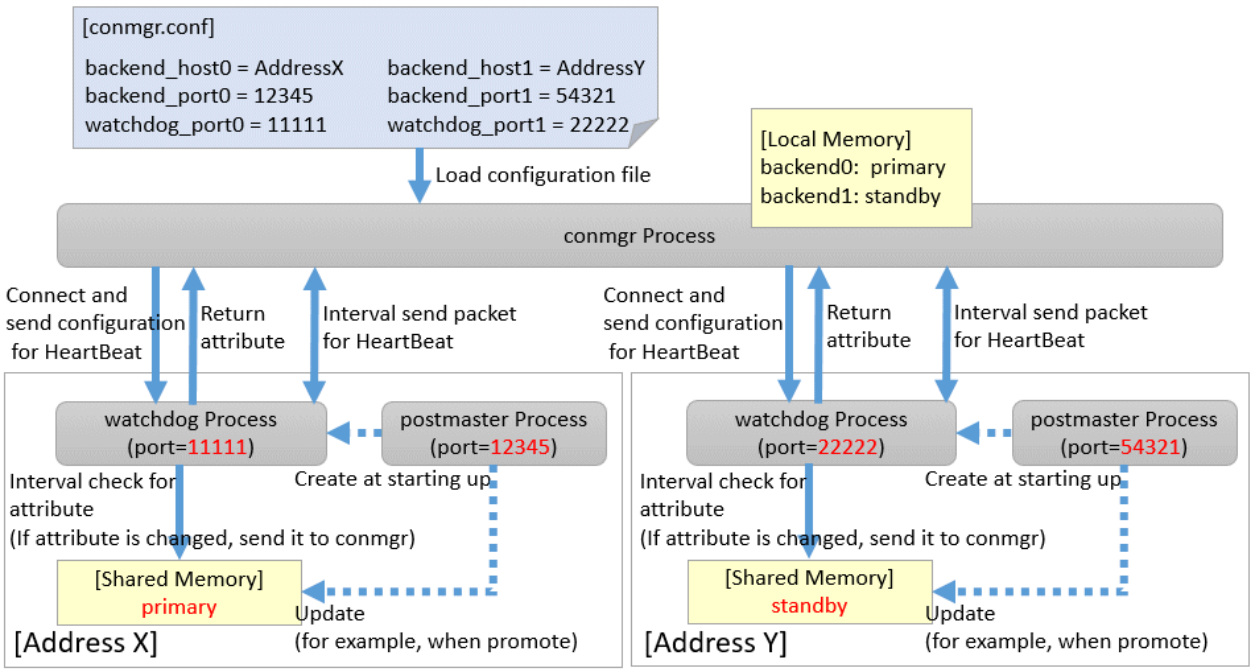
With the read connection redistribution feature, you can specify a target ratio as a decimal value between 0.2 and 0.8 to resolve the imbalance in the number of connections between nodes when a standby server recovers. This applies when standby_reconnect_threshold is enabled.

For example, if you specify 0.3, message notifications and disconnections will be performed for applications (clients) connected to the server with the most connections until the maximum number of connections across all standby servers is 1.3 times or less than the minimum number of connections, aiming to converge to the set ratio.

The default is 0.3. You must restart conmgr process for this parameter change to take effect.

Overview of connections definitions

The following figure shows the relationship between the IP address or host name and the port number set in conmgr.conf and the processes.



2.1.4 Registering the conmgr Process with a Windows Service

To start or stop the conmgr process using a Windows service, register the conmgr process with the Windows service. Describes how to register the conmgr process with a Windows service.

Register the conmgr process with a Windows service by using the cm_ctl command with the service name to register, the user name, the password, and the path to the directory where the conmgr.conf is located.

Example)

The following example is executed when the registration service name is "conmgr", the user name is "fsepuser", and the directory where confgr.conf is located is "D: \conmgr".

```
> cm_ctl register -N "conmgr" -U fsepuser -P ******** -D D:\conmgr
```

Note

- Execute the command as a Connection Manager administrator user with "Administrator" privileges. Execute the command from the [Administrator: Command Prompt] window. Right-click [Command Prompt], and then select [Run as administrator] from the menu to display the [Administrator: Command Prompt] window.
- Do not specify the --complete option when registering Windows services in register mode of the cm_ctl command. This is because the conmgr process may be running in the background if it fails to start using Windows services.
- You must specify a user name and password for the following reasons:

  Because Windows services are started under the Network Service account, the conmgr process is created for that account. As a result, the conmgr process may fail to start on another user. For security reasons, if you do not specify a user name and password, specify the account from the list of Windows services immediately after you register the conmgr process with the Windows service.
- When entering the password for the cm_ctl command, be careful that it is not referenced by other users for security reasons.

2.2 Setting Up the Server Side

On the server side, configure settings for the watchdog process.

2.2.1 Configuring postgresql.conf

Describes the postgresql.conf parameters that must be set when using the Connection Manager.

Parameters to Set

max_connections

An existing PostgreSQL parameter. Add 2 to the value already set.

Connection to the instance is maintained from the time the instance is started to do the following:

- The watchdog process checks the state of the instance.
- The terminator process forces the client to terminate the SQL connection.

shared_preload_libraries

An existing PostgreSQL parameter. Add a watchdog.

The watchdog process and terminator process start when you add watchdog and restart the instance.

watchdog.port (integer)

Specify the port number on which the watchdog process accepts connections for heartbeat monitoring from the conmgr process.

The value must be greater than or equal to 1 and less than or equal to 65535. The default is 27545. The instance must be restarted for this parameter change to take effect.

watchdog.check_attr_interval (integer)

Specify the interval between checking the attributes of a instance.

watchdog process immediately notifies the conmgr process if the attribute changes.

Also, if you are using the standby initial data synchronization waiting feature, it is also used for the interval to check the status of the standby server.

The unit is milliseconds. Specify a value equal to or more than 1 millisecond. The default is 1000 milliseconds. The instance must be restarted for this parameter change to take effect.

watchdog.max_heartbeat_connections (integer)

Specify the maximum number of conmgr processes that connect to watchdog process.

The default is the value specified in max_connections of postgresql.conf.

There is no upper limit, but about 200 bytes of memory are consumed for 1 connection when PostgreSQL is started.

Note

Normally you do not need to consider, but if you have a heartbeat connection with a very large number of conmgr processes, it may violate on the maximum number of file descriptors (You can check it with -n of the ulimit command.) of the OS user limit. This is because the socket for the heartbeat connection consumes the file descriptor. Set the maximum number of file descriptors of the OS user limit to a value larger than the value calculated below from the max_files_per_process parameter value and watchdog.max_heartbeat_connections parameter value in postgresql.conf.

```
max_files_per_process + watchdog.max_heartbeat_connections x 2
```

2.2.2 Introducing the watchdog extension

Execute the CREATE EXTENSION statement with watchdog.

Example)

```
postgres=# CREATE EXTENSION watchdog;
CREATE EXTENSION
```

This allows you to see the pgx_stat_watchdog view for information about the watchdog process.

2.2.3 Windows Firewall Settings

Describes how to enable the port number used by the watchdog process when you enable the Windows Firewall feature.

Windows Server(R) 2016:

1. In the [Windows Firewall] window, click [Advanced settings] on the left side of the window.
2. In the [Windows Firewall with Advanced Security] window, click [Inbound Rules] on the left side of the window.
3. Click [New Rule] on the right side of the window.
4. In the [New Inbound Rule Wizard] window, select [Port], and then click [Next].
5. Select [TCP] and [Specific local ports], then specify the "port number on which the watchdog process accepts connections for life-and-death monitoring from the conmgr process (watchdog.port)" defined in postgresql.conf in the text box, and then click [Next].
6. Select [Allow the connection], and then click [Next].
7. Select the profiles for which this rule applies, and then click [Next].
8. In [Name], specify the desired name(ex: Connection Manager), and then click [Finish].
9. In the [Windows Firewall with Advanced Security] window, check if the added rule is enabled under [Inbound Rules] in the center of the window.

Other than above:

1. In the [Windows Defender Firewall] window, click [Advanced settings] on the left side of the window.
2. In the [Windows Defender Firewall with Advanced Security] window, click [Inbound Rules] on the left side of the window.
3. Click [New Rule] on the right side of the window.
4. In the [New Inbound Rule Wizard] window, select [Port], and then click [Next].
5. Select [TCP] and [Specific local ports], then specify the "port number on which the watchdog process accepts connections for life-and-death monitoring from the conmgr process (watchdog.port)" defined in postgresql.conf in the text box, and then click [Next].
6. Select [Allow the connection], and then click [Next].
7. Select the profiles for which this rule applies, and then click [Next].
8. In [Name], specify the desired name(ex: Connection Manager), and then click [Finish].
9. In the [Windows Defender Firewall with Advanced Security] window, check if the added rule is enabled under [Inbound Rules] in the center of the window.

2.3 Starting the conmgr Process

2.3.1 Starting and Stopping the conmgr Process

Describes starting and stopping the conmgr process.

You can use commands related to Windows services to start, stop, and check the health of the conmgr process.

To use a Windows service, register the confmgr process with the Windows service.

Note

Although it is possible to start and stop the conmgr process by running the cm_ctl command without registering the conmgr process with the Windows service, we recommend that you use the Windows service to start and stop the conmgr process for the following reasons.

The cm_ctl command starts the conmgr process as a user process. Therefore, closing the command prompt window from which the command was executed will force the conmgr process to stop.

Starting the conmgr process

Start with the net start or sc start command and the service name.

You can also start it from the Windows Services window by following the steps below.

1. Display the [Services] window

   In [Administrative Tools], click [Services].

2. Start a service

   From the list of service names, select the conmgr process and click the [Start Service] button.

Stopping the conmgr process

Start with the net stop or sc stop command and the service name.

You can also stop it from the Windows Services window by following the steps below.

1. Display the [Services] window

   In [Administrative Tools], click [Services].

2. Stop a service

   From the list of service names, select the conmgr process and click the [Stop Service] button.

Checking the operating status of the conmgr process

To check whether a service is running immediately after the start operation of the conmgr process, check the status of the service as follows.

1. Display the [Services] window

   In [Administrative Tools], click [Services].

2. Check the status of the service

   Check the service status of the conmgr process from the list of service names.

Use the cm_ctl command to check the operating status of the conmgr process during operation.

See

Refer to "cm_ctl" in the Reference for information on cm_ctl.

2.3.2 Setting of Automatic Start / Stop of conmgr Process

The conmgr process can be started/stopped automatically according to the start/stop of the database server OS.

If the service startup type is "manual", change it to "automatic". By setting it to "automatic", it will start automatically when the database server OS is started, and will automatically stop when the database server OS is shut down.

Note

Please do so as a user with "Administrator" privileges.

Follow the procedure below to switch services.

1. Display the [Services] window

   In [Administrative Tools], click [Services].

2. Switch startup

   Select the service name of the conmgr process, display the [Properties] dialog, and switch the startup type from Manual to Automatic.

You can also change the above settings with the sc config command.

2.4 Removing Setup

Describes how to removing setup the Connection Manager.

Linux

No work is required on the client side.

On the server side, drop watchdog extension by DROP EXTENSION statement and remove it from shared_preload_libraries.

Example)

```
postgres=# DROP EXTENSION watchdog;
DROP EXTENSION
```

Windows

The following work is required on the client side.

1. Unregister Windows service

   Cancel the conmgr process registered in the Windows service.

   In unregister mode of the cm_ctl command, specify the registered service name to cancel the conmgr process of the Windows service.

   Example)

   An execution example is shown when the registered service name is "conmgr".

```
> cm_ctl unregister -N "conmgr"
```

Note

Execute the command as a Connection Manager administrator user with "Administrator" privileges. Execute the command from the [Administrator: Command Prompt] window. Right-click [Command Prompt], and then select [Run as administrator] from the menu to display the [Administrator: Command Prompt] window.

2. Deletion of registration for event log

   If you are outputting to the event log in "2.1.1.2 Preparing for Output to the Event Log", delete the registered event source name.

   Example)

```
> regsvr32 /u /i:"conmgr" "c:\Program Files\Fujitsu\fsepv<x>client64\lib\pgevent.dll"
```

For a multi-version installation

If the conmgr process created using this package is configured to output the error log to the event log, re-register the default event source name using the DLL pathname that was saved in "2.1.1.2 Preparing for Output to the Event Log".

On the server side, use the DROP EXTENSION statement to remove the watchdog extension and remove the watchdog from shared_preload_libraries.

Example)

```
postgres=# DROP EXTENSION watchdog;
DROP EXTENSION
```

Chapter 3 Using from an Application

Describes how to use the Connection Manager from an application.

3.1 Connection Method

When connecting to the instance using ConnectionManager, specify the following values in the connection parameters of the application. Application connection parameters are parameters that specify the database IP address, host name, port number, etc., which are originally specified when connecting to the database from the application. For example, when using libpq, specify "localhost" for the host parameter and specify the port number on which the conmgr process listens for the port parameter.

Connection parameters not shown here are used directly by the instance in the second stage of the connection, connecting to the instance (connecting to an instance without the Connection Manager), and the conmgr process does not check or use it.

Connection destination address

Specify "localhost". Unix domain sockets are not allowed.

It is possible to connect to a remote conmgr process, but it should not be used for other purposes expect such as testing. This is because there is no mechanism between the application and the conmgr process to detect the remote server down or the network link down, making the Connection Manager meaningless.

Port number

Specify the value specified for the port parameter in conmgr.conf.

Connection destination instance attributes

Follow the "Target server" in the application connection switch feature. Refer to "Taget server" in "Connection Information for the Application Connection Switch Feature" in the "Application Development Guide" for information on the target server in the application connection switch feature.

Note

- If you specify 'direct' for the sslnegotiation connection parameter, you cannot use Connection Manager.
- Connection Manager cannot be used if preferPrimary is specified for targetServerType when using the JDBC driver.

3.2 How to Detect Instance Errors

Only special if you are using libpq's asynchronous communication method. For additional discovery methods, refer to "Errors when an Application Connection Switch Occurs and Corresponding Actions" of the for each client driver in the "Application Development Guide" . If the conmgr process goes down while accessing it, or if the conmgr process tries to establish a SQL connection while it is down, the same error is returned as if the instance went down.

3.3 How to Use in libpq

libpq provides very detailed communication control. Therefore, to detect a heartbeat error through the conmgr process, you may need to modify the existing application logic.

See

Refer to "libpq - C Library" in the PostgreSQL Documentation on functions described below.

3.3.1 Specifying a Connection Destination

The host or hostaddr parameter of the connection string should specify a connection destination for only one conmgr process.

Information

The host or hostaddr parameter of the connection string can be a mixture of multiple conmgr process destinations and the postmaster destination. The first connection from an application process is attempted in the listed order, and the second and subsequent connections are attempted in the order in which the previous connection was made. However, if a connection to the conmgr process is confirmed, subsequent connections are always attempted in the listed order.

For example, if conmgr1, conmgr2 are specified, and if conmgr1 does not initially know a server with the attributes specified in the target_session_attrs parameter, it will query conmgr2 for a destination. In the second and subsequent connections, since there was a connection to the conmgr1 process, the connection destinations are queried in the order of the listed conmgr1 and conmgr2.

Also, for example, if postmaster1, conmgr1 is specified, it will try to connect directly to the database instance initially named postmaster1. If this fails, it queries conmgr1 for a destination. On subsequent connections, since there was a connection to the conmgr1 process, it queries the listed postmaster1, then conmgr1, for connections.

3.3.2 Using the Asynchronous Connection Method

An asynchronous connection method is to use a function like PQconnectStart() instead of a function like PQconnectdb (). PQconnectStart() returns without synchronizing the completion of the connection to the database. The user application must then monitor the sockets returned by PQsocket() to be readable or writable, for example by using the poll() system call, according to the values required by the return value of PQconnectPoll().

With the Connection Manager, the socket returned by PQsocket() may change after a call to PQconnectPoll(), so be sure to reacquire the socket that you want to give to the poll() system call using PQsocket(). This behavior is similar to simply specifying multiple hosts in the connection string without using the Connection Manager.

3.3.3 Using an Asynchronous Communication Method

An asynchronous communication method is one in which the application returns control without waiting for a response from the database, and PQsetnonblocking() is used to asynchronize completion of transmission or completion of receipt of all results. Instead of using a function like PQexec(), use a function like PQsendQuery(). In this method, the user application monitors the socket that connects to the database returned by PQsocket(), for example, by using the poll() system call.

For example, if the link to the database goes down, simply monitoring the socket returned by PQsocket() with the poll() system call will not detect it.

However, it is possible to detect the reception of database anomaly detection packets sent from the conmgr process, for example, by monitoring the reception of data on the socket (POLLIN) connecting to the conmgr process returned by PQcmSocket(). Once a reception is detected, the user application need not directly manipulate the packet. By calling something like PQgetResult() or PQcosumeInput() according to the existing application logic, it behaves as if the connection were disconnected. Refer to "Errors when an Application Connection Switch Occurs and Corresponding Actions" in the Application Development Guide on SQLSTATE returned,etc. If you are not using the Connection Manager, PQcmSocket() returns -1.

3.3.4 Behavior of PQhost() or PQhostaddr() or PQport()

PQhost(), PQhostaddr() or PQport() typically return a host parameter or hostaddr parameter or port parameter specified in the connection string by the user application. However, if you specify a connection destination for the conmgr process, the destination for the conmgr process you specify will be changed to the database connection destination information provided

by the conmgr process before the connection is completed. This behavior is similar to simply specifying multiple hosts in the connection string without using the Connection Manager.

3.3.5 Behavior of PQstatus()

If you are using an asynchronous connection method, you can monitor the intermediate state of the connection to the database with PQstatus(). If you are using the Connection Manager, the enum value returned by PQstatus() is appended with the following:

```
CONNECTION_AWAITING_CMRESPONSE
/ * Waiting for a response from the conmgr process * /
```

3.3.6 PQcmSocket()

You can get a socket that leads to the conmgr process. It returns a value equal to or more than 0 for a valid socket, or -1 if you are not connected to the conmgr process.

```
int PQcmSocket(const PGconn *conn);
```

3.4 How to Use in ODBC Driver

Describes points to note when using the Connection Manager using the ODBC driver.

3.4.1 Behavior of SQLGetInfo()

When SQL_SERVER_NAME is specified in the argument InfoType, SQLGetInfo () normally returns the contents set in Servername or Server of the data source. However, if you specify a connection destination for the conmgr process, the destination for the conmgr process you specify will be changed to the database connection destination information provided by the conmgr process before the connection is completed. This behavior is similar to simply specifying multiple hosts in the connection string without using the Connection Manager.

3.5 How to Use in JDBC Driver

Describes points to note when using the Connection Manager using the JDBC driver.

3.5.1 Behavior of loadBalanceHosts Parameter

The loadBalanceHosts parameter is a connection parameter for the JDBC driver to use the load balancing feature. You can specify whether to use the load balancing feature by setting this parameter. However, Connection Manager provides a unique load balancing feature that users cannot specify whether to use or not. Therefore, even if the user sets the loadBalanceHosts parameter to disable the JDBC driver load balancing feature, the Connection Manager load balancing feature is always enabled when connecting to the database via the Connection Manager.

3.6 How to Use in Python Language Package (psycopg)

Describes points to note when using the Connection Manager using the Python language package (psycopg).

In the Python language package (psycopg), you can use the psycopg.Connection class and the psycopg.AsyncConnection class to work with the Connection Manager. If you want to use methods that are not defined in these two classes, also refer to "3.3 How to Use in libpq".

3.6.1 Specifying a Connection Destination

Refer to "3.3 How to Use in libpq".

3.6.2 Behavior of psycopg.ConnectionInfo.host() or psycopg.ConnectionInfo.hostaddr() or psycopg.ConnectionInfo.port()

psycopg.ConnectionInfo.host(), psycopg.ConnectionInfo.hostaddr() or psycopg.ConnectionInfo.port() typically return a host parameter or hostaddr parameter or port parameter specified in the connection string by the user application. However, if you specify a connection destination for the conmgr process, the destination for the conmgr process you specify will be changed to the database connection destination information provided by the conmgr process before the connection is completed. This behavior is similar to simply specifying multiple hosts in the connection string without using the Connection Manager.

3.6.3 Behavior of psycopg.ConnectionInfo.status()

If you are using an asynchronous connection method, you can monitor the intermediate state of the connection to the database with psycopg.ConnectionInfo.status(). If you are using the Connection Manager, the enum value returned by psycopg.ConnectionInfo.status() is appended with the following:

```
CONNECTION_AWAITING_CMRESPONSE
/ * Waiting for a response from the conmgr process * /
```

3.7 How to Use in Go Language

Describes points to note when using the Connection Manager using the Go language.

3.7.1 Specifying a Connection Destination

The host parameter of the connection string should specify a connection destination for only one conmgr process.

Appendix A System Views

A.1 pgx_stat_watchdog

A row in this view corresponds to conmgr process, which is connected to watchdog process. Additional columns may be added in future versions versions.

Column	Type	Description
conmgr_addr	inet	IP address of conmgr process.
conmgr_port	integer	The conmgr (ephemeral) port number that conmgr process is using to communicate with watchdog process. This is not the port number to be set in conmgr.conf.
heartbeat_interval	integer	The interval at which heartbeat packets are sent to and from this conmgr process. The unit is seconds.
heartbeat_timeout	integer	The timeout value for the heartbeat to and from this conmgr process. The unit is seconds.

Knowledge Data Management User's Guide

Windows/Linux

J2UL-3063-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document describes the knowledge data management features of Fujitsu Enterprise Postgres.

Intended readers

This document is intended for those who use the knowledge data management feature.

To read this document, you need to have the following knowledge:

- Fujitsu Enterprise Postgres
- PostgreSQL

Structure of this document

The structure and content of this manual is shown below.

Chapter 1 Knowledge Data Management Feature

This chapter describes the overview of the knowledge data management feature and examples of how knowledge data can be used.

Chapter 2 Vector Data Management Feature

This chapter describes the vector data management feature.

L Chapter 3 Advanced Search Feature for Text Data

This chapter describes the semantic text search and the automatic vectorization feature for semantic search.

L Chapter 4 MCP Server Feature for Business Data Utilization

This chapter describes the MCP server feature for business data utilization.

L Chapter 5 Model Management in the Database

This chapter describes the model management in the database.

L Chapter 6 Graph Management Feature

This chapter describes the graph management feature.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Issue date and version

```
Edition 2.0: March 2026
Edition 1.0: December 2025

Chapter 1 Knowledge Data Management Feature

This section describes an overview of the knowledge data management feature and examples of using knowledge data.

1.1 Overview of the Knowledge Data Management Feature

The Knowledge Data Management feature allows you to search based on semantic relationships using vectors and graphs, and manage those data.

When you use a large language model (LLM) in a retrieval-augmented generation (RAG) approach, you need external knowledge data to give to LLM. Fujitsu Enterprise Postgres can manage knowledge data in vector and graph formats, eliminating the need for a dedicated database for each format. You can also use Fujitsu Enterprise Postgres database multiplexing, access control, data encryption, and other features to securely manage your knowledge data.

In addition to existing searches, the Knowledge Data Management feature enables you to search knowledge data in three ways:

- Similar search of vector data

  Performs a similarity search between the specified vector data and the vector data stored in Fujitsu Enterprise Postgres.

L - Searching text data based on semantic similarity

  Searches for semantic similarity between the specified text and the text stored in Fujitsu Enterprise Postgres using embedding in a semantic vector.

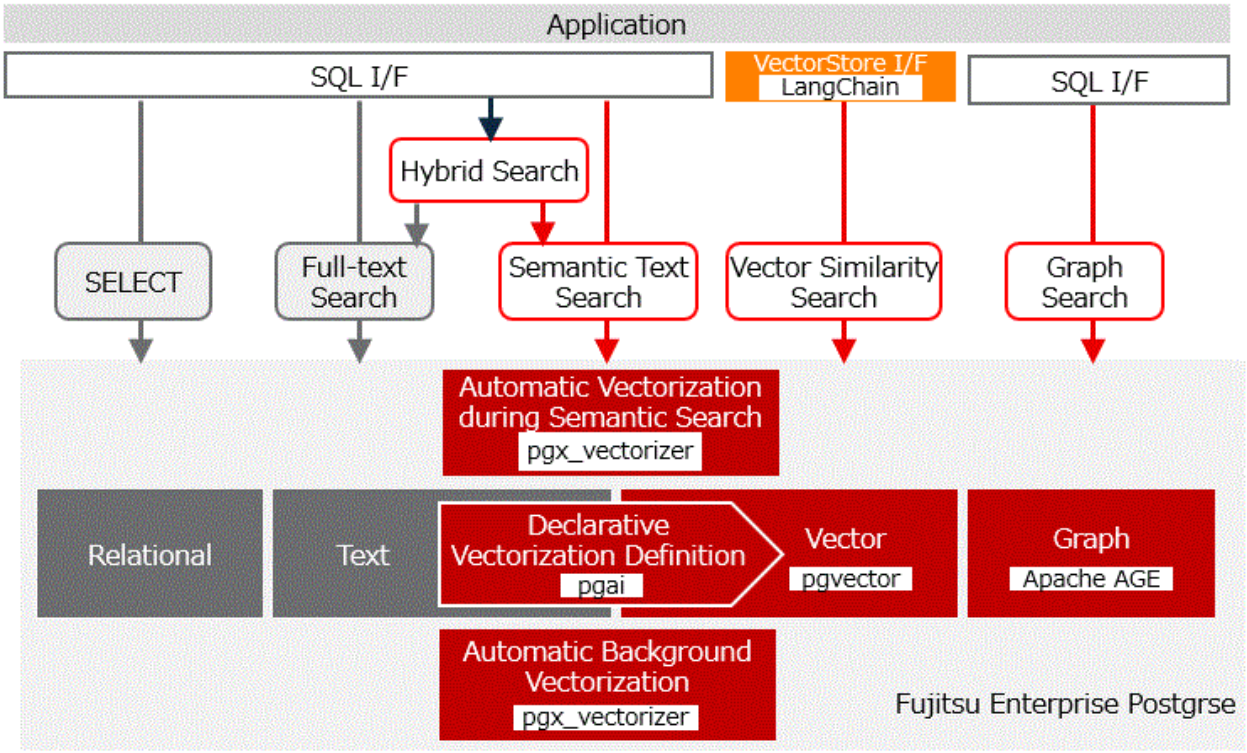
  When you store text data for semantic search in Fujitsu Enterprise Postgres, a vector (semantic vector) that captures the semantic similarity of the text data is automatically generated and stored in the database. When searching, the specified text data is automatically converted to vector data, and semantic search is performed by the vector similarity search.

  A hybrid search that combines text semantic similarity search and full-text search can also be utilized.

L - Searching graphs based on relationships

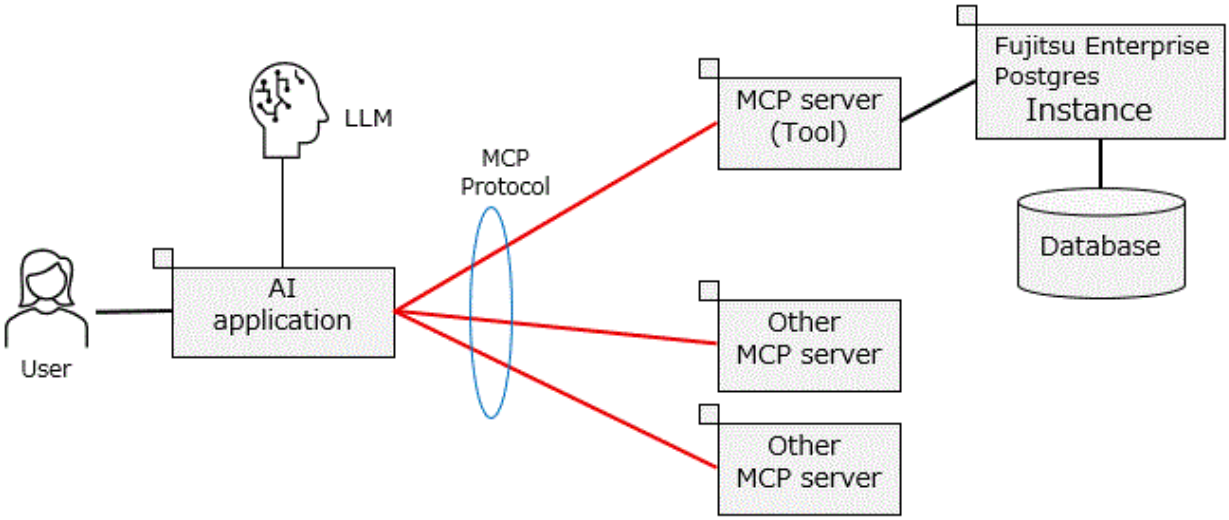
  A graph is a data structure that represents entities and their relationships as nodes and the edges that connect them. You can search graphs based on properties and relationships.

Knowledge data can be accessed by executing SQL queries from the application to Fujitsu Enterprise Postgres. You can also use LangChain, an AI application development framework, to access knowledge data in Fujitsu Enterprise Postgres.



L

In addition, we provide an MCP server feature that utilizes business data stored in Fujitsu Enterprise Postgres by using MCP (Model Context Protocol), which is a protocol for standardizing access to external resources and tools in Agentic AI applications. By having both the application and the external tool side support the MCP protocol, external tools can be used without modifying the application.



The MCP protocol enables LLMs to understand the features provided by the MCP server and to decide whether to call those features themselves. As a result, it is possible to configure an Agentic RAG application that performs external knowledge retrieval based on the LLM's active judgment, rather than a static RAG that extracts external knowledge from the application. Furthermore, we provide a tool to support SQL generation by LLMs to realize ad-hoc queries for relational data.

What the knowledge data management feature can do

The Knowledge Data Management feature enables you to:

- Vector data storage and retrieval using the vector data management feature
  - Storage of float32, float16, bit vectors, and sparse vectors
  - Vector neighbor search by cosine or euclidean distance
  - HNSW and IVFFlat vector index
  - DiskANN-based vector index suitable for large data sets
- Semantic text search and automatic vectorization
  - Automated background vectorization of newly added text data
  - Semantic search with automatic query vectorization, consistent with stored vector representation
  - Use of external vector embedding models such as Ollama and OpenAI
  - Hybrid search combining semantic text search and full-text search
- MCP Server Feature for Business Data Utilization
  - Knowledge data search via MCP server
  - SQL generation by LLM via MCP server
- Model management in the database
  - Management of models in ONNX format
  - Vectorization using ONNX format models in conjunction with Triton Inference Server
- Graph data storage and retrieval using the graph data management feature
  - Storing graphs
  - Exploring and updating graphs with openCypher
- Application development support
  - LangChain linkage

    For access from Python applications using LangChain, refer to the technical documentation available at:

    https://www.postgresql.fastware.com/resource-center

1.2 Examples of Using Knowledge Data

Here are some examples of using knowledge data.

1.2.1 Example of Searching Text Data Based on Semantic Similarity

Here is an example of a typical RAG-based application that utilizes vector embedding of text data. Instead of performing vectorization on the application side, we use the semantic search feature for text data provided by Fujitsu Enterprise Postgres.

1. Creating text data

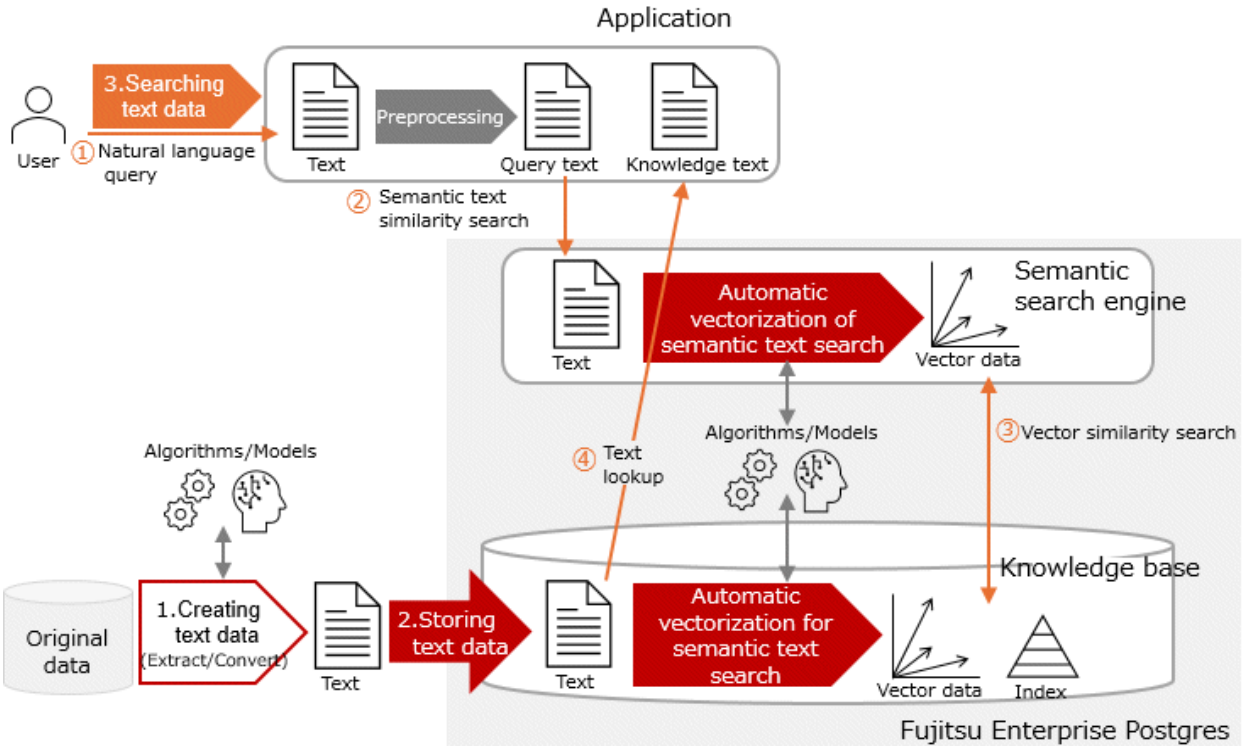
   Use different algorithms and models to extract text from different data in your organization.

2. Storing text data in Fujitsu Enterprise Postgres

   Store the text data in Fujitsu Enterprise Postgres. To use the semantic search function in text, declaratively define the vector representation to be used for the stored textual knowledge data. This automatically creates the vector data necessary for semantic search.

3. Searching text data

   The text semantic search feature returns text that is semantically similar to the text you are searching for. No conversion to vector representation is required on the application side.



1.2.2 Example of Searching a Graph Based on Relationships

Here is an example of a graph as knowledge data is queried in natural language, and the obtained knowledge is converted into text for use.

1. Creating graph data

   Extract graph data from a variety of data in your organization, such as using a relation extraction model.

2. Storing graph data in Fujitsu Enterprise Postgres

   Store the created graph data in Fujitsu Enterprise Postgres. Nodes and edges can be added with Cypher queries using SQL functions.

3. Searching graph data

   To search a graph, you specify a Cypher query to the SQL function. Converts the retrieved properties into a text representation for use.

Chapter 2 Vector Data Management Feature

This chapter describes the vector data management feature, which provides the storage and search of vector data.

L

pgvectorscale, described below, is only available on Linux.

2.1 Setting Up the Vector Data Management Feature

Vector data management features are provided by the OSS's pgvector and pgvectorscale.

Refer to "pgvector" in the Installation and Setup Guide for Server to set up pgvector.

If you use the StreamingDiskANN index, refer to "pgvectorscale" in the Installation and Setup Guide for Server to set up pgvectorscale.

In addition, to use the StreamingDiskANN index, a CPU that supports the AVX2 and FMA instruction sets is required. If you use a CPU that does not support AVX2 and FMA, an error will occur when creating a StreamingDiskANN index for a table that stores vector data, or when inserting data into a table with a StreamingDiskANN index created. Refer to the documentation for each CPU to see if the CPU supports AVX2 and FMA.

2.2 Storing and Searching Vector Data

The vector data management feature provides a new vector data type for storing vector data. Create a table with columns of vector data type and store vector data.

The similarity search of vector data is performed by calculating the distance between two vector data using the distance operator added by the vector data management feature, and by the closeness and ordering of the calculated distance.

Example) Vector similarity search

```
SELECT * FROM items ORDER BY embedding <-> '[3,1,2]' < 5 LIMIT 5;
```

Creating a vector index on a column of the vector data type causes the vector index to be used when searching for similarities using the distance operator.

Point

Similarity searches using vector index are approximate similarity searches.

See

Refer to the pgvector documentation for information about vector data types, vector operations, distance types between vectors, and HNSW and IVFFlat vector indexes.

Refer to the pgvectorscale documentation for information about StreamingDiskANN indexes.

2.3 Protecting Vector Data

Vector data is stored as column values in tables, and can be protected by encryption, backup, multiplexing, replication, access control, and audit settings that specify the table, tablespace, database, or instance in which the vector data is stored.

2.4 Performance Tuning for Similar Search of Vector Data

You can verify that indexes are being used for similar searches of vector data by checking the access plan in the EXPLAIN statement.

Example) Access Plan for Vector Similar Search

Here is an example using pgvectorscale:

```
EXPLAIN SELECT * FROM items ORDER BY embedding <=> '[3,1,2]' LIMIT 5;
                                    QUERY PLAN
-----------------------------------------------------------------------------------
Limit  (cost=24.75..24.96 rows=5 width=33)
   ->  Index Scan using idx_diskann  on items  (cost=24.75..445.75 rows=10000 width=33)
         Order By: (embedding <=> '[3,1,2]'::vector)
(3 rows)
```

See

Each vector index has parameters for tuning. See the documentation for pgvector and pgvectorscale for details.

2.5 Using Vector Data by Applications

If your application wants to work directly with vector data types, introduce a driver for each language in your application. If no driver is used, the vector data type is returned to the application as a string or array type.

See

For information on pgvector drivers for various languages, refer to below.

https://github.com/pgvector/pgvector?tab=readme-ov-file#languages

2.6 Quantitative Limits

Refer to the pgvector documentation for the quantitative limits of the data types provided by pgvector.

Chapter 3 Advanced Search Feature for Text Data

This chapter describes the semantic text search, the automatic vectorization feature for semantic text search and hybrid search.

3.1 Overview

Semantic text search

The semantic text search is a feature that searches for highly relevant texts based on semantic similarity of the text. This is achieved by utilizing vector representations that maintain the semantic similarity of text data.

Automatic vectorization feature

The automatic vectorization feature automatically generates and stores vector representations corresponding to the text data inserted into the table. In the automatic vectorization feature, the vectorized data is stored as a column value of the vector data type in an internally created table, so that re-vectorization of the same text is not necessary. Use an external service called an embedded provider to generate vector representations of text.

The automatic vectorization feature is executed in the background by defining vectorization for the table to be searched. The definition of vectorization includes the embedded model that determines the vector representation used for semantic text search, the method of text segmentation, and the definition of the index. At the same time as defining the vectorization, you can define a vector index for the vector data and a full-text search index for the text chunks.

When a vectorization is defined for table, a corresponding "embedded table" is created. This embedded table stores text chunks, which are units of the original table's text data divided into chunks, and the corresponding vector data. When new text data is added to the original table that defines vectorization the corresponding vector data is automatically and asynchronously added. Until the vector data creation is complete, that text data will not be subject to semantic text search.

Additionally, an "embedded view" that combines the original table and the embedded table is also created.

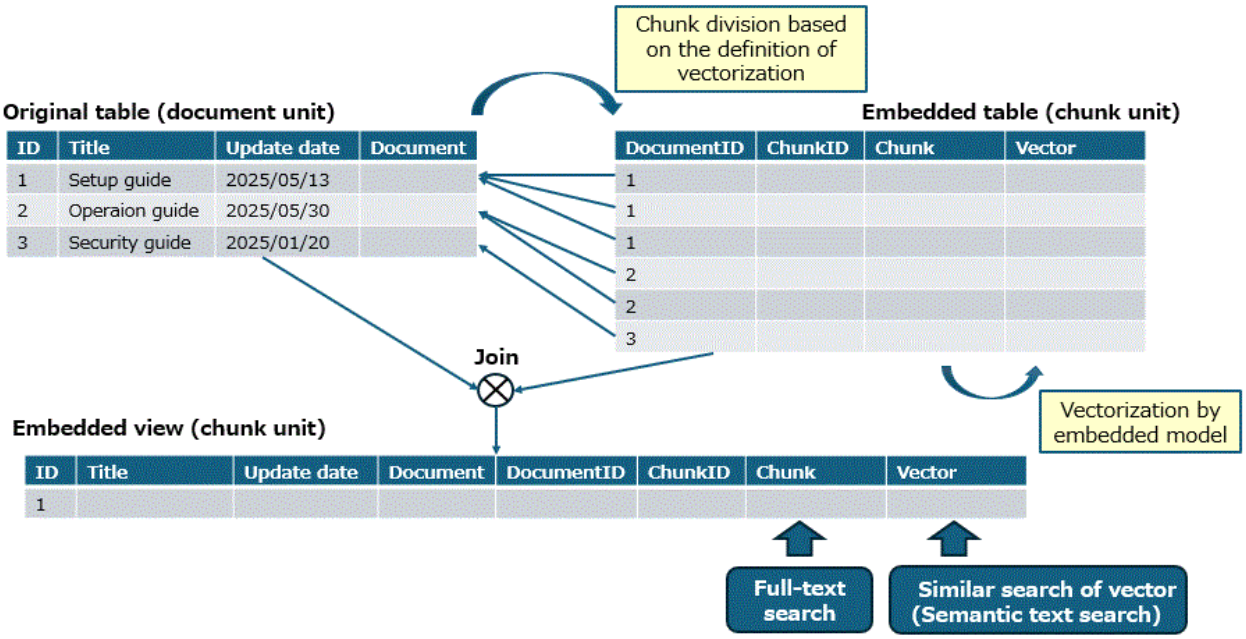
Hybrid search

Hybrid search is a search feature that combines semantic text search using vector representations of text with full-text search based on string matching. By considering not only exact keyword matches but also semantic similarities, it is possible to obtain search results that better align with the search intent, thereby improving search accuracy.

Semantic text search and embedded view

Semantic text search and hybrid search are executed using embedded view as the search target.

When semantic text search and hybrid search are performed for embedded view, the text given as a query is internally converted into a vector representation, and a similarity search is conducted between the vector representation of the stored knowledge data.



3.2 Introduction/Setup

3.2.1 Operating Environment

For details about the packages required for this feature to work, refer to the following sections in the Installation and Setup Guide for Server.

- Required Packages
- Related Software

3.2.2 Setup

Support for semantic text search,automatic vectorization and hybrid search are provided as an extension called pgx_vectorizer. pgx_vectorizer uses pgai, which relies on pgvector and plpython3u.

Refer to "pgvector" in the Installation and Setup Guide for Server to set up pgvector.

If you want to manage ONNX format models in a database and use them for vectorization, refer to "Chapter 5 Model Management in the Database".

If you are already using the pgx_vectorizer extension when migrating from Fujitsu Enterprise Postgres 17 SP1 and 17 SP2, refer to "3.7.3 Migration from Fujitsu Enterprise Postgres 17 SP1 and 17 SP2" to upgrade the pgx_vectorizer extension and the pgai extension.

3.2.2.1 Setting Up pgai

As a superuser, execute the following command to set up pgai. "*<x>*" indicates the product version.

```
$ su -
# cp -r /opt/fsepv<x>server64/OSS/pgai-extension/* /opt/fsepv<x>server64/
```

Configure the following before starting the instance.

Set the *<Python package installation destination>* to the installation destination listed in the "Related Software" of the "Installation and Setup Guide for Server".

```
PYTHONPATH=/opt/fsepv<x>server64/psycopg/python3.11/site-packages/:<Python package
installation destination>:$PYTHONPATH
```

3.2.2.2 Setting Up pgx_vectorizer

Setting parameters in the postgresql.conf file

Set the following parameters.

- Add pgx_vectorizer to the shared_preload_libraries parameter.
- Specify the maximum parallelism for vectorization processing in the pgx_vectorizer.max_vectorize_worker parameter.
- Add the following value to the value of the max_worker_processes parameter:
  - number of databases to enable pgx_vectorizer functionality +pgx_vectorizer.max_vectorize_worker+2
- If you have changed the installation destination of the Fujitsu Enterprise Postgres Server feature to a location other than the standard installation destination, specify the following for the pgx_vectorizer.pgai_worker_path parameter.

```
<Fujitsu Enterprise Postgres server feature Installation Directory>/OSS/pgai-
worker/bin/pgai
```

Enabling the pgx_vectorizer extension

After confirming that the changes to the above parameters have been applied, execute CREATE EXTENSION for the database that will use this feature.

Adding the CASCADE option will also enable the dependent pgai, pgvector, and plpython3u at the same time.

After CREATE EXTENSION, execute the start_vectorize_scheduler function to start the vectorize scheduler. The vectorize scheduler is a feature that schedules workers to perform vectorization.

Example) Connecting to the database "rag_database" using the psql command

```
rag_database=# CREATE EXTENSION IF NOT EXISTS pgx_vectorizer CASCADE;
CREATE EXTENSION
rag_database=# SELECT pgx_vectorizer.start_vectorize_scheduler(); -- Starting the
vectorize scheduler
```

After enabling the extension, execute the pg_ctl reload command to apply the parameter settings provided by pgx_vectorizer.

If you want to delete or modify the database using pgx_vectorizer, refer to "3.7.1 When Deleting/Changing the Database". For unsetting pgx_vectorizer, refer to "3.7.2 Removing of pgx_vectorizer".

Create a database user and set up a connection

Create a database user that the automatic vectorization feature will use when converting vectors in the background, and register it as the user that will convert vectors. Specify a password to use password authentication.

```
CREATE ROLE <worker_user>  PASSWORD `<worker password>` ⋯ LOGIN;
SELECT pgx_vectorizer.set_worker_setting('user', 'VECTORIZE_USER', '<worker_user>');
```

This database user will connect to Fujitsu Enterprise Postgres as an application, so modify the pg_hba.conf file for client authentication. Set it so that the database user created above can connect to the database that uses the pgx_vectorizer function from localhost using password authentication.

```
host    <rag-database>       <worker_user>          127.0.0.1/32          scram-sha-256
host    <rag-database>       <worker_user>          ::1/128               scram-sha-256
```

The background vectorization process runs with the privileges of the OS user that starts Fujitsu Enterprise Postgres. The password required for the above database user to connect to Fujitsu Enterprise Postgres is referenced from the password file of the OS user that starts Fujitsu Enterprise Postgres. Specify the information required to connect to the vectorization process. The password file used is in the default location. For details about the password file, refer to "The Password File" in the PostgreSQL Documentation.

3.2.3 Credentials Protection

3.2.3.1 Encrypting Credentials

The pgx_vectorizer.worker_setting_table, which is created when pgx_vectorizer is set up, should be protected because it stores the API key that the worker performing vectorization uses to access the embedded provider that offers the vector embedding feature.

To encrypt this table, either encrypt the entire database to which the pgx_vectorizer feature is being added in advance, or move this table to an encrypted tablespace after adding the extension feature.

Example) When encrypting the entire database for which this feature is enabled

```
postgres=# CREATE DATABASE rag_database TABLESPACE = encrypted_tablespace;

rag_database=> CREATE EXTENSION pgx_vectorizer;
```

Example) Moving to encrypted table space

```
rag_database=> ALTER TABLE pgx_vectorizer.worker_setting_table SET TABLESPACE
encrypted_tablespace;
```

3.2.3.2 Restrict Access to Credentials

The pgx_vectorizer.worker_setting_table, which stores the credential information, is configured so that only the user who executed the CREATE EXTENSION of the pgx_vectorizer feature can access it. If you want to allow access by other users, use the GRANT statement to grant access privilege to those users.

3.3 Preparation

Semantic text search is achieved by similarity search between vectors (semantic vectors) that store the semantic similarity of text. Therefore, in order to use the semantic text search feature, you need to define vectorization (what kind of vector representation to use) for the text data to be searched and create vector data.

3.3.1 Configuring Embedded Providers (for Workers)

Before defining a vectorization, you must configure the worker process that will perform the vectorization to access the embedded provider.

Example) Settings when using Ollama as an embedded provider

```
rag_database=> SELECT pgx_vectorizer.set_worker_setting('ollama', 'OLLAMA_BASE_URL',
'http://your.ollama.server:11434');
```

Example) Settings when using OpenAI as an embedded provider

```
rag_database=> SELECT pgx_vectorizer.set_worker_setting('openai', 'OPENAI_API_KEY', 'your
api key');
```

Information

Automatic vectorization is performed by worker processes that are regularly initiated. Additionally, the worker processes are initiated by Fujitsu Enterprise Postgres.

Point

In this configuration, credentials for the worker processes to access the embedded provider are stored in an area accessible by Fujitsu Enterprise Postgres. Because the configuration information for the embedded provider, including the API key, is

stored in the table as plain text, place the table in an encrypted tablespace and protect it with the Fujitsu Enterprise Postgres transparent data encryption feature. For instructions, refer to "3.2.3 Credentials Protection".

3.3.2 Configuring Embedded Providers (for Semantic Text Search)

To access embedded providers for semantic text search, use the pgai settings. Refer to the pgai documentation for details.

3.3.3 Definition of Vectorization

The definition of vectorization is done with the pgx_vectorizer.pgx_create_vectorizer function provided by pgx_vectorizer. In the vectorization definition, you can specify information about the table that contains the text data to be vectorized, the embedding model and dimensions directly related to vector representation, chunking processing, as well as specify the timing of vectorization as a schedule. If you want to immediately schedule automatic vectorization in the background with Fujitsu Enterprise Postgres, specify the pgx_vectorizer.schedule_vectorizer function. Additionally, if you want to specify the vectorization later or manually control the timing of vectorization, specify the ai.scheduling_none function.

When using hybrid search, you can simultaneously define a GIN or GiST index for full-text search used in hybrid search.

When using an embedded model managed in the database, specify pgx_vectorizer.pgx_embedding_onnx as the argument embedding for the pgx_vectorizer.pgx_create_vectorizer function. For more details, refer to "5.2.3 Definition of Vectorization".

When defining vectorization, an embedded view combining a table containing text data and a table containing vector data is defined. The embedded view is a view that adds the following columns to the original table, and for each piece of text data in the original table, it holds records divided into chunks.

Column	Type	Description
embedding_uuid	uuid	Text chunk ID
chunk_seq	integer	Sequential number of chunks in a text data
chunk	text	Text chunk
embedding	vector	Vector representation of the chunk

Information

In the following cases, refer to "Definition of full-text search index" to define the index.

- When using an index other than GIN or GiST in hybrid search
- When you have already performed only vectorization and want to add an index for full-text search later

Fujitsu Enterprise Postgres provides pg_trgm and pg_bigm as full-text search features using GIN and GiST indexes. When using these as full-text search features, set up pg_trgm and pg_bigm in advance. Refer to the following for setup instructions.

- pg_trgm

  "Additional Supplied Modules and Extensions" in the PostgreSQL Documentation

- pg_bigm

  "pg_bigm" in the Installation and Setup Guide for Server

Example) Definition of vectorization and full-text search index

Below is an example of simultaneously defining a vectorization and a GIN index for full-text search on the knowledge data table sample_table in text format.

```
rag_database=> SELECT pgx_vectorizer.pgx_create_vectorizer(
     'sample_table'::regclass,
     destination => 'sample_embeddings',
```

```
     embedding => ai.embedding_ollama('all-minilm', 384),
     chunking => ai.chunking_recursive_character_text_splitter('contents'),
     processing => ai.processing_default(batch_size => 200, concurrency => 1),
     scheduling => pgx_vectorizer.schedule_vectorizer(interval '1 hour'),
     indexing => ai.indexing_hnsw(min_rows =>50000, opclass => 'vector_cosine_ops'),
     fulltext_indexing => pgx_vectorizer.pgx_fulltext_indexing_gin(opclass =>
'gin_trgm_ops')
     );
pgx_create_vectorizer
-------------------
                 1 - The ID of the created vectorizer
(1 row)
```

The definition of the full-text search index created by the pgx_create_vectorizer function can be checked in the pgx_vectorizer.pgx_fulltext_index table.

Note

Regarding the table containing text subject to vectorization, the following cannot be changed:

- Changes to the schema containing the table
- Changes to the table name
- Changes to the primary key, addition or removal of columns constituting the primary key
- Name and data type of columns included in the primary key
- Name and data type of columns containing text data subject to vectorization

Changing these may cause automatic vectorization or semantic text search to fail. If you want to change them, or if you have already changed them, you need to redefine the vectorization. In this case, re-vectorization of all text in the target table is required.

Point

Users can implement their own full-text search functionality, other than pg_trgm or pg_bigm provided by Fujitsu Enterprise Postgres, by defining indexes supported by that full-text search functionality and specifying search conditions using its operators, allowing for hybrid search with custom full-text search capabilities.

Definition of full-text search index

If you use an index other than GIN or GiST index for full-text search, manually define the index for the embedding table created after defining the vectorization. The name of the embedding table is the name with "_store" added to the end of the embedding view name specified in the destination argument when defining the vectorization. The column name for text chunks in the embedding table is chunk.

In the following example, a full-text search index my_iam, other than GIN and GiST, is defined in the embedded table sample_embeddings2_store.

```
CREATE INDEX sample_fti ON sample_embeddings2_store (chunk) USING my_iam;
```

Deleting full-text search index

You can delete the full-text search index by removing the information of the full-text search index from the vectorization and then executing the DROP INDEX statement.

```
rag_database=> SELECT
pgx_delete_fulltext_index_config(pgx_vectorizer.get_vectorizer_id(view_name =>
'sample_embeddings');
rag_database=> SELECT indexname FROM pg_indexes where tablename =
```

```
'sample_embeddings_store';
indexname
----------------------------------------
sample_embeddings_store_chunk_idx - It is created for the column called "chunk".

rag_database=> DROP INDEX sample_embeddings_store_chunk_idx;
```

Changing the full-text search index

When changing the full-text search index defined by the pgx_create_vectorizer function, first delete the full-text search index and then define a new index.

```
--Deleting full-text search index
rag_database=> SELECT
pgx_delete_fulltext_index_config(pgx_vectorizer.get_vectorizer_id(view_name =>
'sample_embeddings');
rag_database=> SELECT indexname FROM pg_indexes where tablename =
'sample_embeddings_store';
indexname
----------------------------------------
sample_embeddings_store_chunk_idx - It is created for the column called "chunk".

rag_database=> DROP INDEX sample_embeddings_store_chunk_idx;

-- Adding full-text search index
rag_database=> CREATE INDEX ON sample_embeddings_store USING gin (chunk gin_bigm_ops);
```

3.3.4 Granting Privilege to Execute Functions

When executing the semantic text search and full-text search, you must grant the executing user function privileges that exist in the ai schema.

```
GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA ai TO <user>;
```

3.4 Searching Text Data

3.4.1 Semantic Text Search

For text data with vectorization defined, you can use the semantic text search feature to search for semantically similar text. The pgx_vectorizer.pgx_similarity_search function is used for the semantic text search.

The values in the distance column represent the distance between the text specified as an argument and the chunk, and the smaller the distance value, the higher the similarity to the text.

Example) Semantic text search

```
SELECT * FROM pgx_vectorizer.pgx_similarity_search('sample_embeddings'::regclass, 'text
for search', 5,
'<=>');
embedding_uuid                              | chunk                    | distance
--------------------------------------------+--------------------------+-------------
89A-927B-4271-82A3-6A73E8962B1C             | Action items assigned.   | 0.1027381927364
8E73B5F2-461A-4622-89A9-C1D364F4E19B        | Next steps discussed.    | 0.2938471928374
5D39A6E1-B226-4197-9F03-A78B80A509C2        | Timeline adjusted.       | 0.5183749128735
2F97C1E5-6E8A-400F-8692-177D77740B6A        | Budget approved.         | 0.7815239187521
A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11        | Status update.           | 0.9274618273645
(5 rows)
```

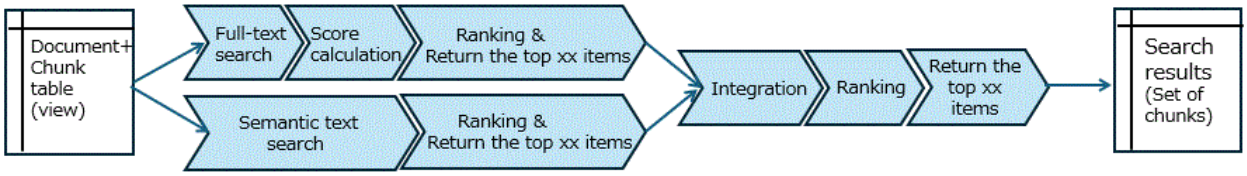
Information

The pgx_vectorizer.pgx_similarity_search function specifies the type of distance to be used in vector similarity searches performed for semantic text searches. If this specification differs from the distance specified when defining an index for vector data, the index will not be used during the search.

3.4.2 Hybrid Search

In hybrid search, results from both semantic text search and full-text search are combined, ranked based on scores considering both results, and the specified number of results are returned in order of highest score.

Hybrid search flow



Hybrid search uses the SQL function pgx_vectorizer.pgx_hybrid_search function. For pgx_vectorizer.pgx_hybrid_search function, refer to "3.8.3.2 Hybrid Search".

In the following example, a search is performed on the embedded view sample_embeddings created by the vectorization definition. The union of the top 10 results of full-text search and semantic text search of text is taken, and the top 20 results based on the final score are returned. In this example, partial match search using the LIKE operator is performed as a full-text search.

Example) Hybrid search

```
rag_database=> SELECT context_id, chunk, score FROM pgx_vectorizer.pgx_hybrid_search('
{
  "target_view": "sample_embeddings",
  "search_fusion": "UNION",
  "topN": 20,
  "semantic": {
    "search_text": "text for search",
    "num_result": 10,
    "score_weight": 10
  },
  "fulltext": {
  "search_condition": "chunk LIKE ''%text%''",
  "score_expression": "CASE WHEN chunk LIKE ''%text%'' THEN 1 ELSE 0 END"
  }
}'::JSONB
);
```

For the return results of the hybrid search, refer to "Hybrid search results".

Also, for improving the search accuracy of hybrid search, refer to "I3.6 Improving the Accuracy of Hybrid Search".

Information

Combined search results are ordered using a method called weighted RRF (Reciprocal Rank Fusion). For more details, refer to "Score calculation".

3.5 Automatic Vectorization Operation

3.5.1 Protecting Vector Data

Vector data for semantic text search is automatically protected by backup, multiplexing, or replication settings that specify the tablespace, database, or instance in which it is stored.

This section describes the points to keep in mind when using Fujitsu Enterprise Postgres features to protect vector data for semantic text search.

Vectorization data using the semantic vector embedding model is a conversion that corresponds the semantic similarity between the original data to the closeness of the distance between vectors. Because there is a risk that the meaning of the original data can be inferred from vector data, it should be protected at the same level as the original data.

Multiple database objects are created by the vectorization definition. These database objects are the targets of protection.

3.5.1.1 Encrypting Vector Data

Several database objects are created for semantic text search, and if you want to encrypt these database objects together, place the entire database in an encryption tablespace.

Example) Encrypting the entire database

```
postgres=# CREATE DATABASE rag_database TABLESPACE = encrypted_tablespace;

rag_database=> CREATE EXTENSION pgx_vectorizer;
```

To encrypt database objects for semantic text search when a single tablespace cannot be used per database, temporarily change the default tablespace to an encrypted tablespace before defining vectorization.

Indexes for vector data are created when the index creation conditions are met. To encrypt an index, change the tablespace after index creation, or create the index manually without specifying an index in the create_vectorizer function. For information about tables containing vector data created by this feature, refer to "3.8.4 Tables/Views Created by Semantic Text Search and Automatic Vectorization Feature".

3.5.1.2 Restricting Access to Vector Data

Access to vector data is restricted by controlling access to the tables in which the vector data is stored. Access restrictions are set using the confidentiality management feature of Fujitsu Enterprise Postgres.

The following is an example of using the confidentiality management feature to grant reference rights to the table sample, which contains text data, and the table sample_embeddings_store, which contains vector data generated by this feature.

1. Refer to the "Confidentiality Management" in the Security Operations Guide to define confidentiality management role, confidentiality matrix, confidentiality level, and confidentiality group.

2. Grant confidentiality privilege for the table to the confidentiality group.

```
SELECT pgx_grant_confidential_privilege('rag_matrix', 'level1', 'group1', '{"schema":
["ALL"], "table": ["SELECT"]}');
```

3. Add tables containing text data and embedded tables as confidentiality object to the confidentiality level.

```
SELECT pgx_add_object_to_confidential_level ('rag_matrix', 'level1',
'[{
    "type":"table",
    "object":[
        {
            "schema":"public",
            "table":["sample"]
        },
        {
            "schema":"public",
            "table":["sample_embeddings_store"]
```

```
        },
    ]
}]');
```

4. Add the role to the confidentiality group.

```
SELECT pgx_add_role_to_confidential_group('rag_matrix', 'group1', '["rag_user"]');
```

Information

A vector table contains foreign keys, vector data, and chunks, but it is not necessary to set access privileges on a column-by-column basis; setting access privileges on a table-by-table basis is sufficient.

The following is an example of setting row-level security for table sample, which contains text data, and table sample_embeddings_store, which contains vector data generated by this function. In this example, sample and sample_embeddings_store contain user names in a column called username, and sample_embeddings_store has the primary key (id) of sample as a foreign key (id). When using row-level security, grant the BYPASSRLS attribute to the user set in VECTORIZE_USER.

1. Refer to the "Confidentiality Management" in the Security Operations Guide to define confidentiality management role, confidentiality matrix, confidentiality level, and confidentiality group.
2. Grant confidentiality privilege for the rowset to the confidentiality group.

```
SELECT pgx_grant_confidential_privilege('rag_matrix', 'level1', 'group1',  '{"table":
["SELECT"], "schema": ["ALL"],"rowset":["SELECT"]}');
```

3. Enable row-level security for the table.

```
ALTER TABLE sample ENABLE ROW LEVEL SECURITY;
ALTER TABLE sample_embeddings_store ENABLE ROW LEVEL SECURITY;
```

4. Ensure that the tables on which the target view is based are checked against the privileges of the view's user.

```
ALTER VIEW sample_embeddings SET (security_invoker = true);
```

5. Add the ai schema, tables containing text data and embedded tables and embedded views as confidentiality objects to the confidentiality level.

```
SELECT pgx_add_object_to_confidential_level ('rag_matrix', 'level1',
'[{
    "type":"schema",
    "object":[
        {"schema":"ai"},
        {"schema":"pgx_vectorizer"}
    ]
},
{
    "type":"table",
    "object":[
        {
            "schema":"public",
            "table": ["sample", "sample_embeddings_store", "sample_embeddings"]
        },
        {
            "schema":"ai",
            "table": ["vectorizer"]
        }
    ]
}]');
```

6. Add the table containing text data and the rowset of the embedded table as confidentiality objects to the confidentiality level.

```
SELECT pgx_add_object_to_confidential_level ('rag_matrix', 'level1',
'[{
    "type":"rowset",
    "object":[
    {
        "schema":"public",
        "table": "sample",
        "rowset_name": "rowset1",
        "rowset_expression":[
        {
            "as": "permissive",
            "using": "username = current_user"
        }]
    },
    {
        "schema":"public",
        "table": "sample_embeddings_store",
        "rowset_name": "rowset1",
        "rowset_expression":[
        {
            "as": "permissive",
            "using": "EXISTS (SELECT 1 FROM public.sample WHERE public.sample.id =
public.sample_embeddings_store.id AND public.sample.\"username\" = current_user)"
        }]
    }
    ]
}]');
```

7. Add the role to the confidentiality group.

```
SELECT pgx_add_role_to_confidential_group('rag_matrix', 'group1', '["rag_user"]');
```

3.5.1.3 Recording Access to Vector Data

The audit log feature of Fujitsu Enterprise Postgres is used to record access to vector data in the audit log. When specifying individual database objects to be audited, also specify the tables that store vector data as audit targets.

For information about tables containing vector data created by this feature, refer to "3.8.4 Tables/Views Created by Semantic Text Search and Automatic Vectorization Feature".

3.5.2 Monitoring Vectorization Processing

If you use automatic background vectorization in your database, the corresponding vector data will be automatically changed when text data is added, updated, or deleted. However, because the generation of vector data for new data is performed asynchronously, newly added data will not be reflected immediately in semantic similarity search. Also, if you use an external service to create vector data, you will need to check for errors.

3.5.2.1 Checking the Vectorization Queue

You can check the number of texts waiting to be vectorized for each vectorization definition by referencing the ai.vectorizer_status view, and you can check the number for a specific vectorization definition by using the ai.vectorizer_queue_pending function.

Example) Check the ai.vectorizer_status view

```
rag_database=> SELECT * FROM ai.vectorizer_status;
-[ RECORD 1 ]-+-------------------------------------
id            | 1
source_table  | public.sample_table
```

```
target_table  | public.sample_embeddings_store
view          | public.sample_embeddings
pending_items | 1000
disabled      | f
```

Example) Check with the ai.vectorizer_queue_pending function

```
SELECT ai.vectorizer_queue_pending( pgx_vectorizer.get_vectorizer_id(view_name =>
'sample_embeddings') );
-[ RECORD 1 ]------------+--
vectorizer_queue_pending | 1000
```

If this value remains at 0 or a low value, you can determine that the vectorization process is on time. If this value tends to increase beyond the execution interval specified in the schedule or data addition interval, refer to 3.5.2.2 Checking the Status of Vectorization Processing" to check whether an error has occurred in the vectorization process, and refer to "3.5.2.3 Checking the Scheduler for Vectorization Processing" to check whether the vectorize scheduler is running.

If no errors have occurred, the vectorization processing speed is likely slow compared to the data addition speed. If the load is temporarily high, start a temporary vectorization process with the pgx_vectorizer.run_vectorize_worker function. If not, change the schedule with the pgx_vectorizer.alter_vectorizer_schedule function, or change the parallelism or the upper limit of the amount of data to be processed in one startup with the pgx_vectorizer.alter_vectorizer_processing function.

Example) Changing the execution interval to 5 minutes

```
SELECT
pgx_vectorizer.alter_vectorizer_schedule(pgx_vectorizer.get_vectorizer_id(view_name =>
'sample_embeddings'), interval '5 m');
```

Example) When changing the parallelism to 2 and the amount of data to be processed at one time to 200

```
SELECT
pgx_vectorizer.alter_vectorizer_processing(pgx_vectorizer.get_vectorizer_id(view_name =>
'sample_embeddings'), batch_size => 200, concurrency => 2);
```

Use a monitoring tool to check the time trend of the number of texts waiting for vectorization. If there is an error in the parameter value set by set_worker_setting, the vectorization process will not be executed. A message will be output to the server log, so please check it together with the ai.vectorizer_status view.

3.5.2.2 Checking the Status of Vectorization Processing

By referring to the ai.vectorizer_errors view, you can check the details of the errors that occurred during the vectorization process, the time of occurrence, the number of occurrences, etc.

Example) Check the details of the most recent error

```
rag_database=> SELECT * FROM ai.vectorizer_errors ORDER BY recorded DESC LIMIT 50;
-[ RECORD 1 ]-------------------------------------------------------------------
-------------------------
id       | 1
message  | embedding provider failed
details  | {"provider": "ollama", "error_reason": "model \"all-minilm\" not fou
nd, try pulling it first"}
recorded | 2025-02-03 06:47:35.958882+00
-[ RECORD 2 ]-------------------------------------------------------------------
-------------------------
id       | 1
message  | embedding provider failed
details  | {"provider": "ollama", "error_reason": "model \"all-minilm\" not fou
```

```
nd, try pulling it first"}
recorded | 2025-02-03 06:47:41.250279+00
```

Example) Check the number of errors for a vectorization definition

```
rag_database=> SELECT COUNT(*) FROM ai.vectorizer_errors WHERE id =
pgx_vectorizer.get_vectorizer_id(view_name => 'sample_embeddings');
 count
-------
    20
(1 row)
```

Check the details of the error and remove the cause. Some embedded providers have a maximum load per period. If an error occurs because the load exceeds these conditions, use the pgx_vectorizer.alter_vectorizer_schedule or pgx_vectorizer.alter_vectorizer_processing function to adjust the worker schedule or parallelism.

3.5.2.3 Checking the Scheduler for Vectorization Processing

You can confirm that the scheduler for vectorization is running in the pg_stat_activity view.

```
SELECT * FROM pg_stat_activity WHERE backend_type LIKE '%pgx_vectorizer%';
```

3.5.3 Temporarily Disabling Vectorization Processing

The vectorization process of this feature is performed periodically according to the specified schedule. For example, if you want to temporarily stop vectorization processing to reduce the impact on other work, you can disable vectorization processing using the ai.disable_vectorizer_schedule function.

```
rag_database=> SELECT
ai.disable_vectorizer_schedule(pgx_vectorizer.get_vectorizer_id(view_name =>
'sample_embeddings')); -- Specify the ID of the vectorizer you want to disable
```

To enable it, run the ai.enable_vectorizer_schedule function.

```
rag_database=> SELECT
ai.enable_vectorizer_schedule(pgx_vectorizer.get_vectorizer_id(view_name =>
'sample_embeddings')); -- Specify the ID of the vectorizer you want to enable
```

3.5.4 Changing the Vector Representation

You can have multiple vector representations for the text you want to perform semantic text search on. A vector representation is associated one-to-one with a vectorization definition, and you can have a different vector representation by defining a new vectorization. In the vectorization definition, you can specify the embedding model to be used, etc. If you do not need the previous vector representation, delete the vectorization definition.

Example) Defining a new vectorizer and deleting the old one

```
rag_database=> SELECT ai.drop_vectorizer(pgx_vectorizer.get_vectorizer_id(view_name =>
'sample_embeddings'), drop_all => true);

rag_database=> SELECT pgx_vectorizer.pgx_create_vectorizer(…);
```

3.5.5 Tuning of Semantic Text Search

A semantic text search internally performs a similarity search on vector data. If an index is not specified for the vector data, all vector data is scanned for each semantic text search. You can check whether an index is being used in a semantic text search by running pgx_similarity_search_checking_index.

Example) Check if an index is used in a semantic text search

```
rag_database=> SELECT * FROM
pgx_similarity_search_checking_index('sample_embeddings'::regclass, 'text for search', 5,
'<=>');
ERROR: opclass of index is vector_ip_ops, but the distance_operator is <+>
```

If search results are output when you execute pgx_similarity_search_checking_index, the index is being used. If the search ends with an error as shown above, the distance operator specified in the index definition may differ from the distance type specified in the semantic text search. If the distance type specified in the semantic text search is incorrect, correct the distance specified. If the distance operator specified in the index definition is incorrect, delete the index and re-create the correct index.

Indexes for vectors explicitly define for the table that stores vectors that are created internally when vectorization is defined.

Example) Changing the vector table index

```
-- Check and delete the old index name
rag_database=> SELECT indexname FROM pg_indexes where tablename =
'sample_embeddings_store';
               indexname
----------------------------------------
 sample_embeddings_store_pkey
 sample_embeddings_store_id_chunk_seq_key
 sample_embeddings_store_embedding_idx - It is created for a column called embedding.
(3 rows)
rag_database=> DROP INDEX sample_embeddings_store_embedding_idx
-- Add the correct index
rag_database=> CREATE INDEX ON sample_embeddings_store USING hnsw (embedding
vector_l1_ops);
```

3.6 Improving the Accuracy of Hybrid Search

Hybrid search is a search method that combines multiple search techniques to leverage their strengths and complement their weaknesses. To improve search accuracy by combining multiple search techniques, it is necessary to understand the search accuracy of each technique and choose a combination method accordingly. Below, we will explain how to calculate the search accuracy of individual search techniques (subqueries) that make up hybrid search.

3.6.1 Overview of Hybrid Search Tuning

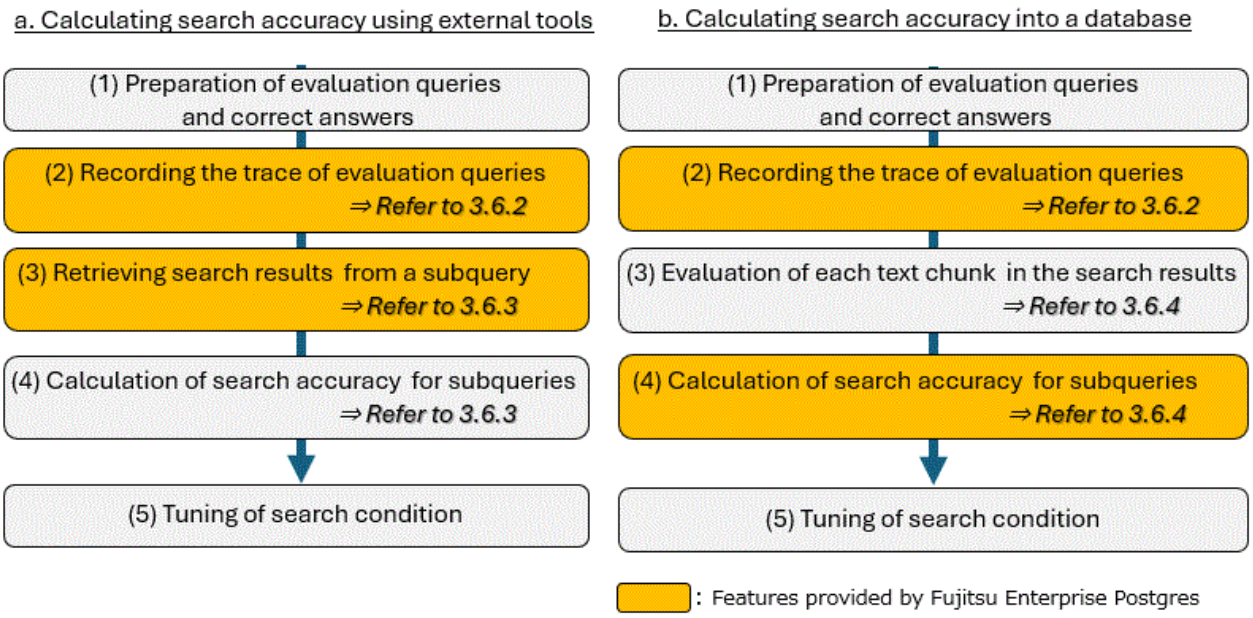
The accuracy of search processing can be calculated by preparing pairs of query conditions for evaluation and correct answers (for example, the search results that should be returned for that query) and comparing the results searched with those query conditions to the correct answers. The result obtained from hybrid search is only the final search result. Since we cannot know what the search results of individual subqueries were, their search accuracy cannot be calculated. Therefore, to calculate the search accuracy of subqueries, we use hybrid search trace information. Trace information is a record of the executed hybrid search, including the search conditions and search results of each subquery executed internally. The search accuracy can be calculated from the subquery search results included in the trace information. The accuracy of hybrid search using trace information can be calculated in the following two ways:

a. Obtain the search results of each subquery recorded as traces and calculate using external evaluation tools.

b. Calculate search accuracy within the database by inputting evaluation results for each text chunk that is a search result into the database.

When evaluating the entire system, such as RAG-based applications, it is appropriate to use method a., which utilizes external evaluation tools. On the other hand, if you want to analyze the accuracy of individual subqueries or text chunks in detail without using tools, method b., which calculates accuracy within the database, is recommended.

Below are the steps for each method.



For basic ideas on the evaluation of knowledge data search, refer to "3.8.6 Evaluation of Knowledge Data Search".

3.6.2 Recording and Deleting Traces of Hybrid Search

To record trace for evaluation queries, a user with trace recording privileges enables the trace and executes a hybrid search using the evaluation queries. As a result, the trace information is recorded in the table. Trace recording can only be done on the primary server. Even if a hybrid search with trace enabled is performed on a hot standby server, the trace will not be recorded. The trace privileges are granted to the database user performing the search by the extension owner using the pgx_grant_access_on_hybrid_search_trace function. To enable the trace, the database user performing the hybrid search sets the enable_hybrid_search_trace parameter to on in their session. Regarding the enable_hybrid_search_trace parameter, refer to "3.8.5 Parameters".

Example) Privilege granted by the owner of the extension

```
rag_databse=# SELECT pgx_vectorizer.pgx_grant_access_on_hybrid_search_trace('app_user');
```

Example) Setting session parameters by users performing searches and executing hybrid searches

```
rag_database=> SET pgx_vectorizer.enable_hybrid_search_trace = 'on';
rag_database=> SELECT * FROM pgx_vectorizer.pgx_hybrid_search(...);
```

When a trace is recorded, a query ID that identifies the search request required for subsequent operations is issued. The query ID is returned as a result of a hybrid search, and can also be confirmed by referring to the table where trace information is recorded (pgx_trace_query table). This table records the database user who executed the hybrid search, the time, and the application name, allowing you to identify the query ID using these details.

Example) The database user who executes the command refers to the query ID of the hybrid search executed within an hour

```
rag_database=> SELECT queryid FROM pgx_vectorizer.pgx_trace_query WHERE retrieval_time >=
(current_timestamp - interval '1 hour') ORDER BY retrieval_time;
queryid
---------
   10001
(1 row)
```

After completing the evaluation and tuning, trace information and evaluation values will be deleted. By deleting records with the target query ID from the pgx_trace_query table, all related information will be removed.

Example) Delete trace information by specifying the query ID

```
rag_database=> DELETE FROM pgx_vectorizer.pgx_trace_query WHERE queryid = 10001;
```

Example) The administrator deletes all trace information older than 30 days

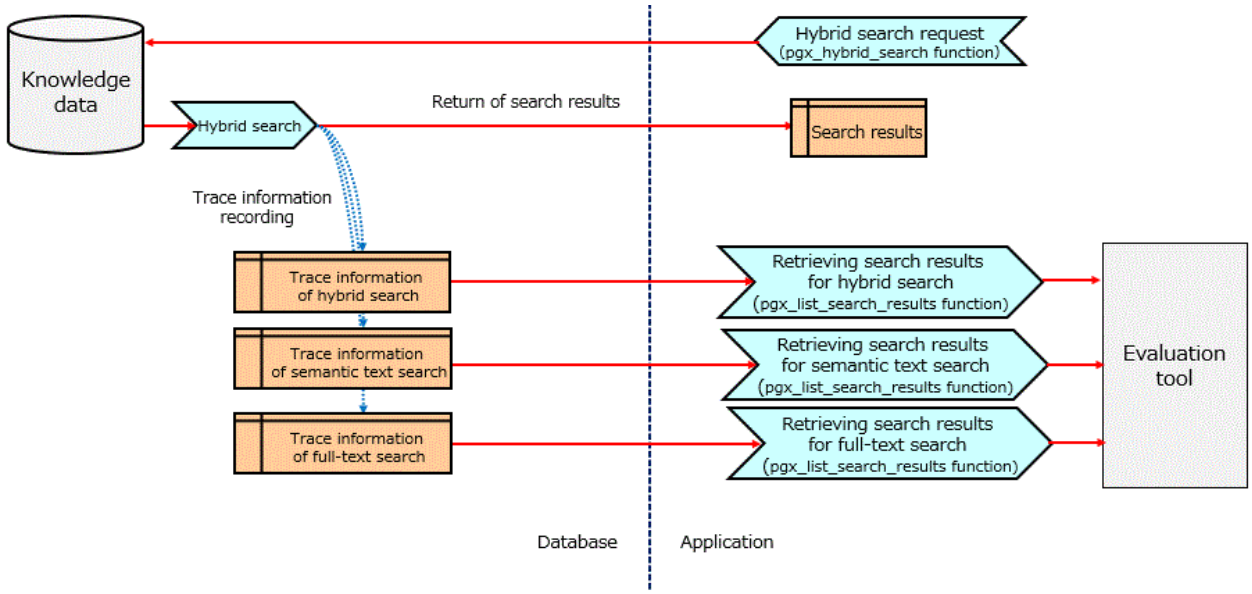
```
rag_databse=# DELETE FROM pgx_vectorizer.pgx_trace_query WHERE retrieval_time <=
(current_timestamp - interval '30 days') ;
```

Information

The trace information includes the search conditions and the knowledge data itself as search results, and is recorded in a common table within the database. Privileges are set so that only the database users and administrators who executed the search process can refer to, update, and delete that trace information.

3.6.3 Calculation of Search Accuracy Using External Tools

When calculating the search accuracy of subqueries using external tools, the search results of each subquery are obtained from trace information.



To retrieve the search results of a subquery, execute the pgx_list_search_results function by specifying the query ID and the type of subquery. When executed, a set of text chunks is returned in descending order of score, in the same format as the hybrid search results.

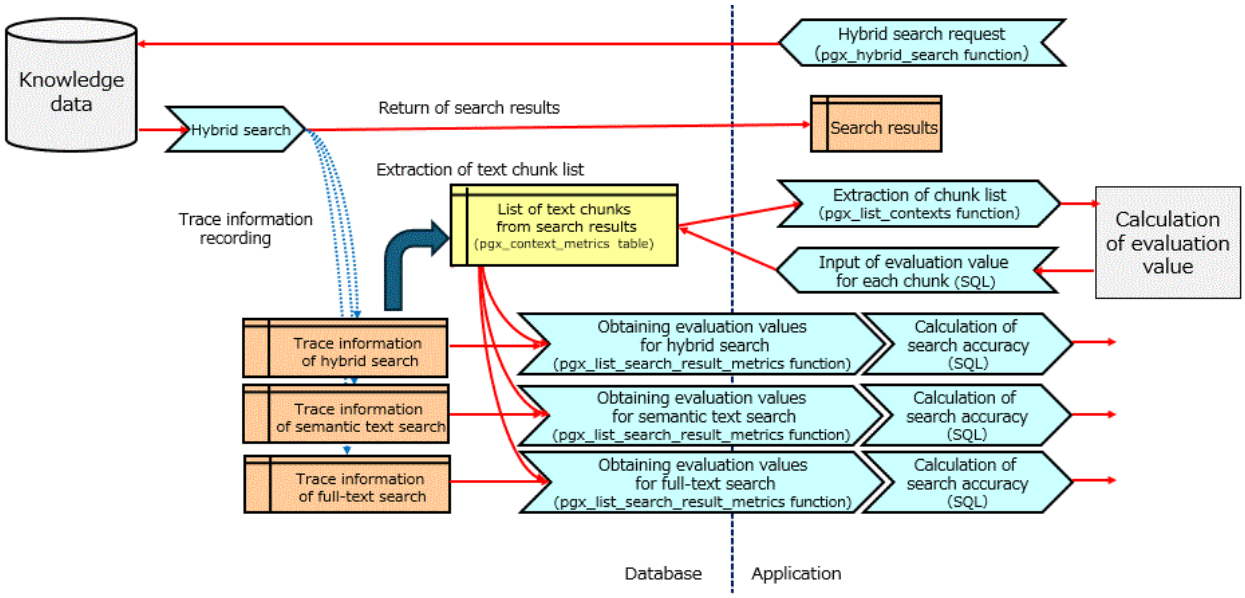
Example) Retrieve the search results of the full-text search subquery with query ID 10001

```
rag_database=> SELECT pgx_vectorizer.pgx_list_search_results(queryid => 10001,
subquery_type => 'fulltext');
```

As a result, by providing the search results of subqueries for evaluation queries and the correct answers corresponding to evaluation queries to the evaluation tool, the search accuracy of subqueries can be calculated.

3.6.4 Calculation of Search Accuracy in the Database

The calculation of search accuracy within a database consists of two major steps: "the calculation of evaluation values for each text chunk in the search results" and "the calculation of search accuracy based on those evaluation values".



Calculation of evaluation values for each text chunk in the search results

Use the pgx_list_contexts function to extract the text chunks returned by the hybrid search executed and any of its constituent subqueries.

Example) Extract the text chunk returned by the hybrid search with query ID 10001 and any of the subqueries

```
rag_database=> SELECT pgx_vectorizer.pgx_list_contexts(queryid => 10001);
```

Match the extracted text chunks with the correct answers for the evaluation queries, calculate the evaluation values for each, and input them into the evaluation value table (pgx_context_metrics table). To input the evaluation values, use the UPDATE statement on the pgx_context_metrics table. For an example of using the UPDATE statement, refer to "3.6.4.1 Example of Calculating Search Accuracy in a Database". The evaluation values can be stored in JSON format to allow calculation of search accuracy using any metric.

Calculation of search accuracy based on evaluation value

The text chunk of the search result from the subquery and its evaluation value can be referenced using the pgx_list_search_result_metrics function. This can be used to calculate search accuracy.

Example) Refer to the search results of full-text search and their evaluation values

```
rag_database=> SELECT pgx_vectorizer.pgx_list_search_result_metrics(queryid => 10001,
subquery_type => 'fulltext');
```

3.6.4.1 Example of Calculating Search Accuracy in a Database

Explain an example of calculating search accuracy.

First, store the evaluation value in the pgx_context_metrics table. Here, input the evaluation value into the relevance_indicator in JSON format.

```
{
  "relevance_indicator": 1
}
```

The evaluation value is set to 1 if the context IDs of the search results are 'AAAA', 'BBBB', or 'DDDD', indicating relevance to the search criteria, and 0 if they are not relevant. In this case, an UPDATE statement is executed on the pgx_context_metrics table using queryid as the key, and the evaluation values for all text chunks are input collectively.

Example) Input of evaluation value using the UPDATE statement

```
rag_database=> UPDATE pgx_vectorizer.pgx_context_metrics
SET context_metrics = jsonb_set(
  context_metrics,
  '{relevance_indicator}',
  CASE
    WHEN context_id IN ('AAAA', 'BBBB', 'DDDD') THEN '1'::jsonb ELSE '0'::jsonb
  END
)
WHERE queryid = 10001;
```

Next, refer to the search results of subqueries that include evaluation values and calculate the search accuracy for each subquery.

Search accuracy is calculated using a search accuracy metric called precision@k. precision@k is a metric that represents the precision when focusing on the top k search results, and can be calculated using the following formula.

$$\text{precision@}k = \frac{\textit{The number of records related to the query among the top k search results returned}}{k}$$

Below, the top 10 search precision (precision@10) for semantic text search is calculated using the relevance_indicator. The same can be calculated for full-text search.

```
rag_database=> SELECT
SUM( (context_metrics ->> 'relevance_indicator'):: integer )::float / COUNT(*) AS
precision_at_10
FROM(
  SELECT context_metrics FROM
  pgx_vectorizer.pgx_list_search_result_metrics(queryid => 10001, subquery_type =>
'semantic')
  ORDER BY score DESC LIMIT 10
);
```

3.6.5 Tuning of Hybrid Search

Tune hybrid search based on calculated search accuracy.

To reduce application modifications due to changes in hybrid search parameters, it is useful to create search functions for each application as user-defined functions.

Below is an example of defining a SQL function that only takes the string you want to search as input. By defining such a function, you can change the topN parameter and score_weight parameter on the database server side.

```
rag_database=> CREATE OR REPLACE FUNCTION mysearch(in text, in text, out uuid, out text,
out float8)
AS $$
SELECT context_id, chunk, score FROM pgx_vectorizer.pgx_hybrid_search(
jsonb_set(
  jsonb_set('{
    "target_view": "sample_embeddings",
    "search_fusion": "UNION",
    "topN": 20,
    "semantic": {
      "num_result": 10,
      "score_weight": 10
    },
    "fulltext": {
      "score_expression": "1"
    }}'::jsonb,
  '{semantic, search_text}', ('"' || $1 || '"')::jsonb),
'{fulltext, search_text}', ('"' || $2 || '"')::jsonb)
```

```
)
$$ LANGUAGE SQL
```

3.7 Management/Maintenance of pgx_vectorizer

3.7.1 When Deleting/Changing the Database

The pgx_vectorizer extension is connected to the database and the vectorize scheduler at all times. Therefore, when deleting or changing this database, be sure to stop the vectorize scheduler before performing any operations.

To stop vectorize scheduler, refer to pg_stat_activity to check the pid of vectorize scheduler connected to the target database, and then use the pg_ctl kill TERM <pid> command or the SQL function pg_terminate_backend() to stop it.

You can check the pid of vectorize scheduler connected to the current database by executing the following SQL. The backend_type of vectorize scheduler includes 'vectorize scheduler'.

```
SELECT pid FROM pg_stat_activity WHERE datid = (SELECT oid FROM pg_database WHERE datname =
current_database()) AND backend_type LIKE '%vectorize scheduler%';
```

Below is an example of using pg_terminate_backend().

```
rag_database=>SELECT pg_terminate_backend(pid) FROM pg_stat_activity WHERE datid = (SELECT
oid FROM pg_database WHERE datname = current_database()) AND backend_type LIKE '%vectorize
scheduler%';

 pg_terminate_backend
----------------------
 t
(1 row)
```

3.7.2 Removing of pgx_vectorizer

1. Connect to the database that is using this feature and execute DROP EXTENSION.

   ```
   rag_databse=# DROP EXTENSION pgx_vectorizer;
   DROP EXTENSION
   ```

2. As a superuser, execute the following command to remove pgai. "*<x>*" indicates the product version.

   ```
   $ su -
   # rm /opt/fsepv<x>server64/<Files copied during setup>
   ```

   Information

   The files copied during setup can be checked below.

   ```
   # find /opt/fsepv<x>server64/OSS/pgai-extension
   ```

3.7.3 Migration from Fujitsu Enterprise Postgres 17 SP1 and 17 SP2

If you have set up the pgx_vectorizer extension with Fujitsu Enterprise Postgres 17 SP1 and 17 SP2, you need to upgrade the pgx_vectorizer extension. Follow the steps below to perform the upgrade.

1. If the database server is running, stop the database server.

   ```
   $ pg_ctl stop -D <data_directory>
   ```

2. Remove pgx_vectorizer from shared_preload_libraries parameter in postgresql.conf.

3. Upgrade the product.

4. Start the database server.

```
$ pg_ctl start -D <data_directory>
```

5. Update pgvector, pgai, and pgx_vectorizer.

```
ALTER EXTENSION vector UPDATE;
ALTER EXTENSION ai UPDATE;
ALTER EXTENSION pgx_vectorizer UPDATE;
```

6. Add pgx_vectorizer to shared_preload_libraries parameter in postgresql.conf.

7. Restart the database server.

```
$ pg_ctl restart -D <data_directory>
```

3.8 Reference

3.8.1 Vectorization Functions

3.8.1.1 Defining Vectorization

For the parameters to specify in the definition of vectorization,refer to the pgai documentation. If you want to perform vectorization within the database, you must specify pgx_vectorizer.schedule_vectorizer as the scheduling.

3.8.1.2 Vectorization Schedule

You can generate vector data from text data in the following ways.

- Manually start vectorization processing
- Perform vectorization processing periodically within the database

The timing of vectorization is determined by the schedule specified when defining vectorization. If schedule_none is specified, periodic vectorization will not be performed. To perform vectorization at a specified time, run the run_vectorize_worker function. If schedule_vectorizer is specified, periodic vectorization will be performed within the database.

Automatic vectorization can be disabled with the ai.disable_vectorizer_schedule function. It can also be re-enabled with the ai.enable_vectorizer_schedule function.

3.8.1.3 Vectorizer Management Functions

The following functions are provided to use for vectorization feature.

Function	Return type	Description
pgx_create_vectorizer([Arguments that can be specified with ai.create_vectorizer], fulltext_indexing => jsonb)	integer	It is used to automatically define full-text search indexes for vectorization and chunks. The ID of the created vectorizer will be returned. In addition to the arguments that can be specified for ai.create_vectorizer, specify the definition of the full-text search index (pgx_fulltext_indexing_gin() or pgx_fulltext_indexing_gist()). fulltext_indexing is optional when only defining vectorization and when using full-text search indexes

Function	Return type	Description
		other than GiST or GIN. If omitted, a full-text search index will not be created.
pgx_fulltext_indexing_gin(target_column text, fastupdate boolean, gin_pending_list_limit integer, opclass text, min_rows integer, create_when_queue_empty boolean)	jsonb	It is used when creating a full-text search index as GIN. The value specified for fulltext_indexing in pgx_create_vectorizer will be returned. target_column is used when using expression indexes or covering indexes. The column name for text chunks is chunk, and the default value for target_column is chunk. Specify the operator class to use in opclass. min_rows specifies the threshold for creating an index. The default is 100000. A full-text search index is created when the number of records in the embedded table exceeds this threshold. create_when_queue_empty is a parameter that specifies the timing for creating a full-text search index. The default is true, and the full-text search index is created after the vector conversion is completed. Other specifiable parameters refer to index storage parameters.
pgx_fulltext_indexing_gist(target_column text, fillfactor integer, buffering text, opclass text, min_rows integer, create_when_queue_empty boolean)	jsonb	It is used when creating a GIST as a full-text search index. The value specified for fulltext_indexing in pgx_create_vectorizer will be returned. Specify the operator class to use in opclass. The settings for target_column, min_rows, and create_when_queue_empty are the same as those of pgx_fulltext_indexing_gin. Other specifiable parameters refer to index storage parameters.
pgx_delete_fulltext_index_config(vectorizer_id integer)	void	It is used when deleting the vector transformation defined by pgx_create_vectorizer. Delete information related to full-text search of vectorization created by the pgx_create_vectorizer function.

Function	Return type	Description
get_vectorizer_id(view_name pg_catalog.pg_regclass)	integer	Returns the ID of the vectorization definition that corresponds to the specified embedded view.
schedule_vectorizer(schedule_interval interval)	json	Specify the interval for the vectorization process in schedule_interval. This function returns a JSON to be specified in the scheduling argument of the create_vectorizer function. If schedule_interval is not specified, 10 minutes will be specified.
alter_vectorizer_processing(vectorizer_id integer, batch_size integer, concurrency integer)	void	Changes the amount of data to be converted at one time and the worker multiplicity for the vectorization definition with the id specified in vectorizer_id.
alter_vectorizer_schedule(vectorizer_id integer, schedule_interval interval)	void	Changes the interval for the vectorization process for the vectorization definition with the id specified in vectorizer_id. If schedule_interval is not specified, 5 minutes will be specified.
run_vectorize_worker(vectorizer_id integer)	integer	Immediately starts the vectorization process for the vectorization definition with the ID specified in vectorizer_id, and starts the vectorization process in the background. Returns the PID of the started process.
start_vectorize_scheduler(void)	void	This will start the vectorize scheduler that connects to the database where this SQL function was executed. If the vectorize scheduler is already running, an error will occur.
pgx_embedding_onnx(model text, dimension integer)	jsonb	Generate a configuration JSON object for use with the pgx_create_vectorizer function. It is used when executing automatic vectorization with a model imported into the database. Specify the model name and the number of dimensions of the vector to be generated. This cannot be omitted. If the specified model is not imported, a warning message will be output.

See

For information about the arguments that can be specified with ai.create_vectorizer, refer to the pgai documentation.

3.8.2 Embedded Provider Management Functions

The following functions are provided to set and reference parameters of the embedded provider.

Function	Return type	Description
get_worker_setting(type text, param text)	text	Specify a combination of type and parameter (param) to get the value set for that parameter. Only the user who executed CREATE EXTENSION can execute this command.
set_worker_setting(type text, param text, value text)	void	Specify the combination of type and parameter (param), and set the value (value) for that parameter. Only the user who executed CREATE EXTENSION can execute this command.

The possible embedded provider names and parameters are:

type	param	Description
openai	OPENAI_API_KEY	OpenAI API key value
voyage	VOYAGE_API_KEY	VoyageAI API key value
ollama	OLLAMA_BASE_URL	Ollama API base url
user	VECTORIZE_USER	Username to connect to the database the worker that performs the vectorization.

3.8.3 Search Functions

3.8.3.1 Semantic Text Search

The following functions are provided for semantic text search.

Function	Return type	Description
pgx_similarity_search(view pg_catalog.regclass, query text, num_result integer defaut 5, distance_operator text default '<=>', OUT embedding_uuid uuid, OUT chunk text, OUT distance float8);	SETOF record	Searches the embedding view specified in view to obtain text similar to the text specified in query. You can display results up to the number specified in num_result. You can specify the distance calculation method using distance_operator.
pgx_similarity_search_checking_index(view pg_catalog.regclass, query text, num_result integer defaut 5, distance_operator text default '<=>', OUT embedding_uuid uuid, OUT chunk text, OUT distance float8);	SETOF record	An error occurs if the index operator defined in the embedding column of the table that references the view does not match the operator specified in distance_operator.

Function	Return type	Description
		Other than the above, it is the same as the pgx_similarity_search function.

3.8.3.2 Hybrid Search

The following functions are provided for hybrid search.

Function	Return type	Description
pgx_hybrid_search(query jsonb, OUT queryid bigint, OUT context_id uuid, OUT chunk text, OUT score float8)	SETOF record	Search the specified embedded view and retrieve the relevant text. For the return value, refer to "3.8.3.3 Details of the pgx_hybrid_search Function". For query details, refer to "Hybrid search results".
pgx_list_search_results(queryid bigint, subquery_type text)	SETOF record	If trace information for the specified query ID is recorded, it returns the search results. If subquery_type is not specified, it returns the results of a hybrid search. If subquery_type is semantic or fulltext, it returns the results of semantic text search or full-text search conducted internally, respectively.
pgx_list_search_result_metrics(queryid bigint, subquery_type text)	SETOF record	Returns search results along with the evaluation value of the text chunk. Other specifications follow the pgx_list_search_results function.
pgx_list_contexts(queryid bigint)	SETOF record	If trace information for the specified query ID is recorded, it extracts and returns a list of text chunks returned as search results in either hybrid search processing or subqueries executed internally. The extracted list of text chunks is inserted into the evaluation value table.
pgx_hybrid_search_trace_size()	bigint	Return the size of the trace information and evaluation value table in bytes.
pgx_grant_access_on_hybrid_search_trace(role name)	None	Grant the necessary access rights to the role for recording and evaluating trace information.
pgx_revoke_access_on_hybrid_search_trace(role name)	None	Revoke the access rights necessary for recording and evaluating trace information assigned to the role.

The pgx_list_search_results function returns a set of records of the following type, in descending order of score.

Column	Type	Description
queryid	bigint	Quiry ID for hybrid search feature.
context_id	uuid	Identifier of the returned text chunk. Unique within the embedded view.
chunk	text	Returned text chunk.
score	real	Hybrid search score. A higher score indicates a better match with the conditions.

The pgx_list_search_results_metrics function returns a set of records of the following type, in descending order of score.

Column	Type	Description
queryid	bigint	Quiry ID for hybrid search feature.
context_id	uuid	Identifier of the returned text chunk. Unique within the embedded view.
chunk	text	Returned text chunk.
score	real	Hybrid search score. A higher score indicates a better match with the conditions.
metrics	jsonb	Evaluation value for each input text chunk.

The pgx_list_contexts function returns a set of records of the following type, in descending order of score.

Column	Type	Description
queryid	bigint	Quiry ID for hybrid search feature.
context_id	uuid	Identifier of the returned text chunk. Unique within the embedded view.
chunk	text	Returned text chunk.

3.8.3.3 Details of the pgx_hybrid_search Function

query argument

Specify search conditions in JSON format for the query argument. Specify the following for each key.

Key	JSON format	Deccription
target_view	string	Embedded view to be searched. Interpreted as pg_catalog.regclass. Cannot be omitted.
search_fusion	string	How to combine semantic text search and full-text search. The default is "UNION". "UNION": Returns the union of each search result. "INTERSECT": Returns the intersection of each search result. "TEXT_ONLY": Returns the intersection with all results of the full-text search.

Key	JSON format	Deccription
		"VECTOR_ONLY": Returns the intersection with all results of the semantic text search. "MINUS_TEXT": Returns the results of the semantic text search excluding the intersection. "MINUS_VECTOR": Returns the results of the full-text search excluding the intersection.
rrf_k	number	Weighted RRF's weight. When a floating-point type is specified, the decimal part is truncated. The default is 60.
topN	number	Maximum number of results returned from hybrid search. When a floating-point type is specified, an error occurs. The default is 20.
semantic.search_text	string	Text to search with semantic text search. Cannot be omitted.
semantic.distance_operator	string	Distance operator in vector comparison. The default is "<=>".
semantic.num_result	number	Maximum number of items to be retrieved by semantic text search. When a floating-point type is specified, an error occurs. If omitted, it is calculated based on topN. If the combination method is "UNION", it is half of topN, otherwise it is the same as topN.
semantic.score_weight	number	Relative weighting (importance) of semantic text search. When a floating-point type is specified, the decimal part is truncated. The default is 1.
fulltext.search_condition	string	Full-text search condition (an expression that returns a boolean value specified in the WHERE clause). The name of the column targeted for full-text search in the embedded view is chunk. Refer to the "3.3.3 Definition of Vectorization" for the definition of the embedded view. Cannot be omitted.
fulltext.num_result	number	Maximum number of items to be retrieved by full-text search. When a floating-point type is specified, an error occurs. If omitted, it is calculated in the same way as semantic.num_result.
fulltext.score_weight	number	Relative weight (importance) of full-text search. When a floating-point type is specified, the decimal part is truncated. The default is 1.
fulltext.score_expression	string	An expression that returns a floating-point score for full-text search.

Key	JSON format	Deccription
		You can refer to tableoid and ctid. It cannot be omitted.

See

For the function used in calculating scores in full-text search, refer to "Full Text Search" in the PostgreSQL Documentation.

Information

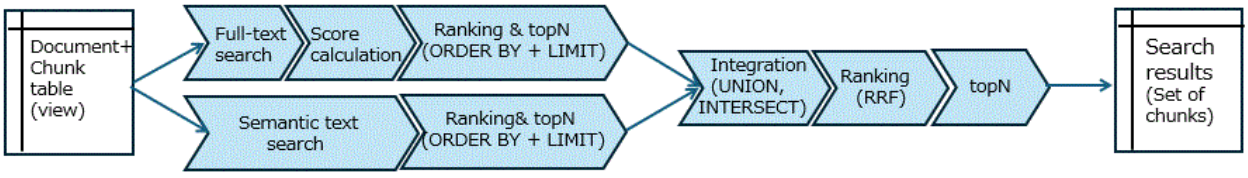
You can specify a matching operator for full-text search as a condition for full-text search. Specify the operator supported by the full-text search index defined in the table to be searched. The search text for full-text search must be specified in the pattern required by the matching operator.

Example) Query argument of the pgx_hybrid_search function

```
{
  "target_view": "sample_embeddings",
  "search_fusion": "UNION",
  "topN": 20,
  "semantic": {
  "search_text": "text for search",
  "distance_operator": "<=>",
  "num_result": 10,
  "score_weight": 1
  },
  "fulltext": {
    "search_condition": "chunk @@ websearch_to_tsquery('search text')",
    "num_result": 10,
    "score_weight": 1,
    "score_expression": "ts_rank_cd(to_tsvector(chunk), websearch_to_tsquery('search
text'))"
  }
}
```

The search conditions specified by the query argument

The search conditions specified by the query argument correspond to the following flow. (This flow is for explaining the meaning of the search process and is not the same as the actual access plan.)



- Full-text search: Perform a full-text search based on the conditions specified in fulltext.search_condition.
- Full-text search score calculation: Perform score calculation using fulltext.score_expression. If not specified, full-text search will result in an error.
- Full-text search ranking & topN: Rank the results in order of highest score. Only the number of search results specified by semantic.num_result from the top will be adopted, and the rest will be discarded.
- Semantic text search: Perform semantic text search based on vector similarity search using semantic.search_text and semantic.distance_operator.

- Semantic text search ranking & topN: Rank results in order of smallest distance from vector similarity search results. Only the number of search results specified by semantic.num_result from the top will be adopted, and the rest will be discarded.
- Integration: Integrate the results of full-text search and semantic text search according to the method specified in search_fusion.
- Ranking: Calculate scores based on the ranks of full-text search and semantic text search and assign final ranks. Use fulltext.score_weight, semantic.score_weight and rrf_k.
- topN: Return only the specified number of results from the top based on the final rank.

Score calculation

The score of the integrated result of multiple ranked results is calculated using a method called weighted RRF (Reciprocal Rank Fusion). Unweighted RRF considers the reciprocal of the rank of each search method as the score and takes the sum of multiple search methods as the final score. The final rank is determined based on that score. Weighted RRF calculates the sum of multiple search methods by multiplying each score by the weight for each search method as a coefficient.

The method for calculating the score WRRF(d) using weighted RRF for a certain search result d is shown below. i represents the search method, and the sum of scores for all search methods is obtained.

$$WRRF(d) = \sum_i w_i \times \frac{1}{k + rank_i(d)}$$

The value of k can be changed with the rrf_k parameter, and the default is 60. The smaller this parameter is, the greater the impact of differences in the original rank.

The rank (ranki(d)) for search results not returned by one of the search methods is considered a sufficiently large value (considered to have no impact on the final score).

Hybrid search results

The pgx_hybrid_search function returns a set of records of the following type.

Column	Type	Description
queryid	bigint	Query ID of the hybrid search feature used to refer to trace information. A valid value will be returned if trace information is recorded. Otherwise, 0 will be returned.
context_id	uuid	Identifier of the returned text chunk. Unique within the embedded view.
chunk	text	Returned text chunk.
score	real	Hybrid search score. A higher score indicates a better match with the conditions.

3.8.4 Tables/Views Created by Semantic Text Search and Automatic Vectorization Feature

For information about the tables and views that pgai creates, refer to the pgai documentation.

pgx_vectorizer creates the following tables.

pgx_vectorizer.worker_setting_table table

Stores information about the parameters used by the embedded provider.

Column	Type	Constraint	Description
type	text	PRIMARY KEY	The type of parameter to set.

Column	Type	Constraint	Description
			The name of the embedded provider or user
parameter	text	PRIMARY KEY	Parameter name
value	text	NOT NULL	Value to set for the parameter

pgx_vectorizer.pgx_fulltext_index table

The pgx_fulltext_index table stores the definition information of the full-text search index created by the pgx_create_vectorizer function.

Column	Type	Reference destination	Description
vectorizerid	integer	ai.vectorizer.id	Vectorization identifier
config	jsonb		Definition information of full-text search index. Configurable values are the return values of the pgx_fulltext_indexing_gin function or the pgx_fulltext_indexing_gist function.

pgx_vectorizer.pgx_trace_query table

Provides information on hybrid search where trace information is recorded.

When a hybrid search is performed with tracing enabled, one record is inserted.

Deleting records from this table also deletes records from the pgx_trace_subquery table, pgx_trace_results table, and pgx_context_metrics table with the same queryid.

Column	Type	Description
queryid	bigint	Hybrid search ID
retrieval_time	timestamp with timezone	Time when hybrid search was conducted
retrieval_user	oid	Database user who performed the hybrid search
application_name	text	Application name that issued the hybrid search. The value of application_name specified
query	jsonb	Search criteria for hybrid search

pgx_vectorizer.pgx_trace_subquery table

Provides information about the subqueries for hybrid searches where trace information is recorded.

When a hybrid search is performed with tracing enabled, multiple records are inserted for each subquery.

Column	Type	Description
queryid	bigint	Hybrid search ID
subquery_seq	smallint	Serial number of subquery conducted within a hybrid search(A serial number closed in a certain hybrid search process)
subquery_type	text	Types of subqueries

Column	Type	Description
		'-' : Overall hybrid search (main query) 'semantic' : Semantic text search 'fulltext' : Full-text search
subquery_text	text	Content of the executed subquery (SQL statement)

pgx_vectorizer.pgx_trace_results table

Provides information about the text chunks returned by each search process of hybrid search and subquery.

When performing a hybrid search with trace information enabled, multiple records corresponding to the text chunks of the search results of each subquery are inserted.

Column	Type	Description
queryid	bigint	Hybrid search ID
subquery_seq	smallint	Serial number of subquery conducted within a hybrid search
context_id	uuid	Returned text chunk ID
chunk	text	Returned text chunk
rank	integer	Rank of text chunks within the same subquery type
score	real	Score of text chunk. Hybrid search overall : Score calculated by RRF Semantic text search : Score based on distance between vectors in text meaning search Full-text search : Score calculated by score_expression in hybrid search processing

In the case of text meaning search, the score is calculated using the distance d between the vector representations of the text chunk and the query text, according to the following formula.

$$score = \frac{1}{1+d}$$

pgx_vectorizer.pgx_context_metrics table

This is a list of text chunks returned by either hybrid search or subquery. When the pgx_list_contexts function is executed, records for the specified query ID are inserted. You can enter any evaluation value in the context_metrics column.

Column	Type	Description
queryid	bigint	Hybrid search ID
context_id	uuid	Returned text chunk ID
context_metrics	jsonb	You can input evaluation values for text chunks.

pgx_vectorizer.pgx_trace_contexts view

Provide information about the text chunks returned by either hybrid search or subqueries.

For hybrid searches conducted with trace information enabled, there are records for each text chunk of search results for each subquery.

Column	Type	Description
queryid	bigint	Hybrid search ID
retrieval_time	timestamp with timezone	Time when hybrid search was conducted
retrieval_user	oid	Database user who performed the hybrid search
application_name	text	Application name that issued the hybrid search. The value of application_name specified
query	jsonb	Search criteria for hybrid search
subquery_type	text	Types of subqueries '-' : Overall hybrid search (main query) 'semantic' : Semantic text search 'fulltext' : Full-text search
subquery_text	text	Content of the executed subquery (SQL statement)
context_id	uuid	Returned text chunk ID
chunk	text	Returned text chunk
rank	integer	Rank of text chunks within the same subquery type
score	real	Score of text chunk. Hybrid search overall : Score calculated by RRF Semantic text search : Score based on distance between vectors in text meaning search Full-text search : Score calculated by score_expression in hybrid search processing
context_metrics	jsonb	You can input evaluation values for text chunks.

3.8.5 Parameters

Describes the parameters to be set in the postgresql.conf file when using the semantic text search and automatic vectorization feature.

- pgx_vectorizer.max_vectorize_worker

  Specify the maximum number of workers that can run simultaneously within an instance and perform vectorization. The number of workers that perform vectorization is determined by the number of vectorization definitions created. This parameter can only be set at server startup. The default is 1. Because workers act as background workers, add the value set for this parameter plus the number of databases with the pgx_vectorizer feature enabled plus 2 to the max_worker_processes parameter, which specifies the maximum number of background workers. If the value set for max_worker_processes is insufficient, the instance cannot start.

- pgx_vectorizer.pgai_worker_path

  Specify the path to the program that performs vectorization processing. Specify *<Fujitsu Enterprise Postgres server feature installation directory>*/OSS/pgai-worker/bin/pgai. The default value is /opt/fsepv*<x>*server64/OSS/pgai-worker/bin/pgai (where "*<x>*" indicates the product version). You can reflect the changes by reloading the configuration file.

- pgx_vectorizer.enable_hybrid_search_trace(boolean)

  Enable trace information for hybrid search. The default is disabled. This parameter can be specified with the SET statement by any user, but additional access rights are required to record trace information. Also, even if this parameter is enabled on a hot standby server, trace information will not be recorded.

3.8.6 Evaluation of Knowledge Data Search

3.8.6.1 Concept of Evaluation for Knowledge Data Search

A knowledge database exists to provide users with appropriate knowledge. It is necessary to evaluate whether it is providing users with appropriate knowledge. For the evaluation of knowledge data (offline evaluation), a set of pairs of queries and results related to those queries (search results that should be returned for those queries) is prepared, and search accuracy is calculated using it.

Basic indicators in offline evaluation of search systems are recall and precision. A high recall state means that records related to the request are included in the search results without omission. A high precision state means that only records related to the request are included in the search results. Recall and precision can be calculated using the following formulas.

$$\text{recall} = \frac{\textit{The number of records related to the query in the returned search results}}{\textit{The number of records related to the inquiry}}$$

$$\text{precision} = \frac{\textit{The number of records related to the query in the returned search results}}{\textit{The number of returned records}}$$

Recall and precision are indicators that well represent whether necessary data is included or unnecessary data is not included. However, there are the following challenges in directly using recall and precision for evaluating knowledge data retrieval.

- Difficulty in defining query-related results

  When the same knowledge is contained in multiple records, returning even one record as a search result satisfies the user's request. Therefore, it is impossible to define a single set of search results that should be returned for that query.

- High cost of preparing query-related results

  Strictly defining query-related results requires determining whether each record in the database is related to the query or not.

To address the first issue, instead of defining the correct set of records to be returned, there is a method to define it by the content and meaning of the data. For example, there is a method to evaluate whether the sentences included in the records support the expected claim.

The preparation cost for the correct answer, which is the second issue, can also be reduced by the above approach. This is because the definition of the correct answer can be made from the content of the query or the content of the correct answer to the query, rather than from (all) records included in the database.

"Judging based on the content of the text" refers to things like the following.

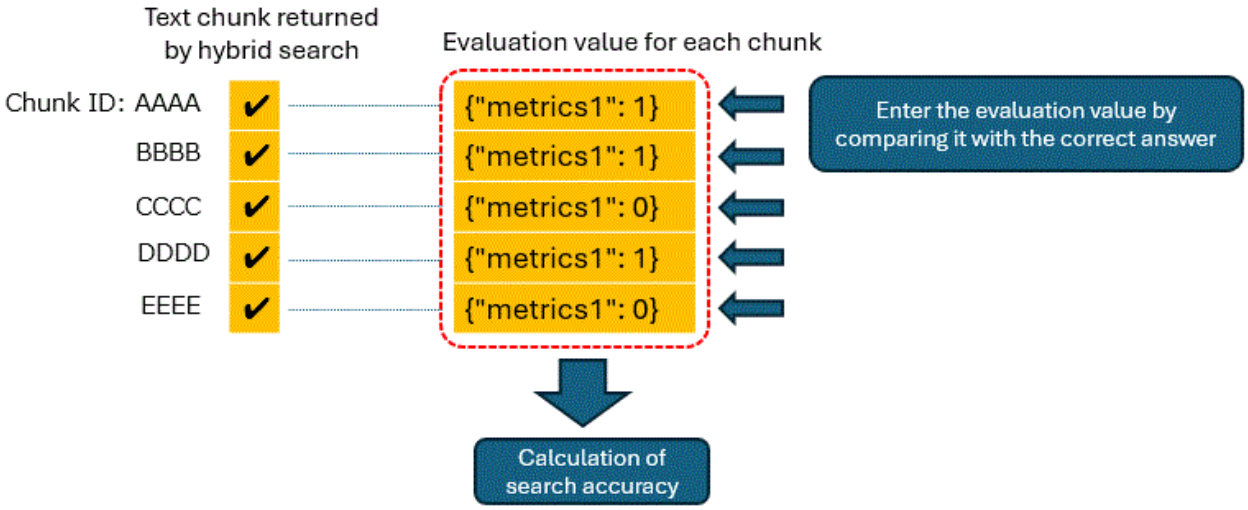
When the statement "Mount Fuji is the highest peak in Japan" is considered correct, if a record contains the sentence "Mount Fuji is 3776 meters high and is recorded as the tallest mountain in Japan", this sentence can be judged to support the correct fact.

In the method of judging based on the content and meaning of the text, it is necessary to extract the statement of fact from the query or correct content and determine whether these statements are included in the search results. While it is certainly possible for humans to perform this task, there is also a method to have language models do it. By doing so, the preparation cost for correctness can be further reduced.

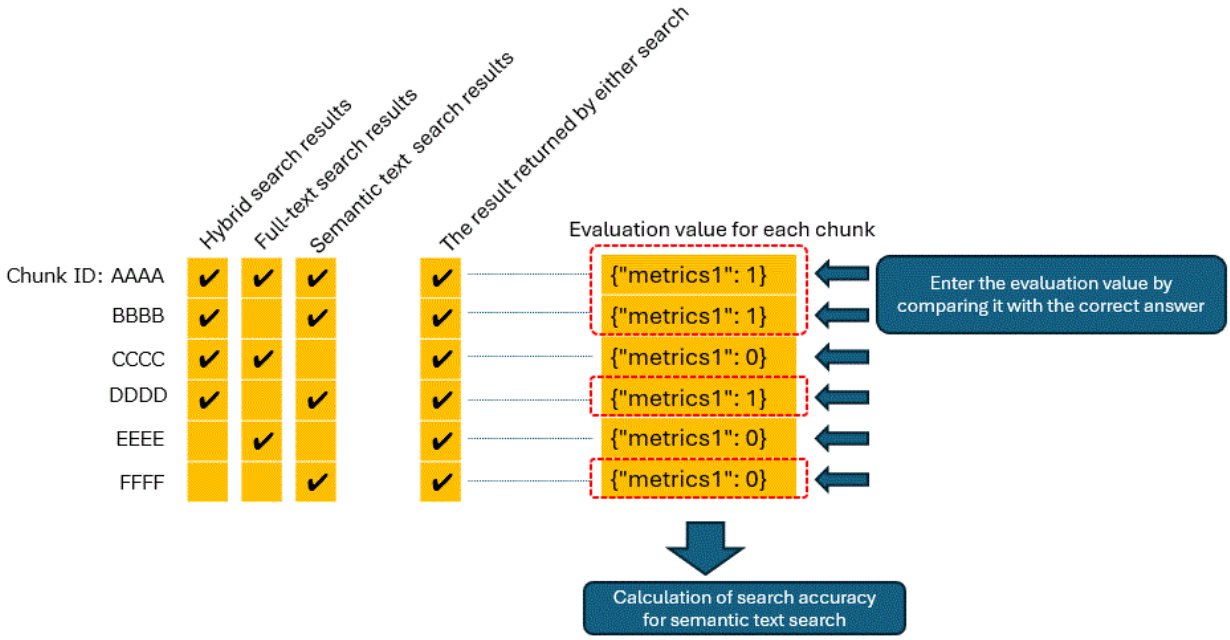
When adopting a method to evaluate search accuracy based on the content included in the records, it is important to note that the evaluated target is not only the implementation method of the search process. This method is a direct evaluation approach of the content obtained as search results. Therefore, not only the search method of the database but also what kind of knowledge is included in the database and how the user converts the content they want to know into queries for the database will affect the evaluation. When evaluating the accuracy of search methods with this approach, it is necessary to identify which part is causing the issue before starting to tune the search method.

3.8.6.2 Evaluation Value per Record and Search Accuracy

There are various metrics to represent search accuracy, but many calculations of search accuracy consist of two steps: obtaining evaluation values for individual records obtained as search results, and calculating search accuracy using the overall evaluation values of individual records (text chunks).



The search accuracy of subqueries can be calculated in the same way. The search accuracy can be evaluated in the same way for both full-text search subqueries and semantic text search. However, the text chunks returned by subqueries and the final hybrid search contain the same ones. Since the evaluation values for the same text chunks are common, these evaluation values can be determined and inputted together, and from there, only the evaluation values related to the text chunks for each subquery can be used to calculate the search accuracy of each subquery.



3.8.6.3 Tuning the Combination Method of Hybrid Search

Based on the search accuracy of each subquery, you can tune the combination method of subqueries. Adjustable parameters include, for example, the weighting between full-text search and semantic text search, and the number of retrievals each subquery returns. If the semantic text search has a higher precision compared to full-text search, it is possible to increase the weight of semantic text search used in the final ranking calculation. Additionally, by setting the number of retrievals (num_results) in subqueries to a larger value than usual to obtain trace information, and calculating search accuracy such as recall and precision for each number of retrievals, recall@k, and precision@k, you can determine the appropriate number of

retrievals from subqueries. As a result of evaluating search accuracy, you may detect issues that cannot be improved by the combination method. In such cases, tuning of both semantic text search and full-text search is performed.

Chapter 4 MCP Server Feature for Business Data Utilization

This chapter describes the MCP server feature for business data utilization.

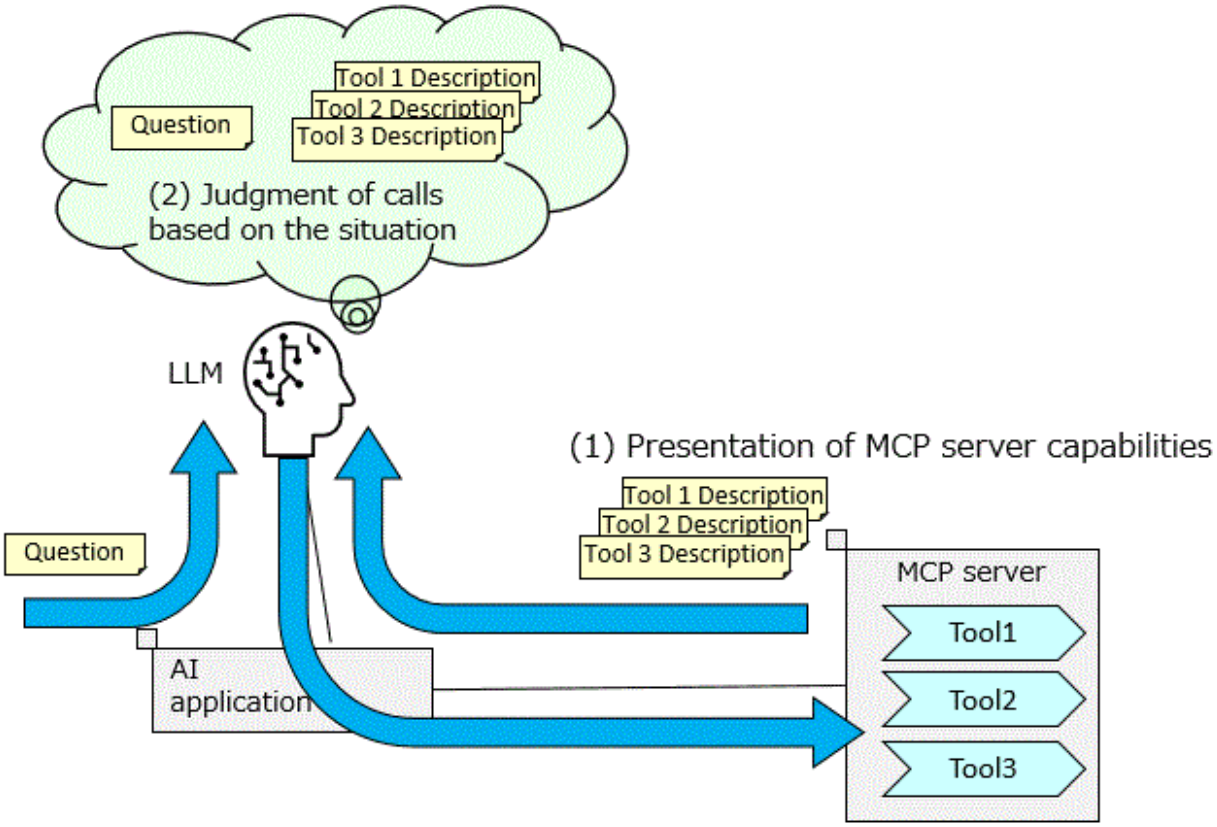
4.1 Overview

The MCP server feature for business data utilization allows business data stored in Fujitsu Enterprise Postgres to be utilized via the MCP (Model Context Protocol) protocol.

MCP is a protocol and architecture for standardizing access to external resources and tools in Agentic AI applications. When both applications and external tools such as databases support the MCP protocol, external tools can be used without modifying the applications.

Each MCP server has its own unique tools. When an AI application and an MCP server are connected, information about the tools, which are the capabilities of the MCP server, is passed to the AI application. The information passed at this time includes not only the input/output interface information of the tool, but also information such as the purpose, meaning, and usage of the tool described in natural language. When this information is presented to the LLM via the AI application, the LLM can determine whether to use the tool based on the tool's description. When the LLM decides to call the tool, that tool is called via the AI application.

All that is required for the AI application to be able to use tools is to register the MCP server that the AI application uses with that AI application.



This feature utilizes an MCP server that allows you to customize the tools published to your application. This is an MCP server that allows MCP server administrators to define tool implementations using SQL statements, and then execute those SQL statements (at the discretion of the LLM) against Fujitsu Enterprise Postgres via the MCP protocol. The tools published on the MCP server can be changed and used according to the application. This feature provides instructions for configuring the MCP server and customizing tools, and preset tools.

Note

- If you allow LLMs completely autonomous access, ensure that the tools called are "safe". For example, if an Agentic AI application has an MCP server registered that performs database access and internet searches, the LLM can perform internet searches using data retrieved from the database as keywords. This could lead to a data breach. Also, if tools that modify the database are available, unintended data modifications could be caused by the LLM. Allowing LLMs completely autonomous access carries such risks. It is the responsibility of the application administrator to decide which tools (which MCP servers) the LLM can use. It is necessary to assess the quality of the LLM and, if it is deemed unreliable, to configure the system so that humans make the final decisions (often called Human-in-the-loop). In this case, the responsibility for the final decision on whether to call a tool rests with the user of the application.
- Attacks such as prompt injection and tool poisoning can inject malicious instructions into LLMs outside the user's awareness. Since complete defense against these attacks is difficult, restrict access via the MCP server to minimize impact even if the LLM exhibits unintended behavior. Since data within the database, comments, and tool definitions on the MCP server could potentially be used as stepping stones for these attacks, ensure that only trusted individuals can modify data or settings on each server.

Knowledge data search or routine processing

As a preset tool, we provide a tool that performs knowledge data search processing such as semantic text search. If you want to use other routine processing from an AI application, implement that routine processing in Fujitsu Enterprise Postgres in the form of stored procedures or views, and the user prepares a tool definition for each routine processing. By registering preset tools and custom tool definitions on the MCP server and registering the MCP server in the AI application, these tools can be used from the AI application.

Ad-hoc queries for business data

If there is a request to perform flexible queries on business data according to the situation at the time, predefined fixed form SQL statement cannot meet that request. For flexible queries, it is necessary to generate SQL statements each time. However, this process requires a solid understanding of table structures and incurs the cost of devising SQL logic from scratch.

LLMs often acquire general SQL knowledge as a result of their training. Therefore, there is a way to have an LLM generate SQL statements by providing the LLM with the content of the target query and the structure of the business data (this is called Text-to-SQL, etc.). Fujitsu Enterprise Postgres provides preset tools as standard to support such use cases.

Note

While LLMs with general SQL knowledge are expected to generate correct SQL statements, they may generate incorrect ones if the data knowledge provided to the LLM is insufficient or the query content is complex. Therefore, when using SQL statements generated by an LLM, it is necessary to cover the impact of errors in operation, such as by having a human review them before execution. The responsibility for the impact of the finally executed SQL statement, including whether to grant the LLM autonomous SQL execution privileges, lies with the users of that application.

Furthermore, incorrect SQL statements can not only generate incorrect results but also potentially lead to outcomes such as data modification or overloading the database server. To prevent such system-wide issues, measures such as setting access rights via the MCP server to the minimum necessary privileges or connecting only to hot standby servers where update queries cannot be executed are required. The responsibility for implementing such preventive measures lies with the administrators of the database server and the MCP server.

4.2 Operating Environment

As an MCP server, prepare the MCP Toolbox for Databases separately, as described in "Related Software" in the Installation and Setup Guide for Server. For MCP Toolbox for Databases, we support usage within the scope described in this manual. Hereafter, MCP server refers to MCP Toolbox for Databases.

In addition, if you use the MCP server via a network or share it with multiple people, separate software called MCP Proxy or MCP Gateway is required to add authentication features to the MCP server.

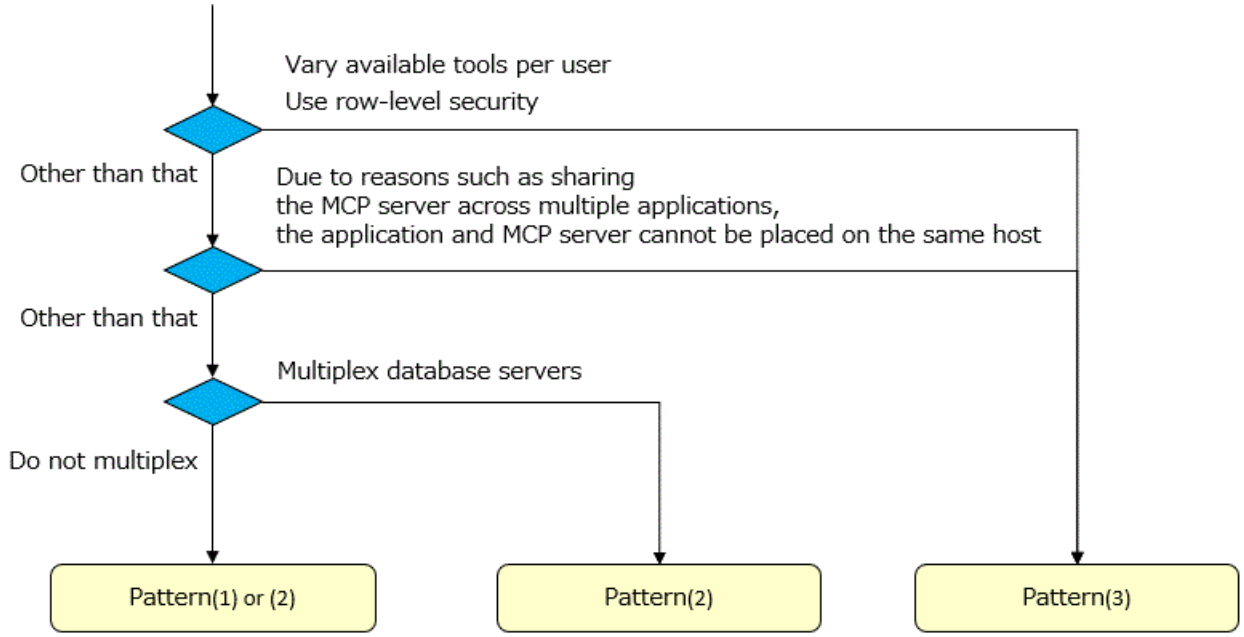
4.3 System Configuration

The MCP Toolbox for Databases assumes that its safety and reliability depend on the network configuration of the operating environment and the security layers built and operated by the organization. It does not have a general-purpose authentication feature for requests from clients and does not support TLS (encryption of communication with clients). Therefore, place the MCP server and the application connecting to the MCP server on the same host. If the application and the MCP server cannot be placed on the same host, the MCP server will receive requests via the network. In this case, it is necessary to secure communication and allow connections only from specific applications. To achieve this, a gateway or reverse proxy software with authentication and TLS termination features should be placed.

As a separate requirement, if fine-grained authorization is desired, such as restricting the tools available to each end-user, software with authorization features for each tool is required. Software called an MCP gateway or MCP proxy, which understands the MCP protocol, should be placed in front of the MCP server.

The MCP server and database server can be on the same host or different hosts, but when configuring an HA setup such as database multiplexing, the MCP server should be placed on a different host from the database server.

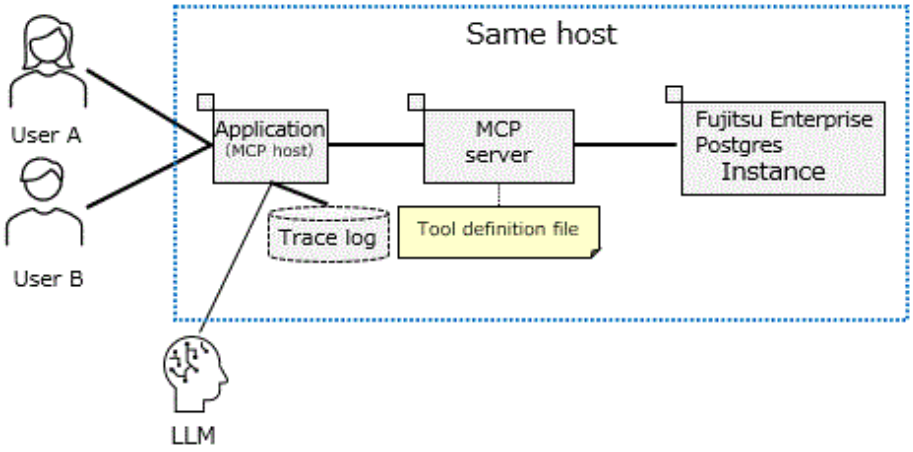
You can select the system configuration based on the following criteria.



Pattern (1) Minimum Configuration

In Pattern (1), the database instance, MCP server, and application can be placed on the same host. Since they are on the same host, the authentication method for database access from the MCP server can use peer authentication in addition to password-based authentication such as SCRAM. The MCP server is configured to accept access only from the same host. Since access from the host where the MCP server operates is accepted, ensure that only trusted applications and trusted users can run and connect to that host.

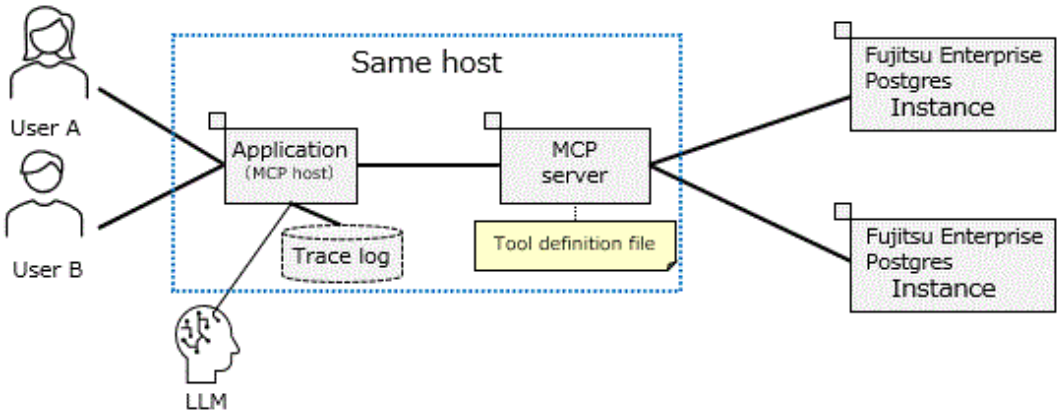
To distinguish end-users for tracing access via the MCP server, logs must be obtained from the authenticating application (MCP host).



Pattern (2) Database HA Configuration

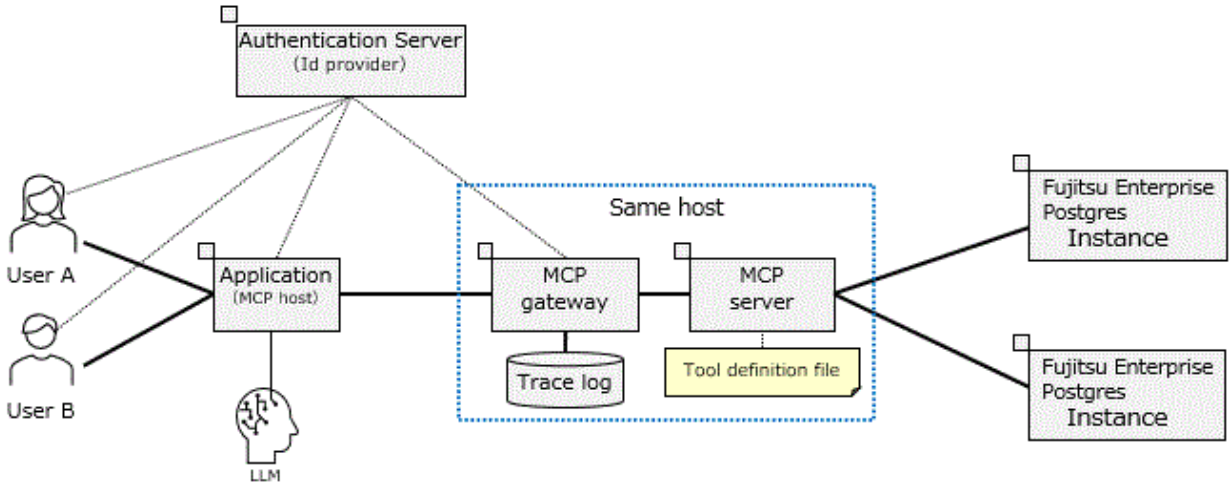
When configuring a cluster, such as database replication, to enhance the availability of access from the MCP server, the MCP server is placed on a host separate from the database. In this case, the MCP server is also placed on the same host as the application.

For database access authentication from the MCP server, you can use password-based authentication such as SCRAM, or certificate authentication using client certificates for TLS connections. The security and tracing considerations between the application and the MCP server are the same as in (1) Minimum Configuration.



Pattern (3) Configuration using MCP Gateway/Proxy

In this configuration, the MCP Gateway/Proxy receives requests via the network. The MCP server should be located on the same host as the MCP Gateway. Access control between the MCP server and the database is the same as in (1) and (2).



The MCP Gateway, which consolidates multiple MCP servers, can centrally perform authentication, authorization, and logging for multiple MCP servers within the system. Select an MCP Gateway that supports the authentication infrastructure used by your organization or system.

4.4 Introduction/Setup

4.4.1 Creation of Database Roles and Configuration of Access Privilege for MCP Servers

Create a database role exclusively for the MCP server and grant only the minimum necessary privileges.

Access via the MCP server may involve automated operations by agents, so create a dedicated database role for the MCP server. Additionally, to minimize the impact of unexpected access, grant only the minimum necessary privileges for business data utilization to that database role.

4.4.2 Installation of MCP Server

Install the MCP server on the host running the MCP server, referring to the MCP Toolbox for Databases documentation.

Example)

```
export VERSION=0.27.0
curl -L -o toolbox https://storage.googleapis.com/genai-toolbox/v$VERSION/linux/amd64/
toolbox
chmod +x toolbox
```

4.4.3 Creating a Configuration File

MCP Toolbox for Databases uses a YAML-formatted configuration file that defines tools and connection information for Fujitsu Enterprise Postgres servers. A single configuration file can include information for multiple destination database servers and multiple tool definitions. It can also be divided into multiple configuration files.

Prepare the configuration file by referring to the sample file in the installation directory of the Fujitsu Enterprise Postgres server feature. For the file to refer to, refer to "4.4.4 Tool Definition" and select it based on the preset tool you want to use.

This section describes basic information about the configuration file.

sources section

The sources section specifies connection information for each destination database. You specify the source name that identifies the connection destination, the corresponding host name, port number, database name, user name, etc. For the user name, specify the MCP server database role created in "4.4.1 Creation of Database Roles and Configuration of Access Privilege for MCP Servers".

If password authentication is used, specify as follows. Environment variables can be referenced as values.

Example) In the case of password authentication

```
kind: sources
name: my-postgresql-source              # Connection identifier
type: postgres                          # Fixed to postgres
host: localhost
port: 27500
database: my_database
user: mcpuser
password: ${PASSWORD}
```

When using peer authentication, specify as follows. Even with peer authentication, the password entry cannot be omitted, so specify a dummy value. Since the path to the directory of the Unix domain socket of the connection destination cannot be directly specified in the host entry, specify it as a host entry under queryParams.

Example) In the case of peer authentication

```
kind: sources
name: my-postgresql-source              # Connection identifier
type: postgres                          # Fixed to postgres
host: localhost
port: 27500
database: my_database
user: mcpuser
password: dummy                         # Dummy password (required in YAML, but not
referenced)
queryParams:
  host: /tmp                            # Path to the Unix Domain Socket
```

When using certificate authentication, specify each option under queryParams as follows.

Example) In the case of certificate authentication

```
kind: sources
name: my-postgresql-source             # Connection identifier
type: postgres                         # Fixed to postgres
host: host1
port: 27500
database: my_database
user: mcpuser
password: dummy                        # Dummy password (required in YAML, but not
referenced)
queryParams:
  sslmode: require
  sslcert: /path/to/mcpuser.crt        # Path to the user's client certificate
  sslkey: /path/to/mcpuser.key         # Path to the user's private key
  sslrootcert: /path/to/ca.crt         # Path to the CA certificate
```

When ensuring the availability of access from the MCP server, such as in a database multiplexing configuration, multiple host names are specified as the connection destination database server for the MCP server, as shown below.

Example) In the case of multiple hosts

```
kind: sources
name: my-postgresql-source       # Connection identifier
type: postgres                   # Fixed to postgres
host: host1
port: 27500
database: my_database
user: mcpuser
```

```
password: dummy                  # Dummy password (required in YAML, but not referenced)
queryParams:
  host: host1,host2               # Comma-separated list of hostnames
  port: 27500,27500              #  Comma-separated list of port numbers, corresponding
to each host
  target_session_attrs: read-only
  sslmode: require
  sslcert: /path/to/mcpuser.crt  # Path to the user's client certificate
  sslkey: /path/to/mcpuser.key   # Path to the user's private key
  sslrootcert: /path/to/ca.crt   # Path to the CA certificate
```

tools section

The tools section describes the definition of tools to be published on the MCP server for each tool . The tool name can be changed, but it must be unique within the MCP server. Modify the value of the source key to the name corresponding to the connection destination database specified in the sources section.

Example)

```
kind: tools
name: db-list-tables                      # Tool identifier
type: postgres-sql                        # Type of tool
source: my-postgresql-source              # Name of the associated data source
description: Lists detailed table information
```

4.4.4 Tool Definition

When using the knowledge data search tool

To perform knowledge data retrieval, you need to set up the knowledge data management feature and prepare for semantic search in advance. Refer to "3.2 Introduction/Setup" to set up automatic vector conversion. Then, define vector conversion for the tables you want to perform semantic text search on.

To use the preset tool for knowledge data semantic search, pgx_vectorizer extension version 3.1 or higher is required. The version of the installed extension can be checked with the \dx meta-command in psql.

To perform semantic text search via the MCP server, the database role used by the MCP server needs privileges for searching. Refer to "3.3.4 Granting Privilege to Execute Functions" to grant privileges to the MCP server database role.

Next, prepare the knowledge data search tool definition to be registered on the MCP server. The definition of the preset tool for knowledge data search is in the following file located in the directory where the Fujitsu Enterprise Postgres server feature is installed. Copy this file and edit the connection destination database information in the sources section. "<*x*>" indicates the product version.

```
cp /opt/fsepv<x>server64/share/mcptoolbox_semsearch_tools_yaml.sample ./
semsearch_tools.yaml
```

For details on the preset tools included in the file, refer to the "4.9.1 Knowledge Data Search Tools".

When using other tools for routine processing

The MCP toolbox for Databases can publish SQL statements (prepared statements) written in configuration files as tools. This allows you to define tools based on business-specific logic. For details, refer to "4.7.2 Adding Your Own Tools".

When using the SQL generation support tools

Prepare the SQL generation support tool definition to be registered on the MCP server. The definition of the preset tool for knowledge data retrieval is the following file located in the directory where the Fujitsu Enterprise Postgres server feature is installed. Copy this file and edit the connection destination database information in the sources section. "<*x*>" indicates the product version.

```
cp /opt/fsepv<x>server64/share/mcptoolbox_text2sql_tools_yaml.sample ./text2sql_tools.yaml
```

For details on the preset tools included in the file, refer to "4.9.2 SQL Generation Support Tools".

When using the knowledge data search tool and the SQL generation support tool simultaneously

The file copied and modified in the above procedure defines information about the same connection destination database with the same source name. If you want to use the two tools for the same database, delete one of the sources sections.

4.5 Using the MCP server

4.5.1 Starting the MCP server

Start the installed MCP server. If there is only one configuration file, specify the file path with the --tools-file option.

Example)

```
./toolbox --tools-file tools.yaml --port 5000
```

If there are multiple configuration files, specify the file paths separated by commas in the --tools-files option.

Example)

```
./toolbox --tools-files tools1.yaml,tools2.yaml --port 5000
```

By default, MCP Toolbox for Databases starts in HTTP server mode and only accepts connections from the same host. Additional options may be required depending on the environment. For details, refer to "4.6.3.1 Access from the Application to the MCP Server".

4.5.2 Registration of MCP server

To access business data from an AI application via an MCP server, register the MCP server with an application that has MCP client functionality.

If the MCP server is running in server mode, the two pieces of information required for registration are the host where the MCP server is running and the MCP server's port number.

4.6 Operation of MCP Server

4.6.1 MCP Server Operation Check

MCP servers are usually called based on the LLM's judgment, but there are cases where you want to check the operation without going through the LLM, such as when you want to test the MCP server. In such cases, MCP Inspector is available as a developer tool. If you register an MCP server with this tool as you would register an MCP server with an AI application, you can obtain a list of tools published on the MCP server and call tools without going through the LLM. Refer to the MCP Inspector documentation for details.

4.6.2 Backup of MCP Server Settings

The MCP server configuration file is a YAML file passed when the MCP server starts. Back up this file.

4.6.3 Security

4.6.3.1 Access from the Application to the MCP Server

Assumptions for MCP server placement

As explained in the system configuration, the MCP server should be placed on the same host as the client, application, or MCP gateway that accesses it. The settings will only allow connections to the MCP server from within the same host. By default, it is set to accept connections only from localhost, so do not change this.

Considerations as an HTTP server

MCP Toolbox for Databases starts as an HTTP server by default. The following options may be necessary when starting the MCP server to operate in an environment where attacks on the HTTP ecosystem, including browsers and DNS, and countermeasures against them exist.

- --allowed-hosts

  This option specifies the hostnames expected as destinations when the MCP server itself is accessed, and specifies the allowed values for the Host header included in HTTP requests. This option should be specified for security reasons, as attacks that utilize the Host header exist.

- --allowed-origins

  This may be necessary to inform the client of the allowed source origins when access from clients such as browsers that adopt the same-origin policy is expected.

4.6.3.2 Access Trace

Configure logging to trace access to the MCP server and tool calls. If it is necessary to identify not only the requesting application but also the end-user for access via the MCP server, logs must be collected at the layer that authenticates the end-user. Collect logs according to the settings of the gateway or reverse proxy used.

MCP server logs are output to standard output. Some messages are output to standard error. Use a log collection method appropriate for how Toolbox is launched (e.g., systemd or container).

Common key in Application/MCP Gateway/MCP Server

When MCP transport is HTTP, its request is always assigned a request ID. Therefore, this ID can be used to cross-reference with the logs of the application or MCP Gateway/Proxy. The request ID is output in the MCP server logs.

Common key between MCP server and database

The following information can identify whether a request is from the MCP server in the database server logs:

- Database role name
- Source hostname
- Application name (listed as connection information in the sources section or a default value; this value is fixed/static)

If it is necessary to cross-reference logs for requests via the MCP server with MCP server logs and database logs, link the logs using timestamp as the key.

Information

If you set the log level of the MCP server to DEBUG, the tool name and its parameters that were called will also be output to the log. The log level is specified by the --log-level option at startup.

4.6.4 Streaming Replication/Database Multiplexing

The binaries and container images officially distributed for MCP Toolbox for Databases do not support Connection Manager. Therefore, when ensuring the availability of access from the MCP server in a multiplexed configuration, specify multiple host names as the connection destination database server for the MCP server.

4.7 Advanced Usage

This section describes advanced usage of the MCP server.

4.7.1 Customize Tools

You can customize tools by editing the tool definitions provided as samples by Fujitsu Enterprise Postgres. For example, for tools used in hybrid searches, the method of merging semantic text search and full-text search results is fixed to UNION, but you can change this to TEXT_ONLY to remove results that do not match the full-text search.

4.7.2 Adding Your Own Tools

MCP toolbox for Databases can publish SQL statements (prepared statements) written in configuration files as tools. This allows you to define tools based on business-specific logic. When defining rules that use prepared statements, the following fields in the configuration file must be described.

Field name	Contents
type	Specify postgres-sql.
source	Specify the name of the connection destination described in the sources section.
statement	Describe the SQL statement to be executed. Arguments can be specified as $1, $2, etc. in the prepared statement format.
parameters	If there are parameters in the prepared statement, you must describe the name, data type, and description of each argument in parameters.
description	Describe the explanation of this tool in natural language. Based on this content, the LLM will infer and determine whether to call the tool. Include information such as the purpose of the tool, its meaning, when to use it, how to use it, and an explanation of the output results.

For examples, refer to the "postgres-sql tool" in the MCP Toolbox for Databases documentation.

4.7.3 Improving the Accuracy of SQL Generation

In SQL generation support by LLM, the LLM generates SQL from the given information. If the only information that can be given is table and column names and data types, the LLM will infer and generate SQL statements from them. In some cases, correct SQL statements can be generated from this information, but in other cases, the accuracy of generation may not be high due to insufficient information.

Some tools for SQL generation support can retrieve comments attached to database objects. By adding descriptions and meanings of tables and columns as comments, additional information can be provided to the LLM.

Comments can be added using PostgreSQL's COMMENT statement.

Example)

```
COMMENT ON TABLE my_table IS 'Employee Information';
COMMENT ON COLUMN my_table.my_column IS 'Employee ID number';
```

Registered comments can be checked using the obj_description function and the col_description function.

Example)

```
=> SELECT obj_description('my_table'::regclass, 'pg_class');
 obj_description
---------------------
Employee Information
(1row)

=> SELECT col_description('my_table'::regclass, 1);
 col_description
--------------------
Employee ID number
(1row)
```

Information

All users who can connect to the database can view comments on objects in that database. Also, all users who can connect to that instance can view comments on shared objects such as roles and databases. Therefore, include only information that connected users are allowed to view in the comments.

Comments added using the method described above can be retrieved along with database object information using several preset tools. However, if the number of database objects returned is large or the comments are lengthy, there is a risk that the LLM's context window will be overwhelmed, causing important information to be buried or truncated. To avoid this problem, one approach is to search for comments on a specific topic and then find database objects that match those comments. This method allows you to return only database objects that match the topic. Furthermore, returning only snippets of matching comments instead of the full text can further prevent the context window from being overwhelmed.

You can create a custom tool that searches for comments based on semantic similarity and returns the corresponding database objects by following these steps.

1. Create a table containing only the necessary database object records from the system catalog where comments are stored
2. Configure semantic text search for the comment table
3. Define an MCP tool to search the comment table
4. Reflect catalog changes

1. Create a comment table

Comments on database objects are stored in the pg_description system catalog. This catalog contains not only comments on user tables but also many comments on built-in functions and operators. Therefore, we will create a table that extracts only the comments of the necessary database objects from here.

In the following example, a table is created that extracts only the comments of schemas, tables, and their columns, and the primary key and index required for subsequent steps are set.

Example)

```
=> CREATE TABLE my_schema.my_comment_table AS SELECT d.classoid, d.objoid, d.objsubid,
d.description
    FROM pg_description AS d
    CROSS JOIN LATERAL pg_identify_object(d.classoid, d.objoid, d.objsubid) AS i
    WHERE i.type SIMILAR TO '(table|view|materialized view|schema)%';
SELECT 10
=> ALTER TABLE my_schema.my_comment_table ADD PRIMARY KEY (classoid,objoid,objsubid);
ALTER TABLE
```

2. Configure semantic text search for the comment table

Define automatic vector conversion for the comment table to enable semantic text search.

Example)

```
SELECT pgx_vectorizer.pgx_create_vectorizer(
    source => 'my_schema.my_comment_table'::regclass,
    destination => 'my_comment_embed',
    embedding => pgx_vectorizer.pgx_embedding_onnx('sample-model-v1',384),
    indexing => ai.indexing_hnsw(opclass=>'vector_cosine_ops'),
    chunking => ai.chunking_recursive_character_text_splitter('description'),
    scheduling => pgx_vectorizer.schedule_vectorizer(interval '24 hours'));
```

3. Define an MCP tool to search the comment table

Add an MCP tool definition to search for comments in the configuration file specified for the MCP server.

Example)

```
kind: tools
name: db_find_db_object_by_meaning
type: postgres-sql
source: my-postgresql-source
description: >
  Retrieves database objects, including schemas, tables, views, sequences, and their
columns,
  by matching the provided text against the objects' internal documentation and comments.
  For each result, the tool provides the object_type (e.g., schema, table, table column),
  the schema_name it belongs to, the object_name itself,
  its fully_qualified_identifier (e.g., public.my_table or public.my_table.my_coumn),
  and a comment_chunk (a fragment of the descriptive comment that is most relevant to the
query).
statement: >
  SELECT rank() OVER(ORDER BY distance ASC),
  (pg_identify_object(classoid, objoid, objsubid)).type AS object_type,
  (pg_identify_object(classoid, objoid, objsubid)).schema AS schema_name,
  (pg_identify_object(classoid, objoid, objsubid)).name AS object_name,
  (pg_identify_object(classoid, objoid, objsubid)).identity AS fully_qualified_identifier,
  s.chunk AS comment_chunk
  FROM pgx_vectorizer.pgx_similarity_search('my_schema.my_comment_embed'::regclass, $1,
10, '<=>') AS s
  CROSS JOIN my_schema.my_comment_embed AS t
  WHERE s.embedding_uuid = t.embedding_uuid;
parameters:
  - name: target-description
    type: string
    description: >
      A description that semantically matches the comments and definitions of the target
database object.
    required: true
```

4. Reflect catalog changes

If you change the comment of a database object after creating a comment table, the change will be reflected in the comment table. Below is an example of SQL that checks for changes in the pg_description catalog and reflects the differences.

Example)

```
BEGIN;

WITH current_descriptions AS (
  -- Read pg_description once
  SELECT d.classoid, d.objoid, d.objsubid, d.description
  FROM pg_description AS d
  CROSS JOIN LATERAL pg_identify_object(d.classoid, d.objoid, d.objsubid) AS i
  WHERE i.type SIMILAR TO '(table|index|sequence|view|materialized view|foreign table|
relation)%'
),
upsert_result AS (
  -- New additions and updates
  INSERT INTO  my_schema.my_comment_table (classoid, objoid, objsubid, description)
  SELECT classoid, objoid, objsubid, description
  FROM current_descriptions
  ON CONFLICT (classoid, objoid, objsubid)
  DO UPDATE SET
    description = EXCLUDED.description
 WHERE my_schema.my_comment_table.description IS DISTINCT FROM EXCLUDED.description
 RETURNING classoid, objoid, objsubid
)
  -- Delete deleted comments
DELETE FROM my_schema.my_comment_table AS mct
WHERE NOT EXISTS (
```

```
  SELECT 1
  FROM current_descriptions AS cd
  WHERE cd.classoid = mct.classoid
    AND cd.objoid = mct.objoid
    AND cd.objsubid = mct.objsubid
);

COMMIT;
```

4.7.4 Restrict SQL to be Executed

In SQL generation support, we use a tool that executes arbitrary SQL statements generated by the LLM. In some situations, the LLM may generate SQL that modifies data or takes a long time to execute. While it is the responsibility of the application user to not allow the execution of such SQL statements, a method to mechanically prevent this on the system side is to use SQL functions that validate queries (SQL statements) passed from the MCP server or add additional restrictions.

Below are examples of functions that add restrictions, such as making transactions read-only or setting timeouts before SQL statement execution, and an example of an MCP tool definition that uses them.

Example) SQL functions used by the tool

```
CREATE OR REPLACE FUNCTION safe_execute_sql(sql_text text)
RETURNS SETOF jsonb
LANGUAGE plpgsql SECURITY INVOKER -- Execute with caller's privilege
AS $$
DECLARE
  r record;
  cleaned_sql text;
BEGIN
  -- Check the statement if necessary
  --

  SET LOCAL transaction_read_only = on; -- Write protection
  SET LOCAL statement_timeout = '3000ms'; -- Timeout in 3 seconds
  SET LOCAL lock_timeout = '500ms'; -- Lock wait up to 0.5 seconds
  SET LOCAL idle_in_transaction_session_timeout = '5000ms';
  SET LOCAL work_mem = '16MB'; -- Memory for sort/hash
  SET LOCAL max_parallel_workers_per_gather = 2; -- Limit the number of parallel workers
  SET LOCAL search_path =  pg_catalog, pg_temp; -- Schema restrictions
  SET LOCAL row_security = on; -- Row-level security enabled

  BEGIN
    FOR r IN EXECUTE sql_text LOOP
      RETURN NEXT to_jsonb(r);
    END LOOP;
  EXCEPTION
    WHEN query_canceled THEN
     RAISE EXCEPTION 'Query execution timeout (3 seconds exceeded)'
       USING HINT = 'Try simplifying your query or adding more specific filters';
    WHEN lock_not_available THEN
      RAISE EXCEPTION 'Lock timeout (resource temporarily unavailable)'
        USING HINT = 'The requested table may be locked by another transaction';
    WHEN insufficient_privilege THEN
      RAISE EXCEPTION 'Permission denied for this operation'
        USING HINT = 'You may not have access to the requested tables or columns';
    WHEN OTHERS THEN
      RAISE EXCEPTION 'Query execution failed: %', SQLERRM
        USING HINT = 'Check your SQL syntax and table names';
  END;

  RETURN;
END;
$$;
```

```
REVOKE ALL ON FUNCTION safe_execute_sql(text) FROM PUBLIC;
GRANT EXECUTE ON FUNCTION safe_execute_sql(text) TO mcpuser;
```

Example) Definition of MCP tool

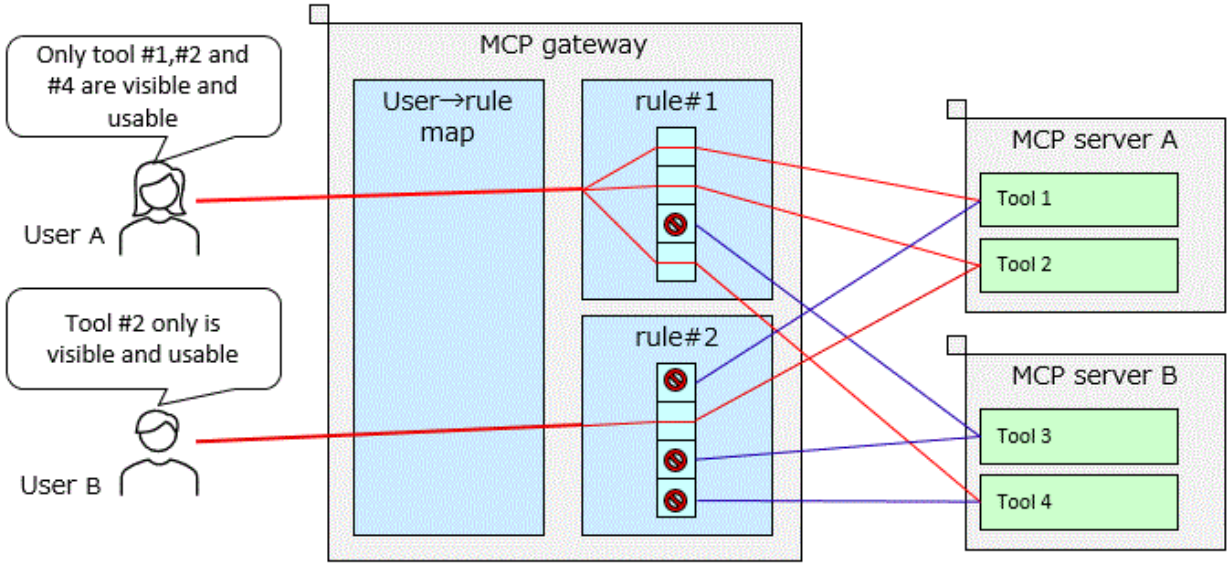
```
kind: tools
name: db_execute_sql
type: postgres-sql
source: my-postgresql-source
description: >
  Execute read-only SQL.
statement: |
  SELECT safe_execute_sql($1) as "_";
parameters:
  - name: sql
    type: string
    description: The SQL query to retrieve data
    required: true
```

4.7.5 Restricting Available Users per Tool

All tools published on the MCP server are available to all users who can connect to the MCP server. If you want to change or restrict the tools available to each connecting user, you can achieve this by identifying (authenticating) the connecting user and applying rules that determine which tools are allowed for each user based on different information (authorization).

The following is an example of how user-specific control is achieved by defining rules that permit the use of certain tools (tool sets) and defining the correspondence between users and tool sets, which determines which rules apply to which users. Here, Rule #1 allows the execution of Tools 1, 2, and 4, and Rule #2 allows only Tool 2. User A is mapped to Rule #1, and User B is mapped to Rule #2.

Example) Image of authorization based on end-user attributes on the MCP server

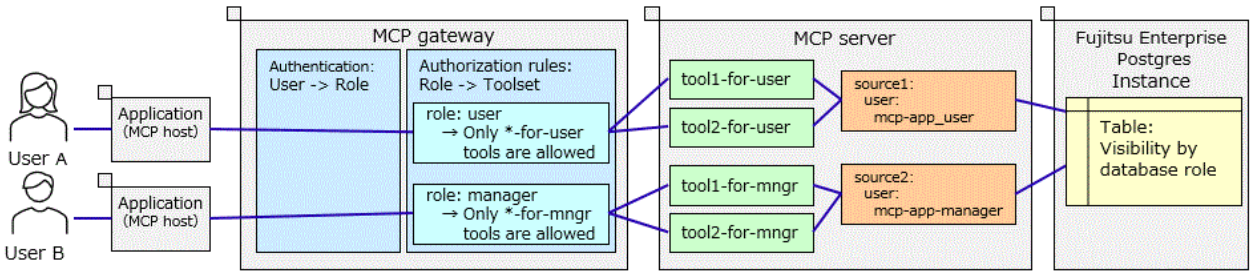


To implement such usage restrictions per user and per tool, software with authentication and authorization features is required. Such software that supports the MCP protocol is called an MCP gateway or MCP proxy. Select an MCP gateway/proxy that is compatible with the authentication infrastructure used in your organization or system.

4.7.6 Utilize Row-Level Security

If you want to allow users to view data with different visibility, Fujitsu Enterprise Postgres offers a row-level security feature. To use the row-level security feature via the MCP server, each end-user needs to have different attributes, such as the

connected database role name. However, MCP Toolbox for Databases currently cannot use such per-user connection information. Therefore, it is achieved by using multiple database connections as described below.



The following is an example of defining two different visibilities for a database based on database roles. Let the two database roles corresponding to the visibilities be mcp-app-user and mcp-app-manager.

1. Configure row-level security

Define row-level security policies for the target table by referring to the confidentiality management feature and PostgreSQL documentation.

2. Creating the MCP server configuration file

Change the connected database role in the sources section of the existing configuration file to mcp-app-user. The tools defined in this configuration file will be for mcp-app-user. Since the same tool definition cannot be used with a different database role, copy the definition and define it as a separate tool. Change the following parts of the definition:

- Change the connected database role in the sources section to mcp-app-manager
- Rename the source in the sources section to make it unique
- Change the source in the tools section to the name replaced above
- Rename all tools in the tools section to make the tool names unique

This modified tool will be for mcp-app-manager.

Start the MCP server using the two definitions.

```
./toolbox --tools-files tools1.yaml,tools2.yaml
```

MCP gateway/proxy settings

By using an MCP gateway/proxy with authorization features per tool, you can associate users with toolsets as shown in "4.7.5 Restricting Available Users per Tool".

- Authenticate connected users and retrieve their attributes
- Determine whether the attributes correspond to mcp-app-user or mcp-app-manager
- If mcp-app-user, allow only tools for mcp-app-user
- If mcp-app-manager, allow only tools for mcp-app-manager

This configuration allows end-users to select and use database connections according to their attributes.

4.8 In Combination with the Features Provided by Fujitsu Enterprise Postgres

When using the official binaries or container images of MCP Toolbox for Databases, MCP Toolbox for Databases does not support the following unique features of Fujitsu Enterprise Postgres.

- Changing the default port number
- Connection Manager

- Trace log extension
- Socket timeout feature
- sslservercertcn parameter
- NCHAR support

4.9 Reference

4.9.1 Knowledge Data Search Tools

The following preset tools, uniquely provided by Fujitsu Enterprise Postgres, are available.

Default tool name	Parameter	Feature
db-list-semsearch-tables	None	For text data that allows semantic text search, retrieve a list of its schema, table, and column names. If there are comments in the columns, return the comments as well.
db-semantic-search	Query text for semantic text search, number of chunks to return, schema, table, and column names to search	Performs semantic text search on the specified table, and returns chunks similar to the query and the primary keys of records containing the chunks.
db-hybrid-search	Query text for semantic text search, query text for full-text search, number of chunks to be returned, schema, table, and column names to be searched	Performs a hybrid search on the specified table and returns similar chunks and the primary keys of records containing those chunks. Returns chunks that match either the semantic text search or the full-text search conditions.

4.9.2 SQL Generation Support Tools

Default tool name	Parameter	Feature	Remarks
db-database-overview	None	Get the current status of the PostgreSQL server. Returns the version, whether it's a replica, uptime, max connections, current connections, active connections, and percentage of connections in use.	
db-execute-sql	SQL statement	Execute SQL statements.	For details, refer to the postgres-execute-sql tool in the Toolbox.
db-list-schemas	Schema name, Owner, Number of returns	Retrieve a list of schemas in the database, excluding system and temporary schemas. For each schema, return its name, owner, permissions, the number of functions, tables, and views it contains, and any comments on the schema.	

Default tool name	Parameter	Feature	Remarks
db-list-tables	Table name	Retrieves a list of tables in the database, excluding those in the system schema. For each table, you can retrieve its name, constraints, indexes, triggers, owner, and comments.	
db-list-views	Schema name, View name	Retrieve a list of views in the database, excluding those in the system schema. For each view, retrieve its name, owner, definition, and comments.	
db-get-column-cardinality	Column name, Schema name, Table name	Returns the estimated cardinality for a specific table column.	For details, refer to the postgres-get-column-cardinality tool in the Toolbox.
db-get-query-plan	Query	For a single SQL statement, generate an EXPLAIN plan without executing it.	
db-list-indexes	Index name, Schema name, Table name	List available indexes, excluding system schemas.	For details, refer to the postgres-list-indexes tool in the Toolbox.
db-list-sequences	Schema name, Sequence name	Get a list of sequences in the database.	For details, refer to the postgres-list-sequences tool in the Toolbox.
db-list-tablespaces	Tablespace name	Get a list of tablespaces in the database.	For details, refer to the postgres-list-tablespaces tool in the Toolbox.
db-list-pg-settings	Configuration parameter name, Number of returns	List to 50 PostgreSQL server configuration parameters and their values by default.	For details, refer to the postgres-list-pg-settings tool in the Toolbox.
db-list-memory-configurations	None	List memory-related configurations in the database.	

Chapter 5 Model Management in the Database

Vectorization is performed using pre-trained models called embedding models. By managing models in a database, you can integrate model deployment (loading) with database operations and achieve fine-grained access control at the model level. When managing models in a database, you can use ONNX format models that integrate a series of processes for vectorization into a single file. Additionally, to perform vectorization (inference by the model), a inference server called Triton Inference Server is used.

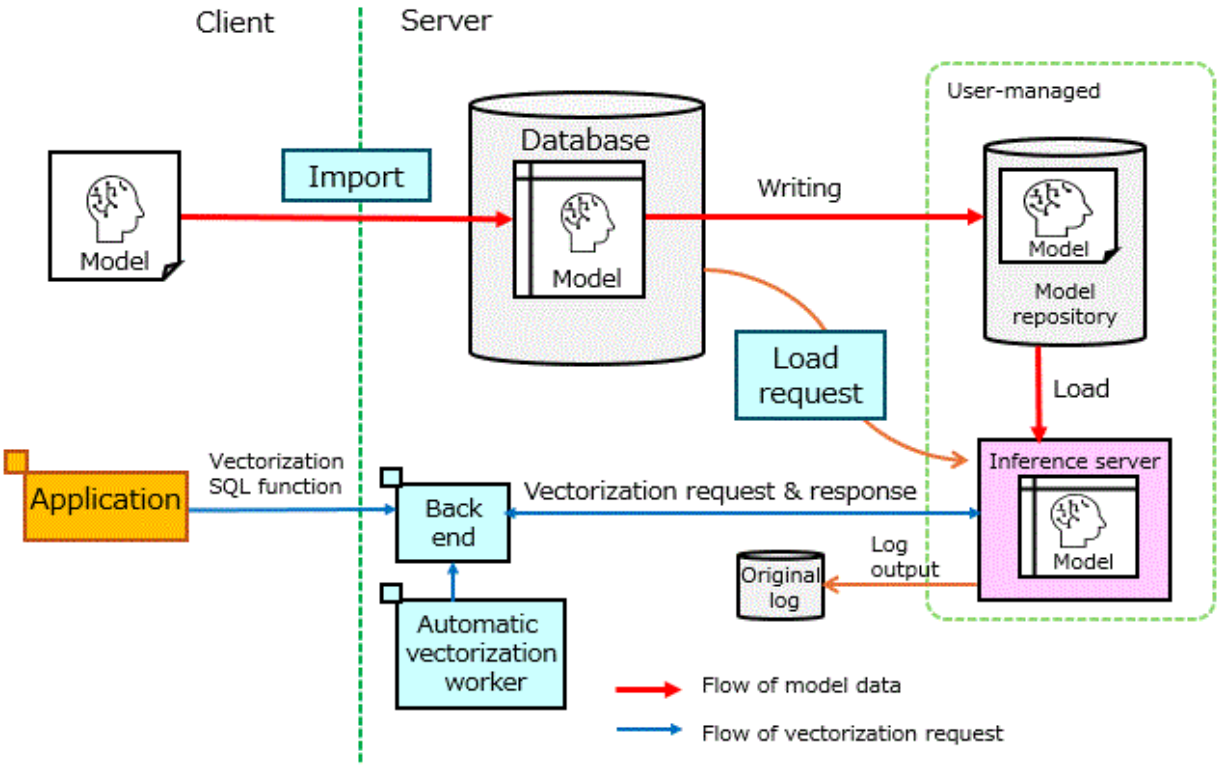
For the formats of models that can be handled by Fujitsu Enterprise Postgres, refer to the "5.5.2 Database-side Model Specifications". Also, for requirements regarding the inference server, refer to "5.5.1 Requirements for the Inference Server".

5.1 Overview

Import the ONNX format text embedding model for vectorization into the database and operate it on an inference server running outside the database. This allows the model to be imported and made available for use through database operations alone, enabling vectorization and semantic text search with the model.

This feature provides an import command as a client feature to INSERT the model file into a table within the database. This operation is called import. After importing the model, a request is executed to make it ready for vectorization using the model. This is called a load request. When a load request is made, the model is loaded onto the inference server, making vectorization using the model possible. The inference server is the server that actually performs calculations based on the model.

Once the model is loaded, vectorization using the model becomes possible. The vectorization process is realized by requesting the inference server to transform text data into vector data and receiving the vector data. The backend process handles the request for vectorization to the inference server and the reception of results.



5.2 Vectorization using ONNX Model

Explain the procedure for vectorization using the ONNX model.

5.2.1 Introduction/Setup

5.2.1.1 Starting the Inference Server

This feature uses Triton Inference Server as the inference server.

Before using this feature, start the Triton Inference Server on the same machine as the database.

Fujitsu Enterprise Postgres provides a sample Dockerfile that meets the above requirements. To create a container image using this sample file, execute the following command. Set the appropriate label for the volumepath option (v option) so that the directory on the host side is visible from the container. "*<x>*" indicates the product version.

```
cp /opt/fsepv<x>server64/share/triton_dockerfile.sample ./triton_dockerfile
$ podman build -f ./triton_dockerfile -t triton_image
$ mkdir -p /path/to/model/repository
$ podman run -d --name triton_container -p8001:8001 -p8002:8002 -v /path/to/model/
repository:/models \
triton_image tritonserver --model-repository=/models --http-port=0 --grpc-port=8001 \
--metrics-port=8002 --backend-config=onnxruntime,device=cpu --model-control-mode=explicit
\
--log-info=true --log-warning=true --log-error=true --log-verbose=0
$ podman container ls # Confirm that the container is running.
```

By using systemd, you can automatically start the created container. Below is an example of starting an inference server as a service using a sample file necessary for the automatic start of the container.

```
$ cp /opt/fsepv<x>server64/share/triton.container.sample \
~/.config/containers/systemd/triton.container
$ systemctl --user daemon-reload
$ systemctl --user start triton.service
```

To achieve model-level access control, configure mutual TLS authentication(mTLS authentication) on the inference server. For details, refer to "5.3.4 Security".

Enable metrics on the inference server to identify the cause when problems occur. Also, enable timestamp formatting for log output.

5.2.1.2 Setting Parameters in the postgresql.conf File

This feature is provided as an extension called pgx_inference. To use the pgx_inference extension, set the following parameters in the postgresql.conf file.

- shared_preload_libraries

  Add pgx_inference. As a result, when the database instance is started, the load launcher is initiated internally.

- max_worker_processes

  Add the number of databases to enable this feature +1. This is the number of worker processes that will be started with this feature.

- pgx_inference.triton_model_repository_path

  Set the path of the model repository specified when setting up the inference server. You can only set the path on the machine where the database is running. It is recommended to prepare a dedicated directory for this function, as model files will be generated or deleted in the directory set in this parameter during loading.

- pgx_inference.triton_grpc_port

  This is the port number used when sending requests to the inference server via gRPC. Set the gRPC port number specified during the setup of the inference server.

- pgx_inference.triton_ort_extensions_library_filename

  Specify the absolute path of the shared library (onnxruntime-extensions) on the server where the Triton Inference Server is running.
  If you use the Dockerfile provided as a sample without changing the installation location of onnxruntime_extensions within the container, set /opt/tritonserver/onnxruntime_extensions/lib/libortextensions.so.

If mTLS authentication is configured on the inference server, set the pgx_inference.triton_use_ssl parameter. For details on the pgx_inference.triton_use_ssl parameter, refer to "5.5.6 Parameters".

5.2.1.3 Enabling pgx_inference and Starting the Load Launcher

Enable the pgx_inference extension and start the load launcher. Additionally, this feature is used in conjunction with automatic vectorization and semantic text search by pgx_vectorizer. If you want to perform semantic text search and automatic vectorization using a model imported into the database, set up pgx_vectorizer along with this feature. For instructions on setting up pgx_vectorizer, refer to "3.2.2.2 Setting Up pgx_vectorizer".

Enabling pgx_inference extension

Execute CREATE EXTENSION for the database that will use this feature.

```
CREATE EXTENSION pgx_inference CASCADE;
```

Starting load launcher

Start the load launcher with the user who executed CREATE EXTENSION.

```
SELECT pgx_inference.pgx_launch_load_launcher();
```

For unsetting pgx_inference, refer to "5.4.1 Removing of pgx_inference".

5.2.2 Model Import and Load

Import the model into the database and load it onto the inference server to enable vectorization using the model.

5.2.2.1 Setting Privilege

This feature is initially available only to the extension owner (the database user who enabled the extension) immediately after installation. For other database users to use this feature, privilege must be granted by the extension owner. The extension owner grants model import and loading privileges to appropriate users. Meanwhile, the model owner grants model usage privileges to appropriate users.

Refer to "5.3.1 Privilege Management" for setting privilege.

5.2.2.2 Model Preparation

Prepare the ONNX pipeline model to be used with this feature.

An ONNX pipeline model is an embedding model that takes text as input and generates embeddings as output. The core of a text embedding model is a neural network model expressed in ONNX format or similar (hereafter referred to as the core model). However, to perform text embedding (vectorization), not only the core model is needed, but also preprocessing such as tokenization and post-processing such as pooling. There are various methods for tokenization and pooling, but they are not independent of the core model and need to be used in combination as intended by the developer. Fujitsu Enterprise Postgres uses a model called the ONNX pipeline model, which consolidates the entire pipeline process for performing text embedding into a single ONNX format file. The specifications for ONNX pipeline models that can be imported with this feature are defined as "5.5.2 Database-side Model Specifications".

5.2.2.3 Model Import

A user with privilege can import a model that meets the database-side model specifications into the database by executing the import subcommand of the pgx_aimodel_tool command. The user who imports the model becomes the owner of that model.

The imported model name and metadata can be checked by executing pgx_get_model_metadata function.

See

For details on the pgx_aimodel_tool command, refer to "pgx_aimodel_tool" in the Reference.

Import the model file on the client

```
pgx_aimodel_tool import -f ./model.onnx -n sample-model-v1 -F embedding -m
'{"version":"v1"}' -d rag_db -h localhost -p 27500 -U model_owner
```

Check the imported model

```
SELECT * FROM pgx_inference.pgx_list_model_metadata();
id |      name         |   function    |         metadata           | model_file_oid |
file_size   | owner |
---+-----------------+-------------+------------------------+---------------
+-----------+------|
1  | sample-model-v1 | embedding    | {"metadata": "sample1"} |      16767    |90000000  |
16329|
2  | sample-model-v2 | embedding    | {"metadata": "sample2"} |      16782    |60000000  |
16330|

(1 row)

SELECT * FROM pgx_inference.pgx_get_model_metadata('sample-model-v1');
id |      name         |   function    |         metadata           | model_file_oid |
file_size   | owner |
---+-----------------+-------------+------------------------+---------------
+-----------+------|
1  | sample-model-v1 | embedding    | {"metadata": "sample1"} |      16767    |90000000  |
16329|

(1 row)
```

Example) When an existing model name is specified as an argument

```
pgx_aimodel_tool import -f ./model.onnx -n sample-model-v1 -F embedding -m
'{"version":"v1"}' -d rag_db -h localhost -p 27500 -U model_owner
pgx_aimodel_tool: error: query failed: ERROR:  model "sample-model-v1" already exist
HINT:  To overwrite the existing model, specify the "--update-on-conflict" option.
```

Example) When overwriting an imported model with the same name

```
pgx_aimodel_tool import -f ./model.onnx -n sample-model-v1 -F embedding -m
'{"version":"v1"}' --update-on-conflict -d rag_db -h localhost -p 27500 -U model_owner
pgx_aimodel_tool: model "sample-model-v1" import completed
```

5.2.2.4 Model Load/Unload

Users who qualify as system administrators for this feature can request the loading of imported models into the database by executing the pgx_load_model function. When a model load is requested, the load launcher running in the database loads the specified model file into the inference process. At this time, the model file is output to the directory set in pgx_inference.triton_model_repository_path parameter.

When the pgx_unload_model function is executed, it requests unloading for the model specified in the argument. As with loading, the requested model is unloaded from the inference server by the load launcher. Once the model is unloaded, vectorization and semantic text search using that model can no longer be performed.

Example) Model load request and retrieval of list

```
SELECT pgx_inference.pgx_load_model('sample-model-v1');
pgx_load_model
-----------------

SELECT * FROM pgx_inference.pgx_list_model_load_requests();
        Name      |     requests    |           last_updated
------------------+-----------------+-----------------------------------
 sample-model_v1  |  load           |  Wed Aug 02 19:09:16.200357 2025 PDT
```

After loading the target model, if the total size of all loaded models exceeds the value set in total_model_size_limit, the loading will result in an error.

```
SELECT pgx_inference.pgx_load_model('sample-model-v1');
ERROR:  could not load model "sample-model-v1"
DETAIL:  toal model size exeed 1000MB
```

Example) Model unload request

```
SELECT pgx_inference.pgx_unload_model('sample-model-v1');
pgx_unload_model
-----------------
```

To check whether the model is available/unavailable after executing the pgx_load_model function and the pgx_unload_model function, check the pgx_triton_model_status view. If the model is unavailable, the reason will be displayed in the reason column of the pgx_triton_model_status view.

Models requested to be loaded will automatically load even after instance restart. Also, load requests propagate to all standby servers and are loaded on each server. Unload requests are also synchronized to all standby servers.

5.2.2.5 Deletion of Imported Model

The imported model can be deleted using the pgx_drop_model function. The pgx_drop_model function specifies the model name. Model deletion can be performed by the model owners and system administrators.

If the model is in use by the automatic vectorization feature, the model cannot be deleted. The model cannot be deleted if it is loaded.

```
SELECT pgx_inference.pgx_drop_model('sample-model-v1');
pgx_drop_model
-----------------
```

5.2.3 Definition of Vectorization

To achieve semantic text search using the imported model with this feature, specify the imported model when defining the vectorization You can use the imported model for vectorization by specifying pgx_vectorizer.pgx_embedding_onnx in the embedding argument of pgx_vectorizer.pgx_create_vectorizer. Specify the model name and the number of dimensions of the generated vector in pgx_vectorizer.pgx_embedding_onnx.

If an unavailable model is specified when executing pgx_create_vectorizer, a warning message will be output. Follow the warning message to load the specified model.

Example) Vectorization definition

Vectorization is defined for the text format knowledge data table "sample_table".

```
SELECT pgx_vectorizer.pgx_create_vectorizer(
'sample_table'::regclass,
destination => 'sample_embeddings',
embedding => pgx_vectorizer.pgx_embedding_onnx('sample-model-v1',384),
chunking => ai.chunking_recursive_character_text_splitter('contents'),
processing => ai.processing_default(batch_size => 200, concurrency => 1),
```

```
scheduling => pgx_vectorizer.schedule_vectorizer(interval '1 hour'),
indexing => ai.indexing_hnsw(min_rows =>50000, opclass => 'vector_cosine_ops'),
);
```

5.3 Operaion

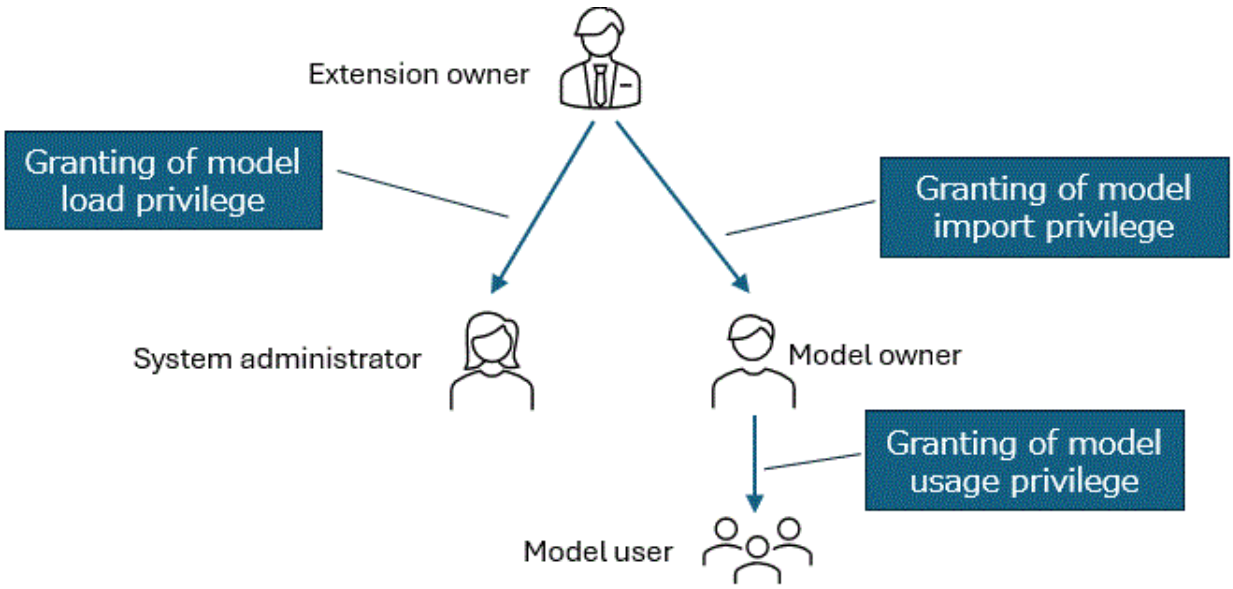
5.3.1 Privilege Management

Explain the privilege for the model.

Users with model import privileges can import their models into the database. The user who imports the model becomes the owner of that model. Only users authorized by the model owner can use that model.

Loading a model requires separate model loading privileges from importing.

The extension owner grants model import and loading privileges to appropriate users. Meanwhile, the model owner grants model usage privileges to appropriate users.



The roles of each user are as follows:

Extension owner: Grants appropriate privileges to each user.

Model owner: Manages each model and grants execution privileges for the model.

System administrator: Properly manages disk consumption and memory usage by the model.

Model user: Uses the model for inference (vectorization).

Additionally, each user is assigned "possible operations (execution of commands and functions)" and "privileges that can be granted or revoked to others". These are shown in the table below.

Operation/Privilege		Extension owner	Model owner	System administrator	Model user
Operation (Execution of commands and functions)	Import model	Possible	Possible	Impossible	Impossible
	Delete model	Possible	Only my model is possible	Possible	Impossible
	Update model	Possible	Only my model is possible	Impossible	Impossible

Operation/Privilege		Extension owner	Model owner	System administrator	Model user
	Refer to model file	Possible	Only my model is possible	Impossible	Impossible
	Load/Unload model	Possible	Impossible	Possible	Impossible
	Reference to the total size of the loaded models	Possible	Impossible	Possible	Impossible
	Use model	Possible	Only my model is possible	Impossible	Only permitted models are possible
	Refer to metadata	Possible	Only my model is possible	Possible	Only permitted models are possible
	Refer to model status	Possible	Only my model is possible	Possible	Only permitted models are possible
Granting/ revoking privilege to others	Import model	Possible	Impossible	Impossible	Impossible
	Delete model	Possible	Impossible	Impossible	Impossible
	Update model	Possible	Impossible	Impossible	Impossible
	Load/Unload model	Possible	Impossible	Impossible	Impossible
	Use model	Possible	Only my model is possible	Impossible	Impossible
	Execution privilege for referencing metadata (function)	Possible	Only my model is possible	Impossible	Impossible
	Execution privilege for referencing model status (function)	Possible	Only my model is possible	Impossible	Impossible

Granting and revoking the necessary privileges for model owners and system administrators is done using the pgx_grant_model_role function and the pgx_revoke_model_role function. These functions can only be executed by extension owners.

Example) Granting of privilege

```
SELECT pgx_inference.pgx_grant_model_role('target_user_name','model_owner') - Grant model
owner privilege to the user named "target_user_name"
```

Example) Revoking of privilege

```
SELECT pgx_inference.pgx_revoke_model_role('target_user_name','model_owner') - Revoke
model owner privilege to the user named "target_user_name"
```

Model users need EXECUTE privileges for the function corresponding to the model ID. The owner of the model should execute the GRANT and REVOKE statements to grant or revoke these privileges.

When a model is imported, it is stored in a table called pgx_models. At this time, a model ID is assigned to the imported model. A function is created for this model ID, which is called the function corresponding to the model ID. The function name corresponding to the model ID can be obtained using the pgx_get_function_by_model_name function.

```
SELECT pgx_inference.pgx_get_function_by_model_name('target_model');
pgx_get_function_by_model_name
-----------------
pgx_embedding_1
(1 row)

GRANT EXECUTE ON FUNCTION pgx_inference.pgx_embedding_1(text) TO target_user_name;
```

To use the functions provided by this feature, you need USAGE privilege on the pgx_inference schema. These privileges are granted to system administrators and model owners through the pgx_grant_model_role function. For model users, the extension owners needs to grant USAGE privilege. As shown in the table above, simply granting USAGE privilege does not allow users to reference or use the model, so it is possible to grant USAGE privilege in advance.

To achieve model-level access control, access control in Triton Inference Server is also necessary. For more details, refer to "5.3.4 Security".

5.3.2 Backup/Restore

All data saved in the tables created by this feature will be subject to backup. For the tables created by this feature and the data saved in them, refer to "5.5.5 Tables/Views".

Files generated in the directory set in pgx_inference.triton_model_repository_path parameter do not need to be backed up. This is because these files are created based on the data stored in the table each time the model is loaded.

If the restore destination instance or database is using this feature, you need to unload and delete the models used in the restore destination instance or database from the inference server before performing the restore. Follow the procedures described in "5.4.1 Removing of pgx_inference" to unload and delete all models.

When restoring backup data created by the pg_dump command or the pg_dumpall command, perform it on a database that is not using this feature. If the target database for restoration already has a model imported, restoration may not be possible. The procedures for restore varies depending on whether or not the semantic text search and the automatic vectorization feature are used.

When using semantic text search and the automatic vectorization feature

Backups are obtained using the pg_dump command. You cannot restore using a backup obtained with the pg_dumpall command.

When performing a restore, the parameters listed in "5.2.1.2 Setting Parameters in the postgresql.conf File" must be set on the instance where the restore is being performed. Additionally, restore separately for each schema where extensions are created.

1. Obtain a backup using the pg_dump command.
   Since the model file is saved as a large object, explicitly specify the -b(--large-objects) option.

   Example)

   ```
   pg_dump -U postgres -d olddb -b -Fc -v -f ./backup_file.dmp
   ```

2. Restore only definitions with the --schema-only option of the pg_restore command.

   Example)

   ```
   pg_restore -U postgres -d newdb --schema-only ./backup_file.dmp
   ```

3. Restore data other than pgai and pgx_vectorizer using the pg_restore command.

   Example)

```
pg_restore --exclude-schema=ai --exclude-schema=pgx_vectorizer --data-only -d newdb ./
backup_file.dmp
```

4. Disable triggers to avoid unique constraint violations with the pg_restore command, and restore the data for pgai and pgx_vectorizer.

   Example)

```
pg_restore --schema=ai --schema=pgx_vectorizer --data-only -d newdb --disable-
triggers ./backup_file.dmp
```

When not using semantic text search and the automatic vectorization feature

Use the backup obtained with the pg_dump command to restore with the pg_restore command.
Since model files are saved as large objects, explicitly specify the -b (--large-objects) option of the pg_dump command. When performing a restore, the parameters listed in "5.2.1.2 Setting Parameters in the postgresql.conf File" must be set on the instance where the restore is being performed.

Example)

```
pg_dump -U postgres -d olddb -b -Fc -v -f ./backup_file.dmp
pg_restore -d newdb ./backup_file.dmp
```

Additionally, you can use the backup obtained with the pg_dumpall command to restore with the psql command.

Example) Backup the instance to be backed up using the pg_dumpall command

```
pg_dumpall -U postgres > pg_dumpall.sql
```

Example) Execute a restore on the instance to be restored

```
psql -U postgres -f pg_dumpall.sql
```

5.3.3 Streaming Replication/Database Multiplexing

When using this feature in a streaming replication or database multiplexing configuration, set up and start the Triton Inference Server on the standby server as well.

In a streaming replication or database multiplexing system, the following operations can only be performed on the primary server.

- Model import
- Model load request/unload request
- Deletion of imported model
- Ggranting access privilege to model/revoking access privilege

These operations performed on the primary server are all replicated to the standby server.

5.3.4 Security

The access privilege for the data stored in the table of this feature are automatically set according to the privileges described in "5.3.1 Privilege Management".

You can use PostgreSQL's security features for the data stored in the table of this feature. If you use transparent data encryption, place the database that uses this function in an encrypted tablespace. This is because the model file is saved in a system catalog called pg_largeobject.

If you want to restrict users who can use the model on a per-model basis, configure the inference server to allow access only from Fujitsu Enterprise Postgres. Specifically, enable mTLS authentication on the inference server and allow only the client certificate used by Fujitsu Enterprise Postgres.

Point

The model files created in the directory specified by the pgx_inference.triton_model_repository_path parameter during model loading are not protected by transparent data encryption. If you want to reduce the risk of model file leakage even slightly, specify a volatile temporary area such as tmpfs for pgx_inference.triton_model_repository_path parameter, and promptly delete unnecessary model files yourself after use. If high confidentiality is required, consider encrypting the entire file system or disk.

5.3.5 Resource Control

In this feature, the model is loaded into memory for calculations based on the model by the inference server. During actual calculations, CPU resources are used. In this feature, resources on the same machine are shared between the database and the inference server. Therefore, it is necessary to consider the impact of resource usage such as memory, CPU, and disk by the database and inference server on the main operations and appropriately control the resources. Additionally, for each resource, consider the following to ensure that the resources used by this feature are not insufficient.

- Memory
  - Total size of the model to be loaded
- CPU
  - Number of simultaneous vectorization processes
  - Parallelism of a single vectorization process
- Disk resources
  (The directory specified in the pgx_inference.triton_model_repository_path parameter)
  - Total size of the model to be loaded

The memory used by this feature can be controlled with the following parameters.

- pgx_inference.total_model_size_limit

  Set the upper limit for the total size of models that can be loaded into the inference server. Basically, use the default value of -1 (unlimited). Set a value other than unlimited when the memory size on the machine is small or there are multiple system administrators who can load models, and you want to limit the mass loading of models by those users.

Check and manage the official documentation of Triton Inference Server regarding the resources used by Triton Inference Server.

https://docs.nvidia.com/deeplearning/triton-inference-server/user-guide/docs/onnxruntime_backend/README.html

5.3.6 Monitoring/Tuning

5.3.6.1 Monitoring Target

To monitor the state of the load launcher, refer to pg_stat_activity.

If you want to check the total size of model files loaded on the inference server, execute the pgx_get_total_model_size function. Additionally, the status of models loaded on the inference server can be checked in the pgx_triton_model_status view.

The logs output by the inference server and the PostgreSQL server logs are output as separate logs.Check the log file specified during the setup of the inference server. Refer to "3.5.2 Monitoring Vectorization Processing" or "3.5.5 Tuning of Semantic Text Search" to monitor vectorization and semantic text search by the imported model, and if there is a possibility of failure, check the server logs. Refer to the timestamps output in the logs to link the PostgreSQL server logs with the inference server logs.

In this feature, the model imported into the database is managed with the prefix "pgx_" added to the model name managed by Fujitsu Enterprise Postgres on the Triton Inference Server, and the suffix "System Identifier (hereinafter referred to as SystemID)" which is a system-specific value generated when creating the database cluster. For example, if imported with the name "sample_model" into a database cluster with SystemID "7553888845569639366", it will be treated as

"pgx_sample_model_7553888845569639366" on the Triton Inference Server. If an error message related to a specific model is output in the server log of Fujitsu Enterprise Postgres, check the log related to the model with the prefix "pgx_" added to the model name in the Triton Inference Server log.

The SystemID of the database cluster can be checked with the following SQL.

```
SELECT system_identifier FROM pg_control_system();
```

5.3.6.2 Parameter Tuning

The directory set in pgx_inference.triton_model_repository_path parameter will output large model files. To avoid the backup size from becoming bloated, set it outside the database cluster.

For GUC parameters related to memory, basically use the default values. If there are other tasks that you want to prioritize over this function, set each parameter to a value other than the default. If the machine's memory size is small or there are multiple system administrators with model loading privileges, loading the model may deplete memory and affect processes other than this function. In this case, set a value other than unlimited for pgx_inference.total_model_size_limit parameter and impose an upper limit on the total size of models that can be loaded.

See

For more information on managing the resources used by the inference server, refer to the official documentation of Triton Inference Server.

https://docs.nvidia.com/deeplearning/triton-inference-server/user-guide/docs/onnxruntime_backend/README.html

5.4 Management/Maintenance of pgx_inference

5.4.1 Removing of pgx_inference

Before deleting this feature, unload and delete all models used by this feature from the inference server.

Unload model

```
SELECT pgx_inference.pgx_unload_all_models();
```

The unload process is performed asynchronously. Refer to the pgx_triton_model_status view to confirm that the unload process is complete.

Delete model

After unloading is complete, delete all models.

```
SELECT pgx_inference.pgx_drop_all_models();
```

After unloading and deleting all models, connect to the database where this feature is used and execute DROP EXTENSION.

```
DROP EXTENSION pgx_inference;
```

When using semantic text search and automatic vectorization features with pgx_vectorizer, execute DROP EXTENSION for pgx_vectorizer with the CASCADE option specified.

```
DROP EXTENSION pgx_vectorizer CASCADE;
```

5.5 Reference

5.5.1 Requirements for the Inference Server

The Triton Inference Server to be used as the inference server for this feature must meet the following requirements.

- The version of Triton Inference Server must be 2.20.0 or later and meet the following requirements:
  - The following APIs are available.

    For details about the API, refer to the official documentation of Triton Inference Server.

    - Model loading: RepositoryModelLoad
    - Model unloading: RepositoryModelUnload
    - Inference: ModelInfer/ModelStreamInfer
    - Model status check: RepositoryIndex
    - Model interface check: ModelConfig
  - The model repository has the structure described in the official documentation of Triton Inference Server.
  - The automatic completion feature of the configuration file is available.
- The model repository of the Triton Inference Server must be located in a place accessible as a local file by Fujitsu Enterprise Postgres.
- It must be accessible via gRPC API.
- ONNX Runtime must be enabled as the backend.
- Including onnxruntime-extensions built without Python, supporting custom operators for the tokenizer.
- The --model-control-mode option is specified as explicit.

5.5.2 Database-side Model Specifications

You can use a model with the following specifications as an embedded model.

Item	Constraint	Remarks
Model format	ONNX format	
Model type (semantics)	Inference Model (Stateless Model)	It is not a learning model (not a stateful model).
Input tensor	1-dimensional tensor of STRING type. It may optionally have an additional dimension for batch processing. It should not require any other inputs (without default values).	
Output tensor	1-dimensional tensor of FLOAT16 type. It may optionally have an additional dimension for batch processing.	Because the vector type in Fujitsu Enterprise Postgres is a single-precision floating-point type.
Operator set and operator	Only operators included in the following domain/version operator sets should be used. ai.onnx: Version X to Y ai.onnx.ml: Version X to Y (Operators provided by onnxruntime-extensions) Ensure that the versions of ai.onnx and ai.onnx.ml are supported by the ONNX Runtime that the Triton server uses as its backend.	Even if the conditions are met, operators not provided by onnxruntime's CPUProvider cannot be used.
Model size	4TB or less	

5.5.3 Characters Available for Use in Model Names

For the model name of the model to be imported with this function, use the following characters. Including characters other than the following may result in failure to load or call the API.

- Alphanumeric (A-Z, a-z, 0-9)
- Underscore (_)
- Hyphen (-)
- Dot (.)

However, the following usages are not allowed.

- Dots cannot be used at the beginning or end. It may be mistaken for a hidden/special name.
- Consecutive dots (..) cannot be used as they may cause path interpretation issues.
- The same model name cannot be used within an instance.

5.5.4 Functions

Function	Return type	Description
pgx_list_model_metadata()	SETOF pgx_models	Get a list of imported models.
pgx_get_model_metadata(model_name text)	SETOF pgx_models	Get detailed information of the specified model.
pgx_get_total_model_size()	bigint	Get the total size of the currently loaded model files.
pgx_load_model(model_name text)	void	Execute the load request for the specified model. If the specified model is not imported, and after loading the model specified in the argument, the total size of all loaded models exceeds the value set by the pgx_inference.total_model_size_limit parameter, the execution will fail.
pgx_unload_model(model_name text, force boolean DEFAULT FALSE)	void	Executes the unload request for the specified model. If the specified model is not imported, and there is a vectorizer referencing the specified model, execution will fail. If the argument force is set to true, the unload request is executed forcibly.
pgx_get_model_load_request(model_name text)	SETOF record	Retrieve records from the pgx_model_load_requests table that correspond to the specified model. The model name is returned instead of the model ID.
pgx_list_model_load_requests()	SETOF record	Retrieve load and unload requests for all models. The model name will be returned instead of the model ID.
pgx_drop_model(model_name text)	void	Delete the imported model.
pgx_grant_model_role(user_name text, role text)	void	Grant the privileges held by the specified role to the user specified by user_name. This function can only be

Function	Return type	Description
		executed by the user who performed CREATE EXTENSION for this feature. The role can be specified as model_owner, meaning the model owner, or system_admin, meaning the system administrator.
pgx_revoke_model_role(user_name text, role text)	void	Revoke the privileges held by the specified role from the user specified by user_name. This function can only be executed by the user who created the extension for this feature. The role can be specified as model_owner, meaning the model owner, or system_admin, meaning the system administrator.
pgx_get_function_by_model_name(model_name text)	text	Get the name of the function created for the model specified in model_name.
pgx_onnx_embed(model text, text_to_infer text)	vector	The specified model is used to convert the text specified in text_to_infer into vectors. If the model specified in the model is not imported or is unavailable, the execution will fail.
pgx_launch_load_launcher()	void	Start the load launcher, which is a worker process that executes load processing.
pgx_unload_all_models()	void	Execute unload requests for all models. Even if there is a vectorizer referencing the model, a message will be output and the unload request will be executed. This function can only be executed by the extension owner.
pgx_drop_all_models()	void	All models will be deleted. Even if you are using models with the automatic vectorization feature, a message will be output and deletion will be performed. This function can only be executed by the extension owner. This function should only be used when returning this feature to an unused state.

5.5.5 Tables/Views

pgx_models table

It can only be referenced as the return value of the pgx_list_model_metadata function and the pgx_get_model_metadata function.

Column	Type	Constraint	Description
id	bigint	PRIMARY KEY	ID assigned to the model
name	text	UNIQUE	Name of the imported model

Column	Type	Constraint	Description
		NOT NULL	
function	text	NOT NULL	The process executed by the imported model. Only embedding can be specified.
metadata	jsonb	NOT NULL	Metadata of the imported model
model_file_oid	oid	NOT NULL	The oid of the model file imported as a large object
file_size	bigint	NOT NULL	Size of the imported model file
owner	oid	NOT NULL	Model owner

pgx_model_load_requests table

It can only be referenced as the return value of the pgx_list_model_load_requests function and the pgx_get_model_load_request function.

Column	Type	Constraint	Description
id	bigint	PRIMARY KEY FOREIGN KEY (id) REFERENCES model_metadata ON DELETE CASCADE	Model ID
request	text		Request sent to the model
last_updated	timestamp with timezone	NOT NULL DEFAULT clock_timestamp()	The time the request was sent

pgx_triton_model_status view

Column	Type	Constraint	Description
id	bigint	PRIMARY KEY FOREIGN KEY (id) REFERENCES model_metadata ON DELETE CASCADE	Model ID
is_available	boolean	NOT NULL	Whether the model is available or not TRUE: Available FALSE: Not Available
reason	text		Reasons why the model is available or unavailable

5.5.6 Parameters

Parameters to set in the postgresql.conf file are shown.

Parameters related to memory

- pgx_inference.total_model_size_limit (integer)

  Set the upper limit for the total size of model files that can be loaded. The default value is -1 (unlimited). If the unit is not specified, it is considered as MB.

Parameters related to the inference server

- pgx_inference.triton_model_repository_path (string)

  Set the path of the model repository specified during the setup of the inference server used in conjunction with Fujitsu Enterprise Postgres. This cannot be omitted. If omitted, the database instance will fail to start. This directory must have permissions set so that the OS user starting Fujitsu Enterprise Postgres can read and write. If the privileges are inappropriate, a warning appears in the server log.

- pgx_inference.triton_ort_extensions_library_filename (string)

  This corresponds to the model_operations.op_library_filename of the Triton Inference Server. Specify the absolute path of the shared library (onnxruntime-extensions) on the server where the Triton Inference Server is running. If you use the Dockerfile provided as a sample without changing the installation location of onnxruntime_extensions within the container, set /opt/tritonserver/onnxruntime_extensions/lib/libortextensions.so.
  To reflect changes in the value, restart the database instance. It cannot be omitted. If omitted, the database instance will fail to start.

- pgx_inference.triton_grpc_port (integer)

  This is the port number used when sending requests to the inference server. set the port number specified during the setup of the inference server. The default value is 8001.

- pgx_inference.triton_use_ssl (boolean)

  Specify whether to enable SSL communication with the Triton Inference Server. The default value is false.

- pgx_inference.triton_grpc_root_certificates (string)

  Specify the path to the CA file for verifying the server certificate chain used for gRPC connection. If the pgx_inference.trtion_use_ssl parameter is true, it cannot be omitted. If omitted, the instance will fail to start.

- pgx_inference.triton_grpc_certificate_chain (string)

  Specify the path of the client certificate chain used for gRPC connection. If the pgx_inference.trtion_use_ssl parameter is true, it cannot be omitted. If omitted, the instance will fail to start.

- pgx_inference.triton_grpc_private_key (string)

  Specify the path to the client private key used for gRPC connection. If the pgx_inference.trtion_use_ssl parameter is true, it cannot be omitted. If omitted, the instance will fail to start.

L

Chapter 6 Graph Management Feature

This chapter describes the graph management feature that provide graph storage and search.

Refer to the Apache AGE documentation for more details.

6.1 Overview of Graph Management Feature

The graph management feature enables you to store and search property graphs in Fujitsu Enterprise Postgres. A graph is a data structure that represents relationships between entities using nodes and edges that connect the nodes. A property graph is a type of graph in which nodes and edges can have information called properties. Graphs that represent relationships can be searched based on relationships and properties. Graph searches are performed using openCypher, a query language for graph databases.

6.2 Installation of Graph Management Feature

Graph management features are provided by the OSS's Apache AGE.

6.2.1 Setting Up the Graph Management Feature

Refer to "Apache AGE" in the Installation and Setup Guide for Server to set up Apache AGE.

6.2.2 Removing the Graph Management Feature

Refer to "Apache AGE" in the Installation and Setup Guide for Server to remove Apache AGE.

6.3 Creating a Graph

Graphs are stored in Fujitsu Enterprise Postgres as a single virtual data object called a graph. Internally, they are saved as multiple database objects under a schema that has one-to-one correspondence with the graph. Graphs are created and deleted using the create_graph and drop_graph functions, which are SQL functions provided by the graph management feature. If the second argument of the drop_graph function is set to true, the database object under the schema that corresponds to the graph will also be deleted.

Example) Creating a graph

```
SELECT create_graph('new_graph');
NOTICE:  graph "new_graph" has been created
 create_graph
--------------

(1 row)
```

Example) Deleting a graph

```
SELECT drop_graph('new_graph', true);
NOTICE: drop cascades to 2 other objects
DETAIL: drop cascades to table new_graph._ag_label_vertex
drop cascades to table new_graph._ag_label_edge
NOTICE: graph "new_graph" has been dropped
 drop_graph
------------

(1 row)
```

Information

When you create a graph, a schema with the same name as the graph is created. Specify a name that does not overlap with existing schemas. In particular, you cannot use reserved names beginning with pg_. Also, do not use names beginning with pgx_.

The schema corresponding to a graph will be deleted when the graph is deleted. Do not create objects under this schema.

You can view a list of graphs and their corresponding schemas (namespaces) stored in a database with the graph management feature enabled by using the following method.

Example) Graph list

```
SELECT * FROM ag_catalog.ag_graph ;
 graphid |    name    | namespace
---------+------------+------------
   81957 | new_graph  | new_graph
   82576 | new_graph2 | new_graph2
   82598 | sample     | sample
(3 rows)
```

6.4 Storing Graph Data

Adding nodes and edges to a graph is done through Cypher queries using cypher functions, which are SQL functions provided by the graph management feature.

Example) Adding nodes and edges

```
SELECT * FROM cypher('new_graph', $$
 CREATE (:Person {name: 'Daedalus'})-[:FATHER_OF]->(:Person {name: 'Icarus'})
 $$) AS (a agtype);
 a
---
(0 rows)
```

In addition to the above, you can also load from a CSV file using the SQL functions load_labels_from_file and load_edges_from_file.

6.5 Protecting Graph Data

Graphs are automatically protected by backup, multiplexing, or replication settings that specify the tablespace, database, or instance in which the graph is saved.

This section describes the points to keep in mind when protecting graph data using Fujitsu Enterprise Postgres features.

Within Fujitsu Enterprise Postgres, graphs are stored as multiple objects under a schema that has one-to-one correspondence with the graph. To protect a graph, configure protection for the database objects that make up the graph.

6.5.1 Encrypting the Graph

A graph consists of multiple database objects, and even after the graph is created by the create_graph function, a new table will be created when a new label is added. If you want to encrypt multiple database objects that make up a graph, including those that will be created in the future, set the default tablespace of the entire database that stores the graph to an encrypted tablespace.

Example) When encrypting the entire database for which this feature is enabled

```
CREATE DATABASE rag_database TABLESPACE = encrypted_tablespace;
CREATE EXTENSION age;
```

To encrypt a graph when you cannot use a single tablespace per database, temporarily change the default tablespace to an encrypted tablespace before the operation that creates the graph.

Example) Specifying table space and creating a graph

```
SET default_tablespace = 'secure_tablespace';
SELECT create_graph('graph1');
```

6.5.2 Restricting Access to Graph

Access to a graph is restricted by access control for the database objects that make up the graph. Access restrictions are set using the confidentiality management feature of Fujitsu Enterprise Postgres. Since graphs have a one-to-one correspondence with schema objects, you can allow or deny access to a graph by specifying access rights for that schema using the confidentiality management feature as follows:

1. Refer to the "Confidentiality Management" in the Security Operations Guide to define confidentiality management role, confidentiality matrix, confidentiality level, and confidentiality group.
2. Grant confidentiality privilege on the schema to the confidentiality group.

   ```
   SELECT pgx_grant_confidential_privilege('rag_matrix', 'level1', 'group1',  '{"schema":
   ["USAGE"]}');
   ```

3. Add the schema corresponding to the graph as a confidentiality object to the confidentiality level.

   ```
   SELECT pgx_add_object_to_confidential_level ('rag_matrix', 'level1',
   '[{
       "type":"schema",
       "object":[
           {
             "schema":"new_graph"
           }
       ]
   }]');
   ```

4. Add roles to the confidentiality group you created to set access rights to the graph.

   ```
   SELECT pgx_add_role_to_confidential_group('rag_matrix', 'group1', '["rag_user"]');
   ```

If you want to set fine-grained access privileges, such as allowing only searches of graphs but not updating them, you can use SQL statements to directly set access privileges for database objects such as the tables that make up the graph.

The privileges required to access a graph are as follows:

- Privileges required to create a graph
  - CREATE privilege for the database
- Privileges required to create and delete new nodes and edges
  - CREATE and USAGE privilege for the schema with the same name as the graph name
  - When adding a node, ownership of the _ag_label_vertex table under the schema with the same name as the graph name
  - When adding an edge, ownership of the _ag_label_edge table under the schema with the same name as the graph name
  - UPDATE privilege for _label_id_seq under the schema with the same name as the graph name
- Privileges required to create and delete nodes and edges that use existing labels
  - USAGE privilege for the schema with the same name as the graph name

- When adding a node, privileges under the schema with the same name as the graph name
  - INSERT privilege (to create), SELECT privilege, and UPDATE privilege (to delete) for the _ag_label_vertex table or a table with the same name as the label name to be added
  - USAGE privilege for the _ag_label_vertex_id_seq sequence or a sequence with the same name as the label name to be added
- Privileges when adding an edge
  - INSERT (create), SELECT, and UPDATE (delete) privileges for the _ag_label_edge table under the schema with the same name as the graph name or the table with the same name as the label name to be added.
  - USAGE privilege for the _ag_label_edge_id_seq sequence or the sequence with the same name as the label name to be added.

- Privileges required to search graphs.
  - USAGE privilege for the ag_catalog schema.
  - USAGE privilege for the schema with the same name as the graph name.
  - SELECT privilege for the table object in the schema with the same name as the graph name.

Information

Graph data structures do not have the concept of rows and columns, so PostgreSQL's row-level security and column-based access control features cannot be applied.

6.5.3 Recording Access to Graph

The audit log feature of Fujitsu Enterprise Postgres is used to record access to the graph in the audit log. When specifying database objects to be audited individually, specify each database object that constitutes the graph.

When adding new labels to a graph, new corresponding tables are created, so those tables must also be specified as targets for auditing.

6.6 Searching Graph

Graph searches are performed using Cypher queries. Cypher queries are specified as strings as arguments to the cypher function, which is an SQL function.

For more information about Cypher queries, refer to the Apache AGE documentation.

Example) Graph search

```
SELECT * FROM cypher('new_graph', $$
 MATCH (:Person {name: 'Daedalus'})-[:FATHER_OF]->(person)
 WITH person.name AS name ORDER BY person.name RETURN name
 $$) AS (v agtype);
    v
----------
 "Icarus"
(1 row)
```

Graph searches allow you to retrieve specific property values or sets of properties for nodes or edges that match a condition. Properties are returned in agType data type added by the graph management feature, which is compatible with JSON types. Graph searches are closed to cypher functions, but the retrieved values can also be combined with searches of other tables in the database.

Example) Combination

```
SELECT (x::json->'properties')->'name' FROM cypher('new_graph', $$
MATCH (x)
```

```
RETURN x $$) AS (x agtype);
  ?column?
------------
 "Daedalus"
 "Icarus"
(2 row)
```

6.7 Adding Labels to Graph

Labels in a graph represent the type of node or edge, and are an important element in expressing the schema of knowledge data stored as a graph. Adding a label is easier than adding a column to a table, but you should plan carefully and consider the impact on your application. By default, only the database user who created the graph can add new labels.

When adding nodes or edges with new labels to a graph, new tables corresponding to each label are created. To encrypt a graph, change the default tablespace to an encrypted tablespace before adding labels. The access rights for these newly created tables are inherited from the access rights for the tables for unlabeled nodes or unlabeled edges, so no additional steps are required if you want to reuse those access rights.

You can check the tablespaces in which tables corresponding to each label of the graph nodes and edges are located with the following SQL.

```
SELECT g2.graphname AS graphname, c.relname AS relname, c.reltablespace AS reltablespace
FROM pg_class c,
rag_databse->  (SELECT g.name AS graphname, l.relation AS relation FROM
ag_catalog.ag_graph AS g, ag_catalog.ag_label AS l WHERE g.graphid = l.graph) AS g2 WHERE
c.oid = g2.relation;
 graphname  |     relname      | reltablespace
------------+------------------+---------------
 new_graph  | _ag_label_vertex |             0
 new_graph  | _ag_label_edge   |             0
 new_graph  | x                |             0
 new_graph  | y                |             0
 new_graph2 | _ag_label_vertex |             0
 new_graph2 | _ag_label_edge   |             0
 sample     | _ag_label_vertex |         80722
 sample     | _ag_label_edge   |         80722
(8 rows)
```

6.8 Performance Tuning of Graph Search

Graph data is stored internally as multiple tables. Graph data searches are implemented as SELECT statements on those tables. The access plan can be checked with the EXPLAIN statement in the same way as for normal SQL statements.

Graph data consists of a table with a record for each node and a table with a record for each edge, and queries corresponding to graph data are implemented by joining and filtering those tables. Therefore, the approach to performance issues in graph searches is the same as for SELECT statements that include joins.

Example) Checking the access plan of a graph search

```
SELECT * FROM cypher('new_graph', $$
EXPLAIN (COSTS off) MATCH (:Person {name: 'Daedalus'})-[:FATHER_OF]->(person)
WITH person.name AS name ORDER BY person.name RETURN name
$$) AS (v agtype);
 QUERY PLAN
----------------------------------------------------------------------------------------------
-------------------------------------------------------------------------
 Sort
 Sort Key: (agtype_access_operator(VARIADIC ARRAY[_agtype_build_vertex(person.id,
_label_name('25995'::oid, person.id), person.properties), '"name"'::agtype]))
 -> Hash Join
 Hash Cond: (person.id = _age_default_alias_1.end_id)
 -> Append
```

```
 -> Seq Scan on _ag_label_vertex person_1
 -> Seq Scan on "Person" person_2
 -> Hash
 -> Hash Join
 Hash Cond: (_age_default_alias_1.start_id = _age_default_alias_0.id)
 -> Seq Scan on "FATHER_OF" _age_default_alias_1
 -> Hash
 -> Seq Scan on "Person" _age_default_alias_0
 Filter: (properties @> '{"name": "Daedalus"}'::agtype)
(14 rows)
```

6.9 Using Graph Data in Applications

The cypher function returns a value of the agType data type. The agType type is a subset of the json type. If you want to handle this data type directly in your application, please install a driver for each language in your application. If you do not use a driver, the agType type will be returned to your application as a string or JSON type.

See

For driver installation, refer to below.

https://github.com/apache/age/tree/master/drivers

6.10 Visualizing Graph Data

You can use the OSS age-viewer as a tool to visualize graph data.

See

For age-viewer installation, refer to below.

https://github.com/apache/age?tab=readme-ov-file#graph-visualization-tool-for-age

6.11 Internal Structure of Graph Data

When you create a graph, a corresponding schema is created, and tables, indexes, and sequence objects are created under it. For more information, see the Apache AGE documentation.

6.12 Quantitative Limits

The total number of nodes and edges must be less than or equal to 2^48 - 1. This restriction applies only to one particular graph.

6.13 Reference

The following SQL functions are provided, refer to Apache AGE documentation for details:

Function	Description
create_graph	Creating a graph
drop_graph	Deleting a graph
cypher	Manipulating graphs with Cypher queries
load_labels_from_file and load_edges_from_file	Loading the graph data

FUJITSU

Fujitsu Enterprise Postgres 18SP1 for x86

Reference Guide

Windows/Linux

J2UL-3066-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document is a command reference, and explains Fujitsu Enterprise Postgres commands and options with features expanded on from PostgreSQL.

Intended readers

This document is aimed at people who manage and operate Fujitsu Enterprise Postgres. Readers of this document are also assumed to have general knowledge of:

- PostgreSQL
- SQL
- Linux
- Windows

Structure of this document

This document is structured as follows:

Chapter 1 Command List and Specification Format

Lists commands and describes their specification format.

Chapter 2 Client Commands

Explains options not listed in "PostgreSQL Client Applications" in the PostgreSQL Documentation.

Chapter 3 Server Commands

Explains commands and options not listed in "PostgreSQL Server Applications" in the PostgreSQL Documentation.

Chapter 4 Mirroring Controller Commands

Explains the Mirroring Controller commands.

Chapter 5 Connection Manager Commands

Explains the Connection Manager commands.

How to read this document

Examples in this document are predominantly for UNIX/Linux.

For Windows, replace values (such as paths in the examples) as appropriate.

Export restrictions

If this document is to be exported or provided overseas, confirm legal requirements for the Foreign Exchange and Foreign Trade Act as well as other laws and regulations, including U.S. Export Administration Regulations, and follow the required procedures.

Issue date and version

```
Edition 2.0: March 2026
Edition 1.0: December 2025
```

Chapter 1 Command List and Specification Format

This chapter lists commands and describes their specification format.

1.1 Command List

This chapter lists commands and options not explained in "PostgreSQL Client Applications" or in "PostgreSQL Server Applications" in the PostgreSQL Documentation.

1.1.1 Client Commands

The commands below have options not explained in "PostgreSQL Client Applications" in the PostgreSQL Documentation.

Command	Functional overview
pg_dumpall	Extract a PostgreSQL database cluster into a script file

The command below is not explained in "Client Applications" in the PostgreSQL Documentation.

Command	Functional overview
L pgx_aimodel_tool	Import model files into the database
pgx_loader	Loads data from an external file into a PostgreSQL table.

1.1.2 Server Commands

The commands below have options not explained in "PostgreSQL Server Applications" in the PostgreSQL Documentation.

Command	Functional overview
pg_ctl	Initialize, start, stop, or control a PostgreSQL server
postgres	PostgreSQL database server

The commands below are not explained in "PostgreSQL Server Applications" in the PostgreSQL Documentation.

Command	Functional overview
pgx_dmpall	Backs up the data directory, tablespaces, and configuration files.
pgx_fjqssinf	Collects failure investigation data
pgx_keystore	Manages keystore

1.1.3 Mirroring Controller Commands

Mirroring Controller has the following commands:

Command	Functional overview
mc_arb	L Start, stop and display the status of the Mirroring Controller arbitration process. W Start, stop and display the status of the Mirroring Controller arbitration process, or register and unregister as a Windows service.

Command	Functional overview
mc_ctl	L Start and stop Mirroring Controller, switch/ disconnect the server, or display the server status. W Start and stop Mirroring Controller, switch/ disconnect the server, display the server status, or register and unregister as a Windows service.

1.1.4 Connection Manager Commands

Connection Manager has the following commands:

Command	Functional overview
cm_ctl	Start, stop or display the status of the conmgr process

1.2 Command Specification Format

The table below shows the command specification format.

Item	Explanation
[ ]	Indicates optional element.
...	Indicates that the item can be specified repeatedly.

Chapter 2 Client Commands

This chapter explains commands and options not listed in "PostgreSQL Client Applications" in the PostgreSQL Documentation.

2.1 pg_dumpall

Name

pg_dumpall -- Extract a PostgreSQL database cluster into a script file

Synopsis

```
pg_dumpall [connectionOption...] [option...]
```

Options

--no-tablespace-encryption

Do not output commands to encrypt tablespaces. Running the generated SQL script will restore the originally encrypted data without being encrypted.

See

Refer to "pg_dumpall" in the PostgreSQL Documentation for details.

2.2 pgx_aimodel_tool

Name

pgx_aimodel_tool --Import model files into the database

Synopsis

```
pgx_aimodel_tool import { import-option | connection-option }
```

Description

The import mode imports the model file into the database.

Options (import-option)

-f *file*
--file=*file*

Receives input from the specified file. If this option is omitted, the standard input is used.

-n *name*
--name=*name*

Specifies the name of the model to import. Cannot be omitted.

-F *function*
--function=*function*

Specifies the capabilities of the model.
Specify embedding to represent a vector transformation. Cannot be omitted.

-m *metadata*
--metadata=*metadata*

Specifies the metadata of the model to import in JSON format.

--update-on-conflict

If a model with the same name is already imported, it will be overwritten.
If this option is not specified, the import fails.
If a model with the specified model name is already loaded, it will be requested to load again on overwrite, replacing the model on the inference server with the new model.

Options (connection-option)

-d *dbname*
--dbname=*dbname*

Specifies the name of the database to connect to.
dbname can specify a connection string. In that case, the content specified as the connection string takes precedence over options specified on the command line.

-h *host*
--host=*host*

Specifies the host name of the machine on which the database server is running.
If the value begins with a slash, it is used as the directory for the Unix domain socket. If this option is omitted, the value of the environment variable PGHOST is used. If the environment variable PGHOST is not set, it uses a Unix domain socket connection.

-p *port*
--port=*port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. If this option is omitted, the value of the environment variable PGPORT is used. If the environment variable PGPORT is not set, it uses 27500.

-U *username*
--username=*username*

Specifies the user name to connect as.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option is useful when there is no user to enter the password for batch jobs or scripts.

-W
--password

Force this command to prompt for a password before connecting to a database.
This option is never essential, since the command will automatically prompt for a password if the server demands password authentication. However, it will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

Diagnostics

0: Normal exit

Other than 0: Abnormal exit

Example

The following is an example of importing a model file on the client:

```
    $ pgx_aimodel_tool import -f ./model.onnx -n sample-model-v1 -F embedding -m
'{"version":"v1"}' -d rag_db -h localhost -p 27500 -U model_owner
```

2.3 pgx_loader

Name

pgx_loader --Loads data from a file into a PostgreSQL table.

Overview

```
pgx_loader load -c command [options...]

pgx_loader recovery -t table
```

Description

The pgx_loader command loads data from an external file into PostgreSQL tables, and commits or rolls back transactions prepared during data load.

In load mode, data is loaded at high speed by executing the COPY FROM command specified in *command* at a certain degree of parallelism. If load is completed successfully, the message below is output to the standard output.

```
LOAD count
Note: count is the number of rows loaded.
```

Refer the pgx_stat_progress_loader view to see the progress of the load process.

In recovery mode, commit or rollback of transactions prepared during data load is performed.

See

Refer to "pgx_stat_progress_loader" in the Operation Guide for pgx_stat_progress_loader view.

Options

-a
--echo-sql

Display the executed command in the standard output.

-c *command*
--copy-command=*command*

Specify the COPY FROM command to be executed. If STDIN is specified for the FROM clause, data will be loaded from the standard input. In this case, SQL superuser privileges (or having one of the roles pg_read_server_files or pg_execute_server_program) are not required, because local user access privileges will be used for external files and external programs, instead of database server access privileges.

"binary" cannot be specified for the FORMAT option of the COPY FROM command specified in this option. Therefore, input files in binary format cannot be specified.

The FREEZE option cannot be specified for the COPY FROM command specified in this option.

See

Refer to "COPY" in the PostgreSQL Documentation for information on the COPY FROM command.

-j *number-of-jobs*
--jobs=*number-of-jobs*

Specify the number of background workers (parallel workers) that the COPY COMMAND should use to simultaneously perform data conversion, table creation, and index creation. This option can dramatically reduce the time for loading a large amount of data on instances that runs on multiple processor machines.

The optimal value depends on the server, client, and network configurations. The number of CPU cores and disk configuration also affect the optimal value. The number of CPU cores of the server is recommended as the initial value

to try. Naturally, if a value that is too large is used, performance degradation will occur due to thrashing and context switching.

Specify a value from 2 to 128. The default is 2.

-t *table*
--table=*table*

Complete the prepared transactions only for the specified table.

-?
--help

Show how to use pgx_loader command line arguments, and exit.

The command line options below control the database connection parameters.

-d *connstr*
--dbname=*connstr*

Specify the database name to connect to.

If this option is not specified, the PGDATABASE environment variable will be used. If the environment variable is not set, your operating-system user name will be used.

-h *host*
--host=*host*

Specify the host name of the machine the database server runs on. If the specified value starts with a slash, it will be used as the directory for a Unix domain socket.

If this option is not specified, the PGHOST environment variable will be used. If the environment variable is not set, it will be considered a Unix domain socket connection.

-p *port*
--port=*port*

Specify the TCP port to be used by the server to monitor the connection, or extension of the local Unix domain socket file.

If this option is not specified, the PGPORT environment variable will be use. If the environment variables is not set, 27500 will be used.

-U *username*
--username=*username*

User name for connection to the database.

-w
--no-password

Never prompt for the password. If the server requires password authentication but other means (such as a .pgpass file) are not available, the connection attempt will fail. This option can be useful in batch jobs, scripts, and so on, where no user is present to enter a password.

-W
--password

Force pgx_loader to prompt for the password before connecting to the database. This option is never essential, since pgx_loader will automatically prompt for the password if the server demands password authentication. However, pgx_loader will waste a connection attempt finding out if the server requires a password. In some cases it is worth specifying this option to avoid the extra connection attempt.

Diagnostics

load mode

0: Normal exit

Other than 0: Abnormal exit

recovery mode

0: There are no prepared transactions that must be completed

3: A prepared transaction was committed

4: A prepared transaction was rolled back

Other than the above: Abnormal exit

Note

The order of the table rows loaded by pgx_loader may not match the order of the file lines. This is because the file lines will have been inserted into the table in parallel, by multiple parallel workers.

Example

The example below loads the file /path/to/data.csv (2000 records) into table tbl using a degree of parallelism of 3.

```
$ pgx_loader load -j 3 -c "COPY tbl FROM '/path/to/data.csv' WITH CSV"
LOAD 2000
```

The example below reads the file /path/to/data.csv (2000 records) from the standard input and loads into table tbl using a degree of parallelism of 3.

```
$ pgx_loader load -j 3 -c "COPY tbl FROM STDIN WITH CSV" < /path/to/data.csv
LOAD 2000
```

The example below completes the transactions prepared for table tbl.

```
$ pgx_loader recovery -t tbl
```

Chapter 3 Server Commands

This chapter explains commands and options not listed in "PostgreSQL Server Applications" in the PostgreSQL Documentation.

3.1 pg_ctl

Name

pg_ctl -- Initialize, start, stop, or control a PostgreSQL server

Synopsis

```
pg_ctl start [-D datadir] [-l filename] [-W] [-t seconds] [-s]
           [-o options] [-p path] [-c] [--keystore-passphrase | --kms-secret]

pg_ctl restart [-D datadir] [-m s[mart] | f[ast] | i[mmediate] ]
             [-W] [-t seconds] [-s] [-o options] [-c]
             [--keystore-passphrase | --kms-secret]
```

Options

--keystore-passphrase

Prompt for the passphrase to open the keystore when using a file-based keystore.

--kms-secret

When you use a key management system as a keystore, you are prompted to enter secret information to open the keystore.

See

Refer to "pg_ctl" in the PostgreSQL Documentation for details.

3.2 pgx_dmpall

Name

pgx_dmpall - Backs up the data directory, tablespaces, and configuration files.

Synopsis

```
pgx_dmpall  [option...]
```

Description

The pgx_dmpall command backs up the data directory, tablespaces, and configuration files. The backup data is stored in the directory specified by backup_destination parameter of postgresql.conf. The pgx_dmpall command also deletes archived Write Ahead Logs (WAL) that are no longer necessary for recovery when the backup completes successfully.

Options

-c

This option only backs up configuration files. The configuration files are as follows:

- postgresql.conf (postgresql.conf)
- File for host-based authentication (pg_hba.conf)
- Configuration file for ident authentication (pg_ident.conf)

If an external reference, such as 'include' in postgresql.conf, is set, the reference destination files are also backed up.

-C fast|spread
--checkpoint=fast|spread

Sets checkpoint mode to fast or spread (default).
If fast is specified, the checkpoint processing at the start of backup becomes quick, but the impact on performance of running applications gets larger due to intense I/O. In spread mode, the impact on applications is smaller but the backup takes longer, because the checkpoint is performed slowly.

-D *datadir*

Specify the data directory. If this option is omitted, the value of the environment variable PGDATA is used.

-f *configFile*

Specify the postgresql.conf configuration file. This option is set if the data directory and the configuration file set in the 'data_directory' parameter of the postgresql.conf file are running in separate directories.

-P *tablespacesListFile*
--tablespaces-list-file=*tablespacesListFile*

Specify the full path of the file containing the names of the tablespaces to be backed up using the copy command, using less than 1024 bytes.

The file format is described below:

tablespaceName<newline>
tablespaceName<newline>
...

Tablespaces not listed in the specified file are backed up to the backup storage directory. If this option is not specified, all tablespaces are backed up using the copy command.
This option can be specified if the -Y option has been specified, and it is used to limit the tablespaces backed up using the copy command.

-U *username*
--username=*username*

Specify the user name of the database superuser. This defaults to the name of the effective user running pgx_dmpall.

-Y *copyCommandFile*
--copy-command=*copyCommandFile*

Specify the full path of the file of the copy command for backup, using less than 1024 bytes. This option cannot be specified together with the -c option.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force pgx_dmpall to prompt for a password before connecting to a database.

This option is never essential, since pgx_dmpall will automatically prompt for a password if the server demands password authentication. However, pgx_dmpall will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

--maintenance-db=*dbname*

Specifies the name of the database to connect to. If not specified, the postgres database will be used; if that does not exist, template1 will be used.

Any database can be specified as long as it can be connected to.

--exclude-copy-cluster

Excludes a database cluster from backup via the copy command. This option can be specified if the -Y option has been specified. If this option is not specified, the database cluster will be backed up using the copy command.

Environment

PGDATA

Specify the data directory. You can overwrite using the -D option.

Diagnostics

0: Normal end

Other than 0: Abnormal end

Notes

This command can only be executed when the database server is running.

Execute this command as a PostgreSQL user account.

Do not update or delete files in the backup storage directory. Otherwise, you may not be able to recover the database.

Do not store other files in the backup storage directory.

This command uses one database connection. To establish a connection, this command uses the IPv4 loopback address 127.0.0.1 on Windows, and the UNIX domain socket on other operating systems. Therefore, permit these connections in pg_hba.conf.

This command cannot be executed on the standby server.

Example

In the following example, the data directory, tablespaces, and configuration files are backed up. At this time, stored WALs are no longer necessary because the backups are destroyed.

```
$ pgx_dmpall
```

Related item

pgx_rcvall

3.3 pgx_fjqssinf

Name

L

pgx_fjqssinf - Collects failure investigation data.

W

pgx_fjqssinf.bat - Collects failure investigation data.

Synopsis

L

```
pgx_fjqssinf  -i {1|2|3} [-w directory]
```

W

```
pgx_fjqssinf  -i {1|2|3} -s installdir -w directory
```

Description

When the cause of a trouble that occurred during the construction or operation of the environment is not identified, information for the initial investigation is collected. The collected investigation information is created in the destination directory as pgx_fjqssinf_YYYYMMDD_HHMMSS/.

Options

-i {1|2|3}

Specifies the incident of the trouble that occurred. 1 is specified for for process error, 2 for process result error, and 3 for no response. This option must be specified for the database server to gather information. Specify 1 when collecting information with the arbitration server.

W

-s installdir

Specify the directory where you installed Fujitsu Enterprise Postgres.

-w directory

L

Specifies the destination directory for the collected data. The default is /tmp.

W

Specifies the destination directory for the collected data.

Environment (When the information is collected by a database server)

PGDATA

Specifies the data directory.

PGDATABASE

Specifies the name of the database to connect to. Any database that can be connected to may be specified.

PGPORT

Specifies the port number of the instance. This should not be specified if the default port number (27500) has not been changed.

PGUSER

Specifies the user name of the database superuser. The database superuser must be configured to allow client authentication.

MCCONTROLDIR

Specifies the Mirroring Controller management directory. This should only be specified when database multiplexing operation is set up.

Environment (When information is collected by an arbitration server)

When operating a database multiplexing, set the following environment variables.

ARBCONTROLDIR

Specifies the management directory for the Mirroring Controller arbitration process.

ARBUSER

Specifies the OS user that initialized the Mirroring Controller arbitration process.

Diagnostics

0: Normal end

Other than 0: Abnormal end

Notes

L

This command must be executed as a superuser (root) account.

W

Execute this command as a user with the "Administrator" privilege (operating system user ID that belongs to the Administrator group).

Example

Below is an example of collecting information for initial investigation in the event of a process failure.

```
    # pgx_fjqssinf -i 1
```

```
   > pgx_fjqssinf.bat -i 1 -s "C:\Program Files\Fujitsu\fsepv<x>server64\" -w "C:\Users\fep
\fjqss"
```

Below is an example of collecting information for an initial investigation by an arbitration server.

```
    # pgx_fjqssinf -i 1
```

3.4 pgx_keystore

Name

pgx_keystore -- Manages keystore

Synopsis

```
pgx_keystore [-a|--enable-auto-open] [option...] keystore_location
```

```
pgx_keystore [-s|--obfuscate-secret] [option...]
```

Description

pgx_keystore enables auto-open of a keystore.

Options

To enable automatic opening using a file-based keystore

-a
--enable-auto-open

Enables auto-open of a keystore. This allows the keystore to open automatically without entering the passphrase when the database server starts.

When auto-open is enabled, an obfuscated copy keystore.aks is created in the same directory where the keystore file keystore.ks is stored. To disable auto-open, delete keystore.aks.

-P *passphrase*
--passphrase=*passphrase*

Specify the passphrase to open the keystore. If this option is omitted, the prompt to enter the passphrase is displayed.

keystore_location

Specify the absolute or relative path of the keystore file.

To enable automatic opening using a key management system as the keystore

-s

--obfuscate-secret

Obfuscates the secret information needed to connect to the key management system. By specifying obfuscated private information as an authentication option in the key management system connection information file, the keystore is opened automatically when the database server is started without entering the key management system credentials.

--secret = *secret*

Specify the secret information required to connect to the key management system. If you omit this option, you are prompted for the secret.

-o *obfuscated-secret-file*

Specifies the file that contains the obfuscated secret. If the file already exists, the command terminates abnormally without overwriting it.

Diagnostics

0: Normal exit

Other than 0: Abnormal exit

Notes

This command can be executed whether the database server is running or stopped. It does not connect to the database server.

This command does not connect to the key management system.

Example

Enables automatic keystore opening when using a file-based keystore.

```
$ pgx_keystore -a /key/store/location/keystore.ks
```

L

Enable automatic keystore opening by obfuscating sensitive credentials when using the key management system as a keystore.

```
$ pgx_keystore -s -o /example/keypassphrase.ksc
Enter secret:
```

3.5 pgx_rcvall

Name

pgx_rcvall - Recovers the data directory, tablespaces, and configuration files.

Synopsis

```
pgx_rcvall [option...]
```

Description

The pgx_rcvall command recovers the data directory, tablespaces, and configuration files using the data that was backed up with pgx_dmpall command and archived Write-Ahead-Log (WAL). If none of the options that indicate the recovery point is specified, all archived WAL are applied and the data will be recovered to the latest point.

Options

-B *backupdir*

Specify the backup storage directory. If the data directory is damaged, this option cannot be omitted.

-D *datadir*

Specify the data directory. If this option is omitted, the value of the environment variable PGDATA is used.

-e *targetTime*

Specify this option to recover the data as of the specified date and time.

targetTime

Specify the time at which the data is recovered. The format is as follows:

```
"YYYY-MM-DD HH:MM:SS"
```

-l

This option displays a list of the backup data information in the backup storage directory that was obtained using the pgx_dmpall command. If the pgx_dmpall command was executed using the copy command (-Y option) for backup, the resources backed up using the copy command will also be listed. This cannot be specified together with -p, -e or -n option.

-n *restorePoint*

Specify this option to recover the data to the specified restore point. Restore points are created with SQL function pg_create_restore_point. If multiple restore points with the same names were created, the first one after the backup was taken is used for recovery. If the specified restore point does not exist, the recovery fails. This cannot be specified together with -e or -p option.

-p

Specify this option to recover the data as of the time when the last backup completed. This cannot be specified together with -e or -n option.

-x

Specify this option if you do not want to include transactions committed at the time specified in the -e option as part of the recovery.

-Y *copyCommandFile*
--copy-command=*copyCommandFile*

Specify the full path of the file of the copy command for recovery, using less than 1024 bytes. This option cannot be specified together with the -l option.

--keystore-passphrase

Prompt for the passphrase to open the keystore when using a file-based keystore.

L

--kms-secret

When you use a key management system as a keystore, you are prompted to enter secret information to open the keystore.

--view-results-of-copying

Output the backup information file that was written by the copy command executed via the pgx_dmpall command. This option cannot be specified together with the -l, -p, -e, -n, or -Y option.

Environment

PGDATA

Specify the data directory. You can overwrite using the -D option.

PGPORT

Specify the port number for connecting to the database.

PGUSER

Specify the user name of the database superuser. This defaults to the name of the effective user running pgx_dmpall.

Diagnosis

0: Normal exit

Other than 0: Abnormal exit

Backup data information

Date

Date the backup data was created using the pgx_dmpall command.

Dir

This is the name of the directory in the backup storage directory that is used to store the backup data.
Directory naming format: Time format (YYYY-MM-DD_HH-MM-SS)

Status

This is the status of the pgx_dmpall command backup data.

COMPLETE: Complete

INCOMPLETE: Incomplete

Resources backed up by the copy command

List of resources that were backed up by the copy command executed via the pgx_dmpall command.

If there are resources that were backed up by the copy command, then database clusters ('pg_data') or tablespace names will be listed, delimited by header and halfwidth comma.

Notes

This command can only be executed when the database server is stopped, except when it is executed with -l option.

Execute this command as a PostgreSQL user account.

Use backup data that was taken from the recovery target data directory.

Before executing this command, disconnect all application database connections. Additionally, do not connect to the database during recovery.

The configuration files are restored from those files that were taken by the last pgx_dmpall (including -c option).

This command connects to the database to determine whether the recovery has completed. So ensure that you set the port number with PGPORT environment variable in the environment where multiple instances exist.

Match the OS timezone setting when running pgx_dmpall/pgx_rcvall to the timezone specified by timezone parameter in postgresql.conf.

Otherwise, data might be recovered to an unexpected time when -e or -p is specified.

If you recover to a past point, a new timeline (history of database updates) begins at that point. That recovery point is the latest point in the new timeline when the recovery is completed. If you subsequently recover to the latest point, the database updates in the new timeline will be replayed.

Valid restore points are the ones that were created in the timeline where the backup had been taken. That means that if you recover to a past point, those restore points created thereafter are unavailable. Therefore, take a backup when you have restored the past data desired.

If the pgx_dmpall command was executed using the copy command (-Y option) for backup, it is necessary to execute this command using the copy command (-Y option) for recovery. However, because the list of resources (database cluster or tablespace) that were backed up using the copy command is recorded in the backup directory, there is no need to specify the target resources when executing this command. The -I option can be used to check the target resources for which a backup is retrieved using the copy command.

Example

In the following example, the data directory, tablespaces, and configuration files are recovered.

```
$ pgx_rcvall -B /home/pgsql/Backupdir
```

In the following example, the data directory and tablespaces are recovered at 10:00:00 on 01-02-2022. The configuration files are recovered at the point at which the last of the data is obtained.

```
$ pgx_rcvall -B /home/pgsql/Backupdir -e "2022-02-01 10:00:00"
```

In the following example, the data directory and tablespaces are recovered up to the time of restore point "before_match_20220210_1". The configuration files are restored from the latest backup.

```
$ pgx_rcvall -B /home/pgsql/Backupdir -n before_match_20220210_1
```

In the following example, the obtained backup data information in the backup storage directory is displayed in a list.

```
$ pgx_rcvall -l
```

Related item

pgx_dmpall

3.6 postgres

Name

postgres -- PostgreSQL database server

Synopsis

```
postgres [option...]
```

Options

-K

Prompt for the passphrase to open the keystore. This option works in single-user mode only, so you must also specify the --single option, as shown below:

postgres --single -K

See

Refer to "postgres" in the PostgreSQL Documentation for details.

Chapter 4 Mirroring Controller Commands

This chapter explains the Mirroring Controller commands.

4.1 mc_arb

Name

L mc_arb - Start, stop, and display the status of the Mirroring Controller arbitration process

W mc_arb - Start, stop, and display the status of the Mirroring Controller arbitration process, or register and unregister it as a Windows service

Overview

```
mc_arb start [-M mcdir] [-w| -W]

mc_arb stop [-M mcdir] [-e]

mc_arb status [-M mcdir]
```

W
```
mc_arb register [-M mcdir] [-w| -W] -P password [-S a[uto] | d[emand]]
mc_arb unregister [-M mcdir]
```

Description

L mc_arb starts, stops, and displays the status of the Mirroring Controller arbitration process.

W mc_arb starts, stops, and displays the status of the Mirroring Controller arbitration process, or registers and unregisters it as a Windows service.

The start mode starts the Mirroring Controller arbitration process.

The stop mode stops the Mirroring Controller arbitration process.

The status mode displays the connection status of the Mirroring Controller arbitration process with the Mirroring Controller processes of the primary server and standby server.

W The register mode registers the Mirroring Controller arbitration process as a Windows service. The -w and -W options can be used to start/stop the Mirroring Controller arbitration process through the Windows service, and when it executes the mc_arb command, the specified option will take effect.

The unregister mode unregisters the Mirroring Controller arbitration process as a Windows service.

If the Mirroring Controller arbitration process has not been started on the server executing the command, stop mode and status mode will terminate with an error.

Additionally, if Mirroring Controller is forcibly stopped on the database server, it may take a few moments until the status mode displays the status of the server connection as offline.

L This command can be executed by any user.

W Execute this command as a user with administrator privileges (operating system user that belongs to the "Administrators" group).

Options

-e

Specify this option to forcibly stop the Mirroring Controller arbitration process on the active server.

Specify this option to stop the Mirroring Controller arbitration process but keep Mirroring Controller running (to stop both, first stop Mirroring Controller of the database server, and then the Mirroring Controller arbitration process). This option can also be specified to halt the arbitration process (by stopping the Mirroring Controller arbitration process) when the fencing command called by the arbitration process becomes unresponsive.

-M *mcdir*

Specify the Mirroring Controller arbitration process management directory.

ASCII characters can be specified in the directory path.

If this option is omitted, the value of the environment variable ARBCONTROLDIR is used.

W

-P *password*

For the register mode, specify the password for the user who executed the command.

W

-S a[uto] | d[emand]

Specify the start type for the Windows service to be registered. You can choose auto or demand as the start type by specifying the entire word or just its first letter. The default is auto.

-w

Waits for operations to finish.

L

This option is the default of start mode.

W

This option is the default of start mode and register mode.

-W

Does not wait for operations to finish.

Environment

ARBCONTROLDIR

Specify the Mirroring Controller arbitration process management directory.

ASCII characters can be specified in the directory path.

You can specify the -M option to override this value.

Diagnostics

0: Normal end

Other than 0: Abnormal end

Notes

If the Mirroring Controller arbitration process is forcibly stopped or communication between the command and the Mirroring Controller arbitration process is interrupted while the Mirroring Controller arbitration process is being stopped, a message that the command is being executed may be output and stopping may terminate in error, even though no other instances of the mc_arb command are being executed.
To solve this issue, ensure that other instances of the mc_arb command are not being executed before forcibly stopping the Mirroring Controller arbitration process.

W

Use the start mode and stop mode to start and stop the Windows service. Before being able to use these modes, use the register mode to register the Mirroring Controller arbitration process as a Windows service.
The mc_arb command must be executed from "Administrator: Command Prompt". Right-click [Command Prompt], and then select [Run as administrator] from the context menu to display the [Administrator: Command Prompt] window.

Example

L

Start the Mirroring Controller arbitration process.

```
$ mc_arb start -M /mcarb_dir/arbiter1
```

Start the Mirroring Controller arbitration process.

```
> mc_arb start -M D:\mcarb_dir\arbiter1
```

Display details of mc_arb status

```
server_id   host            status
(1)         (2)             (3)
```

```
(1) Server identifier
(2) Host name or IP address
(3) Server connection status
    online   : Connected
    offline  : Disconnected
```

4.2 mc_ctl

Name

mc_ctl - Start and stop Mirroring Controller, switch/disconnect the server, or display the server status.

mc_ctl - Start and stop Mirroring Controller, switch/disconnect the server, display the server status, or register and unregister as a Windows service.

Overview

```
mc_ctl start [-M mcdir] [-w| -W] [-f| -F] [--mc-only] [--async-connect-arbiter] [--local-server server_id]

mc_ctl stop [-M mcdir] [[-a] [--mc-only]| [-e][--local-server server_id]]

mc_ctl status [-M mcdir] [--arbiter] [--local-server server_id]

mc_ctl switch [-M mcdir] [--force [--no-fencing ]] [--local-server server_id]

mc_ctl detach [-M mcdir] [--no-fencing] [--local-server server_id]

mc_ctl enable-failover [-M mcdir] [--local-server server_id]

mc_ctl disable-failover [-M mcdir] [--local-server server_id]
```

```
mc_ctl register [-M mcdir] [-w| -W] [-f| -F] [--mc-only] -P password
                [-S a[uto] | d[emand]] [--async-connect-arbiter] [--local-server server_id]
```

```
mc_ctl unregister [-M mcdir] [--local-server server_id]
```

Description

mc_ctl starts and stops Mirroring Controller, switches/disconnects the server, or displays the server status.

mc_ctl starts and stops Mirroring Controller, switches/disconnects the server, displays the server status, or registers and unregisters as a Windows service.

The start mode starts Mirroring Controller. If the --mc-only option is omitted, the command starts a database instance.

The stop mode stops Mirroring Controller. If the --mc-only option is omitted, the database instance is stopped. If --mc-only option is not specified, database instance is also stopped. When executes on standby server without --mc-only, standby server will be detached from primary server.

The status mode displays the status of the servers, database instance processes, and disks monitored by Mirroring Controller. Additionally, if the --arbiter option is specified, Mirroring Controller arbitration process connection status is displayed.

The switch mode switches the primary server. When the server is switched, the database instance on the primary server stops, and the database instance on the standby server is upgraded to primary server and begins degrading operation. This mode can be executed on the primary server and standby server in an environment where the Mirroring Controller process can communicate with the Mirroring Controller process on the other server.

The detach mode forcibly disconnects the standby server. This mode is used to forcibly disconnect the other server when stopping of Mirroring Controller cannot be performed using stop mode (which requires login to the standby server). It can only be executed on the primary server.

The enable-failover mode enables automatic switching and disconnection.

The disable-failover mode disables automatic switching and disconnection.

W

The register mode registers Mirroring Controller as a Windows service. The -w, -W, -f, -F, --mc-only, --async-connect-arbiter, and --local-server options are used when Mirroring Controller is started and stopped as a Windows service. If the mc_ctl command is used to start and stop Mirroring Controller, the option specified in the command will be valid.

The unregister mode unregisters Mirroring Controller as a Windows service.

L

If Mirroring Controller has not been started on the server that executes the command, commands for any mode other than the start mode, and status mode.

Execute this command as an instance administrator.

W

If Mirroring Controller has not been started on the server that executes the command, commands for any mode other than the start mode, status mode, register mode, and unregister mode terminate with an error.

Execute this command as a user with the "Administrator" privilege (operating system user ID that belongs to the Administrator group).

Until you start Mirroring Controller of standby server after starting Mirroring Controller of the primary server, operation can be started with only the primary server. Standby server is incorporated when you start the Mirroring Controller of standby server, and you should be able to operate in the multiplexing configuration.

Options

-a

Specify this option to stop Mirroring Controller on all servers.

-e

Specify this option to forcibly stop Mirroring Controller on the active server.

-f

Specify this option to enable automatic switching and disconnection of Mirroring Controller immediately after startup.

L

This option is the default of start mode.

W

This option is the default of start mode and register mode.

-F

Specify this option to disable automatic switching and disconnection immediately after startup of Mirroring Controller.

--async-connect-arbiter

Specify this option to connect the Mirroring Controller start process asynchronously to the Mirroring Controller arbitration process. This option can be specified to forcibly start Mirroring Controller if the Mirroring Controller arbitration process is not started.

Specify this option if using the Mirroring Controller arbitration server.

--arbiter

Specify this option to display the connection status of the Mirroring Controller arbitration process. This option can be specified if using status mode.

Specify this option if using the Mirroring Controller arbitration server.

--local-server *server_id*

If you run a simulation build of the primary and standby servers in a single server (for system testing, for example), specify this option to identify the server to be operated.

For *server_id*, specify the server identifier specified in the network.conf file. ASCII characters other than single-byte space can be specified in the server identifier. The operations will be executed as if the user has logged in to *server_id*.

--mc-only

Specify this option to start and stop only Mirroring Controller processes. At the start mode, this option can be specified only while the database instance is running. If this option is omitted, the database instance is simultaneously started and stopped.

-M *mcdir*

Specify the Mirroring Controller management directory.

ASCII characters can be specified in the directory path.

If this option is omitted, the value of the environment variable MCCONTROLDIR is used.

--force

Switching with this option specified can only be specified on the standby server. This option is used to perform switching forcibly after performing fencing on the primary server if communication with the Mirroring Controller process of the other server is not possible (due to a network issue between database servers or unresponsive server, for example), thus preventing normal switching. However, if the --no-fencing option is specified, fencing will not be performed on the primary server.

--no-fencing

When switching or disconnection is executed with the --force option specified, fencing of the server to be degraded is circumvented. Therefore, it is necessary for the user to isolate the server to be degraded from the cluster system in advance.

-P *password*

For the register mode, specify the password for the user who executed the command.

-S a[uto] | d[emand]

Specify the start type for the Windows service to be registered. You can choose auto or demand as the start type by specifying the entire word or just its first letter. The default is auto.

-w

Waits for operations to finish.

This option is the default of start mode.

This option is the default of start mode and register mode.

-W

Does not wait for operations to finish.

Environment variable

MCCONTROLDIR

Specifies the Mirroring Controller management directory.

ASCII characters can be specified in the directory path.

You can specify the -M option to override this value.

Diagnostics

0: Normal end

Other: Abnormal end

Notes

The message under execution might be output though the mc_ctl command is not being executed and, besides, it terminate abnormally when the server is downed while processing execution of this command, an automatic switch, and an automatic separation, and the communication between a primary server and the standby server is cut off. Besides, restart Mirroring Controller to solve this problem after confirming that the mc_ctl command is not in progress. Afterwards, execute a necessary operation.

If a time-out error occurs when the mc_ctl command is in progress, the messages may be different from the processes. Take the actions described in the "Action" section of the message.

Automatic switching and disconnection by the enable-failover mode, the disable-failover mode, and the start mode can be enabled/disabled only while Mirroring Controller is running. Therefore, if you want to enable/disable automatic switching and disconnection on starting, specify the -f option or -F option each time you start Mirroring Controller.

W

Use the start mode and stop mode to start and stop the Windows service. To do this, use the register mode to register Mirroring Controller as a Windows service in advance.

In case of postgresql.conf has any incorrect parameter when this command is executed, this command may be abnormally terminated. If this is the case, re-execute it again after correct the parameter in postgresql.conf.

If the arbitration server of Mirroring Controller is used, connection with the arbitration server will be performed on startup even if startup using start mode is executed with the -F option specified, or if executed with --local-server specified.

W

The mc_ctl command must be executed from "Administrator: Command Prompt". Right-click [Command Prompt], and then select [Run as administrator] from the menu to display the [Administrator: Command Prompt] window.

For operation using an arbitration server, the amount of time spent attempting to connect with the arbitration server is calculated, so the Mirroring Controller startup time may take longer.

Example

L

To start Mirroring Controller:

```
$ mc_ctl start -M /mcdir/inst1
```

W

To start Mirroring Controller:

```
> mc_ctl start -M D:\mcdir\inst1
```

Display details of mc_ctl status

```
mirroring status
----------------
(1)

(1)          (2)              (3)
```

```
(1) Arbitration server identifier
(2) Host name or IP address
(3) Mirroring Controller arbitration process connection status
    online  : Connected
    offline : Disconnected (*1)

*1: When Mirroring Controller is stopped, connections to the Mirroring Controller
arbitration process cannot be established, so it will be displayed as "offline".
```

Chapter 5 Connection Manager Commands

This chapter explains the Connection Manager commands.

5.1 cm_ctl

Name

L

cm_ctl - Start, stop or display the status of the conmgr process

W

cm_ctl - Start, stop, and display the status of the conmgr process, or register and unregister it as a Windows service

Synopsis

```
cm_ctl start [-D diretory] [-W] [--complete] [-t seconds]

cm_ctl stop [-D diretory] [-W] [-m {smart | fast | immediate}] [-t seconds]

cm_ctl status [-D directory] [-t seconds] [-i {all | instance | application}]
```

W

```
cm_ctl register [-D directory] [-N servicename] [-U username] [-P password]
                [-S a[uto] | d[emand] ] [-e source] [-W] [--complete] [-t seconds]

cm_ctl unregister [-N servicename]
```

Description

The start mode starts the conmgr process. The command returns at least after the heartbeat monitoring connection is completed with the primary server's instance.

When --complete is specified, wait until all instances configured in conmgr.conf have completed their heartbeat monitoring connections. You can set a timeout for these waits. The default of timeout is 60 seconds. Can be changed using the -t option. If it times out, it simply gives up waiting and the conmgr process remains up.

Note

If the primary is not among the instances configured in the cmgr.conf, use the -W option when starting Connection Manager with the cm_ctl command. Without the -W option, the cm_ctl command will not return until the primary connection is complete.

The stop mode sends a signal to the conmgr process to shut down and wait until the process disappeares.

The default of wait time is 60 seconds. Can be changed using the -t option. If it times out, it simply gives up waiting. There are three shutdown methods, "smart", "fast", and "immediate", specify with the -m option. The "smart" waits until all applications using the conmgr process run out of SQL connections before shutting down. The "fast" forces all applications using the conmgr process to disconnect from the conmgr process before shutting it down. As a result, the SQL connection for the application receives an error. The "immediate" terminates the conmgr process immediately. If nothing is specified, it stops in fast mode.

The status mode, if the commgr process exists, queries the conmgr process for instance and application information known to the conmgr process, and display them to standard output along with the state of conmgr itself.

The -i option allows you to specify what information to query. The "instance" queries information about the instance; The "application" queries information about the application; The "all" queries information about both. conmgr's own information is always displayed. The default time to wait for a query to return is 60 seconds. Can be changed using the -t option.

The register mode registers the conmgr process as a system service on Windows. The -S option allows you to select the service start type, either "auto" (to start the service automatically when the system starts) or "demand" (to start the service upon request).

The unregister mode unregisters the conmgr process from the Windows service.

Options

--complete

Wait until all instances configured in conmgr.conf have completed their heartbeat monitoring connections. If the When used with the -W option, the -W option takes precedence.

-D

-- directory=*directory*

Specify the directory where conmgr.conf is located. If omitted, it refers to the directory specified by the environment variable CMDATA. You cannot omit both.

-i {all | instance | application}

Specify the information to display the status.

-m

--mode={smart | fast | immediate}

Specify the mode of shutdown. The default is fast.

-t *seconds*

--timeout=*seconds*

Specify how long to wait for the operation to complete. The unit is seconds. The default is 60 seconds.

-W

--no-wait

In start mode, cm_ctl command returns immediately after forking conmgr process. In stop mode, the cm_ctl command returns without waiting for the process to disappeare.

-e *source*

The name of the cm_ctl event source to use for output to the event log when running as a Windows service. The default is conmgr. Note that this only controls messages sent from cm_ctl itself. After the conmgr process starts, the event source specified in event_source in conmgr.conf is used. If a failure occurs very early in the conmgr process startup, you may want to use the default event source name conmgr before the event source specified in conmgr.conf is set.

-N *servicename*

The name of the Windows service to register. This name is used as both the system name and the display name. The default is conmgr.

-P *password*

The password for the user who starts the service.

-S *start-type*

Start type of the Windows service to register. The start-type can be auto, demand, or one of the first characters of these two words. If you omit this option, auto is the default.

-U *username*

Username of the user who starts the service. Use the DOMAIN\username format for domain users.

Diagnostics

start mode or stop mode

0: Normal end

2: Timeout occurred

3: Unable to access the specified directory

Other than the above: None of the above

status mode

0: Normal end

3: Unable to access the specified directory

4: conmgr process does not exist

Other than the above: None of the above

register mode

0: Normal end

Other than 0: Abnormal end

unregister mode

0: Normal end

Other than 0: Abnormal end

Privileges

The conmgr process cannot be started by the administrator(e.g. superuser(root) on Linux, users with Windows administrator privileges).

Display details of status mode

The block of information that can be specified with the -i option is used as a unit. There is one blank line between the blocks and no blank lines within the blocks. It includes one or more spaces between columns and between data.

```
$ cm_ctl status -i all
conmgr_status:
status pid
(1)     (2)
ready  3456

instance_information:

(6)           (7)   (8)   (9)
127.0.0.1     12345 5678  2022-02-15 02:03:04
```

```
(1) Status of the conmgr process
    starting : The process is starting its startup sequence but is not ready to accept
               connections from clients.
    ready    : Ready to accept connections from clients.
    stopping : It has received an end instruction and is starting the stop sequence.
```

```
    inactive : The conmgr process does not exist.
(2) PID of the conmgr process
(3) Host name or IP address of the instance
(4) Port number the postmaster listens on
(5) Status of the instance (primary | primary(read-only) | standby | unknown)
    primary            : Primary server
    primary(read-only) : Primary server (default transaction mode is read-only)
    standby            : Standby server
    unknown            : Unknown (*1)
(6) Connection source IP address for conmgr process
(7) Connection source (ephemeral) port number for conmgr process
(8) PID of the connection source
(9) Date and time conmgr process connection
    The ISO 8601 compliant date is followed by a blank, followed by the ISO 8601
    compliant second precision time.
    This representation is a PostgreSQL string representation of type timestamp.

*1) Displays when you cannot connect to the instance.
```

When using the initial data synchronization waiting feature for standby servers

```
$ cm_ctl status -i all
conmgr_status:
status pid
(1)    (2)
ready  3456

instance_information:
addr         port  database_attr application_name replication_state
(3)           (4)   (5)      (6)      (7)
192.0.2.100  27500 standby stanby_1 streaming
192.0.2.110  27500 primary - -
192.0.2.120  27500 standby stanby_2 catchup
192.0.2.130  27500 unknown unknown non-replicated

application_information:
addr         port  pid   connected_time
(8)           (9)   (10)      (11)
127.0.0.1    12345 5678      2022-02-15 02:03:04
```

```
(6) The application_name specified for the instance. For primary servers, "-" is output;
for unknown servers, "unknown" is output.
(7) The replication state of the instance's replication. Outputs the same information as
the "state" column in the pg_stat_replication view. For primary servers, "-" is output;
for unknown servers, "non-replicated" is output.
```

FUJITSU

Fujitsu Enterprise Postgres 18SP1 for x86

Message Guide

Windows/Linux

J2UL-3070-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document explains the messages output by Fujitsu Enterprise Postgres.

Intended readers

This document is intended for the following readers:

- Persons using Fujitsu Enterprise Postgres

Prerequisites

Knowledge of the following topics is required to read this document:

- A general understanding of computers
- Jobs
- PostgreSQL
- Linux
- Windows

Structure of this document

This document is structured as follows:

Chapter 1 Overview of Messages

This chapter explains the format in which messages are output.

Chapter 2 Message List

This chapter explains the output messages.

Chapter 3 Mirroring Controller Messages

This chapter explains messages output by Mirroring Controller.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Issue date and version

```
Edition 2.0: March  2026
Edition 1.0: December  2025

Chapter 1 Overview of Messages

This chapter explains the format of messages.

1.1 Message Format

This section explains the format of messages.

- Output format
- Components

1.1.1 Output Format

The message output format is as follows:

Format of messages returned to an application

```
msgType: msgText
```

Format of messages output to the server message log

```
SQLSTATE: date [processID]: [internalCode-1] user = userName,db = dbName,remote =
clientIpAddress(portNumber) app = appName msgType: msgText
```

See

Refer to "PostgreSQL Error Codes" under "Appendixes" in the PostgreSQL Documentation for information on SQLSTATE.

Note

- Notes on monitoring messages output to the server message log

  Use SQLSTATE to monitor server messages, noting the following:

  - Configuration method

    Refer to "Error Log Settings" under "Setup" in the Installation and Setup Guide for Server for details.

  - Note

    - The user name, client IP address (port number), and application name may sometimes be blank.

- Notes on monitoring messages returned to an application

  You can output SQLSTATE to a message to be returned to an application. The following explains how to configure the settings for outputting SQLSTATE and gives cautions to be observed when doing so.

  - Configuration methods

    - In the SET statement, set the log_error_verbosity parameter to VERBOSE.
    - For an application that uses the C language library, use the PQsetErrorVerbosity function to set message redundancy to PQERRORS_VERBOSE.

  - Notes

    - SQLSTATE is output only to messages to be returned to applications that use the C language library.
    - In some cases, *userName*, *clientIpAddress*(*portNumber*), and *applicationName* may be blank.

- If the email address "pgsql-bugs@postgresql.org" is output to the message and the cause of the error cannot be identified, contact Fujitsu technical support.

Example

Message output to the server message log

```
3D000: 2017-07-10 19:41:05 JST [13899]: [1-1] user = fepuser,db = fep,remote =
127.0.0.1(51902) app = [unknown] FATAL:  database "fep" does not exist
```

1.1.2 Components

This section explains the components of a message.

Message type

The message type indicates the type of error denoted in the message.

The message type will be one of the following:

- Information (INFO, NOTICE, LOG, DEBUG)

  This message type denotes a notification from the system, not an error. There is no need to take action.

- Warning (WARNING)

  This message type denotes that no error occurred but confirmation or action is required by the user. Take the actions described in the "Action" section of the message.

- Error (ERROR, FATAL, PANIC)

  This message type denotes that an error has occurred. Take the actions described in the "Action" section of the message.

- Supplementary information (DETAIL, HINT, QUERY, CONTEXT, LOCATION, STATEMENT)

  This message type denotes supplementary information relating to the previous message. If the message was output in English, the message type will also be in English. (Detail, hint, query, context, location, statement)

Message text

The text of the message reports the status of the system or an error in the system.

The notation "@numeric character@" that appears in "Chapter 2 Message List" indicates an embedded character string. A character string is output to a message that is actually output.

If a message locale other than 'ja' is specified, messages added by Fujitsu Enterprise Postgres will be output in English.

For other message locales, the messages are output in English.

1.2 Mirroring Controller Message Format

This section explains the format of messages output by the Mirroring Controller.

Mirroring Controller messages are output to the following locations:

L - System log

W - Event log

Output format

```
programName[processId]: msgType: msgText (msgNumber)
```

For *programName*, use the value of the syslog_ident parameter or event_source parameter defined in the *serverIdentifier*.conf file.

L

The message types output by Mirroring Controller, their severity, and their corresponding value in the system log are shown in the table below.

L

Table 1.1 Message type, severity, and corresponding value in the system log

Message type	Severity	Meaning	System log
INFO	Information	Provides information not categorized as LOG or NOTICE.	INFO
LOG		Provides information recognized as a particularly important event in tracing the operation history. (Example: Automatic switch is complete)	
NOTICE	Notice	Outputs information that takes into account the user instructions within the program in response to an executed or automatically executed process.	NOTICE
WARNING	Warning	Provides a warning, for example it will soon be impossible to maintain multiplexing capabilities.	WARNING
ERROR	Error	Reports that an error other than FATAL or PANIC has occurred.	ERROR
FATAL		Reports that an error has been detected requiring system recovery in one of the multiplexed database systems. It also reports the content and cause of the error.	CRIT
PANIC		Reports that an error has been detected requiring immediate system recovery in all multiplexed database systems. It also reports the content and cause of the error.	ALERT

W

The message types output by Mirroring Controller, their severity, and their corresponding value in the event log are shown in the table below.

W

Table 1.2 Message type, severity, and corresponding value in the event log

Message type	Severity	Meaning	Event log
INFO	Information	Provides information not categorized as LOG or NOTICE.	INFORMATION
LOG		Provides information recognized as a particularly important event in tracing the operation history. (Example: Automatic switch is complete)	
NOTICE	Notice	Outputs information that takes into account the user instructions within the program in response to an executed or automatically executed process.	
WARNING	Warning	Provides a warning, for example it will soon be impossible to maintain multiplexing capabilities.	WARNING

Message type	Severity	Meaning	Event log
ERROR	Error	Reports that an error other than FATAL or PANIC has occurred.	ERROR
FATAL		Reports that an error has been detected requiring system recovery in one of the multiplexed database systems. It also reports the content and cause of the error.	
PANIC		Reports that an error has been detected requiring immediate system recovery in all multiplexed database systems. It also reports the content and cause of the error.	

The message severity has the following meanings:

- Information

  Informational status. A message that was reported by the system is displayed. No action is required.

- Notice

  Informational status, but a message that should be noted is displayed. If necessary, take the actions described in the "Action" section of the message.

- Warning

  No error has occurred, but the user is requested to check, and take action. Take the actions described in the "Action" section of the message.

- Error

  An error has occurred. Take the actions described in the "Action" section of the message.

Output destination server

Mirroring Controller messages are output by the database server. When using an arbitration server, Mirroring Controller messages are also output by the arbitration server.

- Messages with a message number that starts with "MCA" are output by the database server.
- Messages with a message number that starts with "MCR" are output by the arbitration server.

Chapter 2 Message List

This chapter explains the output messages.

For messages not described in this chapter, check the content of the message and take appropriate action. If the problem cannot be resolved, contact Fujitsu technical staff(support).

needs to set at least @1@ to "max_worker_processes"

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the application is written correctly and the command is being used correctly.

@1@ total checksum verification failure

[Description]

By default, checksums are verified and checksum failures are reported for any possible page corruptions

[System Processing]

Continues processing.

[Action]

Check the message text and confirm that the event indicated in supplementary information reported by the system is a planned event.

@1@ and @2@ are incompatible options

[Description]

The input parameter in invalid.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the application is written correctly and the command is being used correctly.

@1@ can only be called in a sql_drop event trigger function

[Description]

can only be called in a sql_drop event trigger function

[System Processing]

Processing will be aborted.

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ can only be called in a table_rewrite event trigger function

[Description]

The function pg_event_trigger_table_rewrite_oid() can only be called in a table_rewrite event trigger function

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ can only be called in an event trigger function

[Description]

The function pg_event_trigger_ddl_commands() can only be called in a event trigger function

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ cannot be applied to a function

[Description]

SQL row locking clause such as "FOR UPDATE" cannot be applied to a function

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ cannot be applied to a join

[Description]

SQL row locking clause such as "FOR UPDATE" cannot be applied to a join

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ cannot be applied to a WITH query

[Description]

SQL row locking clause such as "FOR UPDATE" cannot be applied to a WITH query

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ cannot be applied to the nullable side of an outer join

[Description]

SQL row locking clause cannot be applied to the nullable side of an outer join

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ cannot be applied to VALUES

[Description]

SQL row locking cannot be applied to VALUES

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ cannot be executed from VACUUM or ANALYZE

[Description]

commands VACUUM or ANALYZE cannot be executed from VACUUM or ANALYZE

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ cannot be used as a role name here

[Description]

Reserved name cannot be used as a role name here

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ cause an error in heartbeat: @2@

[Description]

Cause an error in heartbeat.

[System Processing]

Processing aborts.

[Action]

Check log of Operating System.

@1@ causes an error at application connection: @2@

[Description]

Causes an error at application connection.

[System Processing]

Processing aborts.

[Action]

Check log of Operating System.

@1@ function has @2@ columns available but @3@ columns specified

[Description]

An error occurred, when specified column of the function is different than the available column

[System Processing]

Continues processing.

[Action]

Investigate the cause of the error from the message body, and then remove the cause.

@1@ is not allowed with aggregate functions

[Description]

The return type of function LCS_asString is not allowed with aggregate functions.In this error case,the return type of LCS_asString is "FOR some"

[System Processing]

Processing will be aborted.

[Action]

To investigate the cause of the occurrence from the message, and remove cause

@1@ is not allowed with DISTINCT clause

[Description]

SQL row locking clause such as "FOR UPDATE" is not allowed with DISTINCT clause

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ is not allowed with GROUP BY clause

[Description]

SQL row locking clause such as "FOR UPDATE" is not allowed with GROUP BY clause

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ is not allowed with HAVING clause

[Description]

SQL row locking clause such as "FOR UPDATE" is not allowed with HAVING clause

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ is not allowed with set-returning functions in the target list

[Description]

SQL row locking clause such as "FOR UPDATE" is not allowed with set-returning functions in the target list

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ is not allowed with UNION/INTERSECT/EXCEPT

[Description]

Locking clause is not allowed with UNION/INTERSECT/EXCEPT

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ is not allowed with window functions

[Description]

SQL row locking clause such as "FOR UPDATE" is not allowed with window functions

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ is not an ordered-set aggregate, so it cannot have WITHIN GROUP

[Description]

The function is not an ordered-set aggregate, so it cannot have WITHIN GROUP

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ is not VCI index

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the application is written correctly and the command is being used correctly.

@1@ must be called in REPEATABLE READ isolation mode transaction

[Description]

When creating a new replication slot, we must put CREATE_REPLICATION_SLOT and USE_SNAPSHOT in REPEATABLE READ isolation mode transAction.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the application is written correctly and the command is being used correctly.

@1@ must be called inside a transaction

[Description]

When creating a new replication slot, we must put CREATE_REPLICATION_SLOT and USE_SNAPSHOT in a transAction.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the application is written correctly and the command is being used correctly.

@1@ must not be called in a subtransaction

[Description]

When creating a new replication slot, we must not put CREATE_REPLICATION_SLOT and USE_SNAPSHOT in a subtransAction.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the application is written correctly and the command is being used correctly.

@1@ must not be called inside a transaction

[Description]

When creating a new replication slot, it is not allowed to put CREATE_REPLICATION_SLOT and EXPORT_SNAPSHOT in a transAction.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the application is written correctly and the command is being used correctly.

@1@ must specify unqualified relation names

[Description]

SQL row locking clause such as "FOR UPDATE" must specify unqualified relation names

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ needs a slot to be specified using --slot

[Description]

needs a slot to be specified using --slot

[System Processing]

Processing aborts

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

@1@ the prepared transaction with gid: "@2@"

[Description]

The prepared transaction has been completed.

[System Processing]

Continues processing.

[Action]

No action required.

@1@(@2@) failed for @3@ address "@4@": @5@

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

@1@: Copy of objects for allnodes and Setup of replication table weren't executed

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: could not connect to database "@2@"

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: could not connect to database "postgres" or "template1"

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: could not create file "@2@" for writing

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: could not locate my own executable path

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: could not open file "@2@" for writing

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: could not remove initialize.signal file

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: could not remove scaleout.signal file

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: could not remove scaleout_passfile

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: Failed connect to coodinator

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: Failed copy replication table

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: Failed define objects to datanode

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: Failed make replication object

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: Failed open initialize.signal

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: Failed open postmaster.pid

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: Failed read initialize.signal

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: initialize.signal does not exist

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: out of memory

[Description]

There was insufficient free space in the server's memory during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Estimate memory usage and take the following action:

- If the number of simultaneous connections from client applications is high, reduce it.

- If the number of simultaneous SQL executions is high, reduce it.

@1@: pg_dumpall failed

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: postmaster.pid does not exist

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: query failed: @2@

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: query was: @2@

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

@1@: Stop sever process and re-execute pg_ctl start with longer timeout

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

"@1@" is not a directory

[Description]

Not a directory.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

"@1@" is not pid file: number of line is not enough(expect 4 but @2@)

[Description]

Not pid file: number of line is not enough.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

"root" execution of the conmgr is not permitted.The conmgr must be started under an unprivileged user ID to preventpossible system security compromise. See the documentation formore information on how to properly start the conmgr.

[Description]

"root" execution of the conmgr is not permitted. The conmgr must be started under an unprivileged user ID to prevent possible system security compromise. See the documentation for more information on how to properly start the conmgr.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

"VARYING" cannot have a level number greater than 48

[Description]

Variables that have greather than 48 level have VARYING clause.

[System Processing]

Precompling will be aborted.

[Action]

Remove "VARYNING" clause or change the level number.

Is the server running locally and accepting connections on that socket?

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

Is the server running on that host and accepting TCP/IP connections?

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

a new master encryption key has been set (@1@/@2@)

[Description]

A new encryption key has been set. The current number of save keys is the number on the left, and the maximum number of save keys is the number on the right.

[System Processing]

This is an information messaage when TDE_h is loaded.

[Action]

Provides notification of the current number of saved keys. If the maximum number is reached, the oldest key is deleted first. Check that the operation is as expected, and if it is not as expected, consider modifying postgresql.conf.

aborting any active transactions

[Description]

Rollback any active transactions because the database system is being requested to shut down.

[System Processing]

Continues processing.

[Action]

Retry any necessary applications or commands after restarting the database system.

All directory entries in pg_tblspc/ should be symbolic links.

[Description]

An error occurred due to unexpected directory entry found at specific path

[System Processing]

Cancels processing.

[Action]

Remove those unexpected directories, or set allow_in_place_tablespaces to ON transiently to let recovery complete.

---

another conmgr process is running

[Description]

Another conmgr process is running.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

---

another conmgr process is shutting down

[Description]

Another conmgr process is shutting down.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

---

another conmgr process is starting up

[Description]

Another conmgr process is starting up.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

---

another conmgr process(PID @1@) is running

[Description]

Another conmgr process is running.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

---

application connection is closed by remote in @1@

[Description]

Application connection is closed by remote.

[System Processing]

Processing continues.

[Action]

Check log of remote system.

---

array slice subscript must provide both boundaries

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

When assigning to a slice of an empty array value, slice boundaries must be fully specified.

---

at least one COORDINATOR is needed

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

---

authentication identifier set more than once

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

---

bind message has @1@ parameter formats but @2@ parameters

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

---

bind message has @1@ result formats but query has @2@ columns

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

bind message supplies @1@ parameters, but prepared statement "@2@" requires @3@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

canceling authentication due to timeout

[Description]

Timeout occurred during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Check the following:

- If executing SQL that outputs a large volume of search results, add a conditional expression to filter the results further.

- If numerous SQLs are being simultaneously executed, reduce the number of simultaneously executed SQLs.

- If a large volume of data is to be updated in a single transaction, modify the SQL to reduce the volume of data to be updated in a single transaction.

- If executing a complex SQL, modify it to a simple SQL.

- Check if there are any problems in the network.

- Before conducting maintenance that involves the processing of a large volume of data, use the SET statement to temporarily increase the value of maintenance_work_mem.

canceling statement due to conflict with recovery

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

canceling statement due to statement timeout

[Description]

Timeout occurred during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Check the following:

- If executing SQL that outputs a large volume of search results, add a conditional expression to filter the results further.

- If numerous SQLs are being simultaneously executed, reduce the number of simultaneously executed SQLs.

- If a large volume of data is to be updated in a single transaction, modify the SQL to reduce the volume of data to be updated in a single transaction.

- If executing a complex SQL, modify it to a simple SQL.

- Check if there are any problems in the network.

- Before conducting maintenance that involves the processing of a large volume of data, use the SET statement to temporarily increase the value of maintenance_work_mem.

---

cannot @1@ "@2@" because it has pending trigger events

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

---

cannot @1@ "@2@" because it is being used by active queries in this session

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

---

cannot change client_encoding during a parallel operation

[Description]

This error occurs if a function wants to set client_encoding and is invoked by the parallel query.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that client_encoding is not set by the parallel query operation.

---

cannot create temporary tables during recovery

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

---

cannot enter pipeline mode, connection not idle

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

---

cannot exit pipeline mode while busy

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

---

cannot exit pipeline mode with uncollected results

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

---

cannot replace existing key

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

Try using the function jsonb_set to replace the key value.

cannot uniquely identify the id

[Description]

Could not uniquely identify the id.

[System Processing]

Processing will be aborted.

[Action]

Please refer to the server log, and determine the cause of the error.

certificate does not match private key file "@1@": @2@

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

checkpoints are occurring too frequently (@1@ second apart)

[Description]

Checkpoints are occurring too frequently.

[System Processing]

Continues processing.

[Action]

Consider increasing the value of configuration parameter max_wal_size.

closing all application connections

[Description]

Closing all application connections.

[System Processing]

Processing continues.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

cmdata directory "@1@" does not exist

[Description]

Cmdata directory does not exist.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

---

collect shardinfo connection failed: @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

---

conmgr process is ready

[Description]

Conmgr process is ready.

[System Processing]

Continues processing.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

---

conmgr process is starting

[Description]

Conmgr process is starting.

[System Processing]

Processing continues.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

---

conmgr process shutting down

[Description]

Conmgr process shutting down.

[System Processing]

Continues processing.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

---

conmgr process stopped

[Description]

Conmgr process stopped.

[System Processing]

Processing continues.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

connection manager directory "@1@" does not exist

[Description]

Connection manager directory does not exist.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

connection to client lost

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

connection to server at "@1@" (@2@), port @3@ failed:

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

connection to server at "@1@", port @2@ failed:

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

connection to server on socket "@1@" failed:

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

COPY statement cannot be null

[Description]

COPY statement cannot be null.

[System Processing]

Processing will be aborted.

[Action]

Please specify COPY FROM statement.

could not accept application connection: @1@

[Description]

Could not accept application connection.

[System Processing]

Processing aborts.

[Action]

Check log of Operating System.

could not accept heartbeat connection: @1@

[Description]

Could not accept heartbeat connection.

[System Processing]

Processing aborts.

[Action]

Check log of Operating System.

could not accept new connection: @1@

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

could not accept SSL connection: @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

could not accept SSL connection: EOF detected

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

could not access to cmdata directory "@1@": @2@

[Description]

Could not access to cmdata directory.

[System Processing]

Processing aborts.

[Action]

Check log of Operating System.

---

could not access to connection manager directory "@1@": @2@

[Description]

Could not access to connection manager directory.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

---

could not change directory to "@1@": @2@

[Description]

Could not change directory.

[System Processing]

Processing aborts.

[Action]

Check log of Operating System.

---

could not check the existence of the backend with PID @1@: @2@

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

---

could not connect due to the following errors

[Description]

Could not connect due to the following errors.

[System Processing]

Processing aborts.

[Action]

Check messages near this message.

---

could not connect to conmgr process: @1@

[Description]

Could not connect to conmgr process.

[System Processing]

Processing aborts.

[Action]

Check log of Operating System.

---

could not connect to database @1@: out of memory

[Description]

There was insufficient free space in the server's memory during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Estimate memory usage and take the following action:

- If the number of simultaneous connections from client applications is high, reduce it.

- If the number of simultaneous SQL executions is high, reduce it.

---

could not connect to Ident server at address "@1@", port @2@: @3@

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

could not receive data from server: @1@

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

---

could not receive database system identifier and timeline ID from the primary server: @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

---

could not receive response from Ident server at address "@1@", port @2@: @3@

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

could not sync to pid file "@1@": @2@

[Description]

Could not sync to pid file.

[System Processing]

Processing aborts.

[Action]

Check log of Operating System.

Could not translate client host name "@1@" to IP address: @2@.

[Description]

Supplementary information was output.

[System Processing]

None.

[Action]

Refer to this message together with the message that was output immediately beforehand.

---

could not translate name

[Description]

An error occurred while translating domain name to Kerberos realm name in SSL.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the domain name is written correctly.

---

could not try-lock semaphore: error code @1@

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

---

could not write archive status file "@1@": @2@

[Description]

There was insufficient free space in the disk of the database server during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Delete user data stored in the database server to free up space on the disk.

---

could not write block @1@ in file "@2@": @3@

[Description]

There was insufficient free space in the disk of the database server during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Delete user data stored in the database server to free up space on the disk.

---

could not write block @1@ in file "@2@": wrote @3@ of @4@

[Description]

There was insufficient free space in the disk of the database server during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Delete user data stored in the database server to free up space on the disk.

---

could not write block @1@ in file "@2@": wrote only @3@ of @4@ bytes

[Description]

There was insufficient free space in the disk of the database server during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Delete user data stored in the database server to free up space on the disk.

---

could not write bootstrap write-ahead log file: @1@

[Description]

There was insufficient free space in the disk of the database server during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Delete user data stored in the database server to free up space on the disk.

---

could not write file "@1@": @2@

[Description]

There was insufficient free space in the disk of the database server during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Delete user data stored in the database server to free up space on the disk.

---

could not write pid file "@1@": @2@

[Description]

Could not write pid file.

[System Processing]

Processing aborts.

[Action]

Check log of Operating System.

---

could not write server file "@1@": @2@

[Description]

There was insufficient free space in the disk of the database server during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Delete user data stored in the database server to free up space on the disk.

---

could not write temporary statistics file "@1@": @2@

[Description]

There was insufficient free space in the disk of the database server during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Delete user data stored in the database server to free up space on the disk.

---

could not write to COPY file: @1@

[Description]

There was insufficient free space in the disk of the database server during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Delete user data stored in the database server to free up space on the disk.

---

could not write to file "@1@": @2@

[Description]

There was insufficient free space in the disk of the database server during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Delete user data stored in the database server to free up space on the disk.

---

could not write to log file @1@ at offset @2@, length @3@: @4@

[Description]

There are the following cases:

- failed to write transaction log file

- failed to write transaction log file on backup data storage destination

[System Processing]

Processing will be aborted.

[Action]

Lack of storage space or malfunction of storage allocating the file shown in this message is considered.

If it's ture, recover the database system accoring to "Actions when an Error Occurs" of "Operation Guide" or "Cluster Operation Guide (Database Multiplexing)".

If it's not true, identify the cause according to the informations in this message such as errno, and work around.

The following major causes are considered.

- the file has no permission or the permission has been changed

- power of the storage allocating the file has been turned off

- unmounted the storage allocating the file

- another process or human operated the file

- the storage allocating the file has crashed

---

could not write to pid file "@1@": @2@

[Description]

Could not write to pid file.

[System Processing]

Processing aborts.

[Action]

expected password response, got message type @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

---

expected SSPI response, got message type @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

---

failed to add new prepared transaction "@1@" by worker(@2@)

[Description]

Failed to add new prepared transaction.

[System Processing]

Processing will be aborted.

[Action]

Please refer to the server log, and determine the cause of the error.

---

failed to delete the record with id: @1@(SPI returned: @2@)

[Description]

Could not delete the row in pgx_loader_state table.

[System Processing]

Processing will be aborted.

[Action]

Please refer to the server log, and determine the cause of the error.

---

failed to execute SPI returned @1@

[Description]

Could not execute SPI.

[System Processing]

Processing will be aborted.

[Action]

Please refer to the server log, and determine the cause of the error.

---

failed to fetch id column from "@1@" by worker(@2@)

[Description]

Failed to fetch the id column.

[System Processing]

Processing will be aborted.

[Action]

Please refer to the server log, and determine the cause of the error.

---

failed to send GSSAPI negotiation response: @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

---

failed to update state column of record with id: @1@

[Description]

Failed to update the state column.

[System Processing]

Processing will be aborted.

[Action]

Please refer to the server log, and determine the cause of the error.

---

function call message contains @1@ argument formats but @2@ arguments

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

function call message contains @1@ arguments but function requires @2@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

heartbeat connect is refused: @1@

[Description]

Heartbeat connect is refused.

heartbeat is timed out

[Description]

Heartbeat is timed out.

[System Processing]

Processing aborts.

[Action]

Check log of remote system.

host name must be specified for a verified SSL connection

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

host name must be specified

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

incomplete message from client

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

incomplete multibyte character

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

incomplete startup packet

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

Increase watchdog.max_hb_connections.

[Description]

Increase watchdog.max_hb_connections.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

internal error: received unexpected database pattern_id @1@

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

internal error: received unexpected relation pattern_id @1@

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

invalid argument size @1@ in function call message

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

invalid connection option "@1@"

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

invalid DESCRIBE message subtype @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

invalid frontend message type @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

invalid length of startup packet

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

invalid message format

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

invalid message length

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

invalid parameter '@1@' in configuration file "@2@" line @3@

[Description]

Invalid parameter in configuration file.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

invalid password packet size

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

invalid pid file "@1@"

[Description]

Invalid pid file.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

invalid record length at @1@/@2@: wanted @3@, got @4@

[Description]

invalid record length was found on archive log or transaction log data.

[System Processing]

The following causes could be considered.

- if the log level is information(INFO, NOTICE, LOG, DEBUG)

Continue processing.

- if the log level is error(ERROR, FATAL, PANIC)

Processing will be aborted.

[Action]

If the log level is information(INFO, NOTICE, LOG, DEBUG), no action is required.

When the log level is error(ERROR, FATAL, PANIC), take either of the following actions.

- if this message is output during starting instance

Please restore according to "Deal at the time of abnormality" of "Operation Guide" or "Cluster Operation Guide (Database Multiplexing)".

- if this message is output during recovering

Cannot continue to recover with the current backup data because an archive log in the backup has an error.

Recover from the other backup data.

---

invalid response from primary server

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

---

invalid socket: @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

---

invalid standby message type "@1@"

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

invalid startup packet layout: expected terminator as last byte

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

invalid string in message

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

invalid timeout "@1@"

[Description]

Invalid timeout specified.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

invalid value for integer parameter in configuration file "@1@" line @2@

[Description]

Invalid value for integer parameter in configuration file.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

invalid value for parameter '@1@'

[Description]

Invalid value for parameter.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

invalid value for parameter '@1@' in configuration file "@2@" line @3@

[Description]

Invalid value for parameter in configuration file.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

invalid value for parameter '@1@' of instance #@2@

[Description]

Invalid value for parameter of instance.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

Keystore does not require passphrase.

[Description]

keystore-passphrase command line option and PGX_KEYSTORE_PASSPHRASE environment variable should not be set when using TDE_z extension.

[System Processing]

Processing will be aborted.

[Action]

Remove keystore-passphrase from command line option or unset PGX_KEYSTORE_PASSPHRASE environment variable before starting the server with TDE_z extension loaded.

lack of max_prepared_transactions

[Description]

Lack of max_prepared_transactions.

[System Processing]

Processing will be aborted.

[Action]

Please increase max_prepared_transactions.

level number 77 could not be used for group item

[Description]

A group data item contains the 77 level variable.

[System Processing]

Precompling will be aborted.

[Action]

Remove the variable from the group data item.

level number 77 could not be used in TYPEDEF statement

[Description]

77 level variable is used in the TYPEDEF statement.

[System Processing]

Precompling will be aborted.

[Action]

Change the level number.

Limits the total size of all temporary files used by each process.

[Description]

There was insufficient free space in the disk of the database server during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Delete user data stored in the database server to free up space on the disk.

line @1@ too long in service file "@2@"

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

listening on @1@ port @2@

[Description]

Listening on port.

[System Processing]

Processing continues.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

logical replication target relation "@1@.@2@" uses system columns in REPLICA IDENTITY index

[Description]

Logical replication target relation uses some of the system columns to identify rows which are updated or deleted.

[System Processing]

Processing will be aborted.

[Action]

Usage of system columns for REPLICA IDENTITY should be avoided as these data vary across databases.

---

lost synchronization with server: got message type "@1@", length @2@

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

---

materialize mode required, but it is not allowed in this context

[Description]

Materialize mode required, but it is not allowed in this context.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

---

max_prepared_transactions must be set at least @1@

[Description]

Lack of max_prepared_transactions.

[System Processing]

Processing will be aborted.

[Action]

Please increase max_prepared_transactions.

message contents do not agree with length in message type "@1@"

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

missing "=" after "@1@" in connection info string

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

new primary COORDINATOR has been connected

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

no cmdata directory specified and environment variable CMDATA unset

[Description]

No cmdata directory specified and environment variable CMDATA unset.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

no connection manager directory is specified and environment variable CMDATA is unset

[Description]

No connection manager directory is specified and environment variable CMDATA is unset.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

no data left in message

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

no empty local buffer available

[Description]

There was insufficient free space in the disk of the database server during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Delete user data stored in the database server to free up space on the disk.

no operation mode is specified

[Description]

No operation mode is specified.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

no target server address from Connection Manager

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

node_name is needed for instance #@1@

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

---

node_name is not needed for instance #@1@

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

---

not enough elements in RWConflictPool to record a potential read/write conflict

[Description]

There was insufficient free space in the server's memory during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Estimate memory usage and take the following action:

- If the number of simultaneous connections from client applications is high, reduce it.

- If the number of simultaneous SQL executions is high, reduce it.

---

not enough elements in RWConflictPool to record a read/write conflict

[Description]

There was insufficient free space in the server's memory during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Estimate memory usage and take the following action:

- If the number of simultaneous connections from client applications is high, reduce it.

- If the number of simultaneous SQL executions is high, reduce it.

---

not enough shared memory for data structure "@1@" (@2@ bytes requested)

[Description]

There was insufficient free space in the database server's shared memory during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Estimate memory usage and take the following action:

- If the number of simultaneous connections from client applications is high, reduce it.

- If the number of simultaneous SQL executions is high, reduce it.

---

number of workers must not be negative

[Description]

The number of workers must not be negative.

[System Processing]

Processing will be aborted.

[Action]

Please specify more than one.

---

oldest multixact is far in the past

[Description]

Terminated normally but a warning was output.

[System Processing]

Continues processing.

[Action]

Close open transactions with multixacts soon to avoid wraparound problems.

---

one of -d/--dbname and -f/--file must be specified

[Description]

one of -d/--dbname and -f/--file must be specified

[System Processing]

Processing will be aborted.

[Action]

Check the command-line, and re-execute the command with correct options.

---

out of memory

[Description]

There was insufficient free space in the server's memory during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Estimate memory usage and take the following action:

- If the number of simultaneous connections from client applications is high, reduce it.

- If the number of simultaneous SQL executions is high, reduce it.

---

out of memory allocating GSSAPI buffer (@1@)

[Description]

There was insufficient free space in the client's memory during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Estimate memory usage and take the following action:

- Modify the application to reduce memory usage.

---

out of memory for query result

[Description]

There was insufficient free space in the client's memory during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Estimate memory usage and take the following action:

- Modify the application to reduce memory usage.

---

out of memory on line @1@

[Description]

There was insufficient free space in the server's memory during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Estimate memory usage and take the following action:

- If the number of simultaneous connections from client applications is high, reduce it.

- If the number of simultaneous SQL executions is high, reduce it.

---

out of shared memory

[Description]

There was insufficient free space in the database server's shared memory during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Estimate memory usage and take the following action:

- If the number of simultaneous connections from client applications is high, reduce it.

- If the number of simultaneous SQL executions is high, reduce it.

---

pgx_global_metacache must be set to at least 10MB when enabled.

[Description]

pgx_global_metacache must be set to at least 10MB when enabled.

[System Processing]

Processing will be aborted.

[Action]

Set the pgx_global_metacache parameter to at least 10MB and restart the database.

pgx_loader only available using COPY FROM

[Description]

pgx_loader can be available only COPY FROM command.

[System Processing]

Processing will be aborted.

[Action]

Please specify COPY FROM statement.

pid file "@1@/conmgr.pid" does not exist

[Description]

Pid file does not exist.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

posting list is too long

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

Reduce the value of maintenance_work_mem.

postmaster exited during a parallel loading

[Description]

postmaster exited during a parallel loading.

[System Processing]

Processing will be aborted.

[Action]

Please refer to the server log, and determine the cause of the error.

pre-existing shared memory block (key @1@, ID @2@) is still in use

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

private key file "@1@" has group or world access; file must have permissions u=rw (0600) or less if owned by the current user, or permissions u=rw,g=r (0640) or less if owned by root

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

private key file "@1@" is not a regular file

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

private key file "@1@" must be owned by the database user or root

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

protocol error: id=0x@1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

query failed: @1@

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

query would be affected by row-level security policy for table "@1@"

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

To disable the policy for the table owner, use ALTER TABLE NO FORCE ROW LEVEL SECURITY.

real and effective user IDs must match

[Description]

Real and effective user IDs must match.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

realm name too long

[Description]

An error occurred while translating domain name to Kerberos realm name in SSL.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the domain name is written correctly.

received fast shutdown request

[Description]

Received fast shutdown request.

[System Processing]

Processing continues.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

received immediate shutdown request

[Description]

Received immediate shutdown request.

[System Processing]

Processing continues.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

received invalid response to SSL negotiation: @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

received invalid startup packet

[Description]

Received invalid startup packet.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

received smart shutdown request

[Description]

Received smart shutdown request.

[System Processing]

Processing continues.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

received unencrypted data after GSSAPI encryption request

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

received unencrypted data after SSL request

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

recovery has paused

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

rejected a connection from application due to going shutdown

[Description]

Rejected a connection from application due to going shutdown.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

remote node closes heartbeat connection

[Description]

Remote node closes heartbeat connection.

[System Processing]

Processing aborts.

[Action]

Check log of remote system.

remote node shuts down heartbeat connection

[Description]

Remote node shuts down heartbeat connection.

[System Processing]

Processing aborts.

[Action]

Check log of remote system.

Remove those directories, or set allow_in_place_tablespaces to ON transiently to let recovery complete.

[Description]

An error occurred due to unexpected directory entry found at specific path

[System Processing]

Cancels processing.

[Action]

Remove those unexpected directories, or set allow_in_place_tablespaces to ON transiently to let recovery complete.

results of copying file does not exist

[Description]

The backup data may be corrupted.

[System Processing]

Processing will be aborted.

[Action]

Copy the backup data to the backup storage directory from backup media.

RETURNING list entry has type @1@, but column has type @2@.

[Description]

Supplementary information was output.

[System Processing]

None.

[Action]

Refer to this message together with the message that was output immediately beforehand.

role with OID @1@ does not exist

[Description]

An error occurred during DB Server processing in the database.

[System Processing]

Processing will be aborted.

[Action]

Refer to this message together with the message that was output immediately beforehand.

root certificate file "@1@" does not existEither provide the file or change sslmode to disable server certificate verification.

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

SELECT target entry has type @1@, but column has type @2@.

[Description]

Supplementary information was output.

[System Processing]

None.

[Action]

Refer to this message together with the message that was output immediately beforehand.

SELECT target entry is named "@1@".

[Description]

Supplementary information was output.

[System Processing]

None.

[Action]

Refer to this message together with the message that was output immediately beforehand.

select() failed in postmaster: @1@

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

server certificate for "@1@" does not match host name "@2@"

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

server sent data ("D" message) without prior row description ("T" message)

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

service file "@1@" not found

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

set-valued function called in context that cannot accept a set

[Description]

Set-valued function called in context that cannot accept a set.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

Sleep until another process releases global meta cache because global meta cache cannot be swept away yet. Please increase pgx_global_metacache.

[Description]

Sleep until another process releases global meta cache because global meta cache cannot be swept away yet. Please increase pgx_global_metacache.

[System Processing]

Processing continues.

[Action]

If this message occurs frequently, increase the pgx_global_metacache parameter setting and restart the database.

SSL certificate's common name contains embedded null

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

SSL connection has been closed unexpectedly

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

SSL error: @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

stack depth limit exceeded

[Description]

The depth of the execution stack exceeded the allowable value during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

If executing a complex SQL, modify it to a simple SQL.

standby mode is not supported by single-user servers

[Description]

An error occurred during DB Server processing in the database.

[System Processing]

Processing will be aborted.

[Action]

Refer to this message together with the message that was output immediately beforehand.

started conmgr process successfully

[Description]

Started conmgr process successfully.

[System Processing]

Continues processing.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

starting conmgr process

[Description]

Starting conmgr process.

[System Processing]

Continues processing.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

stopped conmgr process successfully

[Description]

Stopped conmgr process successfully.

[System Processing]

Continues processing.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

String constants with Unicode escapes cannot be used when standard_conforming_strings is off.

[Description]

Supplementary information was output.

[System Processing]

None.

[Action]

Refer to this message together with the message that was output immediately beforehand.

string is not a valid identifier: "@1@"

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

The string may have unclosed double quotation marks.

synchronous_standby_names parser failed

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

Check the value of synchronous_standby_names, which may come from postgresql.conf or the SQL command line.

syntax error in service file "@1@", line @2@

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

syntax error near '@1@' in configuration file "@2@" line @3@

[Description]

Syntax error in configuration file.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

syntax error near end of line in configuration file "@1@" line @2@

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

TDE_h extension must be loaded via shared_preload_libraries

[Description]

The TDE_h extension cannot be dynamically loaded by the user.

[System Processing]

Processing will be aborted.

[Action]

In postgresql.conf specify shared_preload_libraries = 'tde_h'

TDE_h: @1@ failed: @2@ [@3@]

[Description]

The PKCS11 function call failed.

[System Processing]

Processing will be aborted.

[Action]

The specified value in the PKCS11 configuration file (grep11client.yaml) or the TDE_h execution environment is incorrect, or the HPCS is detecting an error. Check the message and take appropriate action according to the reported PKCS11 error code. Also, if you have specified a log in the PKCS11 configuration file, check the output log and take action.

TDE_h: C_Login: @1@ [@2@]

[Description]

The call to the C_OpenSession function of PKCS11 has failed.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and take appropriate action based on the reported PKCS11 error code.

TDE_h: Expected key not found: @1@ [@2@]

[Description]

During encryption or decryption processing TDE_h was not able to find an expected PKCS11 key.

[System Processing]

Processing will be aborted.

[Action]

The keystore and the PKCS11 token key objects are not consistent with each other. This may happen if the keystore and/or PKCS11 token directory have been incorrectly copied (or not copied at all). Check all files have been copied correctly.

TDE_h: Operation is not supported

[Description]

The TDE_h extension cannot be dynamically loaded by the user.

[System Processing]

Processing will be aborted.

[Action]

In postgresql.conf specify shared_preload_libraries = 'tde_h'

TDE_h: HPCS Service API Key is not available at load time

[Description]

The PKCS11 API key associated with the token of Slot ID was not defined at load time.

[System Processing]

This is only a warning message when TDE_h is loaded.

[Action]

The token API key must be known to tde_h before secure keys can be used. Specify the API key at load time with --api-key option, or by GUC tde_h.API_KEY in postgresql.conf. Or, specify the API key at run-time using SELECT pgx_open_keystore(API Key); or SELECT pgx_set_master_key(API Key);

TDE_h: PKCS11 Slot ID is not defined

[Description]

The PKCS11 Slot ID for transparent data encryption is not defined.

[System Processing]

Processing will be aborted.

[Action]

In postgresql.conf set the GUC tded_h.SLOT_ID to the PKCS11 Slot ID configured for transparent data encryption.

TDE_h: Slot @1@ C_GetMechanismInfo CKM_AES_CBC: @2@ [@3@]

[Description]

The specified Slot ID does not support a mechanism required by TDE_h.

[System Processing]

Processing will be aborted.

[Action]

Specify a different token which supports the necessary mechanism.

TDE_h: Slot @1@ C_GetMechanismInfo CKM_AES_KEY_GEN: @2@ [@3@]

[Description]

The specified Slot ID does not support a mechanism required by TDE_h.

[System Processing]

Processing will be aborted.

[Action]

Specify a different token which supports the necessary mechanism.

TDE_h: Slot @1@ C_OpenSession: @2@ [@3@]

[Description]

The call to the C_OpenSession function of PKCS11 has failed.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and take appropriate action based on the reported PKCS11 error code.

TDE_h: Slot @1@ mechanism does not support CKF_DECRYPT

[Description]

The specified Slot ID does not support a mechanism required by TDE_h.

[System Processing]

Processing will be aborted.

[Action]

Specify a different token which supports the necessary mechanism.

TDE_h: Slot @1@ mechanism does not support CKF_ENCRYPT

[Description]

The specified Slot ID does not support a mechanism required by TDE_h.

[System Processing]

Processing will be aborted.

[Action]

Specify a different token which supports the necessary mechanism.

TDE_h: Slot @1@ mechanism does not support CKF_GENERATE

[Description]

The specified Slot ID does not support a mechanism required by TDE_h.

[System Processing]

Processing will be aborted.

[Action]

Specify a different token which supports the necessary mechanism.

TDE_h: Slot @1@ token model '@2@' is not supported

[Description]

The PKCS11 token model at the specified Slot ID is not suported by TDE_h.

[System Processing]

Processing will be aborted.

[Action]

Only "EP11" and "CCA" tokens are supported.

TDE_h: Slot @1@ token model is '@2@'

[Description]

Logs the PKCS11 Slot ID and token model that TDE_h will be using.

[System Processing]

This is an information messaage when TDE_h is loaded.

[Action]

No action is required. Confirm the Slot and token type are as expected.

TDE_h: Unable to initialize for TDE_h environment

[Description]

Failed to initialize execution environment for TDE_h.

[System Processing]

Processing will be aborted.

[Action]

The specified value in the PKCS11 configuration file (grep11client.yaml) or the TDE_h execution environment is incorrect, or the HPCS is detecting an error. Check the message and take appropriate action according to the reported PKCS11 error code. Also, if you have specified a log in the PKCS11 configuration file, check the output log and take action.

TDE_h: Unable to initialize the PKCS11 library: 0x@1@ [@2@]

[Description]

The call to the C_Initalize function of PKCS11 has failed.

[System Processing]

Processing will be aborted.

[Action]

The specified value in the PKCS11 configuration file (grep11client.yaml) or the TDE_h execution environment is incorrect, or the HPCS is detecting an error. Check the message and take appropriate action according to the reported PKCS11 error code. Also, if you have specified a log in the PKCS11 configuration file, check the output log and take action.

TDEz: Operation is not supported

[Description]

The TDE_z extension cannot be dynamically loaded by the user.

[System Processing]

Processing will be aborted.

[Action]

In postgresql.conf specify shared_preload_libraries = 'TDE_z'

TDE_z extension must be loaded via shared_preload_libraries

[Description]

The TDE_z extension cannot be dynamically loaded by the user.

[System Processing]

Processing will be aborted.

[Action]

In postgresql.conf specify shared_preload_libraries = 'TDE_z'

TDE_z: C_Login: @1@ [@2@]

[Description]

The call to the C_OpenSession function of PKCS#11 has failed.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and take appropriate action based on the reported PKCS#11 error code.

TDE_z: Expected key not found: @1@ [@2@]

[Description]

During encryption or decryption processing TDE_z was not able to find an expected opencryptoki key.

[System Processing]

Processing will be aborted.

[Action]

The keystore and the opencryptoki token key objects are not consistent with each other. This may happen if the keystore and/or opencryptoki token directory have been incorrectly copied (or not copied at all). Check all files have been copied correctly.

TDE_z: PKCS11 Slot ID is not defined

[Description]

The opencryptoki Slot ID for transparent data encryption is not defined.

[System Processing]

Processing will be aborted.

[Action]

In postgresql.conf set the GUC TDE_z.SLOT_ID to the opencryptoki Slot ID configured for transparent data encryption.

TDE_z: PKCS11 User PIN is not available at load time

[Description]

The opencryptoki User PIN associated with the token of Slot ID was not defined at load time.

[System Processing]

This is only a warning message when TDE_z is loaded.

[Action]

The token User PIN must be known to TDE_z before secure keys can be used. Specify the User PIN at load time with --user-pin option, or by GUC TDE_z.USER_PIN in postgresql.conf. Or, specify the User PIN at run-time using SELECT pgx_open_keystore(user pin); or SELECT pgx_set_master_key(user pin);

TDE_z: Slot @1@ C_GetMechanismInfo CKM_AES_CBC: @2@ [@3@]

[Description]

The specified Slot ID does not support a mechanism required by TDE_z.

[System Processing]

Processing will be aborted.

[Action]

Specify a different token which supports the necessary mechanism.

TDE_z: Slot @1@ C_GetMechanismInfo CKM_AES_KEY_GEN: @2@ [@3@]

[Description]

The specified Slot ID does not support a mechanism required by TDE_z.

[System Processing]

Processing will be aborted.

[Action]

Specify a different token which supports the necessary mechanism.

TDE_z: Slot @1@ C_OpenSession: @2@ [@3@]

[Description]

The call to the C_OpenSession function of PKCS#11 has failed.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and take appropriate action based on the reported PKCS#11 error code.

TDE_z: Slot @1@ mechanism does not support CKF_DECRYPT

[Description]

The specified Slot ID does not support a mechanism required by TDE_z.

[System Processing]

Processing will be aborted.

[Action]

Specify a different token which supports the necessary mechanism.

TDE_z: Slot @1@ mechanism does not support CKF_ENCRYPT

[Description]

The specified Slot ID does not support a mechanism required by TDE_z.

[System Processing]

Processing will be aborted.

[Action]

Specify a different token which supports the necessary mechanism.

TDE_z: Slot @1@ mechanism does not support CKF_GENERATE

[Description]

The specified Slot ID does not support a mechanism required by TDE_z.

[System Processing]

Processing will be aborted.

[Action]

Specify a different token which supports the necessary mechanism.

TDE_z: Slot @1@ token model '@2@' is not supported

[Description]

The opencryptoki token model at the specified Slot ID is not supported by TDE_z.

[System Processing]

Processing will be aborted.

[Action]

Only "EP11" and "CCA" tokens are supported.

TDE_z: Slot @1@ token model is '@2@'

[Description]

Logs the opencryptoki Slot ID and token model that TDE_z will be using.

[System Processing]

This is an information messaage when TDE_z is loaded.

[Action]

No action is required. Confirm the Slot and token type are as expected.

TDE_z: Unable to initialize the opencryptoki library: 0x@1@ [@2@]

[Description]

The call to the C_Initalize function of PKCS#11 has failed.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and take appropriate action based on the reported PKCS#11 error code.

TDE-type is inconsistent between keystore and postgresql.conf.

[Description]

The TDE type specified in shared_preload_libraries in postgresql.conf does not match the keystore format of the execution environment.

[System Processing]

Processing will be aborted.

[Action]

Inconsistent value specified for shared_preload_libraries in keystore and postgresql.conf. Determine which is correct and take appropriate action.

---

terminating connection due to conflict with recovery

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

---

terminating connection due to idle-session timeout

[Description]

Timeout occurred during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Check the following:

- If executing SQL that outputs a large volume of search results, add a conditional expression to filter the results further.

- If numerous SQLs are being simultaneously executed, reduce the number of simultaneously executed SQLs.

- If a large volume of data is to be updated in a single transaction, modify the SQL to reduce the volume of data to be updated in a single transaction.

- If executing a complex SQL, modify it to a simple SQL.

- Check if there are any problems in the network.

- Before conducting maintenance that involves the processing of a large volume of data, use the SET statement to temporarily increase the value of maintenance_work_mem.

---

terminating connection due to unexpected postmaster exit

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the server is still running.

terminating walsender process due to replication timeout

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

terminator: could not prepare statement for "@1@"

[Description]

Could not prepare statement.

[System Processing]

Processing aborts.

[Action]

Check messages near this message.

terminator: terminated connections: ipaddress="@1@"

[Description]

Terminated connections.

[System Processing]

Processing continues.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

the database system is in recovery mode

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

the database system is not accepting connections

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

the database system is not yet accepting connections

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

the database system is shutting down

[Description]

The database system is shutting down.

[System Processing]

Processing will be aborted.

[Action]

This message is output when the stopping process is operating normally. Retry any necessary applications or commands after restarting the database system.

the database system is starting up

[Description]

The database system is starting up.

[System Processing]

Processing will be aborted.

[Action]

This message is output when the startup process or recovery process is operating normally. Restart any necessary the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

The program "@1@" is needed by @2@ but was not found in thesame directory as "@3@".Check your installation.

[Description]

A required program was not found. Check your installation.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

The program "@1@" was found by "@2@"but was not the same version as @3@.Check your installation.

[Description]

The program was not the same version.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

The sslservercertcn "@1@" could not be verified

[Description]

value of sslservercertcn is different from common name in the server certificate.

[System Processing]

Processing is aborted.

[Action]

Set SSL certificate's common name to sslservercertcn.

timeout expired

[Description]

Timeout occurred during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Check the following:

- If executing SQL that outputs a large volume of search results, add a conditional expression to filter the results further.

- If numerous SQLs are being simultaneously executed, reduce the number of simultaneously executed SQLs.

- If a large volume of data is to be updated in a single transaction, modify the SQL to reduce the volume of data to be updated in a single transaction.

- If executing a complex SQL, modify it to a simple SQL.

- Check if there are any problems in the network.

- Before conducting maintenance that involves the processing of a large volume of data, use the SET statement to temporarily increase the value of maintenance_work_mem.

too long literal in configuration file "@1@" line @2@

[Description]

Too long literal in configuration file.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

too many background workers

[Description]

Up to max_worker_processes background worker can be registered with the current settings.

[System Processing]

Processing will be aborted.

[Action]

Consider increasing the value of configuration parameter max_worker_processes.

---

too many command-line arguments (first is "@1@")

[Description]

Too many command-line arguments.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

---

too many grouping sets present (maximum 4096)

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the items in the GROUPING SET are less than the maximum allowable value.

---

translated account name too long

[Description]

An error occurred while translating account name to Kerberos user name in SSL.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the account name is written correctly.

---

trigger created with DO block cannot be replaced by EXECUTE PROCEDURE

[Description]

Trigger created with DO block cannot be replaced by EXECUTE PROCEDURE.

[System Processing]

Processing is aborted.

[Action]

Please redefine it after deleting the trigger.

---

trigger created with EXECUTE PROCEDURE cannot be replaced by DO block

[Description]

Trigger created with EXECUTE PROCEDURE cannot be replaced by DO block.

[System Processing]

Processing is aborted.

[Action]

Please redefine it after deleting the trigger.

---

type input function @1@ should not be volatile

[Description]

An error occurred during execution of the application or command.

[System Processing]

Continues processing.

[Action]

Check the message text and confirm that functions are not marked as volatile.

---

type modifier input function @1@ should not be volatile

[Description]

An error occurred during execution of the application or command.

[System Processing]

Continues processing.

[Action]

Check the message text and confirm that functions are not marked as volatile.

---

type modifier output function @1@ should not be volatile

[Description]

An error occurred during execution of the application or command.

[System Processing]

Continues processing.

[Action]

Check the message text and confirm that functions are not marked as volatile.

---

type output function @1@ should not be volatile

[Description]

An error occurred during execution of the application or command.

[System Processing]

Continues processing.

[Action]

Check the message text and confirm that functions are not marked as volatile.

---

type receive function @1@ should not be volatile

[Description]

An error occurred during execution of the application or command.

[System Processing]

Continues processing.

[Action]

Check the message text and confirm that functions are not marked as volatile.

type send function @1@ should not be volatile

[Description]

An error occurred during execution of the application or command.

[System Processing]

Continues processing.

[Action]

Check the message text and confirm that functions are not marked as volatile.

unexpected directory entry "@1@" found in @2@

[Description]

Unexpected directory entry found at specific path while recovery.

[System Processing]

Cancels processing.

[Action]

Remove those unexpected directories, or set allow_in_place_tablespaces to ON transiently to let recovery complete.

unexpected EOF on standby connection

[Description]

An error occurred because execution is temporarily impossible.

[System Processing]

Processing will be aborted.

[Action]

Restart the application. If the same error occurs when you restart the application, to check if there are any problems in the database server.

unexpected EOF within message length word

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

unexpected field count in "D" message

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

unexpected message from server during startup

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

unexpected message type "@1@"

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

unexpected message type 0x@1@ during COPY from stdin

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

unexpected response from server; first received character was "@1@"

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

Unicode escapes must be \\uXXXX or \\UXXXXXXXX.

[Description]

Supplementary information was output.

[System Processing]

None.

[Action]

Refer to this message together with the message that was output immediately beforehand.

unrecognized operation mode "@1@"

[Description]

Unrecognized operation mode was specified.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

unrecognized SSL error code: @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

unrecognized stop mode "@1@"

[Description]

Unrecognized stop mode was specified.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

unrecognized value "@1@" for option '-i'

[Description]

Unrecognized value specified for option '-i'.

[System Processing]

Processing aborts.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

unterminated quoted string in connection info string

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

Use '' to write quotes in strings, or use the escape string syntax (E'...').

[Description]

Supplementary information was output.

[System Processing]

None.

[Action]

Refer to this message together with the message that was output immediately beforehand.

Use '' to write quotes in strings. \\' is insecure in client-only encodings.

[Description]

Supplementary information was output.

[System Processing]

None.

[Action]

Refer to this message together with the message that was output immediately beforehand.

Use the escape string syntax for backslashes, e.g., E'\\\\'.

[Description]

Supplementary information was output.

[System Processing]

None.

[Action]

Refer to this message together with the message that was output immediately beforehand.

Use the escape string syntax for escapes, e.g., E'\\r\'.

[Description]

Supplementary information was output.

[System Processing]

None.

[Action]

Refer to this message together with the message that was output immediately beforehand.

waiting conmgr process to connect to watchdog

[Description]

Waiting conmgr process to connect to watchdog.

[System Processing]

Continues processing.

[Action]

Recheck command line, configuration file, or logic of your application. Hint message may follow with this message.

watchdog: could not accept heartbeat connection

[Description]

Could not accept heartbeat connection.

[System Processing]

Processing aborts.

[Action]

Check messages near this message.

watchdog: could not send attribute

[Description]

Could not send attribute.

[System Processing]

Processing aborts.

[Action]

Check messages near this message.

You might need to increase max_worker_processes.

[Description]

You might need to increase max_worker_processes.

[System Processing]

Processing will be aborted.

[Action]

You might need to increase max_worker_processes

An error occurred while setting up the GSS Encoded connection.

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

An error occurred while setting up the SSL connection.

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

An I/O error occurred while sending to the backend.

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

An unexpected result was returned by a query.

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

Cannot connect to Connection Manager when targetServerType is "preferPrimary".

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the application is written correctly and the command is being used correctly.

CommandComplete expected COPY but got:

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

Connection attempt timed out.

[Description]

Timeout occurred during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Check the following:

- If executing SQL that outputs a large volume of search results, add a conditional expression to filter the results further.

- If numerous SQLs are being simultaneously executed, reduce the number of simultaneously executed SQLs.

- If a large volume of data is to be updated in a single transaction, modify the SQL to reduce the volume of data to be updated in a single transaction.

- If executing a complex SQL, modify it to a simple SQL.

- Check if there are any problems in the network.

- Before conducting maintenance that involves the processing of a large volume of data, use the SET statement to temporarily increase the value of maintenance_work_mem.

Could not close SSL certificate file @1@.

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

Could not find a server with specified targetServerType: @1@

[Description]

Could not find a suitable target server.

[System Processing]

Processing is aborted.

[Action]

Check following settings (host, IP address, port number,or targetServer):

- Connection string

- Connection service file

- Data source of JDBC or ODBC

- Environment variables for default connection parameter values(ex. PGHOST)

- Arguments of functions of libpq

- Options of command

Database cannot be null

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

Database connection failed when canceling copy operation

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

Database connection failed when ending copy

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

Database connection failed when reading from copy

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

Database connection failed when starting copy

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

Database connection failed when writing to copy

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

---

enableFdwAcs cannot be set "on" when targetServerType is "preferPrimary".

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the application is written correctly and the command is being used correctly.

Expected an EOF from server, got: @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

Expected command status BEGIN, got @1@.

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

Got @1@ error responses to single copy cancel request

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

GSS Authentication failed

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

hstore key must not be null

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

Interrupted while attempting to connect.

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

Invalid gssEncMode value: @1@

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

Invalid targetServerType value: @1@

[Description]

value of targetserver is invalid.

[System Processing]

Processing is aborted.

[Action]

Set one of the following:

- primary

- standby

- prefer_standby

- any(can be specified only JDBC)

Missing expected error response to copy cancel request

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

Neither Subject.doAs (Java before 18) nor Subject.callAs (Java 18+) method found

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

One or more ClientInfo failed.

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

PreparedStatement can have at most @1@ parameters. Please consider using arrays, or splitting the query in several ones, or using COPY. Given query has @2@ parameters

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the application is written correctly and the command is being used correctly.

Protocol error. Session setup failed.

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

Ran out of memory retrieving query results.

[Description]

There was insufficient free space in the server's memory during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Estimate memory usage and take the following action:

- If the number of simultaneous connections from client applications is high, reduce it.

- If the number of simultaneous SQL executions is high, reduce it.

Read from copy failed.

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

The connection attempt failed.

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

The server does not support GSS Encoding.

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

The server does not support GSS Encryption.

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

The server requested password-based authentication, but no password was provided by plugin @1@

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

The server requested SCRAM-based authentication, but the password is an empty string.

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

The server''s client_encoding parameter was changed to @1@. The JDBC driver requires client_encoding to be UTF8 for correct operation.

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

The server''s DateStyle parameter was changed to @1@. The JDBC driver requires DateStyle to begin with ISO for correct operation.

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

The server''s standard_conforming_strings parameter was reported as @1@. The JDBC driver expected on or off.

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

The sslservercertcn @1@ could not be verified by hostnameverifier @2@.

[Description]

value of sslservercertcn is different from common name in the server certificate.

[System Processing]

Processing is aborted.

[Action]

- Set SSL certificate's common name to sslservercertcn.

- Check the program of class specified by hostnameverifier.

Unable to find pkcs12 keystore.

[Description]

The operating environment such as the status of the connection definition file and the connection method specification is abnormal.

[System Processing]

Processing will be aborted.

[Action]

Confirm that the operating environment such as the status of the connection definition file and the connection method specification is normal.

Unable to load Authentication Plugin @1@

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

Unable to parse URL @1@

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

Unexpected command status: @1@.

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

Unexpected copydata from server for @1@

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

Unknown Response Type @1@.

[Description]

An error occurred during communication between the application and the database server.

[System Processing]

Processing will be aborted.

[Action]

Check if there are any problems in the network, eliminate the cause of any error and re-execute the command.

User cannot be null

[Description]

The database server was disconnected during execution of the application.

[System Processing]

Processing will be aborted.

[Action]

Communication may have been disconnected for the following reasons:

- An error occurred in the communication line (TCP/IP etc.)

- The database server terminated abnormally.

Take the following actions:

- Eliminate the cause of the communication disconnection.

Examine the application and check whether the transaction for implementing update is a long transaction. Judge whether it is a long transaction from the following viewpoints and modify the application.

a) If the COMMIT process is not executed after update, add the COMMIT process.

b) If the total number of update records in a single transaction is high, split it into short transactions.

c) If search was conducted for a long period of time after update, execute COMMIT after update or review the search SQL statement.

- If none of the above situations applies, perform the following:

a) Confirm that the database server has not stopped.

b) If the database server is starting or stopping, re-execute the command after the database server starts.

Value is not an OID: @1@

[Description]

An error occurred during execution of the application or command.

[System Processing]

Processing will be aborted.

[Action]

Check the message text and confirm that the application is written correctly and the command is being used correctly.

Chapter 3 Mirroring Controller Messages

This chapter explains messages output by Mirroring Controller.

3.1 Message Numbers Beginning with MCA00000

3.1.1 MCA00001

could not read file "{0}": exception={1}: {2}

[Description]

Could not read the file.

[Parameters]

{0}: file name

{1}: exception type

{2}: exception detail

[System Processing]

Processing will be aborted.

[Action]

Identify the cause according to the message, and then remove it.

3.1.2 MCA00002

{0}: wrong number of server ID in definition file "{1}"

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.1.3 MCA00003

{0}: server ID not found in definition file "{1}" line {2}

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: line number

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.1.4 MCA00004

{0}: server ID specified in definition file "{1}" too long (max {2} bytes) line {3}

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: max length of server ID

{3}: line number

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.1.5 MCA00005

invalid host name or IP address "{1}" in definition file "{0}"

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: file name

{1}: host name or IP address

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.1.6 MCA00006

{0}: invalid port number in definition file "{1}" line {2}

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: line number

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.1.7 MCA00007

{0}: invalid format specified in definition file "{1}" line {2}

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: line number

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.1.8 MCA00008

{0}: invalid value for parameter "{2}" in definition file "{1}"

[Description]

Invalid parameter was found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: parameter name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.1.9 MCA00009

{0}: no value for parameter "{2}" specified in definition file "{1}"

[Description]

Invalid parameter was found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: parameter name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.1.10 MCA00010

{0}: unrecognized parameter "{2}" in definition file "{1}"

[Description]

Unrecognized parameter was found in definition file.

[Parameters]

{0}: file name

{1}: command name

{2}: parameter name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.1.11 MCA00011

%s: no operation mode specified

[Description]

No operation mode was specified.

[Parameters]

%s: command name

[System Processing]

Processing will be aborted.

[Action]

Re-execute after specifying operation modes.

3.1.12 MCA00012

%s: unrecognized operation mode "%s"

[Description]

Unrecognized operation mode was specified.

[Parameters]

%s: command name

%s: operation mode

[System Processing]

Processing will be aborted.

[Action]

Re-execute after specifying operation modes.

3.1.13 MCA00013

%s: option "%s" duplicated

[Description]

Certain option is duplicated.

[Parameters]

%s: command

%s: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.1.14 MCA00014

%s: "%s" option conflicts with "%s" option

[Description]

Options are conflicting.

[Parameters]

%s: command

%s: option

%s: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.1.15 MCA00015

%s: option requires an argument -- %s

[Description]

No argument specified for the option.

[Parameters]

%s: command

%s: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.1.16 MCA00016

%s: neither "%s" option nor environment variable "%s" specified

[Description]

Both of required option and equivalent environment variable were not specified.

[Parameters]

%s: command

%s: option

%s: environment variable

[System Processing]

Processing will be aborted.

[Action]

Re-execute after specifying required option or equivalent environment variable.

3.1.17 MCA00017

%s: out of memory

[Description]

Out of memory error occurred.

[Parameters]

%s: command

[System Processing]

Processing will be aborted.

[Action]

Obtain free memory space by stopping unnecessary processes or changing system settings.

3.1.18 MCA00018

out of memory

[Description]

Out of memory error occurred.

[System Processing]

Processing will be aborted.

[Action]

Obtain free memory space by stopping unnecessary processes or changing system settings.

3.1.19 MCA00019

detected an error on the monitored object "{0}({1})": {2}

[Description]

An error was detected on the monitored object.

[Parameters]

{0}: monitored object (server, database process, data storage destination directory, transaction log storage destination directory, tablespace directory)

{1}: object name (host name, database process name, directory path)

{2}: error detail ("no response:", "read/write error:" and detailed information)

[System Processing]

Perform failover or detaching.

If failover or detaching is already performed, these functions would be disabled.

[Action]

Refer to the description about workaround for failure of "Cluster Operation Guide (Database Multiplexing)".

3.1.20 MCA00020

unexpected error occurred in the monitoring process: {0}

[Description]

Monitoring process cannot continue because an unexpected error was occurred during its processing.

[Parameters]

{0}: error detail

[System Processing]

Continues processing.

[Action]

Refer to the description about workaround for failure of "Cluster Operation Guide (Database Multiplexing)".

3.1.21 MCA00021

starting to {2} from {0} to {1}.

[Description]

Switching standby server to primary server.

[Parameters]

{0}: server ID of primary server

{1}: server ID of standby server

{2}: "fail over"or"switch over"

[Action]

If Mirroring Controller executed switching automatically, find the message output before this message from system log or event log to identify the cause of switching, and then work around according to the Action of the message.

3.1.22 MCA00022

{2} completed.switched from {0} to {1}

[Description]

Switching standby server to primary server was completed.

[Parameters]

{0}: server ID of primary server

{1}: server ID of standby server

{2}: "fail over"or"switch over"

3.1.23 MCA00023

failed to {2} from {0} to {1}

[Description]

Failed to switch to primary server because of unexpected failure.

[Parameters]

{0}: server ID of primary server

{1}: server ID of standby server

{2}: "fail over"or"switch over"

[System Processing]

Processing of switching will be aborted.

[Action]

Find the message output before this message from display, system log or event log, and then work around according to the Action of the message.

3.1.24 MCA00024

starting to detach standby server "{0}" {1}

[Description]

Detaching standby server because of failure detected on standby server.

[Parameters]

{0}: server ID

{1}: "automatically" or none

[Action]

If Mirroring Controller executed detaching automatically, find the message output before this message from system log or event log to identify the cause of detaching, and then work around according to the Action of the message.

3.1.25 MCA00025

detach standby server "{0}" completed {1}

[Description]

Detached standby server.

[Parameters]

{0}: server ID

{1}: "automatically" or none

3.1.26 MCA00026

failed to {2} standby server "{0}" {1}

[Description]

Failed to detach standby server.

[Parameters]

{0}: server ID

{1}: "automatically" or none

{2}: "detach"

[System Processing]

Processing of detaching will be aborted.

[Action]

Refer to the description about workaround for failure of "Cluster Operation Guide (Database Multiplexing)".

3.1.27 MCA00027

another "{0}" command is running

[Description]

Cannot execute command with this operation mode because another command is running on the same or another server.

[Parameters]

{0}: command name

[System Processing]

Processing will be aborted.

[Action]

There is a case executing another command. Wait for completion of another command on the same or another server, and then re-execute.

In addition, there are the following cases when using mc_ctl command.

There is a case under processing of a failover and an automatic detach by Mirroring Controller. Wait for completion of the processing under operation, and re-execute.

If any of the following cases occurs, there is a possibility that the processing of Mirroring Controller interrupts. Re-execute the mc_ctl command after restarting Mirroring Controller.

- When abnormality occurs in the network

- When another server is downed

- When Mirroring Controller is stopped forcibly

3.1.28 MCA00028

communication timeout of Mirroring Controller occurred server:"{0}"

[Description]

Either of the followings has occurred.

- communication timeout between mc_ctl command and Mirroring Controller process has occurred.

- communication timeout between Mirroring Controller processes have occurred.

- Terminating database instance was not completed in the specified time.

[Parameters]

{0}: server ("localhost"or server ID)

[System Processing]

Processing will be aborted.

[Action]

Completion synchronization for terminating database instance might have timed out, because connections remained. Disconnect all connections, and re-execute it.

Reduce CPU or network load caused by the other processes. If could not reduce it, extend remote_call_timeout in "server identifier".conf.

3.1.29 MCA00029

could not create PID file "{0}" of Mirroring Controller detail of cause:"{1}"

[Description]

Could not create PID file of Mirroring Controller.

[Parameters]

{0}: file name

{1}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Identify the cause according to the message, and then remove it.

3.1.30 MCA00030

could not remove PID file "%s" of Mirroring Controller detail of cause:"%s"

[Description]

Could not remove PID file of Mirroring Controller.

[Parameters]

%s: file name

%s: detail of cause

[Action]

Identify the cause according to the message, and then remove it.

3.1.31 MCA00031

could not read PID file "%s" of Mirroring Controller detail of cause:"%s"

[Description]

Could not read PID file of Mirroring Controller.

[Parameters]

%s: file name

%s: detail of cause

[Action]

Identify the cause according to the message, and then remove it.

3.1.32 MCA00032

invalid contents of PID file "%s" of Mirroring Controller

[Description]

The contents of PID file of Mirroring Controller is invalid.

[Parameters]

%s: file name

[System Processing]

Processing will be aborted.

[Action]

The following causes could be considered.

- The file was stored or replaced by mistake

- The file was corrupted

When starting Mirroring Controller, move or remove the file shown in the message.

When stopping Mirroring Controller, terminate forcibly mc_keeper process and terminate forcibly mc_agent process with using OS command.

3.1.33 MCA00033

Mirroring Controller is already running

[Description]

Mirroring Controller is already running.

[System Processing]

Processing will be aborted.

[Action]

If needed, stop Mirroring Controller, and re-execute.

3.1.34 MCA00034

cannot execute %s command because Mirroring Controller is not running

[Description]

Cannot execute Mirroring Controller command because Mirroring Controller process is not running.

[Parameters]

%s: command name

[System Processing]

Processing will be aborted.

[Action]

Start Mirroring Controller, and re-execute.

3.1.35 MCA00035

failed to start database instance

[Description]

Failed to start database instance.

[System Processing]

Processing will be aborted.

[Action]

Find the database message output in the log files of database output before this message, and then work around according to the Action of the message.

3.1.36 MCA00036

failed to stop database instance target server:"{0}"

[Description]

Failed to stop database instance.

[Parameters]

{0}: target server ("localhost" or server ID)

[System Processing]

Processing will be aborted.

[Action]

Find the database message output in the log files of database on the target server

output before this message, and then work around according to the Action of the message.

3.1.37 MCA00037

Mirroring Controller option is not installed

[Description]

This functionality is enabled by installing Mirroring Controller option.

[System Processing]

Processing will be aborted.

[Action]

To use this functionality, install Mirroring Controller option,and then re-execute.

3.1.38 MCA00038

starting Mirroring Controller

[Description]

Starting Mirroring Controller.

3.1.39 MCA00039

Mirroring Controller started

[Description]

Mirroring Controller started.

3.1.40 MCA00040

failed to start Mirroring Controller

[Description]

Failed to start Mirroring Controller.

[System Processing]

Processing will be aborted.

[Action]

Work around according to the Action of the message output before this message.

On Windows, if there is no message outputted before this message, please refer to the message outputted to an event log.

3.1.41 MCA00041

stopping Mirroring Controller

[Description]

Stopping Mirroring Controller.

3.1.42 MCA00042

Mirroring Controller stopped target server:"{0}"

[Description]

Mirroring Controller stopped.

[Parameters]

{0}: target server ("localhost" or server ID)

3.1.43 MCA00043

failed to stop Mirroring Controller target server:"{0}"

[Description]

Failed to stop Mirroring Controller.

[Parameters]

{0}: target server ("localhost" or server ID)

[System Processing]

Processing will be aborted.

[Action]

Identify the cause from system log or event log on the target server, and work around.

3.1.44 MCA00044

stopping Mirroring Controller forcibly

[Description]

Stopping Mirroring Controller forcibly.

3.1.45 MCA00045

stopped Mirroring Controller forcibly

[Description]

Mirroring Controller stopped forcibly.

3.1.46 MCA00046

enabled failover target server:"{0}"

[Description]

Enabled failover and automatic detach.

[Parameters]

{0}: target server ("localhost" or server ID)

3.1.47 MCA00047

failed to enable failover target server:"{0}"

[Description]

Failed to enable failover and automatic detach.

[Parameters]

{0}: target server ("localhost" or server ID)

[System Processing]

Processing will be aborted.

[Action]

Identify the cause from messages on system log or event log, and work around.

3.1.48 MCA00048

disabled failover target server:"{0}"

[Description]

Disabled failover and automatic detach.

[Parameters]

{0}: target server ("localhost" or server ID)

3.1.49 MCA00049

failed to disable failover target server:"{0}"

[Description]

Failed to disable failover and automatic detach.

[Parameters]

{0}: target server ("localhost" or server ID)

[System Processing]

Processing will be aborted.

[Action]

Identify the cause from messages on system log or event log, and work around.

3.1.50 MCA00050

{0}: server ID "{2}" specified with option "{1}" does not exist in definition file "{3}"

[Description]

server ID specified with the option does not exist in definition file.

[Parameters]

{0}: command name

{1}: option

{2}: server ID

{3}: file name

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options or definition file.

3.1.51 MCA00051

{0}: The IP address or host name of the server where the command was executed in is not found on the definition file "{1}"

[Description]

Either of the followings has occurred.

- The IP address or host name that does not exist is specified.

- The network interface is stopped.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter descriptions of "Cluster Operation Guide (Database Multiplexing)".

3.1.52 MCA00052

{0}: wrong server ID "{2}" in definition file "{1}"

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: server ID

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter descriptions of "Cluster Operation Guide (Database Multiplexing)".

3.1.53 MCA00053

failed to detach standby server

[Description]

Failed to detach standby server

because processing of detaching cannot be continued by something failure.

[System Processing]

Processing of detaching will be aborted.

[Action]

Find the message output before this message from display, system log or event log, and then work around according to the Action of the message.

3.1.54 MCA00054

could not write to file "{0}": exception={1}: {2}

[Description]

Failed to detach or synchronize standby server because could not write to the file.

[Parameters]

{0}: file name

{1}: exception type

{2}: exception detail

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes, and detach or synchronize standby server according to "Actions when an Error Occurs" of "Cluster Operation Guide (Database Multiplexing)".

3.1.55 MCA00055

unexpected error occurred in the monitoring process: {0}

[Description]

Monitoring process could not continue because the unexpected error occured.

[Parameters]

{0}: detail of cause

[System Processing]

Continues monitoring.

[Action]

Check the error detail and eliminate causes.

If you cannot clear the problem, contact Fujitsu technical support.

3.1.56 MCA00056

unexpected error occurred: {0}

[Description]

An unexpected error occurred.

[Parameters]

{0}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate cause.

If you cannot clear the problem, contact Fujitsu technical support.

3.1.57 MCA00057

failed to stop Mirroring Controller forcibly

[Description]

Failed to stop Mirroring Controller forcibly.

[System Processing]

Processing will be aborted.

[Action]

Check [Action] of the message output before this message,and re-execute.

If re-execution fails, terminate forcibly mc_keeper process and terminate forcibly mc_agent process with using OS command.

3.1.58 MCA00058

could not access path "%s" specified as a directory for Mirroring Controller detail of cause:"%s"

[Description]

could not access path specified as a directory for Mirroring Controller.

[Parameters]

%s: path name

%s: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.1.59 MCA00059

system call error occurred:"%s" detail of cause:"%s"

[Description]

System call error occurred.

[Parameters]

%s: system call name

%s: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.1.60 MCA00060

could not get installation path

[Description]

Enterprise Postgres may not be installed.

[System Processing]

Processing will be aborted.

[Action]

Re-install Enterprise Postgres.

3.1.61 MCA00061

could not access path "%1$s" for parameter "%2$s" in definition file "%3$s" detail of cause:"%4$s"

[Description]

could not access path for parameter in definition file.

[Parameters]

%3$s: file name

%2$s: parameter name

%1$s: path name

%4$s: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.1.62 MCA00062

promotion processing completed

[Description]

Promotion processing completed.

3.1.63 MCA00063

promotion processing failed

[Description]

Promotion processing failed.

[System Processing]

Processing will be aborted.

[Action]

Clear the problem according to [Action] of the message which was output before this message in system log or in database server log.

3.1.64 MCA00064

stopped database instance forcibly

[Description]

Database instance stopped forcibly.

3.1.65 MCA00065

failed to stop database instance forcibly

[Description]

Failed to stop database instance forcibly.

[System Processing]

Processing will be aborted.

[Action]

Clear the problem according to [Action] of the message which was output before this message in system log or in database server log.

3.1.66 MCA00067

did not switch during a degeneration use

[Description]

Did not switch during a degeneration use.

[System Processing]

Processing will be aborted.

[Action]

If Mirroring Controller executed switching automatically, find the message output before this message from system log or event log to identify the cause of degeneration, and then eliminate causes according to [Action] of the message and try to switch with command.

3.1.67 MCA00068

{0}: users other than an instance administrator have the access privileges for definition file "{1}"

[Description]

users other than an instance administrator have the access privileges for definition file.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Revoke all the access privileges for users other than an instance administrator.

MCA00069

could not execute because Mirroring Controller of the server "{0}" is not running

[Description]

Could not execute because Mirroring Controller is not running.

[Parameters]

{0}: server ID

[System Processing]

Processing will be aborted.

[Action]

Start Mirroring Controller, and try to switch with command.

3.1.68 MCA00070

Try "%s --help" for more information.\n

[Description]

--help option can show more additional information.

[Parameters]

%s: command name

[System Processing]

None.

[Action]

Check the message output before this message, and refer to descriptions shown by '--help' option.

3.1.69 MCA00071

starting to {0}

[Description]

Switching standby server to primary server.

[Parameters]

{0}: "switch over"

3.1.70 MCA00072

failed to {0}

[Description]

Failed to switch to primary server because of an unexpected failure.

[Parameters]

{0}: "switch over"

[System Processing]

Processing of switching will be aborted.

[Action]

Find the message output before this message from display, system log or event log, and then eliminate causes according to [Action] of the message.

3.1.71 MCA00073

error detected in handling of the database instance detail of cause:"{0}"

[Description]

Error detected in handling of the database instance for the following purposes.

- Obtain the port number of database instance

- Access to the data storage destination directory

[Parameters]

{0}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.1.72 MCA00074

could not read PID file "{0}" of Mirroring Controller detail of cause:"{1}"

[Description]

Could not read PID file of Mirroring Controller.

[Parameters]

{0}: file name

{1}: detail of cause

[Action]

Identify the cause according to the message, and then remove it.

3.1.73 MCA00075

invalid contents of PID file "{0}" of Mirroring Controller

[Description]

The contents of PID file of Mirroring Controller is invalid.

[Parameters]

{0}: file name

[System Processing]

Processing will be aborted.

[Action]

The following causes could be considered.

- The file was stored or replaced by mistake

- The file was corrupted

When starting Mirroring Controller, move or remove the file shown in the message.

When stopping Mirroring Controller, terminate forcibly mc_keeper process and terminate forcibly mc_agent process with using OS command.

3.1.74 MCA00076

cannot execute "{0}" command because Mirroring Controller is not running

[Description]

Cannot execute Mirroring Controller command because Mirroring Controller process is not running.

[Parameters]

{0}: command name

[System Processing]

Processing will be aborted.

[Action]

Start Mirroring Controller, and re-execute.

3.1.75 MCA00077

%s: argument of option "%s" is too long

[Description]

Argument of option is too long.

[Parameters]

%s: command name

%s: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.1.76 MCA00078

%s: invalid option -- %s

[Description]

Invalid option.

[Parameters]

%s: command name

%s: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.1.77 MCA00079

%s: unnecessary operand "%s"

[Description]

Unnecessary operand.

[Parameters]

%s: command name

%s: operand

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting operand.

3.1.78 MCA00080

%s: unrecognized operation mode or no operation mode specified

[Description]

Unrecognized operation mode or no operation mode specified.

[Parameters]

%s: command name

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting or specifying operation mode.

3.1.79 MCA00081

start to enable the parameter "{1}" required to build in the standby server "{0}"

[Description]

Start to enable the parameter required to build in the standby server.

[Parameters]

{0}: server ID

{1}: parameter name

3.1.80 MCA00082

enableing the parameter "{1}" required to build in the standby server "{0}" completed

[Description]

Enableing the parameter required to build in the standby server completed.

[Parameters]

{0}: server ID

{1}: parameter name

3.1.81 MCA00083

failed to enable the parameter "{1}" required to build in the standby server "{0}"

[Description]

Failed to enable the parameter required to build in the standby server.

The following causes could be considered.

- another command is running

- can not access definition file

- parameter does not exist

[Parameters]

{0}: server ID

{1}: parameter name

[System Processing]

Processing will be aborted.

[Action]

- If the parameter is not set

On the primary server, set the parameter of postgresql.conf file according to "parameter" description of "Cluster Operation Guide (Database Multiplexing)" and execute pg_ctl command with reload mode.

- Otherwise

Find the message output before this message from display, system log or event log, and then eliminate causes according to [Action] of the message. Then, on the primary server, set the parameter of postgresql.conf file according to "parameter" description of "Cluster Operation Guide (Database Multiplexing)" and execute pg_ctl command with reload mode.

3.1.82 MCA00084

primary server is already running

[Description]

Primary server is already running.

[System Processing]

Processing will be aborted.

[Action]

The standby server might be running without creating standby.signal. Create standby.signal, and re-execute.

3.1.83 MCA00085

cannot start Mirroring Controller because database instance is not running

[Description]

Cannot start Mirroring Controller because database instance is not running.

[System Processing]

Processing will be aborted.

[Action]

Start database instance, and re-execute.

3.1.84 MCA00086

could not get state of database instance detail of cause:"{0}"

[Description]

Could not get state of database instance.

[Parameters]

{0}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.1.85 MCA00087

unusable character is included in path "%s" specified as a directory for Mirroring Controller

[Description]

Unusable character is included in path specified as a directory for Mirroring Controller.

[Parameters]

%s: path name

[System Processing]

Processing will be aborted.

[Action]

Correct the path specified as a directory for Mirroring Controller according to the message and mc_ctl command descriptions of "Reference".

3.1.86 MCA00088

%1$s: unusable character is included in server ID "%3$s" specified with option "%2$s"

[Description]

Unusable character is included in server ID specified with option.

[Parameters]

%1$s: command name

%2$s: option

%3$s: server ID

[System Processing]

Processing will be aborted.

[Action]

Correct the server ID specified with option according to the message and mc_ctl command descriptions of "Reference".

3.1.87 MCA00089

only instance administrator can execute this command

[Description]

Only instance administrator who created the directory for Mirroring Controller can execute this command.

[System Processing]

Processing will be aborted.

[Action]

Re-execute the command by the instance administrator who created the directory for Mirroring Controller.

3.1.88 MCA00090

could not read file "{0}": Permission denied

[Description]

No read permissions for the file.

[Parameters]

{0}: file name

[System Processing]

Processing will be aborted.

[Action]

Re-execute the command, after granting the read permissions to the file.

3.1.89 MCA00091

host name or IP address "{1}" of the primary server and the standby server in definition file "{0}" are same, but the --local-server option was not specified

[Description]

Host name or IP address of the primary server and the standby server in definition file are same, but the --local-server option was not specified.

[Parameters]

{0}: file name

{1}: host name or IP address

[System Processing]

Processing will be aborted.

[Action]

If the primary server and the standby server are built in the same server, execute the mc_ctl command with the --local-server option.

If the primary server and the standby server are built in the different server, correct host name or IP address in the definition file.

3.1.90 MCA00092

this feature is not available in this edition

[Description]

This feature is not available in this edition.

[System Processing]

Processing will be aborted

[Action]

Please install the right edition for this feature.

3.1.91 MCA00093

installation environment is destroyed

[Description]

Enterprise Postgres may not be installed correctly or may be destroyed.

[System Processing]

Processing will be aborted.

[Action]

Re-install Enterprise Postgres.

3.1.92 MCA00094

%s: invalid argument for option %s

[Description]

Invalid argument for option.

[Parameters]

%s: command name

%s: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.1.93 MCA00095

could not remove file or directory "{0}"

[Description]

Could not remove the file or the directory.

[Parameters]

{0}: file name or directory name

[System Processing]

Processing will be aborted.

[Action]

Check the status of the file or the directory and eliminate causes, and then remove it.

3.1.94 MCA00096

could not write file "{0}": exception={1}: {2}

[Description]

Could not write the file.

[Parameters]

{0}: file name

{1}: exception type

{2}: exception detail

[System Processing]

Processing will be aborted.

[Action]

Identify the cause according to the message, and then remove it.

3.1.95 MCA00097

setup of standby server completed

[Description]

Setup of standby server completed.

3.1.96 MCA00098

setup of standby server failed

[Description]

Setup of standby server failed.

[System Processing]

Processing will be aborted.

[Action]

Find the message output before this message from display, system log or event log, and then eliminate causes according to [Action] of the message.

3.1.97 MCA00099

{0}: server""{1}"" is running as a standby server

[Description]

Could not continue processing because database instance to be duplicated is not running as a primary server.

[Parameters]

{0}: command name

{1}: server ID

[System Processing]

Processing will be aborted.

[Action]

Re-execute this command on the standby server to be set up.

3.2 Message Numbers Beginning with MCA00100

3.2.1 MCA00100

cannot execute {0} command because Mirroring Controller is running

[Description]

Cannot execute this command because Mirroring Controller is running on the server to be set up.

[Parameters]

{0}: command name

[System Processing]

Processing will be aborted.

[Action]

Execute this command on server where primary server is not running. If execute it on the right server, stop Mirroring Controller and then re-execute it.

3.2.2 MCA00101

cannot execute {0} command because database instance is running

[Description]

Cannot execute this command because database instance is running on the server to be set up.

[Parameters]

{0}: command name

[System Processing]

Processing will be aborted.

[Action]

Execute this command on server where primary server is not running. If execute it on the right server, stop database instance and then re-execute it.

3.2.3 MCA00102

{0}: invalid argument value {2} for option {1}

[Description]

Invalid argument for option.

[Parameters]

{0}: command name

{1}: option

{2}: argument value

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting argument value for the option.

3.2.4 MCA00103

could not move file or directory from {0} to {1}

[Description]

Could not move the file or the directory.

[Parameters]

{0}: source file or directory

{1}: target file or directory

[System Processing]

Processing will be aborted.

[Action]

Check the status of the file or the directory and eliminate causes, and then remove it.

3.2.5 MCA00104

could not create directory {0}

[Description]

Could not create the directory.

[Parameters]

{0}: target directory

[System Processing]

Processing will be aborted.

[Action]

Check the status of the directory and eliminate causes, and then remove it.

3.2.6 MCA00105

could not read the access privileges of {0}

[Description]

Could not read the access privileges.

[Parameters]

{0}: target directory

[System Processing]

Processing will be aborted.

[Action]

Check the status of the directory and eliminate causes, and then remove it.

3.2.7 MCA00106

failed to set the access privileges of {0}

[Description]

Failed to set the access privileges.

[Parameters]

{0}: target directory

[System Processing]

Processing will be aborted.

[Action]

Check the status of the directory and eliminate causes, and then remove it.

3.2.8 MCA00107

service "{0}" is not registered

[Description]

Service is not registered.

[Parameters]

{0}: Service name

[System Processing]

Processing will be aborted.

[Action]

Register service, and re-execute.

3.2.9 MCA00108

could not start service "{0}" detail of cause:"{1}"

[Description]

Could not start service.

[Parameters]

{0}: Service name

{1}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.2.10 MCA00109

could not start service "%s" detail of cause:"%s"

[Description]

Could not start service.

[Parameters]

%s: Service name

%s: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.2.11 MCA00110

service "%s" is not registered

[Description]

Service is not registered.

[Parameters]

%s: Service name

[System Processing]

Processing will be aborted.

[Action]

Register service, and re-execute.

3.2.12 MCA00111

Mirroring Controller service "%s" has been registered

[Description]

Mirroring Controller service has been registered with Windows Service.

[Parameters]

%s: Service name

3.2.13 MCA00112

Mirroring Controller service "%s" has been unregistered

[Description]

Mirroring Controller service has been unregistered from Windows Service.

[Parameters]

%s: Service name

3.2.14 MCA00113

service name "%s" is already in use

[Description]

Service name is already in use.

[Parameters]

%s: Service name

[System Processing]

Processing will be aborted.

[Action]

Check the service name, and re-execute.

3.2.15 MCA00114

could not register service "%s" detail of cause: "%s"

[Description]

An error occurred during registration of service.

[Parameters]

%s: Service name

%s: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.2.16 MCA00115

could not unregister service "%s" detail of cause: "%s"

[Description]

An error occurred during deregistration of service.

[Parameters]

%s: Service name

%s: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.2.17 MCA00116

%s: option "%s" is required

[Description]

A required option is not specified.

[Parameters]

%s: command name

%s: option

[System Processing]

Processing will be aborted.

[Action]

Specify the required option, and re-execute.

3.2.18 MCA00117

no authority to execute this command

[Description]

Only the administrative user can run this command.

[System Processing]

Processing will be aborted.

[Action]

Invoke the administrator's prompt, and re-execute this command.

3.2.19 MCA00119

could not receive respons from {0} server({1})

[Description]

An error was detected on the server.

[Parameters]

{0}: monitored object (server)

{1}: server type (primary, candidate primary, standby)

[System Processing]

Perform failover or detaching.

If failover or detaching is already performed, these functions would be disabled.

[Action]

Refer to the description about workaround for failure of "Cluster Operation Guide (Database Multiplexing)".

3.2.20 MCA00120

detected streaming replication error in {0} server({1})

[Description]

A streaming replication error was detected.

[Parameters]

{0}: monitored object (database process)

{1}: server type (primary, candidate primary, standby)

[System Processing]

Perform failover or detaching.

If failover or detaching is already performed, these functions would be disabled.

[Action]

Refer to the description about workaround for failure of "Cluster Operation Guide (Database Multiplexing)".

3.2.21 MCA00121

disk drives are available

[Description]

Database where data storage, transaction log storage and tablespaces are saved is working correctly.

3.2.22 MCA00122

a {0} server({1}) is running normally

[Description]

A server is running normally.

[Parameters]

{0}: server type (primary, candidate primary, standby)

{1}: monitored object (server)

3.2.23 MCA00123

Streaming Replication has started

[Description]

Streaming Replication has started

3.2.24 MCA00124

postmaster is running in {0} server({1})

[Description]

postmaster is running

[Parameters]

{0}: server type (primary, candidate primary, standby)

{1}: monitored object (server)

3.2.25 MCA00125

failed to get the standby server information

[Description]

Failed to get the standby server information

[System Processing]

Perform failover or detaching.

If failover or detaching is already performed, these functions would be disabled.

[Action]

Refer to the description about workaround for failure of "Cluster Operation Guide (Database Multiplexing)".

3.2.26 MCA00126

{0} server({1}) was downed

[Description]

database server was downed

[Parameters]

{0}: server type (primary, candidate primary, standby)

{1}: monitored object (server)

[System Processing]

Perform failover or detaching.

If failover or detaching is already performed, these functions would be disabled.

[Action]

Refer to the description about workaround for failure of "Cluster Operation Guide (Database Multiplexing)".

3.2.27 MCA00127

You can promote the standby server

[Description]

You can promote the standby server

3.2.28 MCA00128

You cannot promote the standby server

[Description]

You cannot promote the standby server

3.2.29 MCA00129

detected a disk I/O error in {0} server({1})

[Description]

A disk I/O error was detected.

[Parameters]

{0}: server type (primary, candidate primary, standby)

{1}: monitored object (server)

[System Processing]

Perform failover or detaching.

If failover or detaching is already performed, these functions would be disabled.

[Action]

Refer to the description about workaround for failure of "Cluster Operation Guide (Database Multiplexing)".

3.2.30 MCA00130

starting to switch over forcibly

[Description]

Starting to switch over forcibly.

3.2.31 MCA00131

succeeded in switching over to {0} forcibly

[Description]

Switching standby server to primary server succeeded.

[Parameters]

{0}: server ID of standby server

3.2.32 MCA00132

failed to switch over to {0} forcibly

[Description]

Failed in processing of switching because of unexpected failure.

[Parameters]

{0}: server ID of standby server

[System Processing]

Processing of switching will be aborted.

[Action]

Find the message output before this message from display, system log or event log, and then work around according to the Action of the message.

3.2.33 MCA00133

starting to detach standby server forcibly

[Description]

Starting to detach standby server forcibly.

3.2.34 MCA00134

succeeded in detaching standby server "{0}" completed forcibly

[Description]

Detached standby server succeeded.

[Parameters]

{0}: server ID

3.2.35 MCA00135

failed to detach standby server "{0}" forcibly

[Description]

Failed to detach standby server.

[Parameters]

{0}: server ID

[System Processing]

Processing of detaching will be aborted.

[Action]

Find the message output before this message from display, system log or event log, and then work around according to the Action of the message.

3.2.36 MCA00136

{0}: the specified option is invalid: "{1}"

[Description]

the specified option is invalid.

[Parameters]

{0}: command name

{1}: option name

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.2.37 MCA00137

disabled standby server "{0}" to automatically switch because of canceling the synchronous replication for standby server

[Description]

Disabled the standby server to automatically switch because of canceling the synchronous replication for standby server.

[Parameters]

{0}: server ID

3.2.38 MCA00138

disabled standby server "{0}" to automatically switch

[Description]

Disabled the standby server to automatically switch.

[Parameters]

{0}: server ID

3.2.39 MCA00139

failed to disable standby server "{0}" to automatically switch

[Description]

Failed to disable the standby server to automatically switch.

[Parameters]

{0}: server ID

[System processing]

Processing will be aborted.

[Action]

The following causes could be considered.

- An error was detected in database server

- Timeout waiting for between Mirroring Controller processes of database server

Identify the cause from messages on system log or event log, and work around.

3.2.40 MCA00140

{0}: invalid server kind specified in definition file "{1}" line {2}

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: line number

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.2.41 MCA00141

{0}: server kind 'arbiter' do not specified in definition file "{2}" despite value 'arbitration' is specified parameter heartbeat_error_action in definition file "{1}"

[Description]

Server kind 'arbiter' do not been specified in network.conf despite value 'arbitration' is specified parameter heartbeat_error_action in "server identifer".conf

[Parameters]

{0}: command name

{1}: file name

{2}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.2.42 MCA00142

{0}: could not specify server kind 'arbiter' in definition file "{3}" because value '{2}' is specified parameter heartbeat_error_action in definition file "{1}"

[Description]

Could not specify server kind 'arbiter' in network.conf because value 'arbitration' is not specified parameter heartbeat_error_action in "server identifer".conf.

[Parameters]

{0}: command name

{1}: file name

{2}: message, arbitration, command, fallback

{3}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.2.43 MCA00143

{0}: second port number to use for the arbitration network is not specified in definition file "{1}"

[Description]

Second port number to use for the arbitration network is not specified in network.conf.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.2.44 MCA00144

{0}: could not specify second port number to use for the arbitration network in definition file "{3}" because value '{2}' is specified parameter heartbeat_error_action in definition file "{1}"

[Description]

Could not specify second port number to use for the arbitration network in network.conf.

[Parameters]

{0}: command name

{1}: file name

{2}: message, command, fallback

{3}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.2.45 MCA00145

{0}: second IP address to use for the arbitration network is not specified in definition file "{1}"

[Description]

Second IP address to use for the arbitration network is not specified in network.conf.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.2.46 MCA00146

{0}: cannot specify second IP Address on server kind 'arbiter' in definition file "{1}"

[Description]

Cannot specify second IP Address on server kind 'arbiter' in network.conf.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.2.47 MCA00147

{0}: could not use parameter '{3}' because value '{2}' is specified parameter heartbeat_error_action in definition file "{1}"
[Discription]
Could not use parameter in "server identifier".conf.

[Parameters]

{0}: command name

{1}: file name

{2}: message, arbitration, command, fallback

{3}: parameter

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.2.48 MCA00148

{0}: could not use option "{3}" because value '{2}' is specified parameter heartbeat_error_action in definition file "{1}"

[Description]

Could not use this option.

[Parameters]

{0}: command

{1}: file name

{2}: message, arbitration, command, fallback

{3}: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options according to the message and mc_ctl command descriptions of "Reference".

3.2.49 MCA00149

requesting arbitration server "{0}" to connect

[Description]

Requesting arbitration server to connect.

[Parameters]

{0}: server ID

[System processing]

Requesting arbitration server to connect.

3.2.50 MCA00150

trying to connect to arbitration server "{0}"

[Description]

Trying to connect to arbitration server.

[Parameters]

{0}: server ID

[System processing]

Trying to connect to arbitration server until success.

3.2.51 MCA00151

succeeded in connection with arbitration server "{0}"

[Description]

Succeeded in connection with arbitration server.

[Parameters]

{0}: server ID

3.2.52 MCA00152

failed to connect to arbitration server "{0}" event:"{1}"

[Description]

Either of the followings has occurred.

- incorrect specification in network.conf

- error occurs in the network between database server and arbitration server

- Mirroring Controller Arbitration process is not running or in the stop processing

- Mirroring Controller Arbitration process or arbitration server detects an error

[Parameters]

{0}: server ID

{1}: "timeout" or "communication error"

[System Processing]

Processing will be aborted.

[Action]

Check the following and identify the cause, and eliminate cause.

- specification about server kind 'arbiter' in network.conf

- the value of arbiter_connect_timeout parameter in "server identifier".conf

- communication status between database server and arbitration server

- Mirroring Controller Arbitration process staring status

- the message in arbitration server

3.2.53 MCA00153

disconnected from arbitration server "{0}"

[Description]

Disconnected from arbitration server.

[Parameters]

{0}: sever ID

3.2.54 MCA00154

timeout waiting for communication with Mirroring Controller Arbitration process server:"{0}"

[Description]

Timeout waiting for communication between Mirroring Controller process and Mirroring Controller Arbitration process.

[Parameters]

{0}: server ID

[System Processing]

Try to connect to arbitration server.

[Action]

Check whether a network error between arbitration server and database server or an error of arbtration server was detected.

If an error was not detected, the value of arbiter_alive_timeout parameter in "server identifier".conf is too short.

Review and extend the value of arbiter_alive_timeout in "server identifier".conf.

3.2.55 MCA00155

failed to open communication environment detail of cause:"{0}"

[Description]

Failed to open communication environment.

[Parameters]

{0}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

3.2.56 MCA00156

invalid port number for server "{0}" in definition file "{1}"

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: server ID

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.2.57 MCA00157

communication error with the arbitration server "{0}" occurred

[Description]

Communication error with the arbitration server occurred.

[Parameters]

{0}: server ID

[System Processing]

Trying to connect.

[Action]

Either of the followings has occurred.

- When Mirroring Controller Arbitration process of a arbitration server is not running

- When abnormality occurs in the network between a database server and arbitration server

Identify the cause from messages on system log or event log in arbitration server or database server, and work around.

3.2.58 MCA00158

failed to start Mirroring Controller because of could not connect to arbitration server "{0}"

[Description]

Failed to start Mirroring Controller because of could not connect to arbitration server.

[Parameters]

{0}: server ID

[System processing]

Processing will be aborted.

[Action]

Work around according to the Action of the message output before this message.

On Windows, if there is no message outputted before this message, please refer to the message outputted to an event log.

MCA00159

requesting arbitration server "{1}" to arbitrate for database server "{0}"

[Description]

Requesting arbitration server to arbitrate for the target server.

[Parameters]

{0}: server ID

{1}: server ID

[System processing]

Requesting arbitration server to arbitrate for the target server.

3.2.59 MCA00160

the arbitration server "{0}" arbitrated status of database server "{1}" as sanity

[Description]

The arbitration server arbitrated status of database server as sanity.

[Parameters]

{0}: server ID

{1}: server ID

3.2.60 MCA00161

the request for arbitration was omitted because fencing command for a database server "{0}" was finished already

[Description]

The request for arbitration was omitted because fencing command for a database server was finished already.

[Parameters]

{0}: server ID

3.2.61 MCA00162

arbitration processing cannot request because the "{0}" command is carrying out

[Description]

Cannot request arbitration processing because command is running on the same or another server.

[Parameters]

{0}: command name

[System Processing]

Processing will be aborted.

3.2.62 MCA00163

timeout waiting for requesting arbitration server "{0}" to arbitrate

[Description]

Timeout waiting for requesting arbitration server to arbitrate.

[Parameters]

{0}: server ID

[System Processing]

Processing will be aborted.

[Action]

Switch or detach server in yourself according to descriptions of "Cluster Operation Guide (Database Multiplexing)".

3.2.63 MCA00164

requesting arbitration server "{0}" to fence database server "{1}"

[Description]

Requesting arbitration server to fence database server.

[Parameters]

{0}: server ID

{1}: server ID

[System Processing]

Requesting arbitration server to fence.

3.2.64 MCA00165

arbitration server "{0}" succeeded in fencing for database server "{1}"

[Description]

Arbtration server succeeded in executing fencing command for the target server.

[Parameters]

{0}: server ID

{1}: server ID

3.2.65 MCA00166

arbitration server "{0}" failed to fence for database server "{1}". detail of cause: check log file in arbitration server

[Description]

Arbitration process failed to execute fencing command for the target server.

[Parameters]

{0}: server ID

{1}: server ID

[System Processing]

Processing will be aborted.

[Action]

Check error message in arbitration server.

If needed, perform switch or detach the database server with manually operation according to descriptions of "Cluster Operation Guide (Database Multiplexing)".

3.2.66 MCA00167

timeout waiting for a request to fence to arbitration server "{0}"

[Description]

Timeout waiting for a request to fence to arbitration server.

[Parameters]

{0}: server ID

[System Processing]

Processing will be aborted.

[Action]

Switch or detach server in yourself according to descriptions of "Cluster Operation Guide (Database Multiplexing)".

3.2.67 MCA00168

arbitration server "{0}" rejected the request to fence database server "{1}"

[Description]

Either of the followings is esteemed.

- The arbtration server is executing arbitration process

- Fencing command was executed just before

[Parameters]

{0}: server ID

{1}: server ID

3.2.68 MCA00169

could not request "{1}" because of disconnecting from arbitration server "{0}"

[Description]

Could not request arbitration server to arbitrate, fence or disable automatically switch because of disconnecting.

[Parameters]

{0}: server ID

{1}: "arbitration" or "fencing" or "disable automatically switch"

[System Processing]

Processing will be aborted.

[Action]

Either of the followings has occurred.

- Mirroring Controller Arbitration process is not running in arbitration server

- Abnormality occurs in the network between database server and arbitration server

Identify the cause from messages on system log or event log in arbitration server or database server, and work around.

3.2.69 MCA00170

rejeceted a request arbitration server "{1}" because database server "{0}" was beening fencing

[Description]

The following requirements shouldn't be executed if it is requested from the database server which is a fencing target.

- request to arbitrate

- request to fence

[Parameters]

{0}: server ID

{1}: server ID

[Action]

Processing will be aborted.

3.2.70 MCA00171

requested arbitration server "{0}" to disable standby server "{1}" to automatically switch

[Description]

Requested arbitraion server to disable the standby server to automatically switch.

[Parameters]

{0}: server ID

{1}: server ID

3.2.71 MCA00172

arbitration server "{0}" fenced standby server "{1}" because of failed to disable the standby server to automatically switch

[Description]

Arbitration server fenced the standby server because of failed to disable the standby server to automatically switch.

[Parameters]

{0}: server ID

{1}: server ID

3.2.72 MCA00173

arbitration server "{0}" tried to fence standby server "{1}" because of failed to disable the standby server to automatically switch, however fencing was failed

[Description]

Arbitration server tried to fence the standby server because of failed to disable the standby server to automatically switch, however fencing was failed.

[Parameters]

{0}: server ID

{1}: server ID

[System Processing]

Processing will be aborted.

[Action]

Switch or detach database server which error has been detected in yourself.

After, identify the cause from messages on system log or event log in arbitration server and work around.

3.2.73 MCA00174

requested standby server "{0}" to disable automatically switching

[Description]

Requested the standby server to disable automatically switching.

[Parameters]

{0}: server ID

3.2.74 MCA00175

{0}: cannot execute switching over forcibly other than on standby server

[Description]

Switching over forcibly needs to be executed only on standby server.

[Parameters]

{0}: command name

[System Processing]

Processing will be aborted.

[Action]

Check whether the server where the command was executed is correct.

Either, check that Mirroring Controller has been degenerate state yet.

3.2.75 MCA00176

{0}: cannot execute detaching forcibly other than on primary server

[Description]

Detaching forcibly needs to be executed only on pimary server.

[Parameters]

{0}: command name

[System Processing]

Processing will be aborted.

[Action]

Check whether the server where the command was executed is correct.

Either, check that Mirroring Controller has been degenerate state yet.

3.2.76 MCA00177

forcible switch over to standby server "{0}" was requested although the data may be not synchronous with primary server

[Description]

Forcible switch over to standby server was requested although the data may be not synchronous with primary server.

[Parameters]

{0}: server ID

[System Processing]

Processing will be continued.

[Action]

Check the data of database server and recovery as necessary, after forcible switch over will be completed.

3.2.77 MCA00178

database server which is able to be switched over is not found

[Description]

Database server which is able to be switched over is not found.

[System Processing]

Processing will be aborted.

3.2.78 MCA00179

starting to detach standby server

[Description]

Starting to detach standby server.

3.2.79 MCA00180

database server which needs to be detached is not found

[Description]

Database server which needs to be detached is not found.

[System Processing]

Processing will be aborted.

3.2.80 MCA00181

database server already has been detached

[Description]

Database server already has been detached.

[System Processing]

Processing will be aborted.

3.2.81 MCA00182

failed to switch over forcibly

[Description]

Failed in processing of switching because of unexpected failure.

[System Processing]

Processing of switching will be aborted.

[Action]

Find the message output before this message from display, system log or event log, and then work around according to the Action of the message.

3.2.82 MCA00183

failed to detach standby server forcibly

[Description]

Failed to detach standby server.

[System Processing]

Processing of detaching will be aborted.

[Action]

Find the message output before this message from display, system log or event log, and then work around according to the Action of the message.

3.2.83 MCA00184

could not {1} because {0} server is abnormal

[Description]

Could not switch over or detach because server is abnormal

[Parameters]

{0}: "primary" or "candidate primary" or "standby"

{1}: "switch over" or "detach"

[System Processing]

Processing will be aborted.

[Action]

Find the message output before this message in the log files on the target server, and work around according to the Action of the message.

3.2.84 MCA00185

value of heartbeat_error_action is different from the value of other server "{0}"

[Description]

Value of heartbeat_error_action is different from the value of other server "{0}".

[Parameters]

{0}: server ID

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting value of heartbeat_error_action to the same value as another server.

3.2.85 MCA00186

restarting Mirroring Controller process because an its error was detected: %s

[Description]

Restarting Mirroring Controller process because an its error was detected.

[Parameters]

%s: error detail ("no response", "down")

[System Processing]

Restarting Mirroring Controller process.

3.2.86 MCA00187

Mirroring Controller process was restarted

[Description]

Mirroring Controller process was restarted.

3.2.87 MCA00188

failed to restart Mirroring Controller

[Description]

Failed to restart Mirooring Controller.

[System Processing]

Processing will be aborted.

[Action]

Work around according to the Action of the message output before this message.

On Windows, if there is no message outputted before this message, please refer to the message outputted to an event log.

After, execute the mc_ctl command to restart Mirroring Controller.

3.2.88 MCA00189

could not access "{0}" file detail of cause:"{1}"

[Description]

Could not access the process information file of OS.

[Parameters]

{0}: file name

{1}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.2.89 MCA00190

invalid contents of "{0}" file

[Description]

Invalid contents of /proc/[pid]/status file.

[Parameters]

{0}: file name

[System Processing]

Processing will be aborted.

[Action]

Check whether mc_keeper process or mc_agent process exists with using OS command.

3.2.90 MCA00191

executing arbitration command and inquiring the result of arbitration

[Description]

Executing arbitration command that execute arbitration.

[System processing]

Degenerate depending on result of arbitration command.

3.2.91 MCA00192

executing fencing command

[Description]

Executing fencing command.

[System processing]

Processing will be continued depending on result of fencing command.

3.2.92 MCA00193

starting degenerate because of result of arbitration command for database server "{0}" result:"{1}"

[Description]

Starting degenerate because of result of arbitration command for target server.

[parameters]

{0}: server ID

{1}: return code of command

3.2.93 MCA00194

degeneracy is not executed because of result of arbitration command to database server "{0}" result:"{1}"

[Description]

Degeneracy is not executed because of result of arbitration command to target server.

[parameters]

{0}: server ID

{1}: return code of command

3.2.94 MCA00195

timeout has occurred during arbitration command has been executing to database server "{0}"

[Description]

Timeout has occurred during arbitration command has been executing to target server.

[Parameters]

{0}: server ID

[System Processing]

Processing will be aborted.

[Action]

Check the state of database server and switch or detach the server with manually operation according to descriptions of "Cluster Operation Guide (Database Multiplexing)" as necessary.

When find process ID of arbitration command, terminate forcibly by using OS command.

3.2.95 MCA00196

{0}: two or more standby server names are specified in the parameter "synchronous_standby_names" in PostgreSQL

[Description]

multiple synchronous standby servers can not be monitored by Mirroring Controller.

[Parameters]

{0}: command name

[System Processing]

Processing will be aborted.

[Action]

Re-execute after specifying single standby server to synchronous_standby_names.

3.2.96 MCA00197

the arbitration server "{0}" didn't arbitrate status of database server "{1}" as sanity

[Description]

Status of the target server was not arbitrated as sanity by arbitration server.

[Parameters]

{0}: server ID

{1}: server ID

[System processing]

Start degenerate processing.

3.2.97 MCA00198

fencing command for database server "{0}" succeeded: result:"{1}"

[Description]

Fencing command for database server succeeded.

[parameters]

{0}: server ID

{1}: return code of command

[System processing]

Processing will be continued.

3.2.98 MCA00199

fencing command for database server "{0}" failed: result:"{1}"

[Description]

Fencing command for database server failed.

[parameters]

{0}: server ID

{1}: return code of command

[System processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

Switch or detach the server with manually operation according to descriptions of "Cluster Operation Guide (Database Multiplexing)" as necessary.

MCA00200

timeout waiting for the fencing command

[Description]

Timeout waiting for the fencing command.

[System processing]

Processing will be aborted.

[Action]

The value of fencing_command_timeout parameter in server identifer.conf is too short.

Review and extend the value of fencing_command_timeout parameter in arbitration.conf.

When find process ID of fencing command, terminate forcibly by using OS command.

3.3 Message Numbers Beginning with MCA00200

3.3.1 MCA00201

executing state-transition-command kind of command:{0}

[Description]

Executing state-transition-command.

[parameters]

{0}: kind of state-transition-command(post-switch, pre-detach, post-attach)

3.3.2 MCA00202

state-transition-command has done kind of command:{0}

[Description]

State-transition-command has done.

[parameters]

{0}: kind of state-transition-command(post-promote, pre-detach, post-attach)

[System processing]

Processing will be continued.

3.3.3 MCA00203

timeout has occurred to state-transition-command kind of command:{0}

[Description]

Timeout has occurred to state-transition-command.

[parameters]

{0}: kind of state-transition-command(post-promote, pre-detach, post-attach)

[System Processing]

Processing of state-transition-command will be aborted.

[Action]

If the process of state-transition-command remained, terminate the process forcibly by using OS command. After checking processing status of state-transition-command, exec the processing of the command manually.

3.3.4 MCA00204

detected recovery from an error on monitoring of table space({0})

[Description]

detected recovery from an error on monitoring of table space

[Parameters]

{0}: directory path of table space

3.3.5 MCA00205

detected no responce on monitoring of database process

[Description]

Detected no responce on monitoring of database process.

[System Processing]

Continues processing.

[Action]

Check the error detail and eliminate causes.

3.3.6 MCA00206

detected recovery from no responce on monitoring of database process

[Description]

Detected recovery from no responce on monitoring of database process.

3.3.7 MCA00207

{0}: the user name specified in parameter db_instance_username of definition file "{1}" is not database superuser

[Description]

The user name specified in parameter db_instance_username is not database superuser.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Re-execute after specifying a database superuser.

3.3.8 MCA00208

{0}: the user name specified in parameter db_instance_username of definition file "{1}" does not exist

[Description]

The user name specified in parameter db_instance_username does not exist.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Re-execute after specifying a database superuser.

3.3.9 MCA00209

{0}: could not specify second IP address to use for the arbitration network in definition file "{3}" because value '{2}' is specified parameter heartbeat_error_action in definition file "{1}"

[Description]

Could not specify second IP address to use for the arbitration network in network.conf.

[Parameters]

{0}: command name

{1}: file name

{2}: message, command, fallback

{3}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.3.10 MCA00210

{0}: cannot specify second port number on server kind 'arbiter' in definition file "{1}"

[Description]

Cannot specify second port number on server kind 'arbiter' in network.conf.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.3.11 MCA00211

{0}: could not use parameter "{2}" because parameter "{3}" is not specified in definition file "{1}"

[Description]

This parameter cannot be specified because the parameter with dependency is not specified in the definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: parameter name

{3}: parameter name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.3.12 MCA00212

{0}: primary_conninfo parameter is not specified in postgresql.auto.conf

[Description]

Primary_conninfo parameter is not specified in postgresql.auto.conf file.

[Parameters]

{0}: command name

[System Processing]

Processing will be aborted.

[Action]

Specify primary_conninfo parameter in postgresql.auto.conf file according to the description of "Setting Up the Standby Center" for disaster recovery of "Cluster Operation Guide (Database Multiplexing)".

3.3.13 MCA00213

values of parameters for abnormality monitoring of operating system or server in server definition file "{1}" are too small for value of heartbeat_interval in arbitration definition file of arbitration server "{0}"

[Description]

Because the values of parameters for abnormality monitoring of the operating system or server in the server definition file are too small compared with the value of heartbeat_interval in the arbitration definition file of the arbitration server, the arbtration for the target database server might be delayed.

[Parameters]

{0}: server ID

{1}: file name

[System Processing]

Depending on the start mode of the mc_ctl command, either of the following processes will be performed.

- When --async-connect-arbiter option is not specified

Processing will be aborted.

- When --async-connect-arbiter option is specified

Continues processing.

[Action]

Take either of the following actions.

- When --async-connect-arbiter option is not specified

Correct the value of parameters for abnormality monitoring of the operating system or server according to the message and "Tuning for Optimization of Degradation Using Abnormality Monitoring With the Arbitration Server" of "Cluster Operation Guide (Database Multiplexing)".

After that, re-execute the mc_ctl command.

- When --async-connect-arbiter option is specified

Correct the parameters for abnormality monitoring of the operating system or server according to the message and "Tuning for Optimization of Degradation Using Abnormality Monitoring With the Arbitration Server" of "Cluster Operation Guide (Database Multiplexing)".

After that, execute the mc_ctl command to restart Mirroring Controller.

3.3.14 MCA00214

{0}: keyword "{1}" is not specified for primary_conninfo parameter in postgresql.auto.conf

[Description]

The required keyword is not specified for primary_conninfo parameter in postgresql.auto.conf file.

[Parameters]

{0}: command name

{1}: keyword name

[System Processing]

Processing will be aborted.

[Action]

Specify the required keyword for primary_conninfo parameter in postgresql.auto.conf file according to the description of "Setting Up the Standby Center" for disaster recovery of "Cluster Operation Guide (Database Multiplexing)".

3.3.15 MCA00215

{0}: keyword "{3}" is not specified for parameter "{2}" in definition file "{1}"

[Description]

The keyword is not specified for the parameter in the definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: parameter name

{3}: keyword name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.3.16 MCA00216

{0}: value that cannot be specified for keyword "{3}" of parameter "{2}" in definition file "{1}" is set

[Description]

The value that cannot be specified for keyword of the parameter in the definition file is set.

[Parameters]

{0}: command name

{1}: file name

{2}: parameter name

{3}: keyword name

[System Processing]

Processing will be aborted.

[Action]

Take either of the following actions.

- When the keyword is application_name

Correct the definition file or postgresql.auto.conf file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

- Otherwise

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.3.17 MCA00217

{0}: could not use parameter "{3}" because parameter "{2}" is specified in definition file "{1}"

[Description]

This parameter cannot be specified because the parameter with exclusive relationship is specified in the definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: parameter name

{3}: parameter name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.3.18 MCA00218

{0}: value 'fallback' could not be specified for parameter heartbeat_error_action because parameter "{2}" is specified in definition file "{1}"

[Description]

The parameter with exclusive relationship is specified although 'fallback' is specified for heartbeat_error_action.

[Parameters]

{0}: command name

{1}: file name

{2}: parameter name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.3.19 MCA00219

you can switch the connection destination of streaming replication of server "{0}"

[Description]

You can switch the connection destination of streaming replication.

[Parameters]

{0}: server ID

3.3.20 MCA00220

you cannot switch the connection destination of streaming replication of server "{0}"

[Description]

You cannot switch the connection destination of streaming replication.

[Parameters]

{0}: server ID

3.3.21 MCA00221

start to build in standby server "{0}"

[Description]

Start to build in standby server.

[Parameters]

{0}: server ID

3.3.22 MCA00222

failed to build in standby server "{0}"

[Description]

Failed to build in standby server.

[Parameters]

{0}: server ID

[System Processing]

Processing will be aborted.

[Action]

Find the message output before this message from display of own and other server, system log or event log, and then work around according to the Action of the message.

3.3.23 MCA00223

build in standby server "{0}" completed

[Description]

Build in standby server "{0}" completed.

[Parameters]

{0}: server ID

3.3.24 MCA00224

start to switch the connection destination of streaming replication

[Description]

Start to switch the connection destination of streaming replication.

3.3.25 MCA00225

failed to switch the connection destination of streaming replication

[Description]

Failed to switch the connection destination of streaming replication.

[System Processing]

Processing of switching will be aborted.

[Action]

Find the message output before this message from display of own and other server, system log or event log, and then work around according to the Action of the message.

3.3.26 MCA00226

start to switch the connection destination of streaming replication of server "{0}"

[Description]

Start to switch the connection destination of streaming replication.

[Parameters]

{0}: server ID

[Action]

If Mirroring Controller executed switching automatically, find the message output before this message from system log or event log to identify the cause of switching, and then work around according to the Action of the message.

3.3.27 MCA00227

failed to switch the connection destination of streaming replication of server "{0}"

[Description]

Failed to switch the connection destination of streaming replication.

[Parameters]

{0}: server ID

[System Processing]

Processing of switching will be aborted.

[Action]

Find the message output before this message from display own and other server, system log or event log, and then work around according to the Action of the message.

3.3.28 MCA00228

switch the connection destination of streaming replication of server "{0}" completed

[Description]

Switch the connection destination of streaming replication completed.

[Parameters]

{0}: server ID

3.3.29 MCA00229

switch forcibly the connection destination of streaming replication of server "{0}" completed

[Description]

Switch forcibly the connection destination of streaming replication completed.

[Parameters]

{0}: server ID

3.3.30 MCA00230

value of primary_conninfo parameter which is specified in postgresql.auto.conf file of server "{0}" has been updated to the value of parameter "{2}" which is specified in definition file "{1}"

[Description]

Value of primary_conninfo parameter which is specified in postgresql.auto.conf file has been updated.

[Parameters]

{0}: server ID

{1}: file name

{2}: parameter name

3.3.31 MCA00231

failed to update value of primary_conninfo parameter which is specified in postgresql.auto.conf file of server "{0}" detail of cause:"{1}"

[Description]

Failed to update value of primary_conninfo parameter which is specified in postgresql.auto.conf file.

[Parameters]

{0}: server ID

{1}: detail of cause

[Action]

Check the error detail and eliminate causes.

3.3.32 MCA00232

update value of parameter "{2}" to "{3}" which is specified in definition file "{1}" of server "{0}" has completed

[Description]

Update value of parameter which is specified in definition file has completed.

[Parameters]

{0}: server ID

{1}: file name

{2}: parameter name

{3}: primary, standby

3.3.33 MCA00233

failed to update value of parameter "{2}" which is specified in definition file "{1}" of server "{0}"

[Description]

Failed to update value of parameter which is specified in definition file.

[Parameters]

{0}: server ID

{1}: file name

[Action]

Find the message output before this message from display of own and other server, system log or event log, and then work around according to the Action of the message.

3.3.34 MCA00234

failed to check the consistency of LSN between server "{0}" and server "{1}"

[Description]

Failed to check the consistency of LSN between the server.

[Parameters]

{0}: server ID

{1}: server ID

[Action]

Find the message output before this message from display of own and other server, system log or event log, and then work around according to the Action of the message.

3.3.35 MCA00235

failed to update value of parameter "{2}" which is specified in file "{1}" of old candidate primary server "{0}"

[Description]

Failed to update value of parameter which is specified on old candidate primary server.

[Parameters]

{0}: server ID

{1}: file name

{2}: parameter name

[Action]

Either of the following processes will be performed befor restarting OS if automatic start and stop of Mirroring Contoroller has been setting, otherwise building in old candidate primary server to new candidate primary server.

- When update postgresql.auto.conf file has failed

Update connection setting of primary_conninfo parameter which is specified in postgresql.auto.conf file to new candidate primary server by executing ALTER SYSTEM SET statement

- When update "server identifier".conf file has failed

Edit setting of standbycenter_mode parameter in 'standby' which is specified in "server identifier".conf file.

3.3.36 MCA00236

Mirroring Controller of the server "{0}" is not running

[Description]

Mirroring Controller of the server "{0}" is not running.

[Parameters]

{0}: server ID

3.3.37 MCA00237

invalid combination of server own server type:{0} other server type:{1}

[Description]

Invalid combination of server.

[Parameters]

{0}: own server type

{1}: other server type

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description to be set reffering disaster recovery operation of "Cluster Operation Guide (Database Multiplexing)".

3.3.38 MCA00238

{0}: cannot execute detaching forcibly other than on operation center

[Description]

Detaching forcibly needs to be executed only on operation center.

[Parameters]

{0}: command name

[System Processing]

Processing will be aborted.

[Action]

Check whether the server where the command was executed is correct.

3.3.39 MCA00239

standbycenter_mode parameter is specified in the definition file "{0}" of primary server

[Description]

standbycenter_mode parameter is specified in the definition file of primary server.

[Parameters]

{0}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description to be set reffering disaster recovery operation of "Cluster Operation Guide (Database Multiplexing)".

3.3.40 MCA00240

promoted to the primary server, although standbycenter_mode parameter is specified in the definition file "{1}" of the server "{0}"

[Description]

Promoted to the primary server, although standbycenter_mode parameter is specified in the definition file.

[Parameters]

{0}: server ID

{1}: file name

[System Processing]

Stop monitoring.

[Action]

Correct the definition file according to the message and parameter description to be set reffering disaster recovery operation of "Cluster Operation Guide (Database Multiplexing)".

3.3.41 MCA00241

write permission is denied on definition file "{0}"

[Description]

Write permission is denied on definition file.

[Parameters]

{0}: file name

[System Processing]

Processing will be aborted.

[Action]

Re-execute the command, after granting the write permissions to the definition file.

3.3.42 MCA00242

{0}: invalid format value is specified for parameter "{2}" in definition file "{1}"

[Description]

The invalid format value is specified for parameter in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: parameter name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.3.43 MCA00243

{0}: value is not set to keyword "{1}" of primary_conninfo parameter in postgresql.auto.conf

[Description]

The value is not set to keyword of primary_conninfo parameter in postgresql.auto.conf.

[Parameters]

{0}: command name

{1}: keyword name

[System Processing]

Processing will be aborted.

[Action]

Set the value for the keyword of primary_conninfo parameter in postgresql.auto.conf file according to the description of "Setting Up the Standby Center" for disaster recovery of "Cluster Operation Guide (Database Multiplexing)".

3.3.44 MCA00244

failed to start monitoring of database process

[Description]

Failed to start monitoring of database process.

[System Processing]

Processing will be aborted.

[Action]

Find the message output before this message from display, system log or event log, and then work around according to the Action of the message. After that, execute the mc_ctl command to restart Mirroring Controller.

3.3.45 MCA00245

checking the consistency of LSN between server "{0}" and server "{1}" is not executed because candidate primary server is abnormal

[Description]

Checking the consistency of LSN is not executed because candidate primary server is abnormal.

[Parameters]

{0}: server ID

{1}: server ID

[System Processing]

Processing will be continued.

[Action]

Find the message output before this message from display, system log or event log, and then work around according to the Action of the message, after switching over will be completed. After that, build in old candidate primary server to new candidate primary server.

3.3.46 MCA00252

The parameter node_role is set on Mirroring Controller process, but the parameter sc_port is not set on Mirroring Controller Arbitration process

[Description]

The parameter node_role is set on Mirroring Controller process, but the parameter sc_port is not set on Mirroring Controller Arbitration process.

[System Processing]

Processing will be aborted.

[Action]

Set sc_port parameter in arbitration.conf of Mirroring Controller arbitration process, if operating in Scaleout Controller configuration. If not, delete node_role parameter from "server identifier".conf of Mirroring Controller process.

3.3.47 MCA00253

The parameter node_role is not set on Mirroring Controller process, but the parameter sc_port is set on Mirroring Controller Arbitration process

[Description]

The parameter node_role is not set on Mirroring Controller process, but the parameter sc_port is set on Mirroring Controller Arbitration process.

[System Processing]

Processing will be aborted.

[Action]

Set node_role parameter in a"server identifier".conf of Mirroring Controller process, if operating in Scaleout Controller configuration. If not, delete sc_port parameter from arbitration.conf of Mirroring Controller arbitration process.

3.3.48 MCA00254

The parameter node_role is "{0}" on Mirroring Controller process, but the node role is "{1}" on Mirroring Controller Arbitration process

[Description]

node_role parameter set in Mirroring Controller process is different from node_role parameter set in the arbitration process of the mirroring controller.

[Parameters]

{0}: node role set in Mirroring Controller arbitration process

{1}: node role set in Mirroring Controller process

[System Processing]

Processing will be aborted.

[Action]

Reconfigure node_role parameter set in "server identifier".conf of Mirroring Controller process to match node_role set in arbs.conf of the Scaleout Controller process.

3.3.49 MCA00255

failed to switch over

[Description]

failed to switch over.

3.3.50 MCA00256

only the Mirroring Controller of the coordinator can be restarted

[Description]

only the Mirroring Controller of the coordinator can be restarted.

3.3.51 MCA00257

restarting Mirroring Controller

[Description]

restarting Mirroring Controller.

3.3.52 MCA00258

failed to restart Mirroring Controller target server:"{0}"

[Description]

failed to restart Mirroring Controller.

[Parameters]

{0}: server ID

3.3.53 MCA00259

failed to connect connection manager

[Description]

failed to connect connection manager.

[System Processing]

Processing will be aborted.

[Action]

Check the status of connection manager.

3.3.54 MCA00260

"{0}" has changed.

[Description]

Parameter in "server identifier".conf was changed.

[Parameters]

{0}: changed parameter

[System Processing]

Processing will be aborted.

[Action]

Reset relevant parameter to its pre-modified values and execute the process again.

3.3.55 MCA00265

detected startup process hang on monitoring of database process:{0}

[Description]

Detected startup process hang on monitoring of database process:{0}

[System Processing]

Continues processing.

[Action]

Check the error detail and eliminate causes.

3.3.56 MCA00266

detected recovery from startup process hang on monitoring of database process

[Description]

Detected recovery from startup process hang on monitoring of database process

3.4 Message Numbers Beginning with MCR00000

3.4.1 MCR00001

could not read file "{0}": exception={1}: {2}

[Description]

Could not read the file.

[Parameters]

{0}: file name

{1}: exception type

{2}: exception detail

[System Processing]

Processing will be aborted.

[Action]

Identify the cause according to the message, and then remove it.

3.4.2 MCR00002

{0}: wrong number of server ID in definition file "{1}"

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.4.3 MCR00003

{0}: server ID specified in definition file "{1}" too long (max {2} bytes) line {3}

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: max length of server ID

{3}: line number

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.4.4 MCR00004

{0}: wrong server ID in definition file "{1}"

[Description]

Could not use a server ID with same name in network.conf.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter descriptions of "Cluster Operation Guide (Database Multiplexing)".

3.4.5 MCR00005

invalid host name or IP address "{1}" in definition file "{0}"

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: file name

{1}: host name or IP address

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.4.6 MCR00006

{0}: invalid port number in definition file "{1}" line {2}

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: line number

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.4.7 MCR00007

{0}: invalid format specified in definition file "{1}" line {2}

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: line number

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.4.8 MCR00008

{0}: invalid value for parameter "{2}" in definition file "{1}"

[Description]

Invalid parameter was found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: parameter name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.4.9 MCR00009

{0}: no value for parameter "{2}" specified in definition file "{1}"

[Description]

Invalid parameter was found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: parameter name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.4.10 MCR00010

{0}: unrecognized parameter "{2}" in definition file "{1}"

[Description]

Unrecognized parameter was found in definition file.

[Parameters]

{0}: file name

{1}: command name

{2}: parameter name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.4.11 MCR00011

%s: option "%s" duplicated

[Description]

Certain option is duplicated.

[Parameters]

%s: command

%s: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.4.12 MCR00012

%s: "%s" option conflicts with "%s" option

[Description]

Options are conflicting.

[Parameters]

%s: command

%s: option

%s: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.4.13 MCR00013

%s: option requires an argument -- %s

[Description]

No argument specified for the option.

[Parameters]

%s: command

%s: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.4.14 MCR00014

%s: neither "%s" option nor environment variable "%s" specified

[Description]

Both of required option and equivalent environment variable were not specified.

[Parameters]

%s: command

%s: option

%s: environment variable

[System Processing]

Processing will be aborted.

[Action]

Re-execute after specifying required option or equivalent environment variable.

3.4.15 MCR00015

%s: argument of option "%s" is too long

[Description]

Argument of option is too long.

[Parameters]

%s: command name

%s: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.4.16 MCR00016

%s: invalid option -- %s

[Description]

Invalid option.

[Parameters]

%s: command name

%s: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.4.17 MCR00017

%s: option "%s" is required

[Description]

A required option is not specified.

[Parameters]

%s: command name

%s: option

[System Processing]

Processing will be aborted.

[Action]

Specify the required option, and re-execute.

3.4.18 MCR00018

%s: unnecessary operand "%s"

[Description]

Unnecessary operand.

[Parameters]

%s: command name

%s: operand

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting operand.

3.4.19 MCR00019

%s: unrecognized operation mode or no operation mode specified

[Description]

Unrecognized operation mode or no operation mode specified.

[Parameters]

%s: command name

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting or specifying operation mode.

3.4.20 MCR00020

Try "%s --help" for more information.\n

[Description]

--help option can show more additional information.

[Parameters]

%s: command name

[System Processing]

None.

[Action]

Check the message output before this message, and refer to descriptions shown by '--help' option.

3.4.21 MCR00021

%s: out of memory

[Description]

Out of memory error occurred.

[Parameters]

%s: command

[System Processing]

Processing will be aborted.

[Action]

Obtain free memory space by stopping unnecessary processes or changing system settings.

3.4.22 MCR00022

another "{0}" command is running

[Description]

Cannot execute command with this operation mode because another command is running on the same or another server.

[Parameters]

{0}: command name

[System Processing]

Processing will be aborted.

[Action]

There is a case executing another command. Wait for completion of another command on the same or another server, and then re-execute.

In addition, there are the following cases when using mc_arb command.

There is a case under processing of an arbitration by Mirroring Controller Arbitration process. Wait for completion of the processing under operation, and re-execute.

If any of the following cases occurs, there is a possibility that the processing of Mirroring Controller Arbitration process interrupts. Re-execute the mc_arb command after restarting Mirroring Controller Arbitration process.

- When abnormality occurs in the network

- When another server is downed

- When Mirroring Controller Arbitration process is stopped forcibly

3.4.23 MCR00023

Mirroring Controller Arbitration process is already running

[Description]

Mirroring Controller Arbitration process is already running.

[System Processing]

Processing will be aborted.

[Action]

If needed, stop Mirroring Controller Arbitration process, and re-execute.

If could not start although Mirroring Controller Arbitration process not started, refer to the description about workaround for failure of "Cluster Operation Guide (Database Multiplexing)".

3.4.24 MCR00024

cannot execute %s command because Mirroring Controller Arbitration process is not running

[Description]

Cannot execute Mirroring Controller Arbitration process command because Mirroring Controller Arbitration process is not running.

[Parameters]

%s: command name

[System Processing]

Processing will be aborted.

[Action]

Start Mirroring Controller Arbitration process, and re-execute.

3.4.25 MCR00025

timeout waiting for communication with Mirroring Controller Arbitration process

[Description]

Timeout waiting for communication with Mirroring Controller Arbitration process.

[System processing]

Processing will be aborted.

[Action]

Check whether a network error was detected.

If an error was not detected, there is a possibility that the load of the system may be the cause, please re-execute after a while.

3.4.26 MCR00026

could not create PID file of Mirroring Controller Arbitration process detail of cause:"{0}"

[Description]

Could not create PID file of Mirroring Controller Arbitration process.

[Parameters]

{0}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Identify the cause according to the message, and then remove it.

3.4.27 MCR00027

could not remove PID file of Mirroring Controller Arbitration process detail of cause:"%s"

[Description]

Could not remove PID file of Mirroring Controller Arbitration process.

[Parameters]

%s: detail of cause

[Action]

Identify the cause according to the message, and then remove it.

3.4.28 MCR00028

could not read PID file of Mirroring Controller Arbitration process detail of cause:"%s"

[Description]

Could not read PID file of Mirroring Controller Arbitration process.

[Parameters]

%s: detail of cause

[Action]

Identify the cause according to the message, and then remove it.

3.4.29 MCR00029

invalid contents of PID file "%s" of Mirroring Controller Arbitration process

[Description]

The contents of PID file of Mirroring Controller Arbitration process is invalid.

[Parameters]

%s: file name

[System Processing]

Processing will be aborted.

[Action]

The following causes could be considered.

- The file was stored or replaced by mistake

- The file was corrupted

When starting Mirroring Controller Arbitration process, move or remove the file shown in the message.

When stopped Mirroring Controller Arbitration process, find ID of process named "mc_arbiter" and terminate forcibly by using OS command.

3.4.30 MCR00030

unexpected error occurred: {0}

[Description]

An unexpected error occurred.

[Parameters]

{0}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate cause.

If you cannot clear the problem, contact Fujitsu technical support.

3.4.31 MCR00031

system call error occurred:"%s" detail of cause:"%s"

[Description]

System call error occurred.

[Parameters]

%s: system call name

%s: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.4.32 MCR00032

failed to open communication environment detail of cause:"{0}"

[Description]

Failed to open communication environment.

[Parameters]

{0}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

To investigate the cause of the occurrence from the message, and remove cause.

3.4.33 MCR00033

could not read file "{0}": Permission denied

[Description]

No read permissions for the file.

[Parameters]

{0}: file name

[System Processing]

Processing will be aborted.

[Action]

Re-execute the command, after granting the read permissions to the file.

3.4.34 MCR00034

could not read the access privileges of {0}

[Description]

Could not read the access privileges.

[Parameters]

{0}: target directory

[System Processing]

Processing will be aborted.

[Action]

Check the status of the directory and eliminate causes, and then remove it.

3.4.35 MCR00035

failed to set the access privileges of {0}

[Description]

Failed to set the access privileges.

[Parameters]

{0}: target directory

[System Processing]

Processing will be aborted.

[Action]

Check the status of the directory and eliminate causes, and then remove it.

3.4.36 MCR00036

could not get installation path

[Description]

FUJITSU Enterprise Postgres may not be installed.

[System Processing]

Processing will be aborted.

[Action]

Re-install FUJITSU Enterprise Postgres.

3.4.37 MCR00037

could not access "{0}" file detail of cause:"{1}"

[Description]

Could not access the process information file of OS.

[Parameters]

{0}: file name

{1}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.4.38 MCR00038

invalid contents of "{0}" file

[Description]

Invalid contents of /proc/[pid]/status file.

[Parameters]

{0}: file name

[System Processing]

Processing will be aborted.

[Action]

Check mc_arbiter process is existed or not in yourself.

3.4.39 MCR00039

unusable character is included in path "%s" specified as a directory for Mirroring Controller Arbitration process

[Description]

Unusable character is included in path specified as a directory for Mirroring Controller Arbitration process.

[Parameters]

%s: path name

[System Processing]

Processing will be aborted.

[Action]

Correct the path specified as a directory for Mirroring Controller Arbitration process according to the message and mc_arb command descriptions of "Reference".

3.4.40 MCR00040

could not access path "%s" specified as a directory for Mirroring Controller Arbitration process detail of cause:"%s"

[Description]

Could not access path specified as a directory for Mirroring Controller Arbitration process.

[Parameters]

%s: path name

%s: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.4.41 MCR00041

{0}: IP address "{2}" specified for parameter "my_address" in definition file "{1}" is not found

[Description]

IP address specified for my_address parameter in arbitration.conf is not found.

[Parameters]

{0}: command name

{1}: file name

{2}: IP address

[System Processing]

Processing will be aborted.

[Action]

Check whether IP address specified by my_address parameter in arbitration.conf is correct or IP address is valid.

3.4.42 MCR00042

could not access path "{0}" for parameter "{1}" in definition file "{2}" detail of cause:"{3}"

[Description]

Either of the followings has occurred.

- File does not exist

- You do not specify a file

- Could not read the access privileges

[Parameters]

{0}: path name

{1}: parameter name

{2}: file name

{3}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.4.43 MCR00043

{0}: users other than a command executor have the access privileges for definition file "{1}"

[Description]

Users other than a command executor have the access privileges for definition file.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Revoke all the access privileges for any users other than a command executor.

3.4.44 MCR00044

only the owner of definition file "{0}" can execute this command

[Parameters]

{0}: file name

[Description]

Only the owner who created the directory for Mirroring Controller Arbitration process can execute this command.

[System Processing]

Processing will be aborted.

[Action]

Re-execute the command by the owner who created the directory for Mirroring Controller Arbitration process.

3.4.45 MCR00045

starting Mirroring Controller Arbitration process

[Description]

Starting Mirroring Controller Arbitration process.

3.4.46 MCR00046

Mirroring Controller Arbitration process started

[Description]

Mirroring Controller Arbitration process started.

3.4.47 MCR00047

failed to start Mirroring Controller Arbitration process

[Description]

Failed to start Mirroring Controller Arbitration process.

[System Processing]

Processing will be aborted.

[Action]

Work around according to the Action of the message output before this message.

On Windows, if there is no message outputted before this message, please refer to the message outputted to an event log.

MCR00048

failed to report Mirroring Controller Arbitration process status

[Description]

Failed to report Mirroring Controller Arbitration process status.

[System Processing]

Processing will be aborted.

[Action]

Work around according to the Action of the message output before this message.

On Windows, if there is no message outputted before this message, please refer to the message outputted to an event log.

3.4.48 MCR00049

stopping Mirroring Controller Arbitration process

[Description]

Stopping Mirroring Controller Arbitration process.

3.4.49 MCR00050

Mirroring Controller Arbitration process stopped

[Description]

Mirroring Controller Arbitration process stopped.

3.4.50 MCR00051

could not stop Mirroring Controller Arbitration process because database server connects

[Description]

Could not stop Mirroring Controller Arbitration process because database server connects.

[System Processing]

Processing will be aborted.

[Action]

Execute mc_arb status command to find connected database server.

Re-execute after stopping Mirroring Controller on database server.

3.4.51 MCR00052

failed to stop Mirroring Controller Arbitration process

[Description]

Failed to stop Mirroring Controller Arbitration process.

[System Processing]

Processing will be aborted.

[Action]

Identify the cause from system log or event log on the target server, and work around.

3.4.52 MCR00053

stopping Mirroring Controller Arbitration process forcibly

[Description]

Stopping Mirroring Controller Arbitration process forcibly.

3.4.53 MCR00054

Mirroring Controller Arbitration process stopped forcibly

[Description]

Mirroring Controller Arbitration process stopped forcibly.

3.4.54 MCR00055

failed to stop Mirroring Controller Arbitration process forcibly

[Description]

Failed to stop Mirroring Controller Arbitration process forcibly.

[System Processing]

Processing will be aborted.

[Action]

Check [Action] of the message output before this message,and re-execute.

If re-execution fails, terminate forcibly mc_arbiter process with OS command.

3.4.55 MCR00056

database server "{0}" requested to arbitrate for database server "{1}" status

[Description]

Accepts a request to arbitrate from the database server which has detected an error.

[Parameters]

{0}: server ID

{1}: server ID

3.4.56 MCR00057

arbitrating the status of database server "{0}"

[Description]

Arbitrating for the status of the database server which was detected an error.

[Parameters]

{0}: server ID

[System Processing]

Arbitrating for the status of the database server which was detected an error.

3.4.57 MCR00058

received response from database server "{0}"

[Description]

A server is running normally.

[Parameters]

{0}: server ID

[System Processing]

Return result to database server.

3.4.58 MCR00059

could not receive response from database server "{0}"

[Description]

Detected the database server to be abnormal.

[Parameters]

{0}: server ID

[System Processing]

Execute fencing command.

3.4.59 MCR00060

rejected a request to arbitrate from database server "{0}"

[Description]

Either of the followings has occurred.

- Fencing command was executed just before

- The arbitration server was in the stop processing

[Parameters]

{0}: server ID

[System Processing]

Rejected a request to arbitrate from the database server.

3.4.60 MCR00061

database server "{0}" requested to fence database server "{1}"

[Description]

Accepted a request to fence from the database server which has detected an error.

[Parameters]

{0}: server ID

{1}: server ID

3.4.61 MCR00062

executing fencing command

[Description]

Executing fencing command.

[System processing]

Executing fencing command.

3.4.62 MCR00063

fencing command for database server "{0}" succeeded: result:"{1}"

[Description]

Fencing command for database server succeeded.

[parameters]

{0}: server ID

{1}: return code of command

[System processing]

Returning result to database server.

3.4.63 MCR00064

fencing command for database server "{0}" failed: result:"{1}"

[Description]

Fencing command for database server failed.

[parameters]

{0}: server ID

{1}: return code of command

[System processing]

Returning result to database server.

3.4.64 MCR00065

timeout waiting for the fencing command

[Description]

Timeout waiting for the fencing command.

[System processing]

Processing will be aborted.

[Action]

The value of fencing_command_timeout parameter in arbitration.conf is too short.

Review and extend the value of fencing_command_timeout parameter in arbitration.conf.

When find process ID of fencing command, terminate forcibly by using OS command.

3.4.65 MCR00066

rejected a request to fence from database server "{0}"

[Description]

Either of the followings is esteemed.

- The arbitration server has been executing arbitration process

- Fencing command has been executed just before

- The arbitration server was in the stop processing

[Parameters]

{0}: server ID

[System Processing]

Rejected a request to fence from database server.

3.4.66 MCR00067

rejected a request to fence from database server "{0}" because the database server is a fencing target

[Description]

The following requirements shouldn't be executed if it is requested from the database server which is a fencing target.

- request to arbitrate

- request to fence

- request to disable automatically switch

[Parameters]

{0}: server ID

[Action]

Processing will be aborted.

3.4.67 MCR00068

database server "{0}" requested to disable standby server "{1}" to automatically switch

[Description]

Accepted a request to disable the standby server to automatically switch.

[Parameters]

{0}: sever ID

{1}: sever ID

3.4.68 MCR00069

requested standby server "{0}" to disable automatically switching

[Description]

Requested the standby server to disable automatically switching.

[Parameters]

{0}: server ID

3.4.69 MCR00070

disabled standby server "{0}" to automatically switch

[Description]

Disabled the standby server to automatically switch.

[Parameters]

{0}: server ID

3.4.70 MCR00071

failed to disable standby server "{0}" to automatically switch

[Description]

Failed to disable the standby server to automatically switch.

[Parameters]

{0}: server ID

[System processing]

Executing fencing command.

3.4.71 MCR00072

omitted to disable standby server "{0}" to automatically switch

[Description]

It is not necessary to disable the standby server to automatically switch because a fencing for this database server is executing.

[Parameters]

{0}: server ID

[System processing]

Processing will be aborted.

3.4.72 MCR00073

connection was requested from database server "{0}"

[Description]

Connection was requested from database server.

[Parameters]

{0}: server ID

[Description]

Try connection to database server.

3.4.73 MCR00074

succeeded in connection with Mirroring Controller process of database server "{0}"

[Description]

Succeeded in connection with Mirroring Controller process of database server.

[Parameters]

{0}: server ID

3.4.74 MCR00075

rejected a request to connect from database server "{0}" because of during the fencing command execution

[Description]

Rejected a request to connect from database server because of during the fencing command execution.

[Parameters]

{0}: server ID

[Action]

Rejected a request to connect from database server.

3.4.75 MCR00076

disconnected from the database server "{0}"

[Description]

Disconnected from the database server.

[Parameters]

{0}: server ID

3.4.76 MCR00077

the disallowed IP address "{0}" tried to access

[Description]

The IP address which is different from the IP address in network.conf tried to access.

[parameters]

{0}: IP Adresses

[System Processing]

Connection will be rejected.

3.4.77 MCR00078

tried to access from database srever with installed different product version IP address:"{0}"

[Description]

tried to access from database server with installed different product version.

[parameters]

{0}: IP address

[System Processing]

Connection will be rejected

[Action]

Match the product version level between arbitration server and database server.

3.4.78 MCR00079

the invalid server ID tried to access IP address:"{0}"

[Description]

The server ID which is different from the server ID in network.conf tried to access.

[Parameters]

{0}: IP address

[System Processing]

Connection will be rejected.

3.4.79 MCR00080

the combination of server IDs of arbitration server is incompatible with that of database server "{0}"

[Description]

The combination of server IDs of arbitration server is incompatible with that of the database server.

[Parameters]

{0}: server ID

[System Processing]

Processing will be aborted.

[Action]

Check the network.conf of both database server and arbitration sever, and correct the file.

3.4.80 MCR00081

the invalid packet received

[Description]

The invalid packet received.

[System Processing]

Connection will be rejected.

3.4.81 MCR00082

{0}: invalid server kind specified in definition file "{1}" line {2}

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

{2}: line number

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "Cluster Operation Guide (Database Multiplexing)".

3.4.82 MCR00083

%s: invalid argument for option %s

[Description]

Invalid argument for option.

[Parameters]

%s: command name

%s: option

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting options.

3.4.83 MCR00084

installation environment is destroyed

[Description]

FUJITSU Enterprise Postgres may not be installed correctly or may be destroyed.

[System Processing]

Processing will be aborted.

[Action]

Re-install FUJITSU Enterprise Postgres.

3.4.84 MCR00085

no authority to execute this command

[Description]

Only the user who possesses an administrative authority can run this command.

[System Processing]

Processing will be aborted.

[Action]

Invoke the administrator's prompt, and re-execute this command.

3.4.85 MCR00086

failed to start service "{0}" detail of cause:"{1}"

[Description]

Failed to start service.

[Parameters]

{0}: Service name

{1}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.4.86 MCR00087

service "{0}" is not registered

[Description]

Service is not registered.

[Parameters]

{0}: Service name

[System Processing]

Processing will be aborted.

[Action]

Register service, and re-execute.

3.4.87 MCR00088

service "%s" for Mirroring Controller Arbitration process was registered

[Description]

Service for Mirroring Controller Arbitration process was registered with Windows service.

[Parameters]

%s: Service name

3.4.88 MCR00089

failed to register service "%s" detail of cause:"%s"

[Description]

An error occurred during registration of service.

[Parameters]

%s: Service name

%s: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.4.89 MCR00090

service name "%s" is already in use

[Description]

Service name is already in use.

[Parameters]

%s: Service name

[System Processing]

Processing will be aborted.

[Action]

Check the service name, and re-execute.

3.4.90 MCR00091

service "%s" for Mirroring Controller Arbitration process was unregistered

[Description]

Service for Mirroring Controller Arbitration process was unregistered from Windows service.

[Parameters]

%s: Service name

3.4.91 MCR00092

failed to unregister service "%s" detail of cause:"%s"

[Description]

An error occurred during deregistration of service.

[Parameters]

%s: Service name

%s: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

3.4.92 MCR00093

an error occurred in Mirroring Controller Arbitration process: {0}

[Description]

An error occurred in Mirroring Controller Arbitration process.

[Parameters]

{0}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

If you cannot clear the problem, contact Fujitsu technical support.

After removing the cause of errors, execute mc_arb command with the -e option to stop Mirroring Controller Arbitration process forcibly.

After that, execute the mc_arb command to start Mirroring Controller Arbitration process.

3.4.93 MCR00094

value of heartbeat_interval in arbitration definition file "{1}" is too large compared with value of parameters for abnormality monitoring of operating system or server in server definition file of database server "{0}"

[Description]

Because the value of heartbeat_interval parameter in the arbitration definition file is too large compared with the value of parameters for abnormality monitoring of the operating system or server in the server definition file of the database server, the arbitration for the target database server might be delayed.

[Parameters]

{0}: server ID

{1}: file name

[System Processing]

Continues processing.

[Action]

Correct the parameters for abnormality monitoring of the operating system or server according to the message and "Tuning for Optimization of Degradation Using Abnormality Monitoring With the Arbitration Server" of "Cluster Operation Guide (Database Multiplexing)".

After that, execute the mc_arb command to restart Mirroring Controller Arbitration process.

3.4.94 MCR00095

start to monitor of database server "{0}"

[Description]

Start to monitor of the database server.

[Parameters]

{0}: server ID

3.4.95 MCR00096

failed to start monitoring of database server "{0}"

[Description]

Failed to start monitoring of the database server.

[Parameters]

{0}: server ID

[System Processing]

Processing will be aborted.

[Action]

Find the message output before this message from display, system log or event log, and then work around according to the Action of the message.

3.4.96 MCR00097

stop Mirroring Controller Arbitration process forcibly because an error has occurred in Mirroring Controller Arbitration process: {0}

[Description]

Stop Mirroring Controller Arbitration process forcibly because an error has occurred in Mirroring Controller Arbitration process

[Parameters]

{0}: detail of cause

[System Processing]

Mirroring Controller Arbitration process will be stopped forcibly.

[Action]

Check the error detail and eliminate causes.

If you cannot clear the problem, contact Fujitsu technical support.

After removing the cause of errors, execute the mc_arb command to start Mirroring Controller Arbitration process.

3.4.97 MCR00098

stop monitoring of database server "{0}"

[Description]

Stop monitoring of the database server.

[Parameters]

{0}: server ID

3.4.98 MCR00099

detected an error on database server "{0}"

[Description]

Either of the followings has occurred.

- The database server is downed

- The arbitration network is abnormal

[Parameters]

{0}: server ID

[System Processing]

Continues processing.

3.5 Message Numbers Beginning with MCR00100

3.5.1 MCR00100

detected recovery of database server "{0}"

[Description]

detected recovery of the database server.

[Parameters]

{0}: server ID

3.5.2 MCR00101

arbitration for database server "{0}" has been delayed

[Description]

Either of the followings has occurred.

- The parameters for abnormality monitoring of the operating system or server are not optimally tuned

- The arbitration server is not responding

[Parameters]

{0}: server ID

[System Processing]

Continues processing.

[Action]

Take either of the following actions.

- When parameters for abnormality monitoring of the operating system or server are not optimally tuned

Correct the value of parameters for abnormality monitoring of the operating system or server according to the message and "Tuning for Optimization of Degradation Using Abnormality Monitoring With the Arbitration Server" of "Cluster Operation Guide (Database Multiplexing)".

After that, execute the mc_ctl command to stop Mirroring Controller, and execute the mc_arb command to stop the Mirroring Controller Arbitration process.

After that, execute the mc_arb command to start the Mirroring Controller Arbitration process, and execute the mc_ctl command to start Mirroring Controller.

- When the arbitration server is not responding

Identify the cause, and then remove it.

3.5.3 MCR00102

connection was requested from Scaleout Controller

[Description]

connection was requested from Scaleout Controller.

[System Processing]

Try connection to Scaleout Controller.

3.5.4 MCR00103

succeeded in connection with Scaleout Controller process

[Description]

succeeded in connection with Scaleout Controller process.

3.5.5 MCR00104

node role of Mirroring Controller Arbitration process has been set to "{0}"

[Description]

node role of Mirroring Controller Arbitration process has been set.

[Parameters]

{0}: node role

3.5.6 MCR00105

The parameter sc_port is not set on Mirroring Controller Arbitration process, but the parameter node_role is set on Mirroring Controller process

[Description]

The parameter sc_port is not set on Mirroring Controller Arbitration process, but the parameter node_role is set on Mirroring Controller process.

[System Processing]

Processing will be aborted.

[Action]

Set sc_port parameter in arbitration.conf of Mirroring Controller arbitration process, if operating in Scaleout Controller configuration. If not, delete node_role parameter from "server identifier".conf of Mirroring Controller process.

3.5.7 MCR00106

The node role is "{0}" on Mirroring Controller Arbitration process, but the parameter node_role is "{1}" on Mirroring Controller process

[Description]

node_role parameter set in Mirroring Controller process is different from node_role parameter set in the arbitration process of the mirroring controller.

[Parameters]

{0}: node role set in Mirroring Controller arbitration process

{1}: node role set in Mirroring Controller process

[System Processing]

Processing will be aborted.

[Action]

Reconfigure node_role parameter set in "server identifier".conf of Mirroring Controller process to match node_role set in arbs.conf of the Scaleout Controller process.

3.5.8 MCR00107

The parameter sc_port is set on Mirroring Controller Arbitration process, but the parameter node_role is not set on Mirroring Controller process

[Description]

The parameter sc_port is set on Mirroring Controller Arbitration process, but the parameter node_role is not set on Mirroring Controller process.

[System Processing]

Processing will be aborted.

[Action]

Set node_role parameter in a"server identifier".conf of Mirroring Controller process, if operating in Scaleout Controller configuration. If not, delete sc_port parameter from arbitration.conf of Mirroring Controller arbitration process.

3.5.9 MCR00108

timeout waiting for communication with Scaleout Controller process

[Description]

timeout waiting for communication with Scaleout Controller process.

[System Processing]

Processing will be aborted.

[Action]

Check whether Scaleout Controller process is in a normal state.

3.5.10 MCR00109

cannot send node status because Scaleout Controller process is not running

[Description]

cannot send node status because Scaleout Controller process is not running.

[Action]

Check the status of Scaleout Controller process.

3.5.11 MCR00110

The node role is "{0}" on Mirroring Controller Arbitration process, but the node role is "{1}" on Scaleout Controller process

[Description]

node_role parameter set in the arbitration process of the mirroring controller is different from node_role parameter set in Scaleout Controller process.

[Parameters]

{0}: node role set in Mirroring Controller arbitration process

{1}: node role set in Mirroring Controller process

[System Processing]

Processing will be aborted.

[Action]

Reconfigure node_role parameter set in "server identifier".conf of Mirroring Controller process to match node_role set in arbs.conf of the Scaleout Controller process.

3.5.12 MCR00111

disconnected from the Scaleout Controller

[Description]

disconnected from the Scaleout Controller.

3.5.13 MCR00112

{0}: wrong number of coordinator node in definition file "{1}"

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "manual".

3.5.14 MCR00113

{0}: no data node in definition file "{1}"

[Description]

Invalid descriptions were found in definition file.

[Parameters]

{0}: command name

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the definition file according to the message and parameter description of "manual".

3.5.15 MCR00114

Scaleout Controller process is already running

[Description]

Scaleout Controller process is already running.

[System Processing]

Processing will be aborted.

[Action]

If needed, stop Scaleout Controller process, and re-execute.

If could not start although Scaleout Controller process not started, refer to the description about workaround for failure of "manual".

3.5.16 MCR00115

cannot execute "{0}" command because Scaleout Controller process is not running

[Description]

Cannot execute Scaleout Controller process command because Scaleout Controller process is not running.

[Parameters]

{0}: command name

[System Processing]

Processing will be aborted.

[Action]

Start Scaleout Controller process, and re-execute.

3.5.17 MCR00116

timeout waiting for communication with Scaleout Controller process

[Description]

timeout waiting for communication with Scaleout Controller process.

[System Processing]

Processing will be aborted.

[Action]

Check whether a network error was detected.

If an error was not detected, there is a possibility that the load of the system may be the cause, please re-execute after a while.

3.5.18 MCR00117

could not create PID file of Scaleout Controller process detail of cause:"{0}"

[Description]

Could not create PID file of Scaleout Controller process.

[Parameters]

{0}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Identify the cause according to the message, and then remove it.

3.5.19 MCR00118

could not remove PID file of Scaleout Controller process detail of cause:"%s"

[Description]

Could not remove PID file of Scaleout Controller process.

[Parameters]

%s: detail of cause

[Action]

Identify the cause according to the message, and then remove it.

3.5.20 MCR00119

could not read PID file of Scaleout Controller process detail of cause:"{0}"

[Description]

could not read PID file of Scaleout Controller process.

[Parameters]

%s: detail of cause

[Action]

Identify the cause according to the message, and then remove it.

3.5.21 MCR00120

invalid contents of PID file "{0}" of Scaleout Controller process

[Description]

The contents of PID file of Scaleout Controller process is invalid.

[Parameters]

{0}: file name

[System Processing]

Processing will be aborted.

[Action]

The following causes could be considered.

- The file was stored or replaced by mistake

- The file was corrupted

When starting Scaleout Controller process, move or remove the file shown in the message.

When stopped Scaleout Controller process, find ID of process named "sc_arbiter" and terminate forcibly by using OS command.

3.5.22 MCR00121

unusable character is included in path "%s" specified as a directory for Scaleout Controller process

[Description]

Unusable character is included in path specified as a directory for Scaleout Controller.

[Parameters]

%s: path name

[System Processing]

Processing will be aborted.

[Action]

Correct the path specified as a directory for Scaleout Controller according to the message and sc_ctl command descriptions of "Reference".

3.5.23 MCR00122

could not access path "%s" specified as a directory for Scaleout Controller process detail of cause:"%s"

[Description]

Could not access path specified as a directory for Scaleout Controller process.

[Parameters]

%s: path name

%s: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Identify the cause according to the message, and then remove it.

3.5.24 MCR00123

The node role is "{0}" on Scaleout Controller process, but the node role is "{1}" on Mirroring Controller Arbitration process

[Description]

The node role of each node set in the Scaleout Controller process differs from the node type set in the each Mirroring Controller arbitration process.

[Parameters]

{0}: node role set in arbs.conf

{1}: node_role set in "server identifier".conf

[System Processing]

Processing will be aborted.

[Action]

Re-execute after correcting the setting value.

3.5.25 MCR00124

an error occurred in Scaleout Controller process: {0}

[Description]

an error occurred in Scaleout Controller process.

[Parameters]

{0}: detail of cause

[System Processing]

Processing will be aborted.

[Action]

Check the error detail and eliminate causes.

If you cannot clear the problem, contact Fujitsu technical support.

After removing the cause of errors, execute sc_ctl command to stop Scaleout Controller process.

If re-execution fails, terminate forcibly sc_arbiter process with OS command.

After that, execute the sc_ctl command to start Scaleout Controller process.

3.5.26 MCR00125

starting Scaleout Controller process

[Description]

starting Scaleout Controller process.

3.5.27 MCR00126

starting Mirroring Controller Arbitration Process: "{0}"

[Description]

starting Mirroring Controller Arbitration Process.

[Parameters]

{0}: directory of relevant Mirroring Controller arbitration process

3.5.28 MCR00127

requesting arbitration server "{0}" to connect

[Description]

requesting arbitration server to connect.

[Parameters]

{0}: directory of relevant Mirroring Controller arbitration process

[System Processing]

Requesting arbitration server to connect.

3.5.29 MCR00128

trying to connect to arbitration server "{0}"

[Description]

trying to connect to arbitration server.

[Parameters]

{0}: directory of relevant Mirroring Controller arbitration process

[System Processing]

Trying to connect to arbitration server until success.

3.5.30 MCR00129

succeeded in connection with arbitration server "{0}"

[Description]

succeeded in connection with arbitration server.

[Parameters]

{0}: directory of relevant Mirroring Controller arbitration process

3.5.31 MCR00130

failed to connect to arbitration server "{0}" event:"{1}"

[Description]

Either of the followings has occurred.

- Mirroring Controller Arbitration process is not running or in the stop processing

- Mirroring Controller Arbitration process or arbitration server detects an error

[Parameters]

{0}: server ID

{1}: "timeout" or "communication error"

[System Processing]

Processing will be aborted.

[Action]

Check the following and identify the cause, and eliminate cause.

- Mirroring Controller Arbitration process staring status

- the message in arbitration server

3.5.32 MCR00131

timeout waiting for communication with Mirroring Controller Arbitration process server:"{0}"

[Description]

Timeout waiting for communication between Scaleout Controller process and Mirroring Controller Arbitration process.

[Parameters]

{0}: directory of relevant Mirroring Controller arbitration process

[System Processing]

Try to connect to arbitration server.

[Action]

Check whether Mirroring Controller arbitration process is in a normal state.

3.5.33 MCR00132

communication error with the arbitration server "{0}" occurred

[Description]

Communication error with the arbitration server occurred.

[Parameters]

{0}: directory of relevant Mirroring Controller arbitration process

[System Processing]

Trying to connect.

[Action]

Check whether Mirroring Controller Arbitration process is running.

Identify the cause from messages on system log or event log in arbitration server, or Scaleout Controller server, and work around.

3.5.34 MCR00133

failed to start Scaleout Controller because of could not connect to arbitration server "{0}"

[Description]

failed to start Scaleout Controller because of could not connect to arbitration server.

[Parameters]

{0}: directory of relevant Mirroring Controller arbitration process

[System Processing]

Processing will be aborted.

[Action]

Work around according to the Action of the message output before this message.

3.5.35 MCR00134

values of parameters for abnormality monitoring of operating system or server in server definition file "{1}" are too small for value of heartbeat_interval in arbitration definition file of arbitration server "{0}"

[Description]

Because the values of parameters for abnormality monitoring of the operating system or server in the server definition file are too small compared with the value of heartbeat_interval in the arbitration definition file of the arbitration server, the arbtration for the target database server might be delayed.

[System Processing]

{0}: server ID

{1}: file name

[System Processing]

Processing will be aborted.

[Action]

Correct the value of parameters for abnormality monitoring of the operating system or server according to the message and "Tuning for Optimization of Degradation Using Abnormality Monitoring With the Arbitration Server" of "Cluster Operation Guide (Database Multiplexing)".

After that, execute the sc_ctl command to restart Scaleout Controller.

3.5.36 MCR00135

Scaleout Controller process started

[Description]

Scaleout Controller process started.

3.5.37 MCR00136

failed to start Scaleout Controller process

[Description]

failed to start Scaleout Controller process.

[System Processing]

Processing will be aborted.

[Action]

Work around according to the Action of the message output before this message.

3.5.38 MCR00137

could not execute "mc_arb status -M {0}"

[Description]

could not execute status mode of mc_arb command.

[Parameters]

{0}: directory of relevant Mirroring Controller arbitration process

[System Processing]

Processing will be aborted.

[Action]

Work around according to the Action of the message output before this message.

3.5.39 MCR00138

failed to report Scaleout Controller process status

[Description]

failed to report Scaleout Controller process status.

[System Processing]

Processing will be aborted.

[Action]

Work around according to the Action of the message output before this message.

3.5.40 MCR00139

stopping Scaleout Controller process

[Description]

stopping Scaleout Controller process.

3.5.41 MCR00140

stopping Mirroring Controller Arbitration Process: {0}

[Description]

stopping Mirroring Controller Arbitration Process.

3.5.42 MCR00141

could not stop Mirroring Controller Arbitration process "{0}"

[Description]

could not stop Mirroring Controller Arbitration process.

[Parameters]

{0}: directory of relevant Mirroring Controller arbitration process

[System Processing]

Processing will be aborted.

[Action]

Work around according to the Action of the message output before this message.

3.5.43 MCR00142

Scaleout Controller process stopped

[Description]

Scaleout Controller process stopped.

3.5.44 MCR00143

could not stop Scaleout Controller process because arbitration server connects

[Description]

could not stop Scaleout Controller process because arbitration server connects.

[System Processing]

Processing will be aborted.

[Action]

Arbitration server communicating with the Scaleout Controller process is found, please re-execute after a while.

3.5.45 MCR00144

failed to stop Scaleout Controller process

[Description]

failed to stop Scaleout Controller process.

[System Processing]

Processing will be aborted.

[Action]

Identify the cause from system log on the target server, and work around.

3.5.46 MCR00145

cannot execute "{0}" command because Mirroring Controller Arbitration process is not running

[Description]

Cannot execute Mirroring Controller Arbitration process command because Mirroring Controller Arbitration process is not running.

[Parameters]

{0}: command name

[Action]

Start Mirroring Controller Arbitration process, and re-execute.

3.5.47 MCR00146

restarting Scaleout Controller process

[Description]

restarting Scaleout Controller process.

3.5.48 MCR00147

"{0}" has changed

[Description]

Parameter in sc.conf was changed.

[Parameters]

{0}: changed parameter

[System Processing]

Processing will be aborted.

[Action]

Reset relevant parameter to its pre-modified values and execute the process again.

3.5.49 MCR00148

failed to restart Scaleout Controller

[Description]

failed to restart Scaleout Controller.

[System Processing]

Processing will be aborted.

3.5.50 MCR00149

add node "{0}" as a managed node by Scaleout Controller Process

[Description]

add node as a managed node by Scaleout Controller Process

[Parameters]

{0}: node name

3.5.51 MCR00150

both datanode "{0}" and coordinator node will perform failover

[Description]

both datanode and coordinator node will perform failover.

[Parameters]

{0}: node name

3.5.52 MCR00151

cannot continue operation on this center

[Description]

cannot continue operation on this center

[Action]

Switch center.

3.5.53 MCR00152

cannot find primary server on coordinator node

[Description]

cannot find primary server on coordinator node.

3.5.54 MCR00153

cannot solve network disconnection between node:"{0}" and node:"{1}"

[Description]

The arbitration process by Scaleout Controller process could not solve the inter-node network disconnection condition.

[Parameters]

{0}: nodename

{1}: nodename

3.5.55 MCR00154

cannot solve network trouble between nodes, need to switch center

[Description]

cannot solve network trouble between nodes, need to switch center.

[Action]

Switch center.

3.5.56 MCR00155

coordinator node will perform failover

[Description]

coordinator node will perform failover.

3.5.57 MCR00156

datanode "{0}" is being detached

[Description]

the target datanode is being detached

[Parameters]

{0}: nodename

3.5.58 MCR00157

datanode "{0}" will perform failover

[Description]

the target datanode will perform failover

[Parameters]

{0}: nodename

3.5.59 MCR00158

failed to perform failover on "{0}"

[Description]

failed to perform failover on the target node.

[Parameters]

{0}: nodename

3.5.60 MCR00159

failover status was not true even the node did failover

[Description]

failover status was not true even the node did failover.

3.5.61 MCR00160

got connection status of unrecognaized coordinator server

[Description]

got connection status of unrecognaized coordinator server.

3.5.62 MCR00161

Invalid server type

[Description]

Invalid server type.

3.5.63 MCR00162

Invalid server

[Description]

Invalid server.

3.5.64 MCR00163

no server with port "{0}" found

[Description]

no server with the specified port found.

[Parameters]

{0}: port number

3.5.65 MCR00164

succeeded in performing failover node "{0}"

[Description]

succeeded in performing failover node.

[Parameters]

{0}: nodename

3.5.66 MCR00165

unknown coordinator server connected

[Description]

unknown coordinator server connected.

3.5.67 MCR00166

could not execute because Mirroring Controller Arbitration process of the node "{0}" is not running

[Description]

could not execute because Mirroring Controller Arbitration process of the target node is not running.

[Parameters]

{0}: directory of relevant Mirroring Controller arbitration process

[System Processing]

Processing will be aborted.

[Action]

Re-execute after starting the specified Mirroring Controller arbitration process.

3.5.68 MCR00167

connection was requested from arbiter server "{0}"

[Description]

connection was requested from arbiter server.

[Parameters]

{0}: directory of relevant Mirroring Controller arbitration process

3.5.69 MCR00168

disconnected from arbitration server "{0}"

[Description]

disconnected from arbitration server.

[Parameters]

{0}: directory of relevant Mirroring Controller arbitration process

FJQSS User's Guide
(Information Collection Tool)

Windows/Linux

J2UL-3051-01ENZ0(00)

November-2025

Preface

This manual describes information to use the outline and the tool of FJQSS (Information Collection Tool).

Purpose of this Manual

The purpose of this manual is to be able to gather the collected information by using FJQSS (Information Collection Tool) when trouble occurs.

Reader of this Manual

This manual is targeted at the user who gathers the collected information when the trouble occurs.

You can obtain information on the method of gathering the function and the collected information of FJQSS (Information Collection Tool) obtain by referring to this manual.

Structure of this Manual

The structure of this manual is as follows:

Chapter 1 outline

Chapter 2 FJQSS (Information Collection Tool)

Appendix A Messages and error codes

Notations

The following notations are used in this manual;

Symbols used in this manual

The following symbols are used in this manual.

Example:[Enter]key

Symbols used in command

This subsection describes the symbols used in the examples of commands.

Example:

```
fjqss_collect [-s]
```

Meaning of Symbols

Symbol	Meaning
[]	The item enclosed with this sign is shown and omissible is shown.

Abbreviations

The following abbreviations are used in this manual:

Operating Systems

Full Name	Abbreviations
Oracle Solaris 9	Solaris 9
Oracle Solaris 10	Solaris 10
Oracle Solaris 11	Solaris 11
Oracle Solaris	Solaris
Red Hat Enterprise Linux 6 (for x86) Red Hat Enterprise Linux 6 (for Intel64)	RHEL6(x86) RHEL6(Intel64)
Red Hat Enterprise Linux 5 (for x86) Red Hat Enterprise Linux 5 (for Intel64)	RHEL5(x86) RHEL5(Intel64)

Export Management Regulations

Our documentation may include special technology based on Foreign Exchange and Foreign Trade Control Law.

In case you export the relevant documentation or to provide any overseas resident with the relevant documentation, permission based on the above law is necessary.

Trademarks and Screenshots

Oracle and Java are registered trademarks of Oracle Corporation, its subsidiaries and its affiliated companies in the United States and other countries.

The names of companies and products, etc. in the sentences inside can be trademarks or registered trademarks of each company.

Chapter 1 Outline

This chapter explains the outline of FJQSS (Information Collection Tool).

1.1 FJQSS (Information Collection Tool)

This appendix explains FJQSS (Information Collection Tool) that archives the information for investigation (middleware logs and operation system logs) with an easy operation. Executing FJQSS right after a problem occurs makes a rapid investigating of the causes.

Chapter 2 Collecting the information

This chapter explains the method of gathering the survey material, the confirm method of the survey material, and notes.

2.1 Collection method

This section explains the operating procedure of FJQSS (Information Collection Tool).

Collecting information can do by using the command. You can operate the Collection by the method that shows the product selection menu, or the method that does not show such the menu.

- 2.1.1 Collecting with showing menu
- 2.1.2 Collecting without showing menu

2.1.1 Collecting with showing menu

This subsection explains the operating procedure of FJQSS (Information Collection Tool) with showing the product selection menu.

Authority to execute

User Authority of the root user is necessary.

Prior confirmation

Set the output directory of the collected information if necessary. The output directory of default is the /var/tmp directory on Solaris, or the /tmp directory on Linux. See [2.3 Changing a path of the output directory] for details of changing the output directory.

Synopsis

If you execute the command specifying the output directory by the parameter:

```
fjqss_collect output_directory
```

If you execute the command specifying the output directory by the environment variable or the environmental configuration file:

```
fjqss_collect
```

Path to this command

```
/opt/FJSVqstl
```

Notes in executing the command

- Do not put fjqss_collect or its copy into any other directory. They work only if they are in the path shown above in [Path to this command].
- Execute this command immediately after the problem occurs.
- Multiple execution of this command is not available. If you do that, the following error message appears:

```
FJQSS is already started. Please restart FJQSS after the executing one ends.
```

Operating procedure

This part explains the operating procedure of FJQSS (Information Collection Tool).

1. Log on to the server, open the console window and execute the information collection command in the console window.

   Hereafter, it explains by the example when outputting the information to the default output directory:

```
> cd /opt/FJSVqstl
> ./fjqss_collect
```

2. The product selection menu appears. It shows the list of the products whose information can be collected.
3. Put the number of the product of which you want to collect the information:

```
-----------------------------------------------------
FJQSS Product Selection
-----------------------------------------------------
  1.MW Product B (Server Side)
  2.MW Product B (Client Side)

Please input a number of the product
of which you want to collect the information.>>1
```

4. Check the indicated name(s) of the middleware (s) whose investigation information are to be collected, then press the [Y] key to start.

   Collection starts and the following indicator appear in the command prompt:

```
The following product information is collected.
        MW Product B (Server Side)

Input 'Y-key' to collect data, or 'N-key' to stop.(default=N):y
preparing:            ######################################## 100% [00:01]
```

   The time and the disk space required for the collection depend on the condition of the target system.

5. Check the contents of the output directory.

   After the FJQSS (Information Collection Tool) has completed the collection, the following prompt appears. Verify that the information have been collected in the directory whose name is indicated in the prompt:

```
The following product information is collected.
        MW Product B (Server Side)

Input 'Y-key' to collect data, or 'N-key' to stop.(default=N):y
preparing:            ######################################## 100% [00:01]
collecting:           ######################################## 100% [00:01]
archiving:            ######################################## 100% [00:01]
compress:             ######################################## 100% [00:15]
Completed.
Gathered investigation informations archived to
    /tmp/ezcollect20121018172939/result20121018172939.tar.gz(206KB)
```

   This is an example on Linux.

   The gathered investigation informations are archived to /var/tmp/⋯ directory on Solaris, or /tmp/⋯ directory in Linux.

   The following files are created in the output directory (ezcollectYYYYMMDDHHMMSS: YYYYMMDDHHMMSS indicates the time (year, month, day, hours, minutes and seconds) that the collection started). See [2.2 Checking the collected information] for the output directory:

- resultYYYYMMDDHHMMSS.tar.gz

  The collected information.

- result.txt

  The result log is a text file to indicate if the collection of information has succeeded.

  This file indicates the names and the results of collection (OK/NG) of each material.

- ez.log

  The activity log of the FJQSS (Information Collection Tool).

Aborting FJQSS (Information Collection Tool)

This subsection explains how to abort running FJQSS (Information Collection Tool).

Although it is recommended that you wait until the collection ends, you can press [CTRL] + [C] key combination to abort the execution if it is necessary. The following prompt appears if [CTRL] + [C] is pressed and the execution is aborted.

```
The following product information is collected.
        MW Product B (Server Side)

Input 'Y-key' to collect data, or 'N-key' to stop.(default=N):y
preparing:            ################## 40% [00:01]
Stopped FJQSS process.
```

The output directory that has been made in the collecting might remain when the executing is aborted. There is no influence in the operation of FJQSS because the output directory will be newly made when FJQSS is executed again.

Moreover, there is no influence in the operation of FJQSS even if the remaining output directory was deleted.

Note

Do not close the command prompt before the collection ends. if you do so, the temporary directories might remain in the work directory. Please delete the following directories if they remain in the work directory.

・ezcollectYYYYMMDDHHMMSS

・ezworkYYYYMMDDHHMMSS

See 2.3 Changing a path of the output directory] for details of the work directory.

2.1.2 Collecting without showing menu

This subsection explains the operating procedure of FJQSS (Information Collection Tool) without showing the product selection menu.

You can use the procedure in the shell script.

Authority to execute

User Authority of the root user is necessary.

Prior confirmation

Verify the product identification name of the product of which you collect the information by the product information showing command. See 2.1.3 Getting the product identification name] for details.

Set the output directory of the collected information if necessary. The output directory of default is the /var/tmp directory on Solaris, or the /tmp directory on Linux. See [2.3 Changing a path of the output directory] for details of changing the output directory.

Synopsis

The specification of product identification name by "-pr <product identification name>" is necessary if you specify the silent mode option by "-s".

If you execute the command specifying the output directory by the parameter:

```
fjqss_collect -pr <product identification name> [-s] output_directory
```

If you execute the command specifying the output directory by the environment variable or the environmental configuration file:

```
fjqss_collect -pr <product identification name> [-s]
```

Description

The fjqss_collect command collects the information required for the investigation.

Option

-pr

This option specifies the product identification name of the product of which you collect the information.

-s

The command runs without asking to the operator. (It runs in silent mode.)

Path to this command

```
/opt/FJSVqstl
```

Notes in executing the command

- Do not put fjqss_collect or its copy into any other directory. They work only if they are in the path shown above in [Path to this command].
- Execute this command immediately after the problem occurs.
- Multiple execution of this command is not available. If you do that, the following error message appears:

```
FJQSS is already started. Please restart FJQSS after the executing one ends.
```

2.1.3 Getting the product identification name

This subsection explains how to get the product identification name which you specify when collecting the information without showing Product Selection Menu.

The product identification name can be got by executing the product information showing command.

Authority to execute

User Authority of the root user is necessary.

Synopsis

```
fjqss_mwpinfolist
```

Description

This command shows the list of the information of products of which the information collection is available.

Each product's information is shown in one line.

The product's Information is shown in order of "No." (number), "KEY" (product identification name), "DispName" (product name) and "Path" (destination directory of the information)

Example of the result of executing the product information showing command:

```
MW Product List
No. KEY        DispName                Path
--------------------------------------------------------------------------------
1.  PRODUCTA  MW PRODUCT A            /opt/FJSVPRDA/server/fjqss_tool1
2.  PRODUCTB  MW PRODUCT B            /opt/FJSVPRDB/server/fjqss_tool1
3.  PRODUCTC  MW PRODUCT C            /opt/FJSVPRDC/server/fjqss_tool1
```

If you collect the information of the product No.1, specify the product identification name "PRODUCTA" as the parameter

to collect the information of the "MW PRODUCT A" by the procedure of 2.1.2 Collecting without showing menu].

Path to this command

```
/opt/FJSVqstl
```

2.2 Checking the collected information

The collected information are created in the output directory (ezcollectYYYYMMDDHHMMSS) as file "resultYYYYMMDDHHMMSS.tar.gz".

The output directory is created at the output specified for an environmental configuration file destination at the output destination. If no destination is specified, then the output directory is created at the /var/tmp directory on Solaris, or the /tmp directory on LInux.

You can specify a path of the output directory if you execute the information collecting command in the console window. See [2.3 Changing a path of the output directory].for details of the environmental configuration file ant the output destination.

Verify that the following file and directory exist:

- Result log (result.txt)

  The result log is a text file to indicate if the collection of information has succeeded.

  This file indicates the names and the results of collection (OK/NG) of each material.

- Collected information (resultYYYYMMDDHHMMSS.tar.gz)

Note

Collected information (resultYYYYMMDDHHMMSS.tar.gz) is compressed and archived by gzip and tar. Collected information contains the following files.

- resultdir

  This directory contains the collected files.

- result.txt

  The result log is a text file to indicate if the collection of information has succeeded.

  This file indicates the names and the results of collection (OK/NG) of each material.

- ez.log

  The activity log of the FJQSS (Information Collection Tool).

- convert.txt

  If the file path name of information collecting is too long and information collecting can't get in former file name, file path name is converted and gathered. Former file path name and Converted file path name are output to convert.txt.convert.txt is output in the form of the following.

  Output form

  <Former file path name>,<Converted file path name>

  convert.txt is output when there was only information collecting for which the conversion of the file path name was necessary.

2.3 Changing a path of the output directory

You can change a path of the output directory by two methods below.

- Specifying a path of the output directory in the option of the information collecting command.
- Specifying a path of the output directory by setting the environment variable.
- Specifying a path of the output directory by updating the environmental configuration file.

The method of specifying in the option of the command explains in 2.1.1 Collecting with showing menu and 2.1.2 Collecting without showing menu]. Hereafter, the method of specifying by the environment variable and by the environmental configuration file will be explained.

-

Specifying a path of the output directory by setting the environment variable

You can specify the directory where the output directory will be created by setting the environment variable EZ_OUTPUTDIR before executing this command.

Description format:

```
EZ_OUTPUTDIR="the directory path where the output directory will be created"
export EZ_OUTPUTDIR
```

Example:

If “/etc/work” is specified to %EZ_OUTPUTDIR%:

```
EZ_OUTPUTDIR=/etc/work
export EZ_OUTPUTDIR
```

Then the directory below will be created as the output directory:

```
/etc/work/ezcollectYYYYMMDDHHMMSS
```

Specifying a path of the output directory by updating the environmental configuration file

Environmental configuration file (FJQSSconf.txt) is a file that defines the operating environment of FJQSS.

It exists in following directory.

```
<Directory where the product is installed>/fjqss_tooln (n=1,2,..,9)
```

The items that can be specified for environmental configuration file are shown below.

Item	Outline	Omission
OutputDir	The directory path where the output directory will be created (*3).	Possible (*2)
WorkDir	The directory path where the work directory (*1) will be created by FJQSS execution (*3).	Possible(*2)

(*1)The work directory is a directory that temporarily stores information necessary for the execution of FJQSS. When FJQSS ends, stored information is automatically deleted.

(*2) If the specification is wrong or omitted, the /var/tmp directory (on Solaris), or the /tmp directory (on Linux) is used.

(*3) You can specify the directory by the relative path from an absolute path or environmental configuration file.

The format of environmental configuration file is shown below.

Description format:

```
OutputDir="the directory path where the output directory will be created"
WorkDir=” work directory”
```

Example:

If “/etc/work” is specified to OutputDir, “/etc/tmp” is specified to WorkDIr.

```
OutputDir=/etc/work
WorkDir=/etc/tmp
```

Then the directory below will be created as the output directory:

```
/etc/work/ezcollectYYYYMMDDHHMMSS
```

And the directory below will be created as the work directory:

```
/etc/tmp/ezworkYYYMMDDHHMMSS
```

Note

If the plural specifications of the output directory is done, then the specification becomes effective in the following order by priority:

1. Specification in the option of the information collecting command.
2. Specification by setting the environment variable.
3. Specification by updating the environmental configuration file.

Appendix A Messages and error codes

A.1 Error Messages

The message which FJQSS outputs can have an error code. See [A.2 Error Codes]. for detail of error codes.

Look for	What to do
FJQSS is already started. Please restart FJQSS after the executing one ends.	Check if FJQSS is running. Multiple execution of it is not available.
The file used with FJQSS is not found. Please contact a Fujitsu technological member. (product= PRODUCT_IDETIFICATION_NAME, errcode= ERROR_CODE)	Please contact the Fujitsu engineer, and pass on the PRODUCT_IDENTIFICATION_NAME, PATH_NAME and ERROR_CODE in the message. About detail meanings of the ERROR_CODE, see [A.2 Error Codes].
Failed in the copy of materials used with FJQSS to the work directory. Please contact a Fujitsu technological member. (PATH= PATH_NAME, errcode= ERROR_CODE)	
Failed in the access of the file used with FJQSS. Please contact a Fujitsu technological member. (errcode= ERROR_CODE)	
The file used with FJQSS is not found or broken. Please contact a Fujitsu technological member. (PATH= PATH_NAME)	
Failed in the access of the directory used with FJQSS. Please contact a Fujitsu technological member. (PATH= PATH_NAME)	
Failed in the current directory change to the work directory. Please contact a Fujitsu technological member. (PATH= PATH_NAME)	
Failed to execute FJQSS.Please contact Fujitsu technical staff.	
There is a wrong option in the command line. Please restart FJQSS with the correct option.	Execute FJQSS again after removing the cause according to the left messages. About Environmental configuration file, see [2.3 Changing a path of the output directory].
Not super-user. Please restart FJQSS by super-user	
A memory is insufficient. Please stop unnecessary applications and restart FJQSS.	
The product specified by the -pr option is not found. Please restart FJQSS with the correct option. (product= PRODUCT_IDETIFICATION_NAME)	
Japanese characters are included in the directory name at the 'OutputDir' of environmental file. Japanese characters cannot be used. Please correct environmental file and restart FJQSS. (environmental file=PATH_NAME)	

Look for	What to do
Japanese characters are included in the directory name at the 'WorkDir' of environmental file. Japanese characters cannot be used. Please correct environmental file and restart FJQSS. (environmental file=PATH_NAME)	
Failed in making the output directory. Please confirm the following. -There must be an authority to make the folder. -Passing in xx bytes or less must be specified. -The length of each directory name must be 255 bytes or less.	
Failed in making the work directory. Please confirm the following. -There must be an authority to make the folder. -Passing in xx bytes or less must be specified. -The length of each directory name must be 255 bytes or less.	
Output directory is too long at the 'OutputDir' of environmental file.Please adjust the output directory to xx bytes or less and restart FJQSS (environmental file= PATH_NAME)	
Work directory is too long at the 'WorkDir' of environmental file. Please adjust the output directory to xx bytes or less and restart FJQSS (environmental file= PATH_NAME)	
The output directory is too long specified in the option. Please adjust the output directory to %s bytes or less and restart FJQSS.	
Japanese characters are included in the output directory specified in the option. Japanese characters cannot be used. Please correct the output directory and restart FJQSS.	
The output directory is too long specified with the environment variable:EZ_OUTPUTDIR. Please adjust environment variable:EZ_OUTPUTDIR to xx byte or less.	
Failed to create log.(PATH=PATH_NAME) Take action indicated the following items: - Create the output folder if it doesn't exist. - Set the role to the output folder.	
Products are not installed.Please make sure that the products that are installed.	
The is no installed product of which FJQSS can collect the information. FJQSS ends.	
Stopped FJQSS process.	No user action is necessary.

A.2 Error Codes

Error Code	Cause
0	No error.

Error Code	Cause
1	Command operand error
2	Insufficient memory
3	Failed to execute without administrator permissions
5	Though "-s" option exists, "-pr" option does not exist
6	FJQSS common component has been already done
10	Middleware products' list file does not exist
11	Middleware product specified with -pr option does not exist
13	The built-in directory of the target middleware product of collecting information does not exist
15	Japanese characters are included in the directory name at the output directory of environmental file
16	Japanese characters are included in the directory name at the work directory of environmental file
17	Too long path name is specified in the directory name at the output directory of environmental file
18	Too long path name is specified in the directory name at the work directory of environmental file
19	Failed to create the output directory
20	Failed to create the work directory
21	Failed to access the directory
22	Failed to copy the common materials and built-in materials of the product directory to the work directory
23	Failed to show the information of the product to collect its information materials
24	Failed to change the current directory to the work directory
25	Too long path name is specified to the parameter that specifies the output directory
26	Japanese characters are included in the parameter that specifies the output directory
27	Products of which collecting information is available are not installed
28	Failed to execute FJQSS

Preface xxxiii
1. What Is PostgreSQL? xxxiii
2. A Brief History of PostgreSQL xxxiii
2.1. The Berkeley POSTGRES Project xxxiv
2.2. Postgres95 xxxiv
2.3. PostgreSQL xxxv
3. Conventions xxxv
4. Further Information xxxv
5. Bug Reporting Guidelines xxxvi
5.1. Identifying Bugs xxxvi
5.2. What to Report xxxvii
5.3. Where to Report Bugs xxxviii
I. Tutorial 1
1. Getting Started 3
1.1. Installation 3
1.2. Architectural Fundamentals 3
1.3. Creating a Database 3
1.4. Accessing a Database 5
2. The SQL Language 7
2.1. Introduction 7
2.2. Concepts 7
2.3. Creating a New Table 7
2.4. Populating a Table With Rows 8
2.5. Querying a Table 9
2.6. Joins Between Tables 11
2.7. Aggregate Functions 13
2.8. Updates 15
2.9. Deletions 15
3. Advanced Features 17
3.1. Introduction 17
3.2. Views 17
3.3. Foreign Keys 17
3.4. Transactions 18
3.5. Window Functions 20
3.6. Inheritance 23
3.7. Conclusion 24
II. The SQL Language 25
4. SQL Syntax 33
4.1. Lexical Structure 33
4.2. Value Expressions 42
4.3. Calling Functions 56
5. Data Definition 59
5.1. Table Basics 59
5.2. Default Values 60
5.3. Identity Columns 61
5.4. Generated Columns 62
5.5. Constraints 64
5.6. System Columns 74
5.7. Modifying Tables 74
5.8. Privileges 77
5.9. Row Security Policies 82
5.10. Schemas 88
5.11. Inheritance 93
5.12. Table Partitioning 96
5.13. Foreign Data 110

5.14. Other Database Objects 110
5.15. Dependency Tracking 111
6. Data Manipulation 113
6.1. Inserting Data 113
6.2. Updating Data 114
6.3. Deleting Data 115
6.4. Returning Data from Modified Rows 115
7. Queries 117
7.1. Overview 117
7.2. Table Expressions 117
7.3. Select Lists 133
7.4. Combining Queries (UNION, INTERSECT, EXCEPT) 135
7.5. Sorting Rows (ORDER BY) 136
7.6. LIMIT and OFFSET 137
7.7. VALUES Lists 137
7.8. WITH Queries (Common Table Expressions) 138
8. Data Types 148
8.1. Numeric Types 149
8.2. Monetary Types 155
8.3. Character Types 155
8.4. Binary Data Types 158
8.5. Date/Time Types 160
8.6. Boolean Type 170
8.7. Enumerated Types 171
8.8. Geometric Types 172
8.9. Network Address Types 175
8.10. Bit String Types 177
8.11. Text Search Types 178
8.12. UUID Type 181
8.13. XML Type 181
8.14. JSON Types 184
8.15. Arrays 194
8.16. Composite Types 203
8.17. Range Types 209
8.18. Domain Types 216
8.19. Object Identifier Types 216
8.20. pg_lsn Type 219
8.21. Pseudo-Types 219
9. Functions and Operators 221
9.1. Logical Operators 221
9.2. Comparison Functions and Operators 222
9.3. Mathematical Functions and Operators 226
9.4. String Functions and Operators 234
9.5. Binary String Functions and Operators 245
9.6. Bit String Functions and Operators 249
9.7. Pattern Matching 251
9.8. Data Type Formatting Functions 270
9.9. Date/Time Functions and Operators 279
9.10. Enum Support Functions 296
9.11. Geometric Functions and Operators 297
9.12. Network Address Functions and Operators 304
9.13. Text Search Functions and Operators 307
9.14. UUID Functions 313
9.15. XML Functions 314
9.16. JSON Functions and Operators 329
9.17. Sequence Manipulation Functions 362
9.18. Conditional Expressions 363
9.19. Array Functions and Operators 366

9.20. Range/Multirange Functions and Operators 370
9.21. Aggregate Functions 376
9.22. Window Functions 384
9.23. Merge Support Functions 385
9.24. Subquery Expressions 386
9.25. Row and Array Comparisons 389
9.26. Set Returning Functions 391
9.27. System Information Functions and Operators 395
9.28. System Administration Functions 416
9.29. Trigger Functions 436
9.30. Event Trigger Functions 437
9.31. Statistics Information Functions 439
10. Type Conversion 441
10.1. Overview 441
10.2. Operators 442
10.3. Functions 446
10.4. Value Storage 450
10.5. UNION, CASE, and Related Constructs 451
10.6. SELECT Output Columns 452
11. Indexes 454
11.1. Introduction 454
11.2. Index Types 455
11.3. Multicolumn Indexes 457
11.4. Indexes and ORDER BY 458
11.5. Combining Multiple Indexes 459
11.6. Unique Indexes 460
11.7. Indexes on Expressions 460
11.8. Partial Indexes 461
11.9. Index-Only Scans and Covering Indexes 464
11.10. Operator Classes and Operator Families 467
11.11. Indexes and Collations 468
11.12. Examining Index Usage 469
12. Full Text Search 470
12.1. Introduction 470
12.2. Tables and Indexes 474
12.3. Controlling Text Search 476
12.4. Additional Features 483
12.5. Parsers 489
12.6. Dictionaries 491
12.7. Configuration Example 500
12.8. Testing and Debugging Text Search 501
12.9. Preferred Index Types for Text Search 506
12.10. psql Support 507
12.11. Limitations 510
13. Concurrency Control 512
13.1. Introduction 512
13.2. Transaction Isolation 512
13.3. Explicit Locking 518
13.4. Data Consistency Checks at the Application Level 524
13.5. Serialization Failure Handling 525
13.6. Caveats 526
13.7. Locking and Indexes 526
14. Performance Tips 528
14.1. Using EXPLAIN 528
14.2. Statistics Used by the Planner 543
14.3. Controlling the Planner with Explicit JOIN Clauses 549
14.4. Populating a Database 551
14.5. Non-Durable Settings 553

15. Parallel Query 555
15.1. How Parallel Query Works 555
15.2. When Can Parallel Query Be Used? 556
15.3. Parallel Plans 557
15.4. Parallel Safety 559
III. Server Administration 561
16. Installation from Binaries 568
17. Installation from Source Code 569
17.1. Requirements 569
17.2. Getting the Source 571
17.3. Building and Installation with Autoconf and Make 571
17.4. Building and Installation with Meson 584
17.5. Post-Installation Setup 596
17.6. Supported Platforms 597
17.7. Platform-Specific Notes 598
18. Server Setup and Operation 604
18.1. The PostgreSQL User Account 604
18.2. Creating a Database Cluster 604
18.3. Starting the Database Server 606
18.4. Managing Kernel Resources 610
18.5. Shutting Down the Server 617
18.6. Upgrading a PostgreSQL Cluster 618
18.7. Preventing Server Spoofing 621
18.8. Encryption Options 622
18.9. Secure TCP/IP Connections with SSL 623
18.10. Secure TCP/IP Connections with GSSAPI Encryption 627
18.11. Secure TCP/IP Connections with SSH Tunnels 627
18.12. Registering Event Log on Windows 628
19. Server Configuration 630
19.1. Setting Parameters 630
19.2. File Locations 634
19.3. Connections and Authentication 635
19.4. Resource Consumption 642
19.5. Write Ahead Log 651
19.6. Replication 662
19.7. Query Planning 669
19.8. Error Reporting and Logging 677
19.9. Run-time Statistics 691
19.10. Vacuuming 693
19.11. Client Connection Defaults 698
19.12. Lock Management 709
19.13. Version and Platform Compatibility 710
19.14. Error Handling 712
19.15. Preset Options 713
19.16. Customized Options 715
19.17. Developer Options 715
19.18. Short Options 721
20. Client Authentication 722
20.1. The `pg_hba.conf` File 722
20.2. User Name Maps 731
20.3. Authentication Methods 733
20.4. Trust Authentication 734
20.5. Password Authentication 734
20.6. GSSAPI Authentication 735
20.7. SSPI Authentication 737
20.8. Ident Authentication 737
20.9. Peer Authentication 738
20.10. LDAP Authentication 738

20.11. RADIUS Authentication 742
20.12. Certificate Authentication 743
20.13. PAM Authentication 743
20.14. BSD Authentication 743
20.15. OAuth Authorization/Authentication 744
20.16. Authentication Problems 746
21. Database Roles 747
21.1. Database Roles 747
21.2. Role Attributes 748
21.3. Role Membership 750

E.4. Release 18 2765
E.5. Prior Releases 2788
F. Additional Supplied Modules and Extensions 2789
F.1. amcheck — tools to verify table and index consistency 2791
F.2. auth_delay — pause on authentication failure 2797
F.3. auto_explain — log execution plans of slow queries 2798
F.4. basebackup_to_shell — example "shell" pg_basebackup module 2801
F.5. basic_archive — an example WAL archive module 2802

F.6. bloom — bloom filter index access method 2803
F.7. btree_gin — GIN operator classes with B-tree behavior 2807
F.8. btree_gist — GiST operator classes with B-tree behavior 2808
F.9. citext — a case-insensitive character string type 2810
F.10. cube — a multi-dimensional cube data type 2813
F.11. dblink — connect to other PostgreSQL databases 2818
F.12. dict_int — example full-text search dictionary for integers 2850
F.13. dict_xsyn — example synonym full-text search dictionary 2851
F.14. earthdistance — calculate great-circle distances 2853
F.15. file_fdw — access data files in the server's file system 2855
F.16. fuzzystrmatch — determine string similarities and distance 2858
F.17. hstore — hstore key/value datatype 2863
F.18. intagg — integer aggregator and enumerator 2871
F.19. intarray — manipulate arrays of integers 2873
F.20. isn — data types for international standard numbers (ISBN, EAN, UPC, etc.) 2877
F.21. lo — manage large objects 2881
F.22. ltree — hierarchical tree-like data type 2883
F.23. pageinspect — low-level inspection of database pages 2890
F.24. passwordcheck — verify password strength 2901
F.25. pg_buffercache — inspect PostgreSQL buffer cache state 2902
F.26. pgcrypto — cryptographic functions 2907
F.27. pg_freespacemap — examine the free space map 2918
F.28. pg_logicalinspect — logical decoding components inspection 2920
F.29. pg_overexplain — allow EXPLAIN to dump even more details 2922
F.30. pg_prewarm — preload relation data into buffer caches 2924
F.31. pgrowlocks — show a table's row locking information 2926
F.32. pg_stat_statements — track statistics of SQL planning and execution 2928
F.33. pgstattuple — obtain tuple-level statistics 2937
F.34. pg_surgery — perform low-level surgery on relation data 2942
F.35. pg_trgm — support for similarity of text using trigram matching 2944
F.36. pg_visibility — visibility map information and utilities 2950
F.37. pg_walinspect — low-level WAL inspection 2952
F.38. postgres_fdw — access data stored in external PostgreSQL servers 2956
F.39. seg — a datatype for line segments or floating point intervals 2968
F.40. sepgsql — SELinux-, label-based mandatory access control (MAC) security module 2971
F.41. spi — Server Programming Interface features/examples 2980
F.42. sslinfo — obtain client SSL information 2982
F.43. tablefunc — functions that return tables (`crosstab` and others) 2984
F.44. tcn — a trigger function to notify listeners of changes to table content 2994
F.45. test_decoding — SQL-based test/example module for WAL logical decoding 2996
F.46. tsm_system_rows — the `SYSTEM_ROWS` sampling method for `TABLESAMPLE` 2997
F.47. tsm_system_time — the `SYSTEM_TIME` sampling method for `TABLESAMPLE` 2998
F.48. unaccent — a text search dictionary which removes diacritics 2999
F.49. uuid-ossp — a UUID generator 3002
F.50. xml2 — XPath querying and XSLT functionality 3004
