Preface

Purpose of this document

This document is intended for users of Fujitsu Enterprise Postgres, and explains how to read the manuals.

Structure of this document

The structure and content of this manual is shown below.

Chapter 1 How to Read the Manuals

This section explains the notational conventions in Fujitsu Enterprise Postgres manuals.

Chapter 2 Trademarks

This section explains the trademarks.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Chapter 1 How to Read the Manuals

The Fujitsu Enterprise Postgres manuals use certain notational conventions and rules. Pay attention to these conventions and rules when reading the Fujitsu Enterprise Postgres manuals.

1.1 Abbreviations of Manual Titles

The following tables list abbreviations of the titles of manuals for Fujitsu Enterprise Postgres as they appear in the manuals.

Formal manual title	Abbreviation in Fujitsu Enterprise Postgres manuals
Fujitsu Enterprise Postgres Release Notes	Release Notes
Fujitsu Enterprise Postgres General Description	General Description
Fujitsu Enterprise Postgres Installation and Setup Guide for Server	Installation and Setup Guide for Server
Fujitsu Enterprise Postgres Installation and Setup Guide for Client	Installation and Setup Guide for Client
Fujitsu Enterprise Postgres Installation and Setup Guide for Server Assistant	Installation and Setup Guide for Server Assistant
Fujitsu Enterprise Postgres Operation Guide	Operation Guide
Fujitsu Enterprise Postgres Cluster Operation Guide (Database Multiplexing)	Cluster Operation Guide (Database Multiplexing)
Fujitsu Enterprise Postgres Cluster Operation Guide (Multi-master Replication)	Cluster Operation Guide (Multi-master Replication)
Fujitsu Enterprise Postgres Cluster Operation Guide (PRIMECLUSTER)	Cluster Operation Guide (PRIMECLUSTER)
Fujitsu Enterprise Postgres Security Operation Guide	Security Operation Guide
Fujitsu Enterprise Postgres Knowledge Data Management Feature User's Guide	Knowledge Data Management Feature User's Guide
Fujitsu Enterprise Postgres Application Development Guide	Application Development Guide
Fujitsu Enterprise Postgres Connection Manager User's Guide	Connection Manager User's Guide
Fujitsu Enterprise Postgres Reference	Reference
Fujitsu Enterprise Postgres Java API Reference	Java API Reference
Fujitsu Enterprise Postgres Npgsql *<v>* API Reference (*1)	Npgsql API Reference
Fujitsu Enterprise Postgres Glossary	Glossary
Fujitsu Enterprise Postgres Messages	Messages
PostgreSQL *<x>* Documentation (*2)	PostgreSQL Documentation

*1: *<v>* indicates the version of Npgsql. For the version, refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description.

*2: *<x>* indicates the version of PostgreSQL that Fujitsu Enterprise Postgres is based on. For the version, refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description.

1.2 System of Manuals and How to Use the Manuals

This section describes the system of manuals for Fujitsu Enterprise Postgres.

1.2.1 System of Manuals

Fujitsu Enterprise Postgres manuals

The table below shows the manuals on Fujitsu Enterprise Postgres.

Use/Purpose	Manual title	Content	When to read
Deciding whether to upgrade the product.	Release Notes	Overview of upgraded features and incompatibility information.	When learning about features upgraded from earlier versions and incompatibility information.
Acquiring an overview of the product and the basic information required for work and operation.	General Description	Description of all available functions associated with each intended purpose or use, and screenshots of operations.	When learning basic information and restrictions that system engineers and operators must know to actually operate the product.
Installing and setting up Fujitsu Enterprise Postgres correctly to enable its use.	Installation and Setup Guide for Server	Procedure for installing and setting up Fujitsu Enterprise Postgres.	When installing and setting up Fujitsu Enterprise Postgres.
Installing the Fujitsu Enterprise Postgres client function correctly to enable its use.	Installation and Setup Guide for Client	Installing the Fujitsu Enterprise Postgres client function.	When installing the Fujitsu Enterprise Postgres client function.
Installing and setting up the Fujitsu Enterprise Postgres Server Assistant.	Installation and Setup Guide for Server Assistant	Procedure for installing and setting up the Fujitsu Enterprise Postgres Server Assistant.	When installing and setting up the Fujitsu Enterprise Postgres Server Assistant.
Operating and managing Fujitsu Enterprise Postgres.	Operation Guide	Description of the tasks required in Fujitsu Enterprise Postgres management and operation.	When learning how to operate and manage the databases.
Performing switchover using database multiplexing mode.	Cluster Operation Guide (Database Multiplexing)	Description of the tasks required for database multiplexing operation.	When using database multiplexing mode to create operating environment for switchover and perform it.
Build/operate a system with a multi-master configuration	Cluster Operation Guide (Multi-master Replication)	Description of setup and operational procedures of a multi-master configuration using multi-master replication feature.	When building and operating a system with a multi-master configuration using multi-master replication feature.
Performing failover using PRIMECLUSTER.	Cluster Operation Guide (PRIMECLUSTER)	Description of how to set up failover and perform operations using PRIMECLUSTER.	When performing failover using PRIMECLUSTER.
Performing security operation.	Security Operation Guide	Description of the tasks required for security operations.	When using security features and performing security

Use/Purpose	Manual title	Content	When to read
			operation in Fujitsu Enterprise Postgres.
Manage and search AI knowledge data.	Knowledge Data Management Feature User's Guide	Description of the overview of the knowledge data management feature and how to use it.	When using Knowledge data management features by Fujitsu Enterprise Postgres.
Applications using the interface provided by Fujitsu Enterprise Postgres.	Application Development Guide	Procedure for creating an application using embedded SQL, JDBC driver, ODBC driver, .NET Data Provider, and Python language (psycopg).	When developing an application using the interface provided by Fujitsu Enterprise Postgres.
Performing high availability system using the Connection Manager feature.	Connection Manager User's Guide	Description of the features, setup, and usage of Connection Manager.	When using Connection Manager features by Fujitsu Enterprise Postgres.
Usage of Fujitsu Enterprise Postgres commands.	Reference	Description of the Fujitsu Enterprise Postgres commands expanded on from PostgreSQL.	When learning Fujitsu Enterprise Postgres command functions, options, and examples of use.
Learning the syntax of the JDBC API.	Java API Reference	Description of the syntax of the JDBC API.	When learning the syntax of the JDBC API.
Learning the syntax of the Npgsql API.	Npgsql API Reference	Description of the syntax of the Npgsql API.	When learning the syntax of the Npgsql API.
Learning the meaning of the terms of Fujitsu Enterprise Postgres.	Glossary	Description of the terms used in the Fujitsu Enterprise Postgres manuals.	When checking the meaning of terms used in the Fujitsu Enterprise Postgres manuals.
Referring to messages from Fujitsu Enterprise Postgres and taking measures for them.	Messages	Description of each message and description of any measures to be taken for it.	When finding out the specific measures for dealing with messages from Fujitsu Enterprise Postgres.

PostgreSQL manual

The table below shows the manual on PostgreSQL-compatible features.

Use/Purpose	Manual title	Content	When to read
Learning about PostgreSQL features.	PostgreSQL Documentation	Official PostgreSQL documentation. Explains all features officially supported by the relevant	When learning how to use PostgreSQL.

Use/Purpose	Manual title	Content	When to read
		version of PostgreSQL.	

1.2.2 Documentation Road Map

This section provides a documentation roadmap, broken down by user role.

Database administrator

The database administrator is a user who performs Fujitsu Enterprise Postgres installation and setup, and who operates and monitors the database.

Refer to the manuals in the table below, according to purpose:

	Purpose	Manual name
Required reading	To learn about upgraded features and incompatibility information	Release Notes
	To read an overview of the software	General Description
	To perform installation and setup	Installation and Setup Guide for Server
		Cluster Operation Guide (Database Multiplexing)
		Cluster Operation Guide (PRIMECLUSTER)
		Connection Manager User's Guide
	To install the Server Assistant	Installation and Setup Guide for Server Assistant
	To operate and monitor	Operation Guide
		Security Operation Guide
		Cluster Operation Guide (Database Multiplexing)
		Cluster Operation Guide (Multi-master Replication)
		Cluster Operation Guide (PRIMECLUSTER)
		Reference
	Using knowledge data management features	Knowledge Data Management Feature User's Guide
	Using Connection Manager features	Connection Manager User's Guide
	Reference	Messages
		Glossary
Refer to as required	To learn about PostgreSQL features	PostgreSQL Documentation

Application developer

The application developer is a user who defines the database and develops applications.

Refer to the manuals in the table below, according to purpose:

	Purpose	Manual name
Required reading	To learn about upgraded features and incompatibility information	Release Notes
	To read an overview of the software	General Description
	To perform installation and setup	Installation and Setup Guide for Client
	To define a database	Operation Guide
	Using knowledge data management features	Knowledge Data Management Feature User's Guide
	To develop applications	Application Development Guide
		Cluster Operation Guide (Multi-master Replication)
		Java API Reference
		Npgsql API Reference
	Using Connection Manager features	Connection Manager User's Guide
	Reference	Messages
		Glossary
Refer to as required	To learn about PostgreSQL features	PostgreSQL Documentation

1.3 Notational Conventions in the Manuals

Manual titles and product names in the manual are abbreviated.

This section explains the notational conventions for abbreviations and platform-specific information in the manuals.

1.3.1 Platform-specific Information

Even manuals whose title has a platform name contains content common to all the platforms supported by Fujitsu Enterprise Postgres. In such cases, the platform-specific information is marked as shown below. Refer to only the necessary information.

Linux

Indicates content concerning Linux.

Windows(R)

Indicates content concerning Windows(R).

1.3.2 Abbreviation of Product Names

The following table lists abbreviations of the names of products related to Fujitsu Enterprise Postgres as they appear in the manuals.

Formal name	Abbreviation
Oracle Solaris 10 and Oracle Solaris 11	Solaris
Red Hat(R) Enterprise Linux(R) 8, Red Hat(R) Enterprise Linux(R) 9 and SUSE Linux Enterprise Server 15	Linux
Red Hat(R) Enterprise Linux(R) 8	RHEL8
Red Hat(R) Enterprise Linux(R) 9	RHEL9
SUSE Linux Enterprise Server 15	SLES 15
Windows(R) 11 Home, Windows(R) 11 Education, Windows(R) 11 Pro and Windows(R) 11 Enterprise	Windows(R) 11
Microsoft(R) Windows Server(R) 2016 Datacenter, Microsoft(R) Windows Server(R) 2016 Standard and Microsoft(R) Windows Server(R) 2016 Essentials	Windows Server(R) 2016
Microsoft(R) Windows Server(R) 2019 Datacenter, Microsoft(R) Windows Server(R) 2019 Standard and Microsoft(R) Windows Server(R) 2019 Essentials	Windows Server(R) 2019
Microsoft(R) Windows Server(R) 2022 Datacenter, Microsoft(R) Windows Server(R) 2022 Standard and Microsoft(R) Windows Server(R) 2022 Essentials	Windows Server(R) 2022
Microsoft(R) Windows Server(R) 2025 Datacenter, Microsoft(R) Windows Server(R) 2025 Standard and Microsoft(R) Windows Server(R) 2025 Essentials	Windows Server(R) 2025
Windows(R) 11 Home, Windows(R) 11 Education, Windows(R) 11 Pro, Windows(R) 11 Enterprise, Microsoft(R) Windows Server(R) 2016 Datacenter, Microsoft(R) Windows Server(R) 2016 Standard, Microsoft(R) Windows Server(R) 2016 Essentials, Microsoft(R) Windows Server(R) 2019 Datacenter, Microsoft(R) Windows Server(R) 2019 Standard, Microsoft(R) Windows Server(R) 2019 Essentials, Microsoft(R) Windows Server(R) 2022 Datacenter, Microsoft(R) Windows Server(R) 2022 Standard, Microsoft(R) Windows Server(R) 2022 Essentials, Microsoft(R) Windows Server(R) 2025 Datacenter, Microsoft(R) Windows Server(R) 2025 Standard and Microsoft(R) Windows Server(R) 2025 Essentials	Windows(R)
Microsoft(R) Edge	Edge
Java Naming and Directory Interface	JNDI
Java(TM) 2 SDK, Standard Edition, Java(TM) 2 Platform, Enterprise Edition, Java(TM) Platform, Standard Edition and Java(TM) Development Kit	JDK
Java(TM) 2 Runtime Environment, Standard Edition and Java(TM) Runtime Environment	JRE
Microsoft(R) Visual Basic(R) for Applications	VBA

Formal name	Abbreviation
Microsoft(R) Visual Basic	Visual Basic
Microsoft(R) Visual Basic.NET	Visual Basic.NET
Microsoft(R) Visual Studio	Visual Studio
Microsoft(R) Visual Studio.NET	Visual Studio.NET
Microsoft .NET Framework	.NET Framework or.NET
Interstage Application Server Enterprise Edition, Interstage Application Server Standard-J Edition and Interstage Web Server	Interstage Application Server
Fujitsu Enterprise Postgres Advanced Edition (64bit)	AE or Fujitsu Enterprise Postgres Advanced Edition
Fujitsu Enterprise Postgres Standard Edition (64bit)	SE or Fujitsu Enterprise Postgres Standard Edition

Remarks: The symbols (R) and (TM) may be omitted in this manual.

1.3.3 Fujitsu Enterprise Postgres Conventions

The naming conventions for the Fujitsu Enterprise Postgres product names and functions used in the Fujitsu Enterprise Postgres manuals are shown below.

1.3.3.1 Server

The names used in the manuals in explanations regarding Fujitsu Enterprise Postgres functions are shown below.

Product name	Name used in manuals
Fujitsu Enterprise Postgres Advanced Edition (64bit) and Fujitsu Enterprise Postgres Standard Edition (64bit)	64-bit product

1.3.3.2 Client

The names used in the manuals in explanations regarding Fujitsu Enterprise Postgres client functions are shown below.

Product name	Name used in manuals
Fujitsu Enterprise Postgres Client (64bit)	64-bit product
Fujitsu Enterprise Postgres Client (32bit)	32-bit product

1.3.4 Symbol Convention

The symbols shown below are used in the manuals.

Symbol	Meaning
[ ]	These symbols indicate characters displayed in a window or dialog box or keyboard keys. Examples: [Setting] dialogue box, [File] menu, [Item name], [OK] button, [Enter] key.

1.4 Notes about Manuals

This section contains notes about the Fujitsu Enterprise Postgres operating environments and manuals.

- Images in figures

  The Fujitsu Enterprise Postgres manuals contain figures showing printouts for Fujitsu Enterprise Postgres to provide the reader an idea of what the printouts look like, but since the figures are only examples, they are incomplete.

- Explanatory examples

  Most of the examples of databases in the Fujitsu Enterprise Postgres manuals are modeled after inventory control databases of retail stores. The design and contents of the databases in the examples are fictitious and do not represent any real database.

- UNIX release version number

  This system conforms to UNIX System V Rel4.2MP.

Chapter 2 Trademarks

- Internet Information Services, Microsoft, MS, MS-DOS, Windows, Windows Server, Visual Basic, Visual Studio and Microsoft .NET Framework are registered trademarks or trademarks of Microsoft Corporation in the U.S. and/or other countries.
- Oracle and Java are registered trademarks of Oracle Corporation and its subsidiaries and affiliated companies in the U.S. and other countries. Product and company names mentioned in this manual are the trademarks or registered trademarks of their respective owners.
- Linux(R) is a registered trademark of Linus Torvalds in the U.S. and other countries.
- Red Hat, RPM, and all Red Hat-based trademarks and logos are registered trademarks or trademarks of Red Hat, Inc. in the U.S. and other countries.
- SUSE and the SUSE logo are registered trademarks of SUSE LLC in the United States and other countries.
- UNIX is a registered trademark of Open Group in the U.S. and other countries.
- Interstage, Systemwalker, PRIMECLUSTER, and Fujitsu Enterprise Postgres are trademarks or registered trademarks of Fujitsu Limited.

Other product and company names mentioned in this manual are the trademarks or registered trademarks of their respective owners.

Glossary..... 1

Index.....6

Glossary

Arbitration command

A user exit (user command) called when an abnormality is detected using operating system/server heartbeat monitoring in database multiplexing mode.

Arbitration server

A dedicated server on which the Server Assistant program is installed.

Archive log

Contains the history of updates made to the database, and is used during recovery.

Backup data storage destination

The directory that stores the backup data.

Client command

A command that is executed from the client machine and used. Also known as a client application.

Confidentiality group

An object that indicates which confidentiality level roles in confidentiality group can acdess.

Confidentiality group role

The targets of GRANT and REVOKE statements executed internally by the confidentiality management feature.

Confidentiality level

A group of data with the same degree of confidentiality.

Confidentiality object

A collection of data classified by confidentiality level, representing an object in the database.

Confidentiality privilege

The privileges indicate how a confidentiality group can access confidentiality objects registered at a certain confidentiality level.

Confidentiality management role

A role that manages confidentiality matrices.

Confidentiality Management

A feature that supports database users in setting appropriate privileges for each database resource.

Confidentiality matrix

A matrix of confidentiality levels and confidentiality groups.

Connection Manager

The replication operation to continue without knowing where the application is connected.

The Connection Manager feature improves the availability.

Data storage destination

The directory that stores the database clusters.

Database cluster

The database storage area on the database storage disk. Database clusters are a collection of databases managed by an instance.

Data masking

A feature that can change the returned data for queries generated by applications, to prevent exposing actual data.

Database multiplexing

Mechanism in which a database is made redundant on multiple servers, by transferring transaction logs (WAL) via the network to enable application jobs to be continued.

Database superuser

A user defined in the database with access privileges for all database objects.

Encoding

Indicates the character set.

Fencing

A process that isolates a database server with an unstable status from the cluster system in database multiplexing mode. This process is implemented as a fencing command.

Fencing command

A user exit (user command) that implements fencing in database multiplexing mode.

Full-text search

A technique or technique for searching for keywords or phrases throughout a document.

Global Meta Cache

The Global Meta Cache feature cache the informations about system catalogs information (catalog meta cache) in shared memory. The catalog meta cache on shared memory is called the Global Meta Cache (GMC).

Graph data

A data structure that represents relationships between entities with nodes and edges between nodes. You can search graphs based on properties and relationships.

Hybrid search

A search method that combines multiple search methods.

Instance

A series of server processes for managing database clusters.

Instance administrator

The OS user account that owns the database cluster files and operates the database server processes.

Instance name

Indicates the instance name.

Key management system

A system that manages data encryption keys when using the transparent data encryption feature.

Knowledge data management feature

Search based on semantic relationships using vectors and graphs, and the ability to manage those data.

Local Meta Cache Limit

The ability to limit the size by removing the Local Meta Cache that has not been accessed for a long time.

Local Meta Cache is a meta cache (system catalog and table definition information) held in local memory.

Masking policy

A method of changing data under specific conditions when it is returned for a query from an application. You can configure masking target, masking type, masking condition and masking format.

Mirrored transaction log

The log that mirrors the transaction log at the backup data storage destination.

Mirroring Controller arbitration process

A process that performs arbitration and fencing on the arbitration server.

Mirroring Controller monitoring process

A process that performs heartbeat monitoring of the Mirroring Controller process. If the Mirroring Controller process returns no response or is down, the Mirroring Controller monitoring process is restarted automatically.

Mirroring Controller process

A process that performs operating system/server and process heartbeat monitoring and disk abnormality monitoring between database servers. Additionally, the process issues arbitration requests to the arbitration server and executes arbitration commands.

Pgpool-II connection pooling

The connection pooling feature of Pgpool-II supported by Fujitsu Enterprise Postgres.

This feature maintains the connection established with the database server and reuses that connection each time a new connection with the same properties (user name, database, and protocol version) arrives. By reducing the connection overhead for the database server, throughput of the whole system is improved.

Pgpool-II failover

The automatic failover feature of Pgpool-II supported by Fujitsu Enterprise Postgres.

If any of the database servers crashes or can no longer be reached, this feature disconnects the server and continues operation on the remaining servers. The streaming replication feature of PostgreSQL is combined with Pgpool-II to achieve a high-availability system.

Pgpool-II load balancing

The load balancing feature of Pgpool-II supported by Fujitsu Enterprise Postgres.

This feature distributes reference queries to multiple database servers, improving throughput of the whole system. The database multiplexing feature or PostgreSQL streaming replication feature is combined with Pgpool-II to reduce the load on the database server.

Pgpool-II server

A server for using the failover, connection pooling, and load balancing features of Pgpool-II. It is a dedicated server that has a server program installed for using these features.

Precision

In a search system, this is an indicator that search results do not contain unwanted results.

Primary server

The server that processes the main database jobs during multiplexed database operation.

Recall

In a search system, this is an indicator that the search results contain the results you want.

RRF (Reciprocal Rank Fusion)

This method calculates the order (rank) of the results of ordering by each search method.

Semantic similarity

It is a measure of how close the meaning of words and sentences are.

Server Assistant

A feature that objectively determines the status of database servers as a third party, and if necessary, isolates affected databases if the database servers are unable to accurately ascertain their mutual statuses in database multiplexing mode, such as due to a network error between database servers, or server instability.

Server Assistant program

A program to be installed on the arbitration server.

Server command

A command used on the database server. Also known as a server application.

Standby server

A server that generates a replicated database synchronized with the primary server, and that can run as an alternative server in case the primary server fails during multiplexed database operation.

State transition command

A user exit (user command) called when Mirroring Controller performs a state transition of a database server in database multiplexing mode. State transition commands include the post-switch command, pre-detach command, and post-attach command.

Transaction log

Contains the history of updates made to the database by transactions. Also known as the WAL (Write-Ahead Log).

Transaction log storage destination

The directory that stores the transaction log.

VCI (Vertical Clustered Index)

An index with columnar data structure suitable for aggregation.

Vector data

By vectorizing information such as text, images and sound, semantic similarity can be calculated and used for search and analysis.

WAL (Write-Ahead Log)

Has the same meaning as 'transaction log'.

WebAdmin program

A GUI-based program installed on a database server or a dedicated WebAdmin server, used to manage database instances.

WebAdmin server

By using the WebAdmin program on a different server to the database server, instances on multiple database servers can be managed from a dedicated WebAdmin server on which the WebAdmin program is installed.

Weighted RRF

RRF considering the weight of each search method.

FUJITSU

Fujitsu Enterprise Postgres 18SP1 for x86

General Description

Windows/Linux

J2UL-3053-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document explains the Fujitsu Enterprise Postgres concepts to those who are to operate databases using it.

This document explains the features of Fujitsu Enterprise Postgres.

Intended readers

This document is intended for people who are:

- Considering installing Fujitsu Enterprise Postgres
- Using Fujitsu Enterprise Postgres for the first time
- Wanting to learn about the concept of Fujitsu Enterprise Postgres
- Wanting to see a functional overview of Fujitsu Enterprise Postgres

Readers of this document are also assumed to have general knowledge of:

- Computers
- Jobs
- Linux
- Windows(R)

Structure of this document

This document is structured as follows:

Chapter 1 Fujitsu Enterprise Postgres Basics

Explains the features of Fujitsu Enterprise Postgres.

Appendix A List of Features

Lists the main features provided by Fujitsu Enterprise Postgres.

Appendix B OSS Supported by Fujitsu Enterprise Postgres

Explains the OSS supported by Fujitsu Enterprise Postgres.

Appendix C Features that can be Used on Servers Other than the Database Server

Explains features that can be used on servers other than the database server.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Index 29

Chapter 1 Fujitsu Enterprise Postgres Basics

Fujitsu Enterprise Postgres maintains the operating methods, interfaces for application development and SQL compatibility of PostgreSQL, while providing expanded features for enhanced reliability and operability.

This chapter explains the functionality extended by Fujitsu Enterprise Postgres.

Refer to "Appendix A List of Features" for feature differences between editions.

Additionally, Fujitsu Enterprise Postgres supports various open source software (OSS). Refer to "Appendix B OSS Supported by Fujitsu Enterprise Postgres" for information on OSS supported by Fujitsu Enterprise Postgres.

Fujitsu Enterprise Postgres has the following features:

- Flexible database recovery
  Not only does Fujitsu Enterprise Postgres recover data to its most recent form when a failure occurs, which is essential for databases, but it can also recover to any point in time. Additionally, backup/recovery can be performed using any copy technology.

- Simple GUI-based installation and operation management
  Fujitsu Enterprise Postgres uses GUI to simplify cumbersome database operations, and allows databases to be used intuitively.

- High reliability by using database multiplexing
  Database multiplexing protects important data and enables highly reliable database operation.

L - High reliability by using the multi-master replication
  By using multi-master replication, where each node's database acts as a master, continue service even during disasters, minimizing the risk of system downtime and data loss, and achieving high reliability.

L - High reliability through a cluster system using Patroni
  Build a highly reliable cluster system in cooperation with Patroni.

L - High reliability by using the failover feature integrated with the cluster software
  Fujitsu Enterprise Postgres links with PRIMECLUSTER, thereby allowing highly reliable systems to be achieved by using failover.

- Seamless migration from Oracle databases
  Fujitsu Enterprise Postgres provides a compatibility feature with Oracle databases that localizes the correction of existing applications and allows easy migration to Fujitsu Enterprise Postgres.

- Storage data protection using transparent data encryption
  Information can be protected from data theft by encrypting data to be stored in the database.

L Also, you to choose an external key management system as the storage location for your encryption keys.

- Policy-based login security
  By defining login security policies as profiles and assigning profiles to database users, you can achieve login management and password operation according to the security policy.

- Management of access control by confidentiality management
  Confidentiality management feature supports the design/management of access privileges and optimizes access control, thereby enhancing security.

- Data masking for improved security
  The data masking feature changes the returned data for queries from applications, to prevent exposing actual data. This improves security for handling confidential data such as personal information.

- Audit logs for improved security
  Audit logs can be used to counter security threats such as unauthorized access and misuse of privileges for the database.

- Enhanced query plan stability
  Allows you to control query planning for SQL statements. This feature is used to prevent performance degradation due to changes in the query plan of SQL statements, such as in core business operations where stabilizing performance is more important than improving the processing performance of SQL statements.

- Increased aggregation performance using the in-memory feature
  The following features help speed up scans even when aggregating many rows.
  - Vertical Clustered Index (VCI)
  - In-memory data

- High-speed data load
  Data from files can be loaded at high speed into Fujitsu Enterprise Postgres tables using the high-speed data load feature.

- High availability by using Connection Manager
  With the Connection Manager features, replication operation can be continued without being aware of the connection destination of the applications.

- Memory usage reduction using Global Meta Cache
  The Global Meta Cache feature loads some of meta cahe information in shared memory. This reduces overall system memory usage.

- Memory usage reduction using Local Meta Cache Limit
  Reduce memory consumption by limiting the metacache that is kept in local memory.

- Protect and efficiently manage and use knowledge data for AI applications
  Knowledge Data Management enables Fujitsu Enterprise Postgres to securely store knowledge data used in RAG-based applications. It also automates part of the processing for knowledge data maintenance and retrieval, enabling efficient operation and utilization.

1.1 Flexible Database Recovery

Threats such as data corruption due to disk failure and incorrect operations are unavoidable in systems that use databases. The ability to reliably recover corrupted databases without extensive damage to users when such problems occur is an essential requirement in database systems.

Fujitsu Enterprise Postgres provides the following recovery features that flexibly respond to this requirement:

- Media recovery, which recovers up to the most recent point in time
- Point-in-time recovery, which can recover up to a specific point in time
- Backup/recovery that can integrate with various copy technologies

Media recovery, which recovers up to the most recent point in time

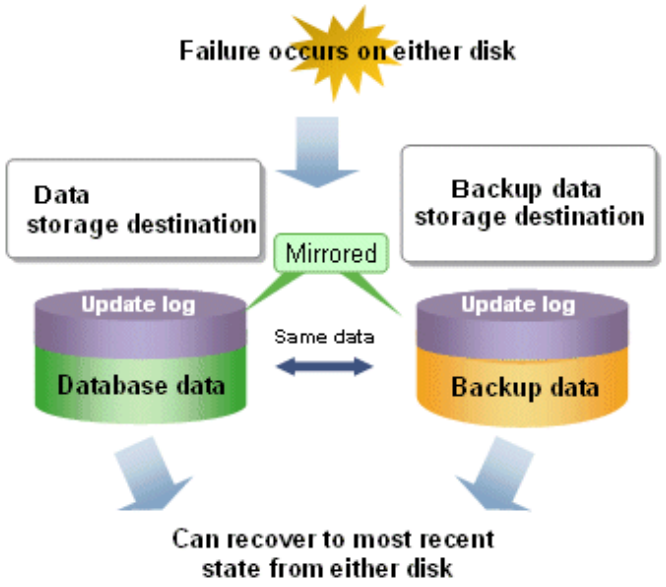
When a disk failure occurs, media recovery can recover data to how it was immediately before the failure.

In order to recover the database, Fujitsu Enterprise Postgres accumulates a history of database update operations, such as data additions and deletions, as an update log.

Fujitsu Enterprise Postgres retains a duplicate (mirror image) of the update log after backup execution on the data storage destination and on the backup data storage destination. Therefore, the data on one disk can be used to recover to the most recent state of the database even if a disk failure has occurred on the other.

Media recovery is executed using either a GUI tool provided with Fujitsu Enterprise Postgres (WebAdmin) or server commands.

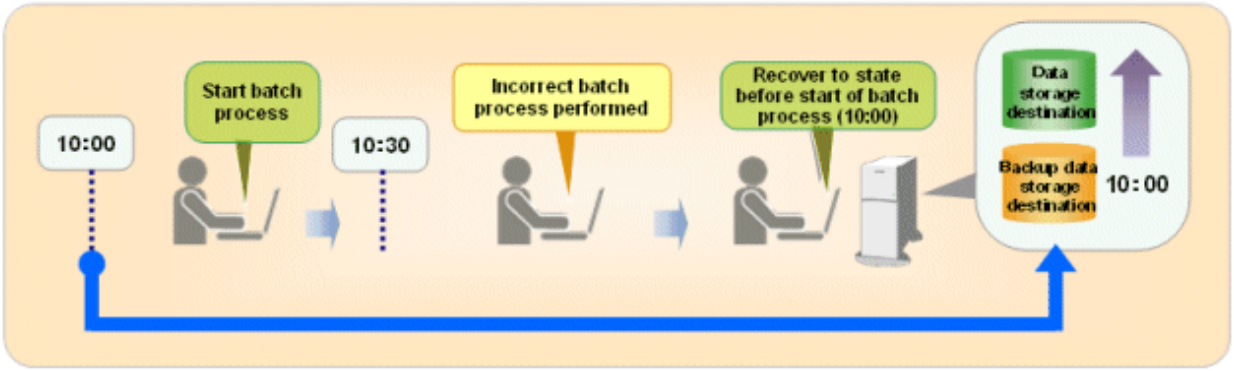
Recovery using WebAdmin requires less time and effort, since WebAdmin automatically determines the scope of the operation.



Point-in-time recovery, which can recover up to a specific point in time

Point-in-time recovery can be used to recover a database that has been updated by an incorrect operation, for example, by specifying any date and time before the incorrect operation.

Point-in-time recovery is executed using Fujitsu Enterprise Postgres server commands.



Backup/recovery that can integrate with various copy technologies

It is possible to back up to the backup data storage destination, or to any backup destination using any copy technology implemented by user exits.

L

For example, by using the high-speed copy feature of the storage device, the processing time for backup of large databases can be greatly reduced.

See

Refer to "Backup/Recovery Using the Copy Command" in the Operation Guide for information on backup/recovery using user exits.

1.2 Simple GUI-Based Installation and Operation Management

Fujitsu Enterprise Postgres provides WebAdmin, which is a GUI tool for a range of tasks, from database installation to operation management. This allows the databases to be used simply and intuitively.

WebAdmin can be used for Fujitsu Enterprise Postgres setup, creating and monitoring a streaming replication cluster, database backups, and for recovery. Depending on the configuration, WebAdmin can be used to manage Fujitsu Enterprise Postgres instances in a single server, or instances spread across multiple servers.

- Setup

  To perform setup using WebAdmin, you must create an instance. An instance is a set of server processes that manage a database cluster (database storage area on the data storage destination disk). Instances can be created easily and with only minimal required input, because the tool automatically determines the optimal settings for operation.

- Database backup/recovery

  Database backup and recovery can be performed using simple GUI operations.

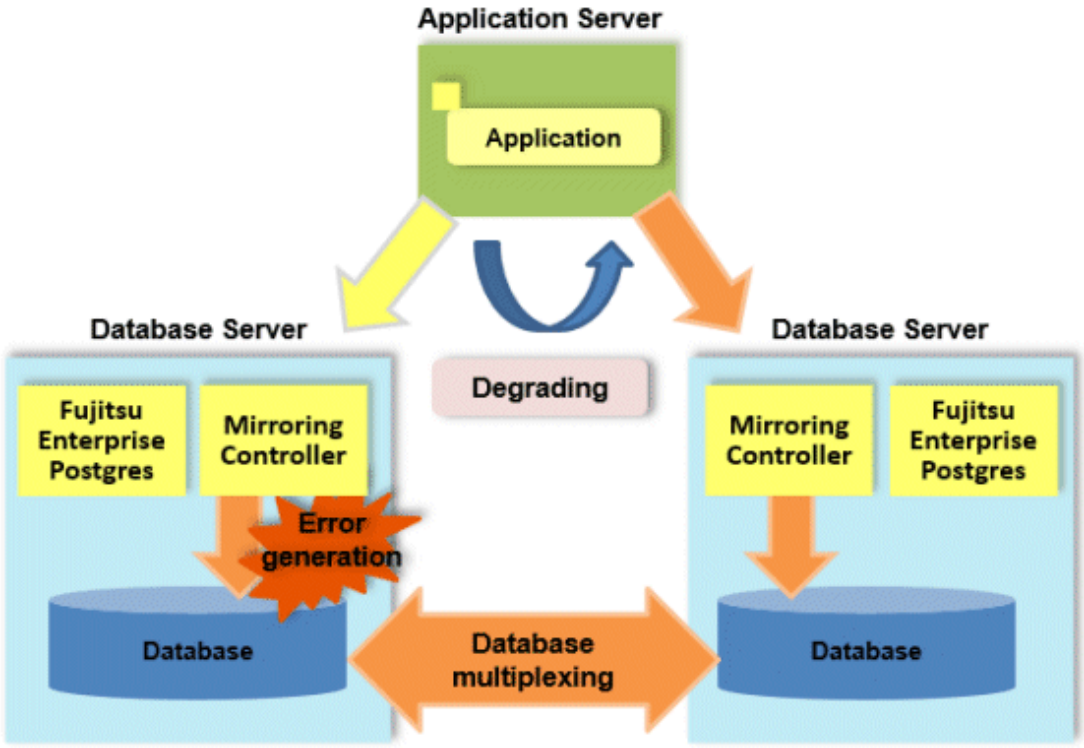
  In particular, Fujitsu Enterprise Postgres can automatically identify and isolate the location of errors. This simplifies the recovery process and enables faster recovery.

In addition, Fujitsu Enterprise Postgres provides the following expanded features in pgAdmin:

- NCHAR type
- Expanded trigger definition
  - REPLACE feature
  - Function call feature

1.3 High Reliability with Database Multiplexing

It is vital for systems that use databases to protect data from damage or loss caused by a range of factors such as hardware and software errors. Database multiplexing protects important data and enables highly reliable database operation.



Fujitsu Enterprise Postgres not only mirrors a database using the PostgreSQL streaming replication feature, but also provides simplified switchover and standby disconnection features as well as a feature to detect faults in elements that are essential for the continuity of database process, disk, network, and other database operations.

Even if a switchover is performed, the client automatically distinguishes between the primary and standby servers, so applications can be connected transparently regardless of the physical server.

The Mirroring Controller option enables the primary server (the database server used for the main jobs) to be switched automatically to the standby server if an error occurs in the former.

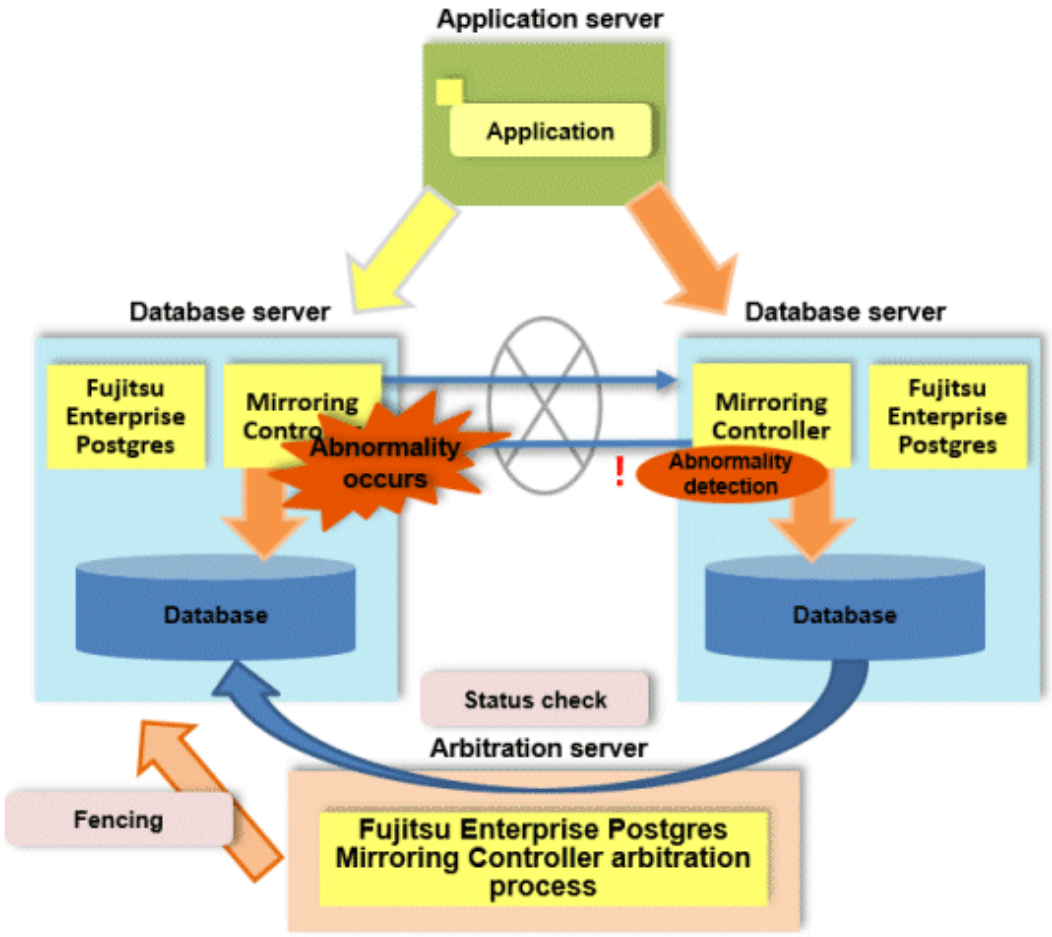
In addition, by using the data on the standby server, reference jobs such as data analysis and form output can be performed in parallel to the jobs on the primary server.

Operation using the arbitration server

Mirroring Controller may not be able to correctly determine the status of the other server if there is a network issue between database servers or a server is in an unstable state. As a result, both servers will temporarily operate as primary servers, so it may be possible to perform updates from either server.

The Server Assistant is a feature that objectively checks the status of database servers as a third party and isolates (fences) unstable servers in such cases.

In database multiplexing mode, the Server Assistant is made available by adding a new server (arbitration server) on which the Server Assistant is installed. Using an arbitration server can prevent the issue mentioned above (both servers temporarily operating as primary servers) and enables highly reliable operation.



See

Refer to the Cluster Operation Guide (Database Multiplexing) for information on the database multiplexing.

L

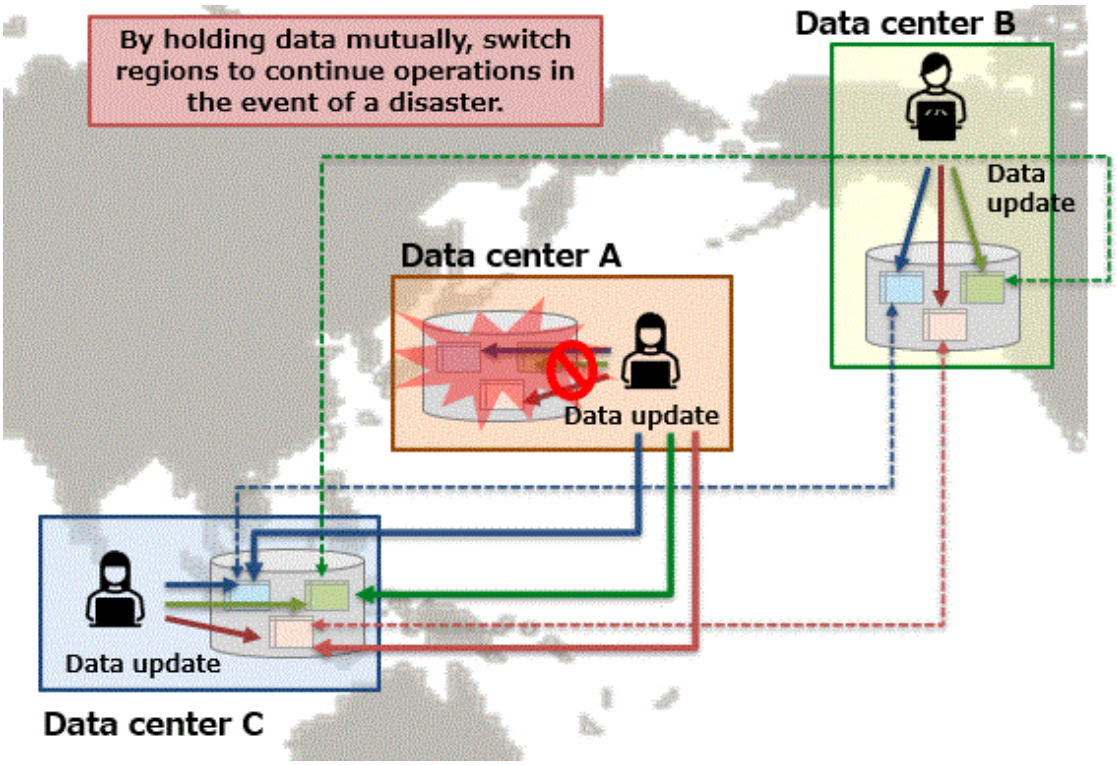
1.4 High Reliability Using the Multi-master Replication

With the multi-master replication feature provided by Fujitsu Enterprise Postgres, you can build a replication configuration that allows independent data update processing on multiple nodes. In this multi-master configuration, all nodes function as masters, allowing clients to write (update, insert, delete) data to any node, and those changes are automatically synchronized to all other nodes. By utilizing this multi-master replication feature, you can enhance business continuity in disaster recovery.

Enhancing business continuity in disaster recovery

In traditional single-master configurations, standby nodes are prepared in case of unforeseen circumstances, and if the master node stops due to a disaster, a failover process is required to promote the standby node to a new master. In this case, there are costs associated with preparing standby nodes, and there is a certain amount of time and risk of data loss involved in the failover process.

In a multi-master configuration, all nodes feature as independent masters, so even if one node stops, the remaining nodes can continue the service. For example, by building a multi-master replication configuration between geographically separated data centers, if one data center completely stops functioning due to a disaster such as an earthquake or a large-scale power outage, the other data center can quickly take over all processing. This minimizes system downtime and ensures business continuity while reducing the risk of data loss due to data transfer.



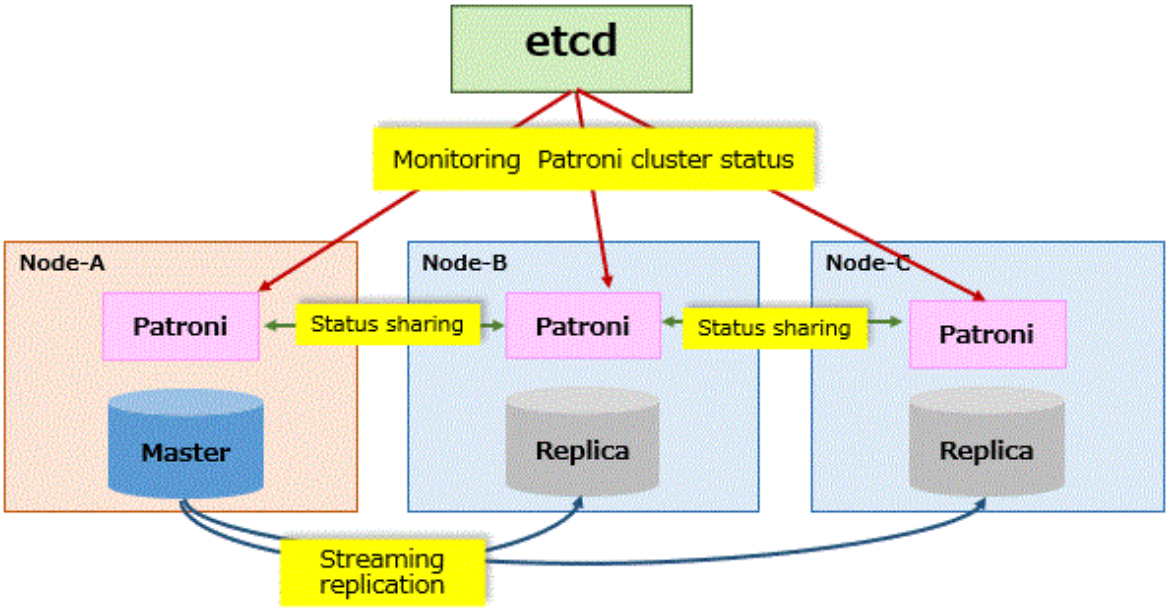
See

Refer to the Cluster Operation Guide (Multi-master Replication) for information on the multi-master replication.

L

1.5 High Reliability through a Cluster System Using Patroni

By combining Fujitsu Enterprise Postgres with Patroni and etcd, a highly available cluster system can be built. This cluster system provides automatic failover, replication management, cluster state monitoring, and automatic recovery feature, realizing highly reliable system operation. In particular, Patroni automates leader election and replica management of PostgreSQL instances by utilizing the etcd cluster as a Distributed Consensus Store (DCS), reducing the burden of operation management.



See

Refer to "Building a Cluster System Using Patroni" in the Operation Guide for information about cluster systems using Patroni.

L

1.6 High Reliability Using Failover Integrated with the Cluster Software

If the system stops, services are interrupted until recovery is complete. In large-scale systems, the interruption takes longer, and may cause significant disruption for many people receiving the services.

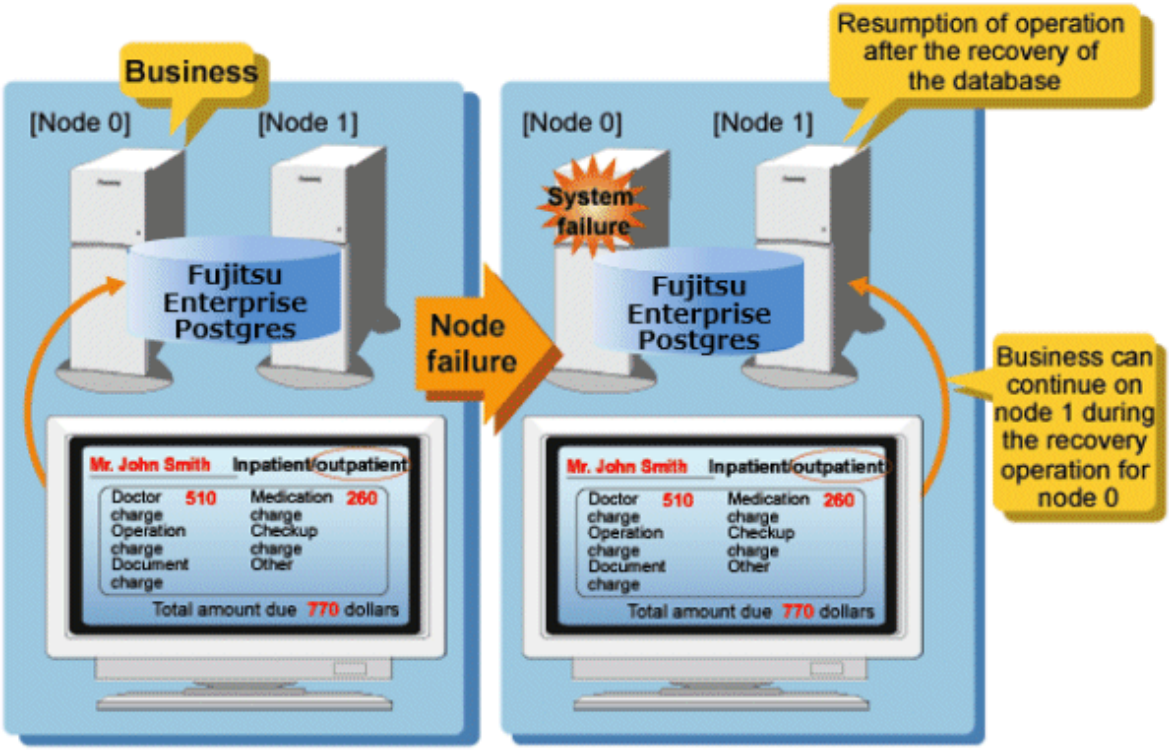
In Fujitsu Enterprise Postgres, the failover feature integrated with the cluster software can minimize the system stoppage time when an issue occurs.

Medical accounting system

Some hospitals with a large number of patients manage and operate the various data required for accounting in a database. If this accounting system stops and takes several minutes to recover, it is expected that this will have a significant impact.

But if failover is applied to this kind of system and an issue occurs on the operating server, it is quickly switched and the standby server takes over operation, so that services are provided without interruption.

The example below illustrates a medical accounting system using failover.



See

Refer to the Cluster Operation Guide (PRIMECLUSTER) for information on the failover feature integrated with the cluster software.

1.7 Seamless Migration from Oracle Databases

Fujitsu Enterprise Postgres supports Orafce, to provide compatibility with Oracle databases.

Using the compatibility feature reduces the cost of correcting existing applications and results in easy database migration.

See

Refer to "Compatibility with Oracle Databases" in the Application Development Guide for information on compatible features.

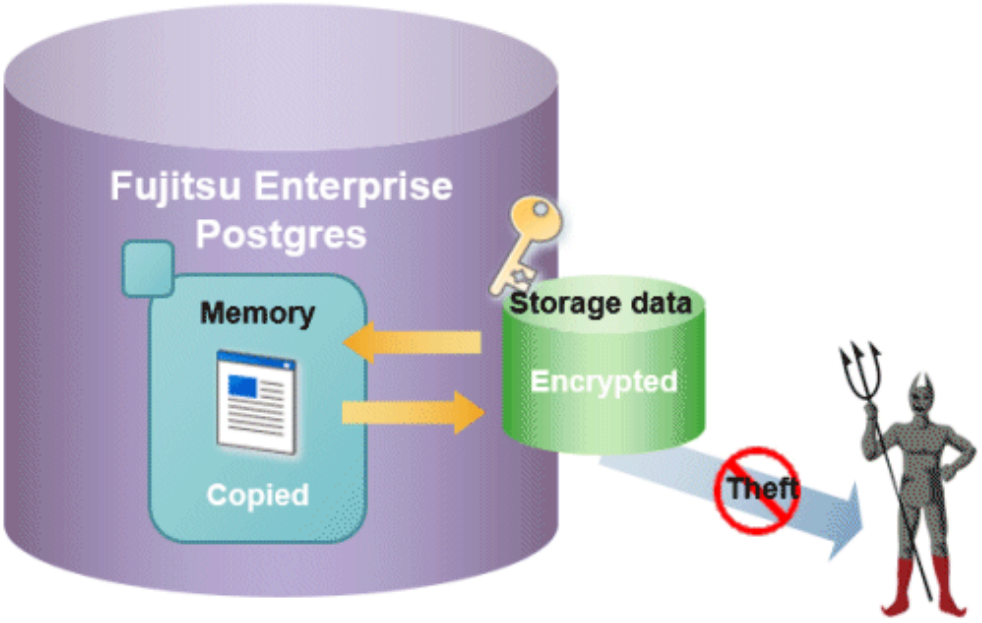
1.8 Storage Data Protection Using Transparent Data Encryption

The encryption of data to be stored in a database is essential under the following encryption requirements of PCI DSS (Payment Card Industry Data Security Standard), the data security standard of the credit industry:

- Confidential information (such as credit card numbers) can be encrypted.
- The encryption key and data are managed as separate entities.
- The encryption key is replaced at regular intervals.

To satisfy these requirements, Fujitsu Enterprise Postgres provides a transparent data encryption feature. Note that PostgreSQL uses an encryption feature called pgcrypto, which can also be used in Fujitsu Enterprise Postgres, but requires

applications to be modified. Therefore, we recommend using Fujitsu Enterprise Postgres's transparent data encryption feature.



The transparent data encryption feature also allows you to choose an external key management system as the storage location for your encryption keys.

See

Refer to "Protecting Storage Data Using Transparent Data Encryption" or "Using Transparent Data Encryption with Key Management Systems as Keystores" in the Operation Guide for information about transparent data encryption.

Refer to "Protecting Storage Data Using Transparent Data Encryption" in the Operation Guide for information about transparent data encryption.

If you use the --save-fullpage option of the pg_waldump command for a WAL file output by an instance that uses transparent data encryption, an error may occur. This option is a function that displays database pages that have been processed through compression or encryption included in WAL in their unprocessed state (expanded or decrypted). However, since the pg_waldump command does not have complete access to the database, it cannot obtain the information necessary for decryption. Therefore, if there is WAL that needs to be decrypted, executing a command with this option will result in an error.

1.9 Role-Based Access Control and Directory Service Integration for Security Management

Fujitsu Enterprise Postgres supports robust database operations by enabling fine-grained access control within the database based on user roles through Role-Based Access Control (RBAC). It also integrates with external directory services, allowing for centralized user management across the organization and automatic assignment of database privileges.

Access control using RBAC

RBAC is a method of managing privileges through roles, rather than directly granting privileges to users. Fujitsu Enterprise Postgres provides the following features based on this RBAC concept to achieve stronger access control.

- Policy-based Login Security
- Management of Access Control by Confidentiality Management

Centralized user management with directory services

Directory services centralize user information on a network and provide a foundation for authentication and authorization. Fujitsu Enterprise Postgres enhances its integration with directory services by supporting the following:

ldap2pg support

Fujitsu Enterprise Postgres supports ldap2pg, allowing you to synchronize Fujitsu Enterprise Postgres roles with an LDAP directory (a directory service protocol). This enables the integration of user information centrally managed in the directory service with Fujitsu Enterprise Postgres roles.

Refer to "ldap2pg" in the Installation and Setup Guide for Client for details.

LDAP authentication support

Fujitsu Enterprise Postgres supports user authentication via LDAP. In addition to managing users within the database itself, you can authenticate logins to the database using user information stored in the organization's directory service.

Refer to "LDAP Authentication File Settings" in the Installation and Setup Guide for Server for details.

1.9.1 Policy-based Login Security

By defining login security policies as profiles and assigning profiles to database users, you can automatically lock users who are not connected to the database for an extended period of time and enforce password authentication policies.

Profiles can have the following settings:

- Managing dormant users
- Managing policies when using password authentication
  - Set a password life time
  - Restrict password reuse
  - Lock users that have failed to log in continuously
  - Set a grace period after the password life time until the database can no longer be operated
  - If the account is locked due to repeated login failures, set the period during which the lock will be automatically unlocke.
  - Set a grace period (gradual password rollover time) for using old passwords after changing password

This enables login management and password management according to the security policy.

Refer to "Policy-based Login Security" in the Operation Guide for details.

1.9.2 Management of Access Control by Confidentiality Management

The confidentiality management feature supports the realization of access control according to the confidentiality level of data. We also support the work of confirming that operations are being performed according to access control.

This feature can only be used in Advanced Edition.

Access control

Access to sensitive data must be restricted in order to comply with the laws and rules governing data protection regulations. However, designing the access control is not easy in databases with diverse data and users performing diverse tasks. This is because for every combination of all database object and all role that can access the data, you must decide whether to allow access and define it in the database.

In our real world, we don't do that. For example, in a business group data with the same confidentiality level, and group several roles accessing to that data. After that, it makes more sense to consider whether access should be granted for combinations of group of data and group of roles. Because once data is added, deciding which group it belongs to naturally determines who can access it. When adding a role, it is enough to think about which role's group (called a confidentiality group) to add it to. The confidentiality management feature supports such a natural design.

Also, data belonging to a high level of confidentiality may need to be protected against unauthorized access to physical media and files, as well as access from users who can log into the database. The confidentiality management feature can force the encryption of tables belonging to high confidentiality levels. Similarly, you can force roles that belong to a confidentiality group to have attributes less than or equal to those set for the confidentiality group. Such table encryption and role management can also be designed naturally with this feature.

Inspection of operation

In order to comply with the laws and rules that define data protection regulations, it is necessary to ensure that the database is operated safely as designed. If you are using the confidentiality management feature, you do not have to worry about such things. However, if table or role definitions are changed without using this feature, it must be detected timely. The confidentiality management feature does not prohibit or detect such acts. Instead, use audit logs to detect such changes, etc.

However, even if they detect it, they may forget to deal with it. In order to prevent this, it is necessary to periodically check the differences between the confidentiality levels and confidentiality groups and the actual table and role definitions. At that time, you can use theconfidentiality management feature provided to obtain the difference.

See

Refer to "Confidentiality Management" in the Security Operation Guide for details.

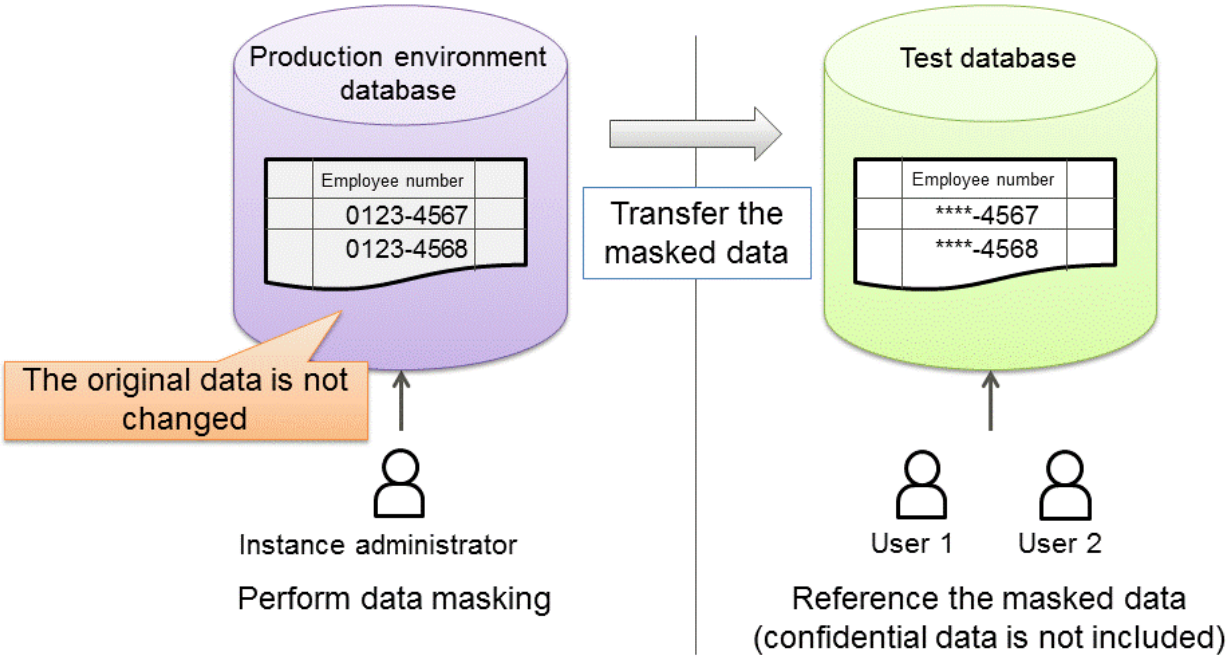
1.10 Data Masking for Improved Security

Fujitsu Enterprise Postgres provides a data masking feature that protects data to maintain security of data handled in systems.

The data masking feature changes the returned data for queries from applications and makes it available for reference without exposing the actual data.

For example, for a query of employee data, digits except the last four digits of an eight-digit employee number can be changed to "*" so that it can be used for reference.

Also, the data changed by the data masking feature can be transferred to a test database so that users who perform testing or development can reference the data. As production data should not be used in a test or development environment because of the risk of data leakage, this feature enables data that is similar to actual production data to be safely used in those environments.



See

Refer to "Data Masking" in the Operation Guide for information on data masking.

1.11 Security Enhancement Using Audit Logs

Details relating to database access can be retrieved in audit logs. The audit log feature can be used to counter security threats such as unauthorized access to the database and misuse of privileges.

In PostgreSQL, logs output as server logs can be used as audit logs by using the log output feature. There are, however, logs that cannot be analyzed properly, such as SQL runtime logs, which do not output the schema name. Additionally, because the output conditions cannot be specified in detail, log volumes can be large, which may lead to deterioration in performance.

The audit log feature of Fujitsu Enterprise Postgres enables retrieval of details relating to database access as an audit log by extending the feature to pgaudit. Additionally, audit logs can be output to a dedicated log file or server log. This enables efficient and accurate log monitoring.

This feature can only be used in Advanced Edition.

See

Refer to "Audit Log Feature" in the Security Operation Guide for details.

1.12 Enhanced Query Plan Stability

Fujitsu Enterprise Postgres estimates the cost of query plans based on SQL statements and database statistical information, and selects the least expensive query plan. However, like other databases, Fujitsu Enterprise Postgres does not necessarily select the most suitable query plan. For example, it may suddenly select unsuitable query plan due to changes in the data conditions.

In mission-critical systems, stable performance is more important than improved performance, and changes in query plans case to be avoided. In this situation, pg_hint_plan and pg_dbms_stats can be used to stabilize the query plan.

See

Refer to "Enhanced query plan stability" in the Operation Guide for information on enhanced query plan stability.

Note

For pg_hint_plan and pg_dbms_stats, take advantage of features introduced when installing Fujitsu Enterprise Postgres. Fujitsu Enterprise Postgres does not support other similar open-source features.

1.13 Increased Aggregation Performance Using the In-memory Feature

Fujitsu Enterprise Postgres provides the in-memory feature, which uses columnar index and memory-resident data. This reduces disk I/Os and enhances aggregation performance.

This feature can only be used in Advanced Edition.

Columnar index

Many aggregation processes may require a large portion of data in a particular column. However, traditional row data structure reads unnecessary columns, resulting in inefficient use of memory and CPU cache, and slower processing. Fujitsu Enterprise Postgres provides a type of columnar index, VCI (Vertical Clustered Index). This addresses the above issues, and enhances aggregation performance.

VCI provides the following benefits:

- Minimizes impact on existing jobs, and can perform aggregation using job data in real time.
- Provided as an index, so no application modification is required.
- Stores data also on the disk, so aggregation jobs can be quickly resumed using a VCI even if a failure occurs (when an instance is restarted).
- If the amount of memory used by VCI exceeds the set value, aggregation can still continue by using VCI data on the disk.

It also provides the features below:

- Disk compression
  Compresses VCI data on the disk, minimizing required disk space. Even if disk access is required, read overhead is low.
- Parallel scan
  Enhances aggregation performance by distributing aggregation processes to multiple CPU cores and then processing them in parallel.

In-memory data

The following features keep VCI data in memory and minimize disk I/Os on each aggregation process.

- Preload feature
  Ensures stable response times by loading VCI data to memory before an application scans it after the instance is restarted.
- Stable buffer feature
  Reduces disk I/Os by suppressing VCI data eviction from memory by other job data.

Purposes of this feature

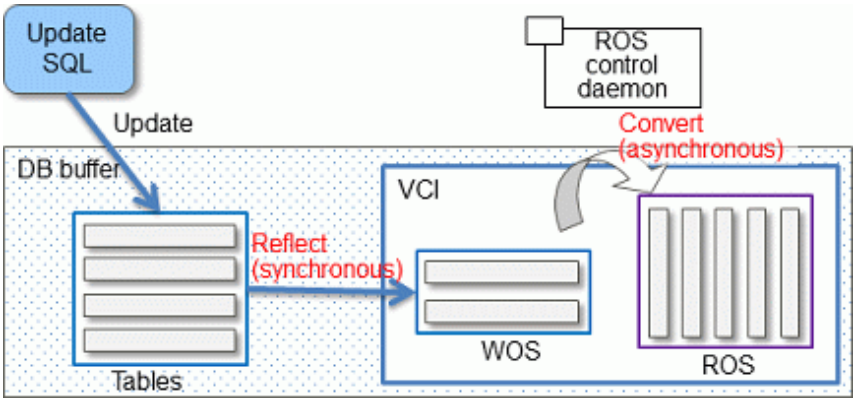
This feature has a data structure that can efficiently use the newly added resources, and aims to enhance the existing aggregation processing in normal operations to be faster than parallel scan. It shares the same purpose of enhancing aggregation performance with the parallel scan feature that is provided separately, but differs in that it speeds up nightly batch processes by utilizing available resources.

VCI architecture

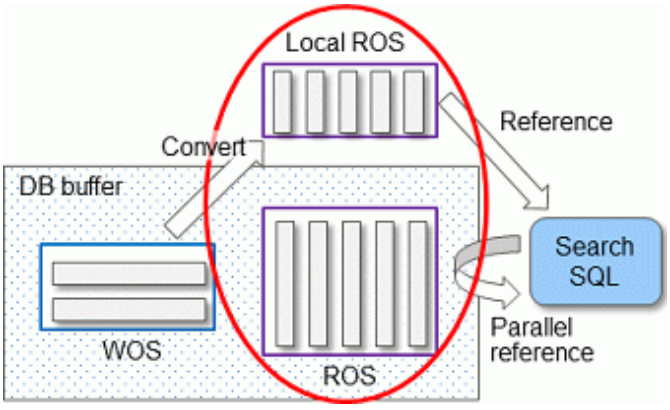
This section briefly explains VCI architecture as it contains basic terminology required, for example, when setting parameters.

Update and aggregation operations to enable real time use of job data are described.

VCI has write buffer row-based WOS (Write Optimized Store) in addition to the columnar data structure ROS (Read Optimized Store). Converting each update into a columnar index has a significant impact on the update process response times. Therefore, data is synchronously reflected to the row-based WOS when updating. After a certain amount of data is stored in WOS, the ROS control daemon asynchronously converts it to ROS. As above, the entire VCI is synchronized with the target table column, minimizing update overhead.



The same scan results can be obtained without a VCI by using WOS in conjunction with ROS. More specifically, WOS is converted to Local ROS in local memory for each aggregation process, and aggregated with ROS.



See

Refer to "Installing and Operating the In-memory Feature" in the Operation Guide for information on installation and operation of VCI.

Refer to "Scan Using a Vertical Clustered Index (VCI)" in the Application Development Guide for information on scan using a VCI.

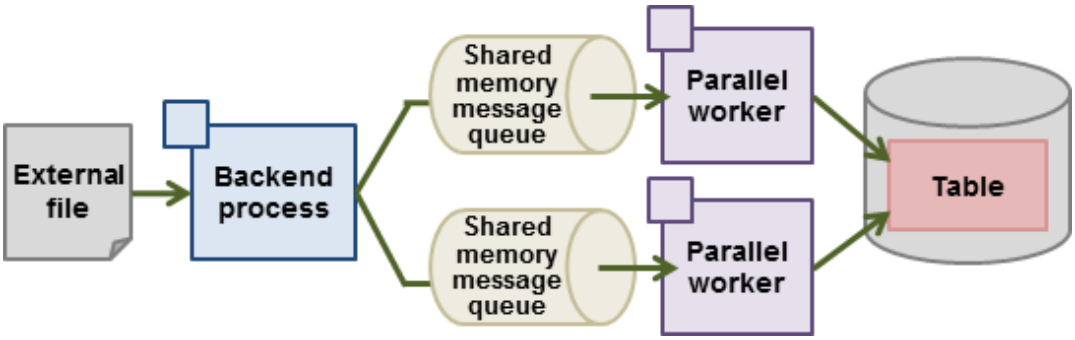
1.14 High-Speed Data Load

High-speed data load executes COPY FROM commands using multiple parallel workers. Because conversion of data from the external file to the appropriate internal format, table creation, and index creation are performed in parallel, it is possible to load large volumes of data at high speed.

This feature can only be used in Advanced Edition.

Architecture of high-speed data load

High-speed data load is required for parameter setting and resource estimation, so a brief description of its architecture is provided below.



High-speed data load uses a single backend process collaborating with multiple parallel workers to perform data load in parallel. Data is exchanged between the backend process and parallel workers via shared memory message queues. The backend process distributes the loaded data of external files to multiple parallel workers. Each parallel worker then converts the data loaded from the shared memory message queue into the appropriate internal format, and inserts it into the table. If the table has indexes, their keys are extracted and inserted into the index page.

See

Refer to "High-Speed Data Load" in the Operation Guide for details.

1.15 High availability by using Connection Manager

The Connection Manager provides the following features. You can use these features to increase system availability.

This feature can only be used in Advanced Edition.

Heartbeat monitoring feature

Detects kernel panics between the server running the client and the server running the instance, physical server failures, and inter-server network link downs, and notifies the client or instance. The client is notified as an error event through the SQL connection, and the instance will be notified in the form of a force collection of SQL connections with clients that are out of service.

Transparent connection support feature

When an application wants to connect to an instance of an attribute (Primary/Standby) configured with replication, it can do so without knowing which server the instance is running on.

Load balancing and read connection redistribution feature

With load balancing, if selection is possible, connections can be preferentially made to the server accepting the fewest connections.

Using read connection redistribution, when a standby server is promoted, Connection Manager disconnects existing connections, allowing the promoted server to focus on the workload of the newly added primary server. Only connections using Connection Manager are disconnected, and the disconnection occurs when a new query is executed.

Additionally, when the number of connections between standby servers becomes uneven, existing connections can be disconnected. This gives applications an opportunity to reconnect, thereby balancing the number of connections. For example, this can handle changes in the number of connections due to the addition or removal of standby servers, or the suspension of specific operations. Only non-update connections using Connection Manager are disconnected, and the disconnection occurs when a new query is executed.

Initial data synchronization waiting feature for standby servers

You can exclude standby servers that are not synchronized with the primary server on a transaction-by-transaction basis from the connection destination candidates.

Information

The available client drivers for Connection Manager are libpq (C language library), ECPG (embedded SQL in C), ECOBPG (embedded SQL in COBOL), JDBC driver, ODBC driver, Python language package (psycopg) and Go language.

See

Refer to the Connection Manager User's Guide for details.

1.16 Memory Usage Reduce with Meta cache Reduction and Limit

When executing SQL, you must refer to the definition of the table or index you want to access. These definitions are cached in the local memory of the backend process separately from the shared memory buffer of the database on shared_buffers because they are referenced each time SQL is executed. The direct definition is a tuple of system catalogs. The cache for this tuple is called "Catalog Cache". A structure that makes the definition easy to use is called a "Relations Cache". And in Fujitsu Enterprise Postgres, these two are collectively called "Meta Cache".

The meta cache will be kept indefinitely for performance reasons. In a large database, a single backend process accesses a large number of tables and so on, which results in a large meta-cache for the backend process. As a result, the sum of the local memory of the backend process may exceed the realistic memory size.

On the other hand, the feature to reduce the meta cache for the entire instance by sharing the meta cache between backend processes is the Global Meta Cache feature. The current Global Meta Cache feature only shares the catalog cache. Therefore, the metacache in Global Meta Cache now refers to the catalog cache.

What you still cannot share using the current Global Meta Cache feature and need to keep in local memory is the information (Meta cache header) and relation cache to access Global Meta Cache in shared memory. If you do not use the Global Meta Cache feature, keep the catalog and relation caches in local memory. The meta cache held in local memory is called the "Local Meta Cache". The feature to limit the size of a Local Meta Cache by removing it if it has not been accessed for a long time is the Local Meta Cache limit feature.

The Global Meta Cache feature and the Local Meta Cache limit feature can be used together to provide the strictest control over memory consumption. Of course, you can use only one or the other.

However, the Global Meta Cache feature has several percent overhead to access shared memory. The Local Meta Cache limit feature also causes the overhead of reholding the metacache because it may discard the previously held metacache. Therefore, consider using these features when your estimates do not allow for memory consumption.

1.16.1 Memory Usage Reduction Using Global Meta Cache

The Global Meta Cache feature cache the meta cache in shared memory. The meta cache on shared memory is called the Global Meta Cache (GMC).

Without this feature, the meta cache was cached in per-process memory. Therefore, there was a problem increase in memory usage in environments with large databases and large numbers of connections. The Global Meta Cache feature enables sharing of meta caches on shared memory, thereby reducing overall system memory usage.

This feature can only be used in Advanced Edition.

Meta cache

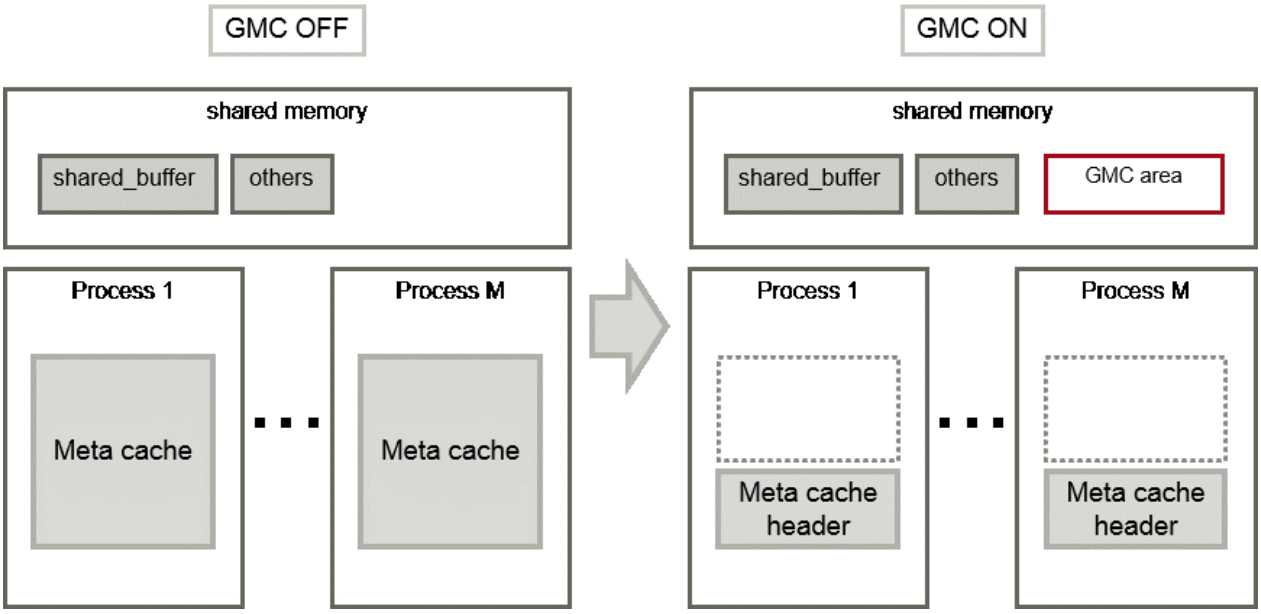
Processing a query involves parsing the query, creating the plan, executing the plan, and so on. PostgreSQL process accesses the system catalog to perform these steps. Once accessed, the system catalog tuples are cached in per-process memory. The

direct definition is one tuple of system catalogs. Each process performs faster query processing by searching the meta cache instead of searching for the required tuples in the system catalog each time.

The meta cache usage increases in proportion to the number of tables and columns accessed. It is cached on a per-process basis, so the system's overall meta cache usage increases in proportion to the number of connections.

Architecture of Global Meta Cache feature

Describes the architecture of the Global Meta Cache feature.



When the GMC feature is on, the per-process meta cache is cached in the GMC area on shared memory. Reference to the GMC area and process-specific work information is cached in the memory of each process. PostgreSQL process searches the meta cache for each process and accesses the GMC based on the reference information. If there is no reference information in the process's memory, it searches the GMC area. If the GMC area also does not have a corresponding meta cache, it accesses the system catalog to create meta cache.

Also, sharing the meta cache does not cause any loss of data consistency. If the system catalog or table definition changes while a transaction is running, the cache deletion or creation does not affect outside of the process running the transaction. After the transaction commits, the GMC area cache is deleted or created. If other transactions are referencing the cache when GMC is tried to be deleted, the deletion is deferred until there are no more references. After a commit, a new transaction sees the new cache instead of the old one.

See

Global Meta Cache feature is disabled by default. Refer to "Global Meta Cache" in the Operation Guide for information how to decide whether introduce it or not and usage.

1.16.2 Memory Usage Reduction Using Local Meta Cache Limit

Local Meta Cache Limit feature limits the size of a Local Meta Cache by removing it if it has not been accessed for a long time.

Of the definitions that SQL accesses, the main factors that make the Local Meta Cache bloat are tables and indexes. In addition, table column definitions are also maintained as a catalog cache.

For example, in a system where one long-lived connection is shared by various businesses, one connection (that is, backend process) will access many tables. If there are 3,000 such connections, and each connection accesses a table of 50,000, the total amount of memory consumed by the 3,000 backend processes may be a few terabytes.

In such a case, using this feature may reduce it to about several tens of gigabytes.

This feature can only be used in Advanced Edition.

Architecture of Local Meta Cache Limit feature

When this feature is enabled, the caching strategy is to keep the cache as long as possible within the specified upper limit. If holding a new cache exceeds the limit, consider locality of reference and delete the cache from the one with the longest unreferenced time.

However, because the cache used by active transactions cannot be deleted, if a transaction uses a large number of caches, the cache may be held above the limit. In this case, delete the cache at the end of the transaction.

See

Local Meta Cache limit feature is disabled by default. Refer to "Local Meta Cache Limit" in the Operation Guide for information how to decide whether introduce it or not and usage.

1.17 Protect and Efficiently Manage and Use Knowledge Data for AI Applications

Generative AI applications, where accuracy and reliability are critical, often use an approach called RAG that leverages external data sources to improve the accuracy of the generated AI responses and make use of expertise and up-to-date information. Fujitsu Enterprise Postgres provides knowledge data management capabilities for using Fujitsu Enterprise Postgres as an external data source in the RAG approach.

Knowledge in the RAG approach is expressed in text and graph form, and vector data is also leveraged for fast retrieval. Knowledge data management allows you to centralize the management of knowledge data such as vectors and graphs in Fujitsu Enterprise Postgres. In addition to eliminating the need for a dedicated database for each data type, you can protect your knowledge data with the reliable and secure features of Fujitsu Enterprise Postgres.

In addition, the knowledge data management supports:

- Vector data management feature

  This feature stores and retrieves vector data.

L - Semantic text search and automatic vectorization

  Text Semantic Search is a feature that retrieves semantically similar text data from Fujitsu Enterprise Postgres without requiring the application to process vector data. You can also use hybrid search that combines semantic text search and full-text search.

  Automated vectorization is a feature to automatically generate and manage semantic vectors used for semantic search of text, based on declarative specifications.

  Vectorization is performed using pre-trained models called embedding models. At this time, not only external vector embedding models such as Ollama and OpenAI can be used, but also model managed in the database can be used.

- MCP server feature for business data utilization

  Generative AI applications are increasingly dominated by Agentic AI, which aims to achieve goals autonomously. Business data stored in Fujitsu Enterprise Postgres can be utilized by using MCP (Model Context Protocol), which is a standard interface in Agentic AI.

- Graph management feature

  This feature stores and retrieves graph data.

- LangChain linkage

  Knowledge data stored in Fujitsu Enterprise Postgres is available to RAG-based applications using LangChain.

See

Refer to the Knowledge Data Management Feature User's Guide for details.

Appendix A List of Features

The following table lists the main features provided by Fujitsu Enterprise Postgres.

Category	Feature	Linux		Windows	
		AE	SE	AE	SE
Operational management tools	WebAdmin	Y	Y	Y	Y
Improved reliability and availability	Database multiplexing	Y	N	Y	N
	Multi-master replication	Y	N	N	N
	Cluster system using Patroni	Y	N	N	N
	Failover (integration with PRIMECLUSTER)	Y (*1)	Y (*1)	N	N
	Backup/recovery using user exits	Y	N	Y	N
	Connection Manager	Y	N	Y	N
Application development	Embedded SQL integration Java integration ODBC integration .NET Framework integration Python language (psycopg) integration	Y	Y	Y	Y
	Go language integration	Y	Y	N	N
	Features compatible with Oracle databases	Y	Y	Y	Y
Security	Transparent data encryption	Y	Y	Y	Y
	Transparent data encryption using a key management system	Y	Y	N	N
	Data masking	Y	Y	Y	Y
	Audit log	Y	N	Y	N
	Confidentiality management	Y	N	Y	N
	Policy-based Login Security	Y	Y	Y	Y
Support for AI application development	Knowledge data management	Y	Y	Y(*2)	Y(*2)
Performance	In-memory feature	Y	N	Y	N
	High-speed data load	Y	N	Y	N
	Global Meta Cache	Y	N	Y	N
	Local Meta Cache Limit	Y	N	Y	N
Cloud integration	Database Monitoring with Amazon CloudWatch	Y	Y	Y	Y
	Autoscale of Replica Servers through Amazon EC2 Auto Scaling Integration	Y	N	N	N
Performance tuning	Enhanced query plan stability	Y	Y	Y	Y

Y: Provided

N: Not provided

*1: Supported on RHEL only. Also, it cannot be used simultaneously with database multiplexing.

*2: The following features are not available on Windows
- Speed up retrieval processing of vector data management feature
- Semantic text search and automatic vector conversion
- Full-text search
- MCP server feature for business data utilization
- Model management in the database
- Graph management feature

See

For more information on third-party tools that can work with Fujitsu Enterprise Postgres, refer to the "Third-party tools that work with Fujitsu Enterprise Postgre" available at:

https://www.postgresql.fastware.com/resource-center

Appendix B OSS Supported by Fujitsu Enterprise Postgres

The OSS supported by Fujitsu Enterprise Postgres is listed below.

OSS name	Version and level	Platform		Description	Reference
		Linux	Windows		
PostgreSQL	18.3	Y	Y	Database management system	PostgreSQL Documentation
orafce	4.16.3	Y	Y	Oracle-compatible SQL features	"Compatibility with Oracle Databases" in the Application Development Guide
Pgpool-II	4.6.5	Y	N	Failover, connection pooling, load balancing, etc.	"Pgpool-II" in the Installation and Setup Guide for Server
oracle_fdw	2.8.0	Y	Y	Connection to the Oracle database server	"oracle_fdw" in the Installation and Setup Guide for Server
pg_statsinfo	17.0-2	Y	N	Collection and accumulation of statistics	"pg_statsinfo" in the Installation and Setup Guide for Server
pg_hint_plan	18.1.8.0	Y	Y	Tuning (statistics management, query tuning)	- "pg_hint_plan" in the Installation and Setup Guide for Server - "Enhanced Query Plan Stability" in the Operation Guide
pg_dbms_stats	14.0	Y	Y		- "pg_dbms_stats" in the Installation and Setup Guide for Server - "Enhanced Query Plan Stability" in the Operation Guide
pg_repack	1.5.3	Y	N	Table reorganization	"pg_repack" in the Installation and Setup Guide for Server
pg_rman	1.3.18	Y	N	Backup and restore management	"pg_rman" in the Installation and Setup Guide for Server
pgBackRest	2.57.0	Y	N		"pgBackRest" in the Installation and Setup Guide for Server
pgAdmin4	9.11	N	Y (*1)	Operation and development GUI	Operation Guide
pgBadger	13.2	Y	N	Log analysis	"pgBadger" in the Installation and Setup Guide for Server

OSS name	Version and level	Platform		Description	Reference
		Linux	Windows		
pg_bigm	1.2-20250903	Y	N	Full-text search (multibyte)	"pg_bigm" in the Installation and Setup Guide for Server
ldap2pg	6.5.1	Y	N	Managing user	- "LDAP Authentication File Settings" in the Installation and Setup Guide for Server - "ldap2pg" in the Installation and Setup Guide for Client
PostgreSQL JDBC driver	42.7.8	Y	Y	JDBC driver	"JDBC Driver" in the Application Development Guide
psqlODBC	17.00.0007	Y	Y	ODBC driver	"ODBC Driver" in the Application Development Guide
Npgsql	10.0.1 8.0.8	Y (*2)	Y	.NET data provider (*3)	".NET Data Provider" in the Application Development Guide
psycopg	3.2.13	Y	Y	Python driver	"Python Language Package (psycopg)" in the Application Development Guide
pgx	5.8.0	Y	N	Go language	"Go Language" in the Application Development Guide
pgvector	0.8.1	Y	Y	Vector data storage, operation, and search (*4)	"pgvector" in the Installation and Setup Guide for Server
pgvectorscale	0.9.0	Y	N	Accelerating vector data search processing (*5)	"pgvectorscale" in the Installation and Setup Guide for Server
Apache AGE	1.6.0 for PG17	Y	N	Graph data storage and search (*6)	"Apache AGE" in the Installation and Setup Guide for Server
pgai	0.9.2	Y	N	Vectorization of text data using external embedding model and declarative vectorization specification (*7)	Knowledge Data Management Feature User's Guide
pg_cron	1.6.7	Y	N	SQL Job scheduler	"pg_cron" in the Installation and Setup Guide for Server
pgactive	2.1.7	Y	N	Multi-master replication	Cluster Operation Guide (Multi-master Replication)

OSS name	Version and level	Platform		Description	Reference
		Linux	Windows		
Patroni	4.1.0	Y	N	High availability management tool (*8)	"Building a Cluster System Using Patroni" in the Operation Guide
etcd	3.6.7	Y	N	Distributed consensus store (*9)	"Building a Cluster System Using Patroni" in the Operation Guide
PostGIS	3.5.4	L (*10)	N	Geographic information system extension	PostGIS Build Instructions (*11)

Y: Supported

L: Limited support

N: Not supported

*1: Server mode is not supported.
*2: In order for Npgsql to operate, an .NET provided by Microsoft is required, but check the support version of the provider for the OS version on which .NET can operate.

*3: Multiple Npgsql module versions are available. Use the one compatible with your project's .NET target framework.

*4: pgvector by itself cannot generate vector data. pgai allows you to generate vector data for text data using an external embedded model. To use vector representations in other data formats, use software or services that generate vector data and store the generated vector data in a database.
The manual may refer to pgvector documentation. Refer to the documents published at the following site:
https://github.com/pgvector/pgvector/blob/v0.8.1/README.md

*5: The manual may refer to pgvectorscale documentation. Refer to the documents published at the following site:
https://github.com/timescale/pgvectorscale/blob/0.9.0/README.md

*6: The manual may refer to Apache AGE documentation. Refer to the documents published at the following site:
https://age.apache.org/age-manual/master/index.html

*7: The manual may refer to pgai documentation. Refer to the documents published at the following site:
https://github.com/timescale/pgai/blob/pgai-v0.9.2/README.md

*8: The manual may refer to Patroni documentation. Refer to the documents published at the following site:
https://patroni.readthedocs.io/en/latest/

*9: The manual may refer to etcd documentation. Refer to the documents published at the following site:
https://etcd.io/docs/v3.6/

*10: OSS is not included in the Fujitsu Enterprise Postgres program and does not provide a fix. Therefore, you should refer to the PostGIS Build Instructions and download the required OSS.
The PostGIS Build Instructions will be updated once a version with new fixes is released by the community and verified by Fujitsu. A revision of the PostGIS Build Instructions will be notified when the fix for server feature is provided. Build according to the updated PostGIS Build Instructions to take advantage of the new modified version.

*11: Refer to the PostGIS Build Instructions to complete the build and setup. The PostGIS Build Instructions can be obtained from the following site:
https://www.postgresql.fastware.com/knowledge-base/how-to/installing-postgis

Appendix C Features that can be Used on Servers Other than the Database Server

This chapter explains the configuration and operating environment of features to be installed and used on servers other than the database server when used in conjunction with the Fujitsu Enterprise Postgres database server.

In this chapter, Fujitsu Enterprise Postgres programs are referred to as server programs.

Below are features to be installed and used on servers other than the database server:

- WebAdmin
- Server Assistant
- Pgpool-II (failover, connection pooling, and load balancing)

C.1 WebAdmin

If there is only one database server, WebAdmin is normally installed on the same server as the database (the WebAdmin program can be installed at the same time as the server program).

If there are multiple database servers, database server instances can be managed collectively if a dedicated WebAdmin server is used. In this case, the WebAdmin program is installed on the WebAdmin server, and the server program and WebAdmin program are installed on the database server.

See

- Refer to "1.2 Simple GUI-Based Installation and Operation Management" for information on WebAdmin.
- Refer to "Determining the Preferred WebAdmin Configuration" in the Installation and Setup Guide for Server for information on the server configuration when using WebAdmin.
- Refer to "Required Operating System" in the Installation and Setup Guide for Server for information on the operating environment of WebAdmin.

C.2 Server Assistant

To use the Server Assistant, the Server Assistant program is installed on a dedicated server (arbitration server).

See

- Refer to "Overview of Database Multiplexing Mode" in the Cluster Operation Guide (Database Multiplexing) for information on the Server Assistant and the server configuration.
- Refer to "Required Operating System" in the Installation and Setup Guide for Server Assistant for information on the operating environment of the Server Assistant.

C.3 Failover, Connection Pooling, and Load Balancing Features of Pgpool-II

Pgpool-II is software that is placed between the database server and database client to relay the connection.

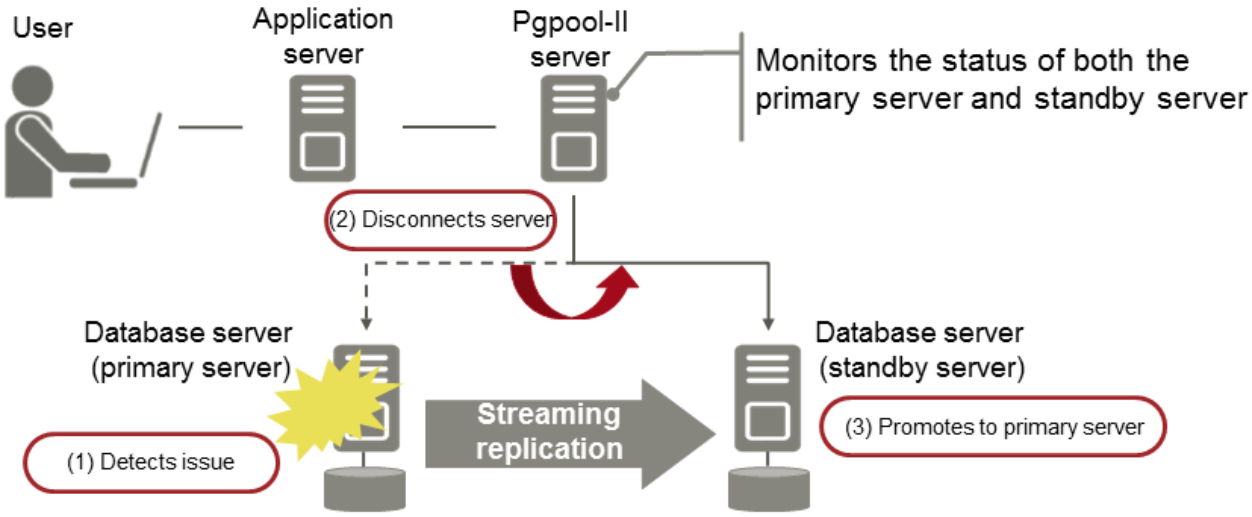
Pgpool-II provides the failover, connection pooling, and load balancing features for use during streaming replication.

Failover

In PostgreSQL, a database can be made redundant (building a high availability system) using synchronous streaming replication.

If the database server of either the primary server or standby server fails or is no longer accessible when using synchronous streaming replication, jobs will stop.

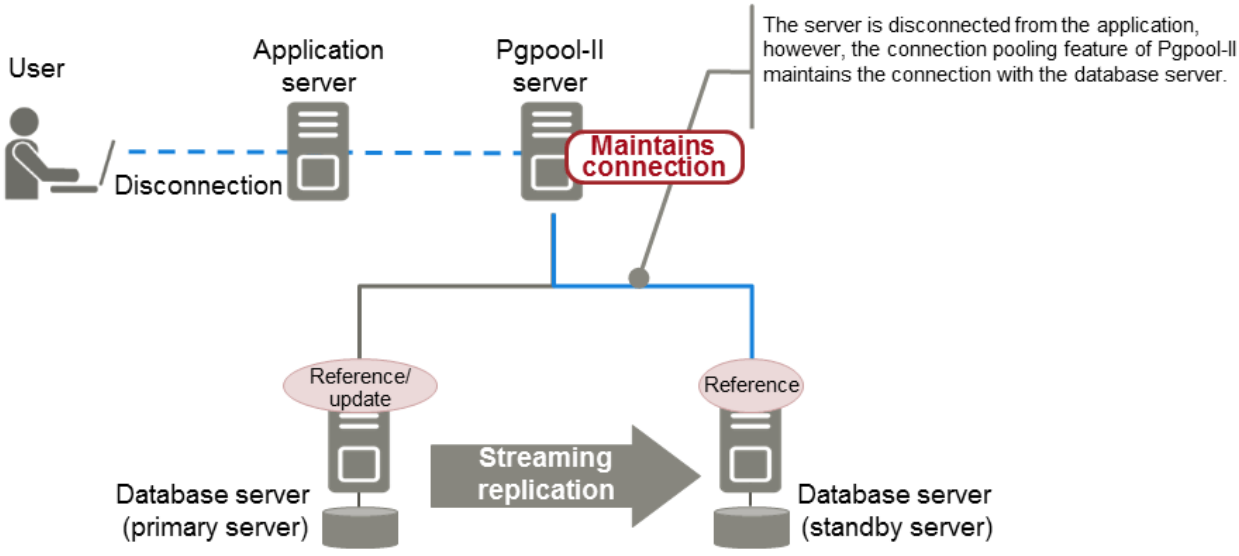
Failover monitors the status of each database and automatically disconnects the server when an error occurs. As a result, jobs can continue uninterrupted on the remaining server.



Connection pooling

This feature maintains (pools) the connection established with the database server, and reuses that connection each time a new connection with the same properties (user name, database, and protocol version) arrives.

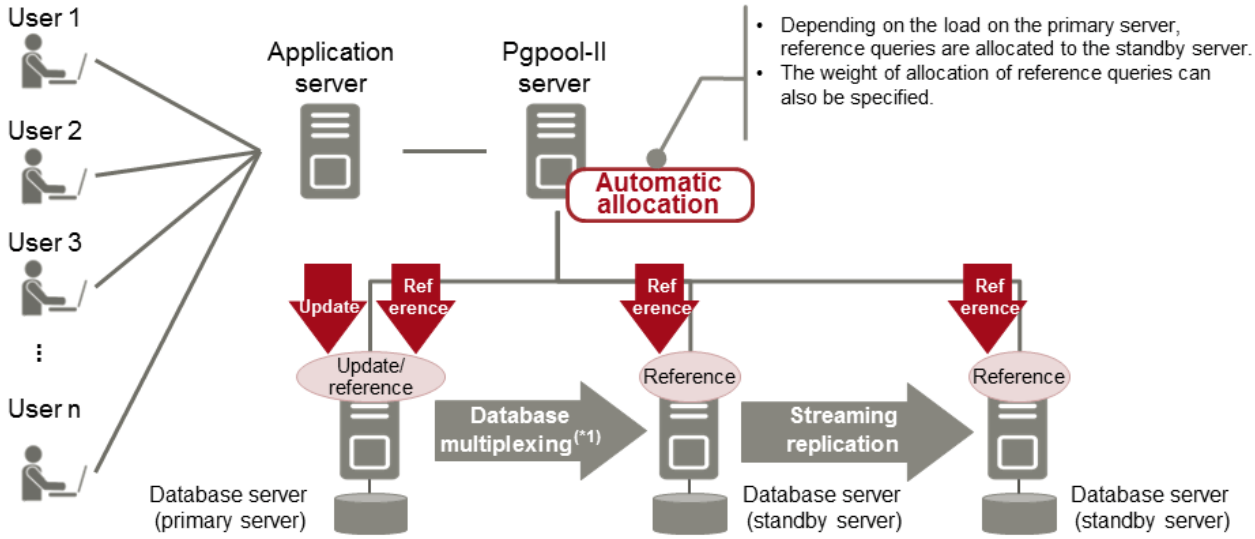
Connection pooling reduces the connection overhead for the database server, improving throughput of the whole system.



Load balancing

This feature distributes reference queries to multiple database servers, improving throughput of the whole system.

By combining load balancing with the Fujitsu Enterprise Postgres database multiplexing feature or the PostgreSQL streaming replication feature, load on the database server is reduced.



*1: The arbitration server used during database multiplexing has been omitted from this document.

See

- Refer to "System configuration when using Pgpool-II" in the Installation and Setup Guide for Server for information on the server configuration when using Pgpool-II.
- Refer to "Required Operating System" in the Installation and Setup Guide for Server for information on the operating environment of Pgpool-II.

FUJITSU

Fujitsu Enterprise Postgres 18SP1 for x86

Release Notes

Windows/Linux

March-2026

FUJITSU

Fujitsu Enterprise Postgres 18SP1 for x86

Release Notes

Linux

J2UL-3076-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document provides release information for Fujitsu Enterprise Postgres.

Structure of this document

This document is structured as follows:

Chapter 1 New Features and Improvements

Explains the new features and improvements in this version.

Chapter 2 Compatibility Information (List)

Provides a list of incompatible items when migrating from previous versions.

Chapter 3 Compatibility Information (Details)

Explains incompatibilities and corrective actions to be taken when migrating from previous versions.

Chapter 4 Program Updates

Explains updates incorporated in this version.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Issue date and version

```
Edition 2.0: March 2026
Edition 1.0: December 2025

Chapter 1 New Features and Improvements....1
1.1 Features Added in 18 SP1....1
1.1.1 AI Application Development Support....1
1.1.1.1 MCP Server Feature for Business Data Utilization....1
1.1.2 Operation....2
1.1.2.1 Load Balancing Functionality Enhancement in HA Configuration....2
1.1.2.2 Building a Cluster System Using Patroni....2
1.1.2.3 Geographic Distribution Across Multiple Regions (n:n)....2
1.1.2.4 Autoscale of Replica Servers through Amazon EC2 Auto Scaling Integration....2
1.1.3 Application Development....2
1.1.3.1 Go Language Integration....3
1.1.4 OSS....3
1.1.4.1 PostgreSQL Rebase....3
1.1.4.2 OSS Updates Provided....3
1.2 Features Added in 18....3
1.2.1 AI Application Development Support....3
1.2.1.1 In-database Inference....3
1.2.2 Operation....3
1.2.2.1 Multi-master Replication....4
1.2.3 Application Development....4
1.2.3.1 COBOL Performance Improvement....4
1.2.4 Install....4
1.2.4.1 RPM-based Installation....4
1.2.5 OSS....4
1.2.5.1 PostgreSQL Rebase....4
1.2.5.2 OSS Updates Provided....4

Chapter 2 Compatibility Information (List)....6
2.1 If the version before migration is Fujitsu Enterprise Postgres 18....6
2.2 If the version before migration is Fujitsu Enterprise Postgres 17 SP2....6
2.3 If the Version Before Migration is Fujitsu Enterprise Postgres 17 SP1....7
2.4 If the Version Before Migration is Fujitsu Enterprise Postgres 17....7
2.5 If the Version Before Migration is Fujitsu Enterprise Postgres 16 SP1....8
2.6 If the Version Before Migration is Fujitsu Enterprise Postgres 16....9
2.7 If the Version Before Migration is Fujitsu Enterprise Postgres 15 SP2....10
2.8 If the Version Before Migration is Fujitsu Enterprise Postgres 15 SP1....11
2.9 If the Version Before Migration is Fujitsu Enterprise Postgres 15....12
2.10 If the Version Before Migration is FUJITSU Enterprise Postgres 14 SP1....13
2.11 If the Version Before Migration is FUJITSU Enterprise Postgres 14....14
2.12 If the Version Before Migration is FUJITSU Enterprise Postgres 13 SP1....15
2.13 If the Version Before Migration is FUJITSU Enterprise Postgres 13....17
2.14 If the Version Before Migration is FUJITSU Enterprise Postgres 12 SP1....18
2.15 If the Version Before Migration is FUJITSU Enterprise Postgres 12....20
2.16 If the Version Before Migration is FUJITSU Enterprise Postgres 11....21
2.17 If the Version Before Migration is FUJITSU Enterprise Postgres 10....23
2.18 If the Version Before Migration is FUJITSU Enterprise Postgres 9.6....25
2.19 If the Version Before Migration is FUJITSU Enterprise Postgres 9.5....26

Chapter 3 Compatibility Information (Details)....29
3.1 Installation/Setup Incompatibility....29
3.1.1 Removing Old llvm Support for JIT compilation....29
3.1.2 Removing Operating System Support for Client Feature....29
3.1.3 Removing Old llvm Support for JIT compilation....29
3.1.4 Removing Operating System Support for Client Feature....29
3.1.5 Removing Operating System Support for Server Feature....30
3.1.6 Removing Operating System Support for Server Assistant Feature....30

3.1.7 Python Version Changes Required When Using PL/Python....30
3.1.8 Modifying the Installation of pgBackRest....30
3.1.9 Removing Operating System Support for Client Feature....31
3.1.10 Removing Operating System Support for Server Feature....31
3.1.11 How max_wal_senders is calculated....31
3.1.12 How max_worker_processes is calculated....31
3.1.13 Removing Operating System Support for Client Feature....31
3.1.14 Removing Operating System Support for Client Feature....32
3.1.15 Removing Operating System Support for Server Feature....32
3.1.16 Changing kernel parameter settings when an instance is created with WebAdmin....32
3.1.17 Removing Operating System Support for Client Feature....33
3.1.18 Removing Operating System Support for Server Feature....33
3.1.19 Changing the Way OSS is Set Up....34
3.1.20 Modifying Pgpool-II Installation Handling....34
3.1.21 Changing Core and Log File Paths when Instance is Created with WebAdmin....34
3.1.22 Renaming WebAdmin Services....35
3.1.23 Changing the Features Targeted for Installation in a 64-bit Environment....35
3.1.24 Changing the Access Permissions of the Windows Client Installation Folder....35
3.1.25 Changing the WebAdmin Installation Method....35
3.2 Application Migration Incompatibility....36
3.2.1 Output File Change....36
3.2.2 Changing the OID of the Data Type (NCHAR type) that Handles National Characters....36
3.2.3 Changed the Specification Method of the Application Connection Switch Feature....36
3.2.4 Changes in ecpg/ecobpg Handling of Zero-Length Unicode Identifiers....36
3.2.5 Changing the display result when data masking is applied to NaN, infinity, -infinity....37
3.2.6 Changing the Valid Range of Identifiers Defined by the DECLARE STATEMENT statement....37
3.2.7 Changing Precompile Results....37
3.2.8 Changing the Trigger Replacement Process....38
3.2.9 Adding a TAP Test Framework....38
3.2.10 Change the "elif" Statement Behavior in ecobpg....38
3.2.11 Changed to Error when Running an Operator or Function that Returns non Data Types for Masking Type....39
3.2.12 Changing the Method of Specifying the Application Connection Switch Feature....40
3.2.13 Changing the order of servers to be connected by the Application Connection Switch Feature....40
3.2.14 PostgreSQL Compatibility of Embedded SQL Applications in C and COBOL....41
3.2.15 Changing Vertical Clustered Index (VCI)....41
3.2.16 Changing how to Use the Features Compatible with Oracle Databases....41
3.3 Operation Migration Incompatibility....42
3.3.1 Deprecation of Some Encryption Algorithms in pgcrypto....42
3.3.2 Deprecation of Certificates Signed Using SHA1....42
3.3.3 Abolition of Message Numbers....42
3.3.4 Adding the key_name Column to the View pgx_tde_master_key....43
3.3.5 Changing the Output of the Status Mode of the cm_ctl Command....43
3.3.6 Rename column "master_pid" in pgx_loader_state to "leader_pid"....44
3.3.7 Adding a Message to Output when the Database Server watchdog detects that the Connection Manager is down....44
3.3.8 Change the Error Information when the Connection Manager re-executes SQL on the Failed Connection....45
3.3.9 Changing the Value of the Category Column in the pg_settings view....45
3.3.10 Changing pgx_stat_lwlock of the Statistics View....46
3.3.11 Changing the Behavior of pgx_rcvall....47
3.3.12 Mirroring Controller no Longer Retries to Monitor Database Processes when they are Detected as Down....47
3.3.13 Changing the Name and Parameter Name of the Mirroring Controller Post-Promote Command....47
3.3.14 Changing Mirroring Controller User Command Input Values....48
3.3.15 Changing the Maximum Number of Connections per Server....48
3.3.16 Changing the Encryption Settings Using the ALTER TABLESPACE Statement....48
3.3.17 Changing the Default Configuration of the Cluster System Using Database Multiplexing....48
3.3.18 Changing the Default Operation when mc_ctl Command Options are Omitted....49
3.3.19 Changing the Connection Settings when Mirroring Controller Connects to an Instance....49
3.3.20 Changing the Status Display of the Mirroring Controller Server....50

3.3.21 Changing the Operation when the synchronous_standby_names Parameter is Changed during Database Multiplexing Operation 50
3.3.22 Changing Masking Policy Definition for Unsupported Data Types 51
3.4 JDBC Driver Incompatibility 51
3.4.1 Changing the targetServerType Value 51
3.4.2 Changing the Statement Cache Limit Setting Method 51
3.5 ODBC Driver Incompatibility 52
3.5.1 Cannot specify prefer-read for target_session_attrs 52
3.6 .NET Data Provider Incompatibility (Information for Using Npgsql 10 or Later) 52
3.7 .NET Data Provider Incompatibility (Information for using Npgsql 8 with Fujitsu Enterprise Postgres 18 SP1 or Later) 52
3.7.1 Npgsql NuGet Package Name and Version Change 52
3.8 .NET Data Provider Incompatibility (Information for Fujitsu Enterprise Postgres 18 and Earlier) 53
3.8.1 .NET Application Development and Operating Environment Changes 53
3.8.2 Changing the Specification Method and Specified Values for the Application Connection Switch Feature 53
3.8.3 Changing the Behavior of the Application Connection Switch Feature 54
3.8.4 Behavior Change when Multiple Host Information is Specified in the Connection String 54
3.8.5 Changing the TargetServerType Value 55
3.8.6 Changing the Server Explorer View in Visual Studio Integration with .NET Data Provider 55
3.9 C Library (libpq) Migration Incompatibility 55
3.9.1 Changing when "prefer-read" is Specified for the target_session_attrs Parameter 55
3.10 oracle_fdw Incompatibility 56
3.10.1 Changing the Oracle Client Version 56
3.11 pg_statsinfo Incompatibility 56
3.11.1 Changing Simple Report Items 56
3.11.2 Change the Contents of the bgwriter Table in the statsrepo Schema 56
3.11.3 Rename Columns in statement Table in statsrepo Schema 57
3.11.4 Change the Default Value of the stattarget Column of the column Table in the statsrepo Schema 57
3.12 pgaudit Incompatibility 57
3.12.1 Repairing Unwanted Output in the Audit Log 57
3.12.2 Changing to Output Extra NEW and OLD Values in the Audit Log when the Trigger Function Executes 57
3.13 pg_dbms_stats Incompatibility 58
3.13.1 Change in Execution Plan due to Fixed Height of Btree index 58
3.13.2 Incompatibility of Import Features with Fixed Height of Btree index 58
3.14 orafce Incompatibility 59
3.14.1 Interface changes due to enhancements to the DBMS_SQL package 59
3.15 psycopg Incompatibility 59
3.15.1 Python Version Changes Required When Using psycopg 59
3.16 WebAdmin Incompatibility 59
3.16.1 Added SNI hostname verification functionality 59
3.16.2 Linux server behavior changes for login authentication 60
3.16.3 Changing the default value of the item 'Number of digits for floating values' which is set in the section 'SQL options' 60
3.16.4 Cannot specify prefer-read for target_session_attrs 60
3.17 Connection Manager Incompatibility 60
3.17.1 Behavior change when "read-write" is specified for the target_session_attrs parameter 60
3.18 Confidentiality Management Incompatibility 61
3.18.1 Changes due to Changes in the pg_dump Specification 61
3.18.2 Changing Permission Settings by Changing the CREATEROLE Permission 61
3.18.3 Change due to Restriction of CREATEROLE Privilege 61

Chapter 4 Program Updates 63
4.1 Fujitsu Enterprise Postgres 18 SP1 Program Updates 63
4.2 Fujitsu Enterprise Postgres 18 Program Updates 64

Index 66

Chapter 1 New Features and Improvements

This chapter explains Fujitsu Enterprise Postgres new features and improvements added in this version.

Table 1.1 New features and improvements

Version and level	Classification	Feature	Provided in AE	Provided in SE
18 SP1	AI Application Development Support	MCP Server Feature for Business Data Utilization	Y	Y
	Operation	Load Balancing Functionality Enhancement in HA Configuration	Y	-
		Building a Cluster System Using Patroni	Y	-
		Geographic Distribution Across Multiple Regions (n:n)	Y	-
		Autoscale of Replica Servers through Amazon EC2 Auto Scaling Integration	Y	-
	Application Development	Go Language Integration	Y	Y
	OSS	PostgreSQL Rebase	Y	Y
		OSS Updates Provided	Y	Y
18	AI Application Development Support	In-database Inference	Y	Y
	Operation	Multi-master Replication	Y	-
	Application Development	COBOL Performance Improvement	Y	Y
	Install	RPM-based Installation	Y	Y
	OSS	PostgreSQL Rebase	Y	Y
		OSS Updates Provided	Y	Y

1.1 Features Added in 18 SP1

This section explains new features and improvements in Fujitsu Enterprise Postgres 18 SP1.

1.1.1 AI Application Development Support

This section explains the new feature related to support AI application development.

- MCP Server Feature for Business Data Utilization

1.1.1.1 MCP Server Feature for Business Data Utilization

This feature enables the utilization of business data stored in Fujitsu Enterprise Postgres via the Model Context Protocol (MCP). Accessing business data stored in the database through MCP facilitates easier integration between AI applications and the database. Additionally, users can easily utilize business data from AI applications.

See

Refer to Knowledge Data Management Feature User's Guide for details.

1.1.2 Operation

This section explains the new feature related to Operation.

- Load Balancing Functionality Enhancement in HA Configuration
- Building a Cluster System Using Patroni
- Geographic Distribution Across Multiple Regions (n:n)
- Autoscale of Replica Servers through Amazon EC2 Auto Scaling Integration

1.1.2.1 Load Balancing Functionality Enhancement in HA Configuration

Enhances load balancing functionality in HA configurations for Fujitsu Enterprise Postgres. The following Connection Manager features improve overall system stability and operational efficiency:

- Load balancing and read connection redistribution feature
- Initial data synchronization waiting feature for standby servers

See

Refer to "Connection Manager Features" in the Connection Manager User's Guide for details.

1.1.2.2 Building a Cluster System Using Patroni

By combining Fujitsu Enterprise Postgres with Patroni and etcd, which are provided as OSS, we will build a high-availability cluster system. This cluster system provides automatic failover, replication management, cluster state monitoring, and automatic recovery feature, realizing highly reliable system operation.

See

Refer to "Building a Cluster System Using Patroni" in the Operation Guide for details.

1.1.2.3 Geographic Distribution Across Multiple Regions (n:n)

While Fujitsu Enterprise Postgres 18 only supported a 1:1 region configuration, it now enables configurations across multiple regions (n:n).

See

Refer to Cluster Operation Guide (Multi-master Replication) for details.

1.1.2.4 Autoscale of Replica Servers through Amazon EC2 Auto Scaling Integration

Using Amazon EC2 Auto Scaling, you can improve the efficiency of reference operations by automatically scaling out or scaling in a group of replicated database servers based on database load.

See

Refer to "Autoscale of Replica Servers through Amazon EC2 Auto Scaling Integration" in the Operation Guide for details.

1.1.3 Application Development

This section explains the new features related to application development.

- Go Language Integration

1.1.3.1 Go Language Integration

Supports the Go language interface, widely used in cloud application development.

See

Refer to "Go Language" in the Application Development Guide for details.

1.1.4 OSS

This section explains the new feature related to OSS.

- PostgreSQL Rebase
- OSS Updates Provided

1.1.4.1 PostgreSQL Rebase

The PostgreSQL version that Fujitsu Enterprise Postgres is based on is 18.3.

1.1.4.2 OSS Updates Provided

The OSS provided by Fujitsu Enterprise Postgres has been updated.

See

Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for details.

1.2 Features Added in 18

This section explains new features and improvements in Fujitsu Enterprise Postgres 18.

1.2.1 AI Application Development Support

This section explains the new feature related to support AI application development.

- In-database Inference

1.2.1.1 In-database Inference

Provides the ability to import and use ONNX format models in the database. In Fujitsu Enterprise Postgres 18, only embedded models with vectorization can be imported. You can make the imported model available and implement vectorization for semantic text search.

See

Refer to "Protect and Efficiently Manage and Use Knowledge Data for AI Applications" in the General Description for details.

1.2.2 Operation

This section explains the new feature related to Operation.

- Multi-master replication

1.2.2.1 Multi-master Replication

The multi-master replication feature enables the construction of a replication configuration where independent data updates can be processed on multiple nodes. In this multi-master configuration, all nodes function as masters, allowing clients to write (update, insert, delete) data to any node, and those changes are automatically synchronized to all other nodes.

By utilizing this multi-master replication feature, you can enhance business continuity in disaster recovery.

See

Refer to Cluster Operation Guide (Multi-master Replication) for details.

1.2.3 Application Development

This section explains the new features related to application development.

- COBOL Performance Improvement

1.2.3.1 COBOL Performance Improvement

Caching of host variables in the COBOL precompiler. This function is expected to improve the processing performance of embedded COBOL applications that use host variables.

See

Refer to "Embedded SQL in COBOL" in the Application Development Guide for details.

1.2.4 Install

This section explains the new feature related to install.

- RPM-based Installation

1.2.4.1 RPM-based Installation

You can now install from RPM packages.

See

Refer to Installation and Setup Guide for Server, Installation and Setup Guide for Client, and Installation and Setup Guide for Server Assistant for details.

1.2.5 OSS

This section explains the new feature related to OSS.

- PostgreSQL Rebase
- OSS Updates Provided

1.2.5.1 PostgreSQL Rebase

The PostgreSQL version that Fujitsu Enterprise Postgres is based on is 18.

1.2.5.2 OSS Updates Provided

The OSS provided by Fujitsu Enterprise Postgres has been updated.

See

Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for details.

Chapter 2 Compatibility Information (List)

Lists incompatible items when migrating from previous versions.

2.1 If the version before migration is Fujitsu Enterprise Postgres 18

Classification	Reference
Installation/Setup	There is no incompatibility.
Application	There is no incompatibility.
Operation	There is no incompatibility.
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	There is no incompatibility.
.NET Data Provider (When using .NET Framework)	3.7.1 Npgsql NuGet Package Name and Version Change
C Library (libpq)	There is no incompatibility.
oracle_fdw	There is no incompatibility.
pg_statsinfo	There is no incompatibility.
pgaudit	There is no incompatibility.
pg_dbms_stats	There is no incompatibility.
orafce	There is no incompatibility.
psycopg	There is no incompatibility.
WebAdmin	3.16.1 Added SNI hostname verification functionality
Connection Manager	There is no incompatibility.
Confidentiality Management	There is no incompatibility.

2.2 If the version before migration is Fujitsu Enterprise Postgres 17 SP2

Classification	Reference
Installation/Setup	3.1.1 Removing Old llvm Support for JIT compilation
Application	3.2.1 Output File Change
Operation	There is no incompatibility.
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	There is no incompatibility.
.NET Data Provider (When using .NET Framework)	There is no incompatibility.
C Library (libpq)	There is no incompatibility.
oracle_fdw	There is no incompatibility.

Classification	Reference
pg_statsinfo	There is no incompatibility.
pgaudit	There is no incompatibility.
pg_dbms_stats	There is no incompatibility.
orafce	There is no incompatibility.
psycopg	3.15.1 Python Version Changes Required When Using psycopg
WebAdmin	3.16.1 Added SNI hostname verification functionality
Connection Manager	There is no incompatibility.
Confidentiality Management	There is no incompatibility.

2.3 If the Version Before Migration is Fujitsu Enterprise Postgres 17 SP1

Classification	Reference
Installation/Setup	3.1.1 Removing Old llvm Support for JIT compilation
	3.1.2 Removing Operating System Support for Client Feature
Application	3.2.1 Output File Change
Operation	There is no incompatibility.
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	There is no incompatibility.
.NET Data Provider (When using .NET Framework)	There is no incompatibility.
C Library (libpq)	There is no incompatibility.
oracle_fdw	There is no incompatibility.
pg_statsinfo	There is no incompatibility.
pgaudit	There is no incompatibility.
pg_dbms_stats	There is no incompatibility.
orafce	There is no incompatibility.
psycopg	3.15.1 Python Version Changes Required When Using psycopg
WebAdmin	3.16.1 Added SNI hostname verification functionality
Connection Manager	There is no incompatibility.
Confidentiality Management	There is no incompatibility.

2.4 If the Version Before Migration is Fujitsu Enterprise Postgres 17

Classification	Reference
Installation/Setup	3.1.1 Removing Old llvm Support for JIT compilation

Classification	Reference
	3.1.2 Removing Operating System Support for Client Feature
Application	3.2.1 Output File Change
Operation	There is no incompatibility.
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	3.8.1 .NET Application Development and Operating Environment Changes
.NET Data Provider (When using .NET Framework)	3.8.1 .NET Application Development and Operating Environment Changes
C Library (libpq)	There is no incompatibility.
oracle_fdw	There is no incompatibility.
pg_statsinfo	There is no incompatibility.
pgaudit	There is no incompatibility.
pg_dbms_stats	There is no incompatibility.
orafce	There is no incompatibility.
WebAdmin	3.16.1 Added SNI hostname verification functionality
Connection Manager	There is no incompatibility.
Confidentiality Management	There is no incompatibility.

2.5 If the Version Before Migration is Fujitsu Enterprise Postgres 16 SP1

Classification	Reference
Installation/Setup	3.1.1 Removing Old llvm Support for JIT compilation
	3.1.2 Removing Operating System Support for Client Feature
	3.1.3 Removing Old llvm Support for JIT compilation
	3.1.4 Removing Operating System Support for Client Feature
	3.1.5 Removing Operating System Support for Server Feature
	3.1.6 Removing Operating System Support for Server Assistant Feature
	3.1.7 Python Version Changes Required When Using PL/Python
Application	3.2.1 Output File Change
Operation	There is no incompatibility.
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	3.8.1 .NET Application Development and Operating Environment Changes
.NET Data Provider (When using .NET Framework)	3.8.1 .NET Application Development and Operating Environment Changes
C Library (libpq)	There is no incompatibility.
oracle_fdw	There is no incompatibility.

Classification	Reference
pg_statsinfo	3.11.1 Changing Simple Report Items
	3.11.2 Change the Contents of the bgwriter Table in the statsrepo Schema
	3.11.3 Rename Columns in statement Table in statsrepo Schema
	3.11.4 Change the Default Value of the stattarget Column of the column Table in the statsrepo Schema
pgaudit	There is no incompatibility.
pg_dbms_stats	There is no incompatibility.
orafce	3.14.1 Interface changes due to enhancements to the DBMS_SQL package
WebAdmin	3.16.1 Added SNI hostname verification functionality
Connection Manager	There is no incompatibility.
Confidentiality Management	There is no incompatibility.

2.6 If the Version Before Migration is Fujitsu Enterprise Postgres 16

Classification	Reference
Installation/Setup	3.1.1 Removing Old llvm Support for JIT compilation
	3.1.2 Removing Operating System Support for Client Feature
	3.1.3 Removing Old llvm Support for JIT compilation
	3.1.4 Removing Operating System Support for Client Feature
	3.1.5 Removing Operating System Support for Server Feature
	3.1.6 Removing Operating System Support for Server Assistant Feature
	3.1.7 Python Version Changes Required When Using PL/Python
Application	3.2.1 Output File Change
Operation	There is no incompatibility.
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	3.8.1 .NET Application Development and Operating Environment Changes
.NET Data Provider (When using .NET Framework)	3.8.1 .NET Application Development and Operating Environment Changes
C Library (libpq)	There is no incompatibility.
oracle_fdw	There is no incompatibility.
pg_statsinfo	3.11.1 Changing Simple Report Items
	3.11.2 Change the Contents of the bgwriter Table in the statsrepo Schema
	3.11.3 Rename Columns in statement Table in statsrepo Schema
	3.11.4 Change the Default Value of the stattarget Column of the column Table in the statsrepo Schema
pgaudit	There is no incompatibility.
pg_dbms_stats	There is no incompatibility.

Classification	Reference
orafce	3.14.1 Interface changes due to enhancements to the DBMS_SQL package
WebAdmin	3.16.2 Linux server behavior changes for login authentication
Connection Manager	There is no incompatibility.
Confidentiality Management	There is no incompatibility.

2.7 If the Version Before Migration is Fujitsu Enterprise Postgres 15 SP2

Classification	Reference
Installation/Setup	3.1.1 Removing Old llvm Support for JIT compilation
	3.1.2 Removing Operating System Support for Client Feature
	3.1.3 Removing Old llvm Support for JIT compilation
	3.1.4 Removing Operating System Support for Client Feature
	3.1.5 Removing Operating System Support for Server Feature
	3.1.6 Removing Operating System Support for Server Assistant Feature
	3.1.7 Python Version Changes Required When Using PL/Python
	3.1.8 Modifying the Installation of pgBackRest
	3.1.9 Removing Operating System Support for Client Feature
	3.1.10 Removing Operating System Support for Server Feature
Application	3.2.1 Output File Change
Operation	There is no incompatibility.
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	3.8.1 .NET Application Development and Operating Environment Changes
.NET Data Provider (When using .NET Framework)	3.8.1 .NET Application Development and Operating Environment Changes
C Library (libpq)	There is no incompatibility.
oracle_fdw	There is no incompatibility.
pg_statsinfo	3.11.1 Changing Simple Report Items
	3.11.2 Change the Contents of the bgwriter Table in the statsrepo Schema
	3.11.3 Rename Columns in statement Table in statsrepo Schema
	3.11.4 Change the Default Value of the stattarget Column of the column Table in the statsrepo Schema
pgaudit	3.12.1 Repairing Unwanted Output in the Audit Log
pg_dbms_stats	3.13.1 Change in Execution Plan due to Fixed Height of Btree index
	3.13.2 Incompatibility of Import Features with Fixed Height of Btree index
orafce	3.14.1 Interface changes due to enhancements to the DBMS_SQL package
WebAdmin	3.16.2 Linux server behavior changes for login authentication

Classification	Reference
	3.16.3 Changing the default value of the item 'Number of digits for floating values' which is set in the section 'SQL options'
Connection Manager	There is no incompatibility.
Confidentiality Management	3.18.1 Changes due to Changes in the pg_dump Specification
	3.18.2 Changing Permission Settings by Changing the CREATEROLE Permission
	3.18.3 Change due to Restriction of CREATEROLE Privilege

2.8 If the Version Before Migration is Fujitsu Enterprise Postgres 15 SP1

Classification	Reference
Installation/Setup	3.1.1 Removing Old llvm Support for JIT compilation
	3.1.2 Removing Operating System Support for Client Feature
	3.1.3 Removing Old llvm Support for JIT compilation
	3.1.4 Removing Operating System Support for Client Feature
	3.1.5 Removing Operating System Support for Server Feature
	3.1.6 Removing Operating System Support for Server Assistant Feature
	3.1.7 Python Version Changes Required When Using PL/Python
	3.1.8 Modifying the Installation of pgBackRest
	3.1.9 Removing Operating System Support for Client Feature
	3.1.10 Removing Operating System Support for Server Feature
Application	3.2.1 Output File Change
Operation	3.3.1 Deprecation of Some Encryption Algorithms in pgcrypto
	3.3.2 Deprecation of Certificates Signed Using SHA1
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	3.8.1 .NET Application Development and Operating Environment Changes
.NET Data Provider (When using .NET Framework)	3.8.1 .NET Application Development and Operating Environment Changes
C Library (libpq)	There is no incompatibility.
oracle_fdw	There is no incompatibility.
pg_statsinfo	3.11.1 Changing Simple Report Items
	3.11.2 Change the Contents of the bgwriter Table in the statsrepo Schema
	3.11.3 Rename Columns in statement Table in statsrepo Schema
	3.11.4 Change the Default Value of the stattarget Column of the column Table in the statsrepo Schema
pgaudit	3.12.1 Repairing Unwanted Output in the Audit Log
pg_dbms_stats	3.13.1 Change in Execution Plan due to Fixed Height of Btree index
	3.13.2 Incompatibility of Import Features with Fixed Height of Btree index
orafce	3.14.1 Interface changes due to enhancements to the DBMS_SQL package

Classification	Reference
WebAdmin	3.16.2 Linux server behavior changes for login authentication
	3.16.3 Changing the default value of the item 'Number of digits for floating values' which is set in the section 'SQL options'
Connection Manager	There is no incompatibility.
Confidentiality Management	3.18.1 Changes due to Changes in the pg_dump Specification
	3.18.2 Changing Permission Settings by Changing the CREATEROLE Permission
	3.18.3 Change due to Restriction of CREATEROLE Privilege

2.9 If the Version Before Migration is Fujitsu Enterprise Postgres 15

Classification	Reference
Installation/Setup	3.1.1 Removing Old llvm Support for JIT compilation
	3.1.2 Removing Operating System Support for Client Feature
	3.1.3 Removing Old llvm Support for JIT compilation
	3.1.4 Removing Operating System Support for Client Feature
	3.1.5 Removing Operating System Support for Server Feature
	3.1.6 Removing Operating System Support for Server Assistant Feature
	3.1.7 Python Version Changes Required When Using PL/Python
	3.1.9 Removing Operating System Support for Client Feature
	3.1.10 Removing Operating System Support for Server Feature
	3.1.11 How max_wal_senders is calculated
	3.1.12 How max_worker_processes is calculated
Application	3.2.1 Output File Change
Operation	3.3.1 Deprecation of Some Encryption Algorithms in pgcrypto
	3.3.2 Deprecation of Certificates Signed Using SHA1
	3.3.7 Adding a Message to Output when the Database Server watchdog detects that the Connection Manager is down
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	3.8.1 .NET Application Development and Operating Environment Changes
.NET Data Provider (When using .NET Framework)	3.8.1 .NET Application Development and Operating Environment Changes
C Library (libpq)	There is no incompatibility.
oracle_fdw	There is no incompatibility.
pg_statsinfo	3.11.1 Changing Simple Report Items
	3.11.2 Change the Contents of the bgwriter Table in the statsrepo Schema
	3.11.3 Rename Columns in statement Table in statsrepo Schema
	3.11.4 Change the Default Value of the stattarget Column of the column Table in the statsrepo Schema

Classification	Reference
pgaudit	3.12.1 Repairing Unwanted Output in the Audit Log

	3.11.4 Change the Default Value of the stattarget Column of the column Table in the statsrepo Schema
pgaudit	3.12.1 Repairing Unwanted Output in the Audit Log
pg_dbms_stats	3.13.1 Change in Execution Plan due to Fixed Height of Btree index
	3.13.2 Incompatibility of Import Features with Fixed Height of Btree index
orafce	3.14.1 Interface changes due to enhancements to the DBMS_SQL package
WebAdmin	3.16.2 Linux server behavior changes for login authentication
	3.16.3 Changing the default value of the item 'Number of digits for floating values' which is set in the section 'SQL options'
	3.16.4 Cannot specify prefer-read for target_session_attrs
Connection Manager	3.17.1 Behavior change when "read-write" is specified for the target_session_attrs parameter

2.15 If the Version Before Migration is FUJITSU Enterprise Postgres 12

Classification	Reference
Installation/Setup	3.1.2 Removing Operating System Support for Client Feature
	3.1.3 Removing Old llvm Support for JIT compilation

	3.13.2 Incompatibility of Import Features with Fixed Height of Btree index
orafce	3.14.1 Interface changes due to enhancements to the DBMS_SQL package
WebAdmin	3.16.2 Linux server behavior changes for login authentication
	3.16.4 Cannot specify prefer-read for target_session_attrs

Chapter 3 Compatibility Information (Details)

This chapter explains incompatible items and actions required when migrating from an earlier version to Fujitsu Enterprise Postgres 18. SP1 Check compatibility before migrating and take the appropriate action.

3.1 Installation/Setup Incompatibility

3.1.1 Removing Old llvm Support for JIT compilation

Incompatibility

In Fujitsu Enterprise Postgres 18, the following llvm which JIT compilation can use have been removed when operating on RHEL8.

- llvm version 13
- llvm version 14

Action method

None.

3.1.2 Removing Operating System Support for Client Feature

Incompatibility

In Fujitsu Enterprise Postgres 17 SP2 , the following operating systems have been removed.

- Windows(R) 10

Action method

None.

3.1.3 Removing Old llvm Support for JIT compilation

Incompatibility

In Fujitsu Enterprise Postgres 17, the following llvm which JIT compilation can use have been removed.

[RHEL8]

- llvm version 9
- llvm version 10
- llvm version 11
- llvm version 12

[SLES 15]

- llvm version 7

Action method

None.

3.1.4 Removing Operating System Support for Client Feature

Incompatibility

In Fujitsu Enterprise Postgres 17 or later, the following operating systems have been removed.

- RHEL8.5 or earlier
- SLES 15 SP3 or earlier

Action method

None.

3.1.5 Removing Operating System Support for Server Feature

Incompatibility

In Fujitsu Enterprise Postgres 17 or later, the following operating systems have been removed.

- RHEL8.5 or earlier
- SLES 15 SP3 or earlier

Action method

None.

3.1.6 Removing Operating System Support for Server Assistant Feature

Incompatibility

In Fujitsu Enterprise Postgres 17 or later, the following operating systems have been removed.

- RHEL8.5 or earlier
- SLES 15 SP3 or earlier

Action method

None.

3.1.7 Python Version Changes Required When Using PL/Python

Incompatibility

In Fujitsu Enterprise Postgres 17 or later, when operating on RHEL8, changes the required Python version to 3.9.x when using PL/Python based on the Python 3 language.

Action method

None.

3.1.8 Modifying the Installation of pgBackRest

Incompatibility

In Fujitsu Enterprise Postgres 16 or later, pgBackRest is not automatically installed during server and client installation.

Action method

If you want to use pgBackRest, install pgBackRest separately from the server or client installation.

If you want to use pgBackRest on the same server as the database server, refer to "Setting Up and Removing OSS" in the Installation and Setup Guide for Server.

If you want to use pgBackRest on a different server than the database server, refer to "Setting Up and Removing OSS" in the Installation and Setup Guide for Client.

3.1.9 Removing Operating System Support for Client Feature

Incompatibility

In Fujitsu Enterprise Postgres 16 or later, the following operating systems have been removed.

- RHEL7
- SLES 12

Action method

None.

3.1.10 Removing Operating System Support for Server Feature

Incompatibility

In Fujitsu Enterprise Postgres 16 or later, the following operating systems have been removed.

- RHEL7
- SLES 12

Action method

None.

3.1.11 How max_wal_senders is calculated

Incompatibility

In Fujitsu Enterprise Postgres 15 SP1 or later, Fujitsu Enterprise Postgres uses the following values from the value set for the max_wal_senders parameter:

Policy-based password management in a streaming replication environment : Number of direct downstream hot standby servers

Action method

If necessary add a value for the max_wal_senders parameter.

3.1.12 How max_worker_processes is calculated

Incompatibility

In Fujitsu Enterprise Postgres 15 SP1 or later, Fujitsu Enterprise Postgres uses the following values from the value set for the max_worker_processes parameter:

Default value to use : 1

Policy-based password management in a streaming replication environment with a hot standby server : 1

Action method

If necessary add a value for the max_worker_processes parameter.

3.1.13 Removing Operating System Support for Client Feature

Incompatibility

In FUJITSU Enterprise Postgres 12 SP1 or later, the following operating systems have been removed.

- Windows Server(R) 2012

- Windows Server(R) 2012 R2

Action method

None.

3.1.14 Removing Operating System Support for Client Feature

Incompatibility

In FUJITSU Enterprise Postgres 13 or later, the following operating systems have been removed.

- SLES 12 SP4 or earlier

Action method

None.

3.1.15 Removing Operating System Support for Server Feature

Incompatibility

In FUJITSU Enterprise Postgres 13 or later, the following operating systems have been removed.

- SLES 12 SP4 or earlier

Action method

None.

3.1.16 Changing kernel parameter settings when an instance is created with WebAdmin

Incompatibility

For FUJITSU Enterprise Postgres 13 and later, changes kernel parameter settings for WebAdmin instance creation.

FUJITSU Enterprise Postgres 12 or earlier

Kernel Parameters	Value	Calculated Value
SHMMAX	If *currentValue* < *calculatedValue*, configure the calculated value	`((1800 + 270 * max_locks_per_transaction) * max_connections + (1800 + 270 * max_locks_per_transaction) * autovacuum_max_workers + (770 + 270 * max_locks_per_transaction) * max_prepared_transactions + (shared_buffer) + (16 * 1024 * 1024) + ( 770 * 1024)) * 1.05`

SHMALL	Specify *currentValue* + *calculatedValue*	`(SHMMAX / PAGESIZE) + 1`
		
		`PAGESIZE = 4K`

SEMMNI	Specify *currentValue* + *calculatedValue*	`ceil((max_connections + autovacuum_max_workers + 4) / 16)`
SEMMNS	Specify *currentValue* + *calculatedValue*	`ceil((max_connections + autovacuum_max_workers + 4) / 16) * 17`

FUJITSU Enterprise Postgres 13 or later

Kernel Parameters	Value	Calculated Value
SHMMAX	Do not change value	-
SHMALL	Do not change value	-

SEMMNI	Specify *currentValue* + *calculatedValue*	- For instances of FUJITSU Enterprise Postgres 9.5 to 11:
		`ceil((max_connections + autovacuum_max_workers + max_worker_processes + 5) / 16)`
		- For Fujitsu Enterprise Postgres 12 and later instances:
		`ceil((max_connections + autovacuum_max_workers + max_wal_senders + max_worker_processes + 5) / 16)`

SEMMNS	Specify *currentValue* + *calculatedValue*	- For instances of FUJITSU Enterprise Postgres 9.5 to 11:
		`ceil((max_connections + autovacuum_max_workers + max_worker_processes + 5) / 16) * 17`
		- For Fujitsu Enterprise Postgres 12 and later instances:
		`ceil((max_connections + autovacuum_max_workers + max_wal_senders + max_worker_processes + 5) / 16) * 17`

Action method

None.

3.1.17 Removing Operating System Support for Client Feature

Incompatibility

In FUJITSU Enterprise Postgres 12 or later, the following operating systems have been removed.

- Windows(R) 7
- Windows Server(R) 2008
- RHEL6

Also, the 32 bit Linux client can no longer be installed because RHEL 6 has been removed from the operating system.

Action method

None.

3.1.18 Removing Operating System Support for Server Feature

Incompatibility

In FUJITSU Enterprise Postgres 12 or later, the following operating systems have been removed.

- RHEL6

Action method

None.

3.1.19 Changing the Way OSS is Set Up

Incompatibility

FUJITSU Enterprise Postgres 12 or later do not place OSS extension modules in the executable directory. The OSS extension modules must be placed in the executable directory when you set up OSS.

Refer to "Setting Up and Removing OSS" in the Installation and Setup Guide for Server for details.

Action method

None.

3.1.20 Modifying Pgpool-II Installation Handling

Incompatibility

For FUJITSU Enterprise Postgres 12 or later, Pgpool-II is not automatically installed when you install the server. Therefore, if you want to take advantage of Pgpool-II, install it separately from the server installation.

The extension modules required for the database server are shipped with the server program. You should set up Pgpool-II on the database server side, even if Pgpool-II is to be used on a different server than the database server.

Refer to "Setting Up and Removing OSS" in the Installation and Setup Guide for Server for details.

Action method

None.

3.1.21 Changing Core and Log File Paths when Instance is Created with WebAdmin

Incompatibility

In FUJITSU Enterprise Postgres 12 or later, change the core and log file paths when creating an instance in WebAdmin.

FUJITSU Enterprise Postgres 11 or earlier

Log File Path: /var/tmp/fsep_*version*/*instanceAdminUser_instanceNamePortNumber*/log

Core File Path: /var/tmp/fsep_*version*/*instanceAdminUser_instanceNamePortNumber*/core

version: product version_edition_architecture

［Example］

Log File Path: /var/tmp/fsep_110_AE_64/naomi_myinst27599/log

Core File Path: /var/tmp/fsep_110_AE_64/naomi_myinst27599/core

FUJITSU Enterprise Postgres 12

Log File Path: /var/tmp/fsep_*version*/*instanceAdminUser_instanceNamePortNumber*/log

Core File Path: /var/tmp/fsep_*version*/*instanceAdminUser_instanceNamePortNumber*/core

version: product version_WA_architecture

［Example］

Log File Path: /var/tmp/fsep_120_WA_64/naomi_myinst27599/core

Core File Path: /var/tmp/fsep_120_WA_64/naomi_myinst27599/log

Action method

None.

3.1.22 Renaming WebAdmin Services

Incompatibility

In FUJITSU Enterprise Postgres 12 or later, change the service name registered when you set up WebAdmin.

FUJITSU Enterprise Postgres 11 or earlier

fsep_*x*SP*z*_*edition*_64_WebAdmin_Port1

fsep_*x*SP*z*_*edition*_64_WebAdmin_Port2

FUJITSU Enterprise Postgres 12 or later

fsep_xSPz_WA_64_WebAdmin_Port1

fsep_xSPz_WA_64_WebAdmin_Port2

Action method

None.

3.1.23 Changing the Features Targeted for Installation in a 64-bit Environment

Incompatibility

32 bit Linux client can no longer be installed on RHEL7 in FUJITSU Enterprise Postgres 10 or later.

Note: 32 bit Linux client can install on RHEL6 in FUJITSU Enterprise Postgres 11 or earlier.

Action method

None.

3.1.24 Changing the Access Permissions of the Windows Client Installation Folder

Incompatibility

In FUJITSU Enterprise Postgres 10 or later, when changed for install folder the Windows client from default, the access permissions of the installed files and folder changes to read and execute.

The above changes apply to non-administrators.

This incompatibility occurs with all supported Windows client operating systems. Refer to "Required Operating System" in the Installation and Setup Guide for Client for information on the operating environment.

Action method

This change was made simply to enhance security, therefore, no action is normally required.

However, if existing access permissions are required, this change can be reverted by running *installDir*\setup\revert_cacls.bat as an administrator after installation.

3.1.25 Changing the WebAdmin Installation Method

Incompatibility

In FUJITSU Enterprise Postgres 9.6 or later, WebAdmin is not installed automatically during server installation. Therefore, install WebAdmin separately.

Action method

None.

3.2 Application Migration Incompatibility

3.2.1 Output File Change

Incompatibility

In Fujitsu Enterprise Postgres 18, generates two temporary files during execution of the ecobpg command.

These temporary files are deleted upon successful or abnormal termination of the ecobpg command.

If an issue occurs during ecobpg command execution, these temporary files may remain. In such cases, delete them.

File names are output in the following format:

```
Output_filename.4-digit_random_number.{COB|IPB}.ecw
```

Action method

None.

3.2.2 Changing the OID of the Data Type (NCHAR type) that Handles National Characters

Incompatible

In Fujitsu Enterprise Postgres 15, OIDs for national character data types (NCHAR types) have changed.

Action method

If you are using a national character data type (NCHAR type), recompile the application and run it with Fujitsu Enterprise Postgres 15 or later clients.

3.2.3 Changed the Specification Method of the Application Connection Switch Feature

Incompatible

In Fujitsu Enterprise Postgres 15, the name of the "target server" specified by the application connection switch feature will be changed.

Action method

For applications that specify a target server as the application connection switch feature, change the target server according to the table below, recompile, and then execute using a client of Fujitsu Enterprise Postgres 15 or later.

Table 3.1 Specified name of the target server.

Target of use	Before modification	After modification
Leverage .NET Data Provider	TargetServerType	TargetSessionAttributes

3.2.4 Changes in ecpg/ecobpg Handling of Zero-Length Unicode Identifiers

Incompatible

In Fujitsu Enterprise Postgres 15, if the SQL statement contains a zero-length Unicode identifier, Change precompilation to fail.

Action method

None.

3.2.5 Changing the display result when data masking is applied to NaN, infinity, -infinity

Incompatibility

In FUJITSU Enterprise Postgres 14, the display result when data masking is applied to NaN, infinity, and -infinity will be changed.

FUJITSU Enterprise Postgres 13 SP1 or earlier

If the float type NaN, infinity, and -infinity are partially masking with (9,1,2), the following will be displayed.

```
NaN : 99
Infinity : 99
-Infinity : 99
```

FUJITSU Enterprise Postgres 14 or later

If the float type NaN, infinity, and -infinity are partially masking with (9,1,2), the following will be displayed.

```
NaN : NaN
Infinity : Infinity
-Infinity : -Infinity
```

Action method

If the application is analyzing the SQL masking output result, please consider the non-numeric output result and correct it.

3.2.6 Changing the Valid Range of Identifiers Defined by the DECLARE STATEMENT statement

Incompatibility

In FUJITSU Enterprise Postgres 14 will change the valid range of identifiers defined by a DECLARE STATEMENT statement in ecpg/ecobpg.

FUJITSU Enterprise Postgres 13 SP1 or earlier

The valid range is now per process.

FUJITSU Enterprise Postgres 14 or later

The valid range is now per file.

Action method

None.

3.2.7 Changing Precompile Results

Incompatibility

In FUJITSU Enterprise Postgres 14 removed the ECPGdeclare/ECPGopen function. Therefore, results precompiled from earlier versions of FUJITSU Enterprise Postgres will not be available in FUJITSU Enterprise Postgres 14.

Action method

Rebuild the application.

3.2.8 Changing the Trigger Replacement Process

Incompatibility

In FUJITSU Enterprise Postgres 14 will change restricted triggers to not be supported by replace operations (OR REPLACE).

FUJITSU Enterprise Postgres 13 SP1 or earlier

You can replace a constraint trigger.

[Example]

```
=# CREATE OR REPLACE CONSTRAINT TRIGGER my_constraint_trigger AFTER DELETE ON my_table
-# FOR EACH ROW
-# EXECUTE PROCEDURE funcA();
CREATE TRIGGER
```

FUJITSU Enterprise Postgres 14 or later

It does not support replacing a constraint trigger.

[Example]

```
=# CREATE OR REPLACE CONSTRAINT TRIGGER my_constraint_trigger AFTER DELETE ON my_table
-# FOR EACH ROW
-# EXECUTE PROCEDURE funcA();
ERROR:  CREATE OR REPLACE CONSTRAINT TRIGGER is not supported
```

Action method

None.

3.2.9 Adding a TAP Test Framework

Incompatibility

In FUJITSU Enterprise Postgres 13, the TAP testing framework allows users to create and run TAP tests for their own extensions.

TAP test framework stored in:

```
<FUJITSU Software Enterprise Postgres installation directory>/lib/pgxs/src/test/perl/PostgreSQL/Test
```

Action method

None.

3.2.10 Change the "elif" Statement Behavior in ecobpg

Incompatibility

The "elif" statement now works correctly with FUJITSU Enterprise Postgres 13.

FUJITSU Enterprise Postgres 12 or earlier

The decision of the "elif" statement is made whether or not the "ifdef/ifndef" condition is met.

[Example]

```
000000     EXEC SQL ifdef DEF1 END-EXEC.
000000     Operation (1).
000000     EXEC SQL elif DEF2 END-EXEC.
000000     Operation (2).
```

```
000000     EXEC SQL else END-EXEC.
000000     Operation (3).
```

If "DEF1" and "DEF2" are true, both "Operation (1)" and "Operation (2)" are executed.

FUJITSU Enterprise Postgres 13 or later

If the condition "ifdef/ifndef" is met, the judgment of the "elif" statement is not enforced.

[Example]

```
000000     EXEC SQL ifdef DEF1 END-EXEC.
000000     Operation (1).
000000     EXEC SQL elif DEF2 END-EXEC.
000000     Operation (2).
000000     EXEC SQL else END-EXEC.
000000     Operation (3).
```

If "DEF1" and "DEF2" are true, only "Operation (1)" is executed.

Action method

Check your existing application and fix the elif statement to work correctly.

3.2.11 Changed to Error when Running an Operator or Function that Returns non Data Types for Masking Type

Incompatibility

In FUJITSU Enterprise Postgres 12, changed to error when running an operator or function that returns non Data Types for Masking type.

FUJITSU Enterprise Postgres 11 or earlier

In the following cases, the operator or function in 3) may be executed without masking.

This is an incorrect result because the data containing the masking column is performed without masking.

1) Create a Masking policy. and

2) Execute a SELECT statement. and

3) Execute an operator or function in the SELECT statement of 2). and

4) The operator or function argument of 3) includes a subquery. and

5) The operator or function argument of 3) contains the column to be protected created in 1). and

6) The operator or function of 3) returns a type not listed in "Data Types for Masking" in "Operation Guide".

FUJITSU Enterprise Postgres 12 or later

Operator or function results of 3) in the following error.

```
ERROR:  The output data type is incompatible with the confidential policy.
HINT:  Data type of the result value(s) produced by expression/function using confidential columns
is not supported by Data masking module. Consider removing confidential columns from such
expressions/functions.
```

This is correct because the operator or function returns a data type not listed in "Data Types for Masking" in "Operation Guide".

Action method

Do one of the following to ensure that the results are identical to those of FUJITSU Enterprise Postgres 11 and earlier:

1) Modify the Masking policy to prevent masking from being performed for the user executing the SQL.

2) Modify SQL to not use operators or functions that return types not listed in "Data Types for Masking" in "Operation Guide".

3.2.12 Changing the Method of Specifying the Application Connection Switch Feature

Incompatibility

The target server specified using the application connection switch feature is changed to the same name as that of PostgreSQL.

Action method

Use the FUJITSU Enterprise Postgres 10 or later client to execute applications that have the target server specified as the application connection switch feature after changing the target server and specified value as listed below and recompiling.

Specified name of the target server

Usage target	Before correction	After correction
JDBC driver	No change	
ODBC driver	TargetServer	target_session_attrs
.NET Data Provider	target_server	TargetServerType
Connection service file	target_server	target_session_attrs
Library (libpq) for C	target_server Environment variable (PGXTARGETSERVER)	target_session_attrs Environment variable (PGTARGETSESSIONATTRS)
Embedded SQL	target_server	target_session_attrs
psql	Environment variable (PGXTARGETSERVER)	Environment variable (PGTARGETSESSIONATTRS)

Specified value for the target server

Server selection order	JDBC driver	.NET Data Provider		Other driver	
		Before correction	After correction	Before correction	After correction
Primary server	No change	primary	master	primary	read-write
Standby server	No change	-	slave	-	-
Priority given to a standby server	No change	prefer_standby	preferSlave	prefer_standby	prefer-read
Any	No change	-	any	-	any

3.2.13 Changing the order of servers to be connected by the Application Connection Switch Feature

Incompatibility

Changes the order of the servers to be connected when you use the application connection switch feature.

FUJITSU Enterprise Postgres 9.6 or earlier

On subsequent connections within the same process, the server with the server attributes specified in target_session_attrs will try to connect first.

For example, if you specify host=host1, host2, host3 and target_session_attrs = read-write in a connection string in keyword/value format, and if host2 is the primary server during the first connection attempt, the connection attempts are made to host2, host3, and host1 in that order.

FUJITSU Enterprise Postgres 10 or later

Always attempt connections in the order specified in the connection string.

For example, if you specify host=host1, host2, host3 in a connection string in keyword/value format, connections are always attempted in the following order: host1, host2, host3.

Action method

None.

3.2.14 PostgreSQL Compatibility of Embedded SQL Applications in C and COBOL

Incompatibility

Embedded SQL applications in C and COBOL that were compiled with FUJITSU Enterprise Postgres 9.6 or earlier cannot be used in the FUJITSU Enterprise Postgres 10 client.

Action method

Use the FUJITSU Enterprise Postgres 10 or later client to execute the applications only after recompiling them with the FUJITSU Enterprise Postgres 10 or later client.

3.2.15 Changing Vertical Clustered Index (VCI)

Incompatibility

In FUJITSU Enterprise Postgres 10, the functions below have been added to the functions for which VCI is not used.

Type	Function
Date/time functions	age(timestamp) current_date current_timestamp current_time localtime localtimestamp
Session information functions	current_user current_role

Action method

To use VCI, specify the second argument when using the age function, and specify other functions as subqueries.

[Example]

Before: select age(column A), current_date from table

After: select age(column A, **now()**), **(select current_date)** from table

3.2.16 Changing how to Use the Features Compatible with Oracle Databases

Incompatibility

In FUJITSU Enterprise Postgres 9.6 or later, to use the features compatible with Oracle databases, create a new instance and execute the following command for the "postgres" and "template1" databases:

CREATE EXTENSION oracle_compatible

Action method

None.

3.3 Operation Migration Incompatibility

3.3.1 Deprecation of Some Encryption Algorithms in pgcrypto

Incompatibility

In Fujitsu Enterprise Postgres 15 SP2 and later, the PostgreSQL extension pgcrypto does not support the use of the encryption algorithm, which has become a legacy algorithm in the OpenSSL3 family, by default.

The encryption algorithms that are no longer available by default are:

- BF
- CAST5
- DES-ECB
- DES-CBC
- MD4
- Whirlpool

Action method

If you use a legacy OpenSSL provider, create an OpenSSL configuration file and set the parameters in postgresql.conf. Refer to "Settings for Using Legacy OpenSSL Providers" in the Installation and Setup Guide for Server for information .

3.3.2 Deprecation of Certificates Signed Using SHA1

Incompatibility

In Fujitsu Enterprise Postgres 15 SP2 and later, you cannot connect to a database server using a certificate signed using SHA1.

Action method

Resubmit the certificate used for certificate authentication with SHA2 or higher.

3.3.3 Abolition of Message Numbers

Incompatibility

In Fujitsu Enterprise Postgres 15, the message number output at the end of the message is abolished.

Message numbers are output for messages output by Mirroring Controller.

For FUJITSU Enterprise Postgres 14 SP1 or earlier

The message number was printed at the end of the message.

[example]

```
3D000: 2017-07-10 19:41:05 JST[13899]: [1-1] user=fepuser,db=fep,remote=127.0.0.1(51902)
app=[unknown] FATAL: database "fep" does not exist (10571)
```

For Fujitsu Enterprise Postgres 15

No message number is output at the end of the message.

[example]

```
3D000: 2023-04-10 19:41:05 JST [13899]: [1-1] user = fepuser,db = fep,remote = 127.0.0.1(51902)
app = [unknown] FATAL: database "fep" does not exist
```

Action method

None.

3.3.4 Adding the key_name Column to the View pgx_tde_master_key

Incompatibility

In Fujitsu Enterprise Postgres 15, add a key_name column to the view pgx_tde_master_key.

Action method

None.

3.3.5 Changing the Output of the Status Mode of the cm_ctl Command

Incompatibility

Changes the display of the output of the status mode of the cm_ctl command.

(If it has been modified by the P number PH21029, and you have applied an urgent fix that includes it, FUJITSU Enterprise Postgres 14 will work.)

When the cm_ctl command was executed in status mode, there was omission of the output of the header "pid" displayed in "application_information" which outputs the information of the application.

Correct the following in PH21029.

- Add ':' to 'application_information' to output application information
  Output "application_information:"
- Add the header "pid" output to "application_information"
  Outputs "pid" whose header information is missing.
- Changes the number of digits in the numeric portion of connected_time
  Change the display start position of the date and time connected to the conmgr process to correct the gap between the start position of the header and the numeric part. (5 digits backward)

This fix causes the following incompatibilities when running the cm_ctl command in status mode:

- Add ":" to the display of "application_information"
- Display the header "pid" in "application_information"
- Change the output start position of the "connected_time" header of "application_information"
- Change the start of the date and time output of "connected_time" in "application_information" to 5 digits later.

FUJITSU Enterprise Postgres 13 SP1 or earlier

```
application_information
addr         port  connected_time
10.xxx.x.xx  99999 21655 2021-10-20 09:18:51
```

FUJITSU Enterprise Postgres 14

```
application_information:
addr         port  pid       connected_time
10.xxx.x.xx  99999 21655     2021-10-20 09:18:51
```

When analyzing the output of the cm_ctl command in status mode in a batch or shell script, it may not work correctly if the header is referenced and the third is "connected_time".

For example, when identifying a row of data (numeric part), a string up to the header "addr", "port", and "connected_time" one row before is searched for and identified.

Action method

If you are using a batch or shell script to parse the output of the cm_ctl command in status mode, modify it to take into account the number of digits in the header and numeric part of the output.

3.3.6 Rename column "master_pid" in pgx_loader_state to "leader_pid"

Incompatibility

In FUJITSU Enterprise Postgres 14 renames column "master_pid" to "leader_pid" in the pgx_loade_state table.

Action method

None.

3.3.7 Adding a Message to Output when the Database Server watchdog detects that the Connection Manager is down

Incompatibility

When using the Connection Manager, if the database server watchdog detects that the Connection Manager is down, it will output a message to the database server.

Incompatibilities may occur if:

1) The application server is using the Connection Manager. and

2) The database server is running the watchdog process. and

3) 1) Application server or Connection Manager goes down.

FUJITSU Enterprise Postgres 12, 13, 13SP1, 14, 14SP1, 15

If the database server watchdog detects that the Connection Manager is down, the following message is not output.

```
WARNING:  watchdog: error in heartbeat connection (20331): host=xxx.xxx.xxx.xxx port=xxxxx
pid=xxxxx
```

FUJITSU Enterprise Postgres 12 SP1, 15SP1 or later

If the database server watchdog detects that the Connection Manager is down, the following message may be output.

```
WARNING:  watchdog: error in heartbeat connection (20331): host=xxx.xxx.xxx.xxx port=xxxxx
pid=xxxxx
```

Action method

If you are monitoring the database log for watchdog messages, change the monitoring setting to one that takes into account the possible output of these messages.

3.3.8 Change the Error Information when the Connection Manager re-executes SQL on the Failed Connection

Incompatibility

In FUJITSU Enterprise Postgres 12 SP1 allows an application using the Connection Manager to change the error information when attempting to execute SQL again on a connection that the Connection Manager has determined to be in error due to a database error.

The changed error information is included in the error presented in "Errors when an Application Connection Switch Occurs and Corresponding Actions" for each client driver in "Application Development Guide".

Incompatibilities may occur if the following conditions are met:

1) The application uses one of the following drivers. and

-libpq (C Library)

-ECPG (Embedded SQL in C)

2) You are using the Connection Manager. and

3) The database server to which the application in 1) was connected goes down. and

4) The Connection Manager notifies the application in 1) of an error when the database is down in 3). and

5) The application in 1) does not disconnect from the database server that is down, but executes SQL using the connection.

FUJITSU Enterprise Postgres 12, 13 or later

The error information returned depends on the actual database server error condition.

FUJITSU Enterprise Postgres 12 SP1

The following error information is returned:

- For libpq (C Library): CONNECTION_BAD (PQstatus () return value)
- For ECPG (Embedded SQL in C): 57P02 (SQLSTATE return value)

Action method

Consider that the above error may be returned during the SQL error determination process.

Also, if you encounter an error about switching application destinations as described in "Errors when an Application Connection Switch Occurs and Corresponding Actions" for each client driver in "Application Development Guide", you should explicitly disconnect and reconnect or rerun the application.

3.3.9 Changing the Value of the Category Column in the pg_settings view

Incompatibility

For FUJITSU Enterprise Postgres 13, change the value of the category column in the pg_settings view.

FUJITSU Enterprise Postgres 12 or earlier

Original value	wrong value
Preset Options	Fujitsu Enterprise Postgres Parameters
Customized Options	Preset Options
Developer Options	Customized Options

This is an incorrect result because it is different from the original value.

FUJITSU Enterprise Postgres 13 or later

The correct value is the category column in the pg_settings view.

Action method

Replaces the category column in the pg_settings view with the values before migration, so that the results are the same as before migration.

3.3.10 Changing pgx_stat_lwlock of the Statistics View

Incompatibility

In FUJITSU Enterprise Postgres 13, change the wait event name displayed in the lwlock_name column of the statistics view pgx_stat_lwlock.

Wait Event Name

FUJITSU Enterprise Postgres 12 or earlier	FUJITSU Enterprise Postgres 13
clog (*1)	XactBuffer
commit_timestamp (*1)	CommitTSBuffer
subtrans (*1)	SubtransBuffer
multixact_offset (*1)	MultiXactOffsetBuffer
multixact_member (*1)	MultiXactMemberBuffer
async (*1)	NotifyBuffer
oldserxid (*1)	SerialBuffer
wal_insert (*1)	WALInsert
buffer_content (*1)	BufferContent
buffer_io (*1)	BufferIO
replication_origin (*1)	ReplicationOriginState
replication_slot_io (*1)	ReplicationSlotIO
proc (*1)	LockFastPath
buffer_mapping (*1)	BufferMapping
lock_manager (*1)	LockManager
predicate_lock_manager (*1)	PredicateLockManager
parallel_hash_join (*3)	ParallelHashJoin
parallel_query_dsa (*2)	ParallelQueryDSA
session_dsa (*3)	PerSessionDSA
session_record_table (*3)	PerSessionRecordType
session_typmod_table (*3)	PerSessionRecordTypmod
shared_tuplestore (*3)	SharedTupleStore
tbm (*2)	SharedTidBitmap
parallel_append (*3)	ParallelAppend
serializable_xact (*4)	PerXactPredicateList
shared_mcxt (*4)	SharedMcxt
meta_cache_map (*4)	MetaCacheMap
global_metacache (*4)	GlobalCatcache
cached_buf_tranche_id (*4)	CachedBufTranche

*1）Events added in FUJITSU Enterprise Postgres 9.6.

*2）Events added in FUJITSU Enterprise Postgres 10.

*3) Events added in FUJITSU Enterprise Postgres 11.

*4) Events added in FUJITSU Enterprise Postgres 12.

Action method

None.

3.3.11 Changing the Behavior of pgx_rcvall

Incompatibility

In FUJITSU Enterprise Postgres 13, change the pgx_rcvall command to fail if the -e option of the pgx_rcvall command specifies a future time or if the -n option specifies a list appointment that does not exist.

FUJITSU Enterprise Postgres 12 or earlier

All archived WALs are applied for recovery if the -e option of the pgx_rcvall command specifies a time in the future, or if the -n option specifies a list appointment that does not exist.

FUJITSU Enterprise Postgres 13 or later

The pgx_rcvall command fails if the -e option of the pgx_rcvall command specifies a time in the future, or if the -n option specifies a list appointment that does not exist.

Action method

Specify recovery objectives correctly, if necessary.

3.3.12 Mirroring Controller no Longer Retries to Monitor Database Processes when they are Detected as Down

Incompatibility

For the FUJITSU Enterprise Postgres 12 Mirroring Controller, change the heartbeat monitoring of the database process so that it does not retry monitoring when it detects down.

Action method

None.

3.3.13 Changing the Name and Parameter Name of the Mirroring Controller Post-Promote Command

Incompatibility

In the FUJITSU Enterprise Postgres 12 Mirroring Controller, change the name of the post-promote command, which is the state transition command, and the parameter name in the server configuration file that specifies the post-promote command.

FUJITSU Enterprise Postgres 11 or earlier

- Command Name

  post-promote command

- The parameter name in the server configuration file that specifies the post-promote command

  post_promote_command

FUJITSU Enterprise Postgres 12 or later

- Command Name

  post-switch command

- The parameter name in the server configuration file that specifies the post-promote command

  post_switch_command

Action method

The post_promote_command parameter in the server configuration file continues to be available in FUJITSU Enterprise Postgres 12 or later.If specified in the server configuration file, it acts as a post-switch command.You cannot specify the post_promote_command and post_switch_command parameters at the same time.

3.3.14 Changing Mirroring Controller User Command Input Values

Incompatibility

In FUJITSU Enterprise Postgres 12, arguments (Fixed value: primarycenter) have been added to the following user commands:

- Fencing command of the database server
- Arbitration command
- Post-switch command
- Pre-detach command
- Post-attach command

Action method

If you are checking the number of arguments in a user command, increase the number of arguments by one.

3.3.15 Changing the Maximum Number of Connections per Server

Incompatibility

In FUJITSU Enterprise Postgres 10, the maximum number of connections per server is changed from 262,143 to 65,535.

Action method

None.

3.3.16 Changing the Encryption Settings Using the ALTER TABLESPACE Statement

Incompatibility

In FUJITSU Enterprise Postgres 10, the ALTER TABLESPACE statement can be used to change the tablespace encryption settings if data is not stored in the tablespace.

Action method

None.

3.3.17 Changing the Default Configuration of the Cluster System Using Database Multiplexing

Incompatibility

In FUJITSU Enterprise Postgres 10, a split brain will not occur if heartbeat monitoring using an admin network times out, so the default is changed to a system configuration requiring an arbitration server acting as a third party.

FUJITSU Enterprise Postgres 9.6 or earlier

A cluster system comprises two database servers.

FUJITSU Enterprise Postgres 10 or later

By default, a cluster system comprises two database servers and an arbitration server.

Action method

If selecting the same system configuration as that in FUJITSU Enterprise Postgres 9.6 or earlier, set the parameters below in the server configuration file to perform automatic degradation unconditionally when a heartbeat abnormality is detected during OS/server heartbeat monitoring.

- Parameter: heartbeat_error_action
- Value: fallback

3.3.18 Changing the Default Operation when mc_ctl Command Options are Omitted

Incompatibility

In FUJITSU Enterprise Postgres 10, the default operation when the mc_ctl command options below are omitted has been changed:

- The -f option during start mode
- The -w option during start mode

FUJITSU Enterprise Postgres 9.6 or earlier

- If the -f option is omitted, automatic switching and disconnection immediately after the startup of Mirroring Controller will not be enabled.
- If the -w option is omitted, the system will not wait for operations to finish.

FUJITSU Enterprise Postgres 10 or later

- Even if the -f option is omitted, automatic switching and disconnection immediately after the startup of Mirroring Controller will be enabled.
- Even if the -w option is omitted, the system will wait for operations to finish.

Action method

If selecting the same operation as that in FUJITSU Enterprise Postgres 9.6 or earlier, take the action below when executing start mode of the mc_ctl command.

- If the -f option is omitted, specify the -F option.
- If the -w option is omitted, specify the -W option.

3.3.19 Changing the Connection Settings when Mirroring Controller Connects to an Instance

Incompatibility

In FUJITSU Enterprise Postgres 10, Mirroring Controller changes the connection setting below when connecting to an instance to detect failure of each database element.

- Application name

FUJITSU Enterprise Postgres 9.6 or earlier

- The application name is an empty string.

FUJITSU Enterprise Postgres 10 or later

- The application name is 'mc_agent'.

Action method

There is no method for changing the application name.

Therefore, if there is an application that identifies a database connection session of Mirroring Controller with the application name being an empty string, modify the process so that identification is performed using 'mc_agent'.

3.3.20 Changing the Status Display of the Mirroring Controller Server

Incompatibility

In FUJITSU Enterprise Postgres 10, the condition for displaying an abnormality for the process (WAL receive process) that receives transaction logs has been changed in regard to the server status display performed in status mode of the mc_ctl command of Mirroring Controller.

- Role of the applicable server (host_role): standby (standby)
- Display item: DBMS process status (db_proc_status)
- Display content: abnormal (abnormal process name)
  The applicability for incompatibility is determined based on whether 'wal_receiver' is included in the abnormality process name.

FUJITSU Enterprise Postgres 9.6 or earlier

Displays an abnormality when Mirroring Controller detects that the WAL send process has stopped.

FUJITSU Enterprise Postgres 10 or later

Displays an abnormality when Mirroring Controller detects that a streaming replication connection has not been established with the primary server using the WAL receive process.

Action method

If there is an application that determines the WAL receive process status from the display content retrieved using status mode of the mc_ctl command, modify as below to determine at the same level of accuracy as previously. However, this is not recommended due to incompatibilities accompanying the improvement in accuracy.

- If 'wal_sender' is included in the abnormal process name displayed in the 'abnormal' db_proc_status item of the 'primary' host_role, it is determined that an abnormality has occurred in the WAL receive process.
- If 'wal_sender' is not included in the abnormal process name displayed in the 'abnormal' db_proc_status item of the 'primary' host_role, it is determined that an abnormality has not occurred in the WAL receive process.

3.3.21 Changing the Operation when the synchronous_standby_names Parameter is Changed during Database Multiplexing Operation

Incompatibility

In FUJITSU Enterprise Postgres 9.6 or earlier, Mirroring Controller periodically accesses the database to retrieve the synchronous_standby_names parameter value using the SHOW command, and automatically recovers if changes are detected, in case the user accidentally changes the synchronous_standby_names parameter in postgresql.conf during database multiplexing mode. However, because this process uses the CPU of the database server for redundancy and SQL statements are executed with high frequency, these processes are not executed by default in FUJITSU Enterprise Postgres 10.

FUJITSU Enterprise Postgres 9.6 or earlier

Mirroring Controller checks if the synchronous_standby_names parameter in postgresql.conf has been mistakenly changed by the user.

FUJITSU Enterprise Postgres 10 or later

By default, Mirroring Controller does not check if the synchronous_standby_names parameter in postgresql.conf has been mistakenly changed by the user.

Action method

If selecting the same operation as that in FUJITSU Enterprise Postgres 9.6 or earlier, set the parameter below in the server definition file.

- Parameter: check_synchronous_standby_names_validation
- Value: 'on'

3.3.22 Changing Masking Policy Definition for Unsupported Data Types

Incompatibility

The data masking feature of FUJITSU Enterprise Postgres is updated so that an error occurs when a masking policy is defined for a column of an unsupported data type (array type or timestamp with timezone type).

FUJITSU Enterprise Postgres 9.5

The definition of a masking policy for a column of array type or timestamp with timezone type ends normally, but an error occurs when accessing a column of a table for which the policy is defined.

FUJITSU Enterprise Postgres 9.6 or later

An error occurs when defining a masking policy for a column of array type or timestamp with timezone type.

Action method

If a policy that was defined in FUJITSU Enterprise Postgres 9.5 includes masking of a column of an unsupported data type (array type or timestamp with timezone type), perform one of the following in FUJITSU Enterprise Postgres 9.6 or later:

- Ignore the error if the masking policy contains columns of only these data types, or delete the policy with the pgx_drop_confidential_policy system administration function.
- If the masking policy target contains columns of these data types and a supported data type, delete the problematic columns with the pgx_alter_confidential_policy system function.

3.4 JDBC Driver Incompatibility

3.4.1 Changing the targetServerType Value

Incompatibility

In FUJITSU Enterprise Postgres 13, the value of targetServerType specified in the connection string was changed. Therefore, the previously used values are no longer available.

Action method

If you specified a value for targetServerType, change the value as follows:

Table 3.2 Specified values for the target server

Server Selection Order	FUJITSU Enterprise Postgres 12 or earlier	FUJITSU Enterprise Postgres 13
Primary Server	master	primary
Standby Server	slave	secondary
Prefer Standby Server	preferSlave	preferSecondary
Any	any	any

3.4.2 Changing the Statement Cache Limit Setting Method

Incompatibility

FUJITSU Enterprise Postgres 9.6 changes the way the statement cache cap is set.

FUJITSU Enterprise Postgres 9.5 or earlier

The maxStatements parameter of the connection string or the setMaxStatements method.

FUJITSU Enterprise Postgres 9.6 or later

Specified in the connection string or property by the preparedStatementCacheQueries and preparedStatementCacheSizeMiB parameters.

Action method

None.

3.5 ODBC Driver Incompatibility

3.5.1 Cannot specify prefer-read for target_session_attrs

Incompatibility

FUJITSU Enterprise Postgres 14 users will not see the "prefer-read" radio button in the "Target_Session_Attrs" item of the data source option selection screen.

Action method

Select prefer-standby.

3.6 .NET Data Provider Incompatibility (Information for Using Npgsql 10 or Later)

There is no incompatibility.

See

When migrating from Fujitsu Enterprise Postgres 18 or earlier, also refer to "3.8 .NET Data Provider Incompatibility (Information for Fujitsu Enterprise Postgres 18 and Earlier)".

3.7 .NET Data Provider Incompatibility (Information for using Npgsql 8 with Fujitsu Enterprise Postgres 18 SP1 or Later)

3.7.1 Npgsql NuGet Package Name and Version Change

Incompatibility

In Fujitsu Enterprise Postgres 18 SP1, the Npgsql NuGet package names will be changed as follows, and the package versions will be updated from 17.0.0 to 18.0.0.

Fujitsu Enterprise Postgres 18

```
Npgsql.17.0.0.nupkg
Npgsql.DependencyInjection.17.0.0.nupkg
Npgsql.GeoJSON.17.0.0.nupkg
Npgsql.Json.NET.17.0.0.nupkg
Npgsql.NetTopology.17.0.0.nupkg
Npgsql.NodaTime.17.0.0.nupkg
Npgsql.OpenTelemetry.17.0.0.nupkg
```

Fujitsu Enterprise Postgres 18 SP1

```
Npgsql.18.0.0.nupkg
Npgsql.DependencyInjection.18.0.0.nupkg
Npgsql.GeoJSON.18.0.0.nupkg
Npgsql.Json.NET.18.0.0.nupkg
Npgsql.NetTopology.18.0.0.nupkg
Npgsql.NodaTime.18.0.0.nupkg
Npgsql.OpenTelemetry.18.0.0.nupkg
```

Action method

Update or reinstall the package, then rebuild the application.

See

When migrating from Fujitsu Enterprise Postgres 18 or earlier, also refer to "3.8 .NET Data Provider Incompatibility (Information for Fujitsu Enterprise Postgres 18 and Earlier)".

3.8 .NET Data Provider Incompatibility (Information for Fujitsu Enterprise Postgres 18 and Earlier)

3.8.1 .NET Application Development and Operating Environment Changes

Incompatibility

In Fujitsu Enterprise Postgres 17 or later, the following .NET have been removed from the environment required to develop and run .NET applications:

- .NET 6.0
- .NET 7.0

Action method

None.

3.8.2 Changing the Specification Method and Specified Values for the Application Connection Switch Feature

Incompatibility

In Fujitsu Enterprise Postgres 15, the name of the "target server" specified by the connection switching function will be changed from "TargetServerType" to "TargetSessionAttributes", and the specified value will also be changed.

Action method

If the target server is specified, change the target server and specified value as follows.

Table 3.3 How to specify the connection destination switching function of the application and the specified value

Fujitsu Enterprise Postgres version		FUJITSU Enterprise Postgres 9.6 or earlier	FUJITSU Enterprise Postgres 10/11/12	FUJITSU Enterprise Postgres 13/14	Fujitsu Enterprise Postgres 15
Keywords to specify in the connection string		target_server	TargetServerType	TargetServerType	TargetSessionAttributes
Server selection order	Primary Server	primary(*1)	master(*1)	primary(*1)	read-write(*1) primary(*2)
	Standby Server	-	slave(*2)	standby(*2)	standby read-only(*2)
	Prefer Primary Server	-	-	-	prefer-primary
	Prefer Standby Server	prefer_standby	preferSlave	preferStandby	prefer-standby
	Any	-	any	any	any

*1: A primary server whose default transaction mode is read-only are not selected.

*2: A primary server whose default transaction mode is read-only is also selected.

3.8.3 Changing the Behavior of the Application Connection Switch Feature

Incompatibility

In Fujitsu Enterprise Postgres 15, when only one Host keyword is specified in the connection string, if a target server other than Any is specified, an exception will occur.

FUJITSU Enterprise Postgres 14 SP1 earlier

For example, if the connection string specifies "Host=host1, TargetServerType=primary", it will connect to host1 if host1 is the appropriate connection target.

Fujitsu Enterprise Postgres 15

For example, if "Host=host1, TargetSessionAttributes=primary" is specified in the connection string, an exception will always occur because the target server other than Any is specified for the specification of only one host information.

Action method

None.

3.8.4 Behavior Change when Multiple Host Information is Specified in the Connection String

Incompatibility

In Fujitsu Enterprise Postgres 15, when multiple hosts are specified in the connection string, even if one of them has an empty string specified, if another connectable connection destination is specified, that connection destination will be connected. In the old version, if there was even one host with an empty string, an exception would occur at that point.

FUJITSU Enterprise Postgres 14 SP1 earlier

For example, if "Host = host1," is specified in the connection string, an exception will always occur because the second host information is an empty string.

Fujitsu Enterprise Postgres 15

For example, if the connection string specifies "Host = host1," and if host1 is reachable, it will connect to host1 without throwing an exception.

Action method

None.

3.8.5 Changing the TargetServerType Value

Incompatibility

In FUJITSU Enterprise Postgres 13, the value of TargetServerType specified in the connection string was changed. Therefore, the previously used values are no longer available.

Action method

If you specified a value for TargetServerType, change the value as follows:

Table 3.4 Specified values for the target server

Server Selection Order	FUJITSU Enterprise Postgres 9.6 or earlier	FUJITSU Enterprise Postgres 10/11/12	FUJITSU Enterprise Postgres 13
Primary Server	primary	master	primary
Standby Server	-	slave	standby
Prefer Standby Server	prefer_standby	preferSlave	preferStandby
Any	-	any	any

3.8.6 Changing the Server Explorer View in Visual Studio Integration with .NET Data Provider

Incompatibility

FUJITSU Enterprise Postgres 10 or later, the following changes occur when you view database resources in Server Explorer.

- "Schema Name.Table Name" display under the Tables folder.
- The Indexes folder is not displayed.
- The Triggers folder does not displayed.
- The Sequences folder is not displayed.
- The Procedures folder does not displayed.

Action method

None.

3.9 C Library (libpq) Migration Incompatibility

3.9.1 Changing when "prefer-read" is Specified for the target_session_attrs Parameter

Incompatibility

In FUJITSU Enterprise Postgres 14 changes the attach server priority if any of the following servers are specified simultaneously with "prefer-read" as the target_session_attrs parameter:

- Primary server (default_transaction_read_only = ON)
- Standby server

FUJITSU Enterprise Postgres 13 SP1 or earlier

The primary server (default_transaction_read_only = ON) and standby servers have the same priority.

FUJITSU Enterprise Postgres 14 or later

Standby servers connect in preference to primary servers (default_transaction_read_only = ON).

Action method

None.

3.10 oracle_fdw Incompatibility

3.10.1 Changing the Oracle Client Version

Incompatibility

FUJITSU Enterprise Postgres 12 change the version of the Oracle client used to build oracle_fdw to 11.2.

Action method

Use Oracle client version 11.2 or later.

Also,if a file named libclntsh.so.11.1 does not exist in OCI library, create a symbolic link named libclntsh.so.11.1.

3.11 pg_statsinfo Incompatibility

3.11.1 Changing Simple Report Items

Incompatibility

In Fujitsu Enterprise Postgres 17, the following items have been removed from the BGWriter Statistics items output by the simple report function.

- Written Buffers By Backend (Average)
- Written Buffers By Backend (Maximum)
- Backend Executed fsync (Average)
- Backend Executed fsync (Maximum)

Action method

None.

3.11.2 Change the Contents of the bgwriter Table in the statsrepo Schema

Incompatibility

In Fujitsu Enterprise Postgres 17, remove buffers_backend and buffers_backend_fsync from the columns in the bgwriter table in the statsrepo schema.

Action method

None.

3.11.3 Rename Columns in statement Table in statsrepo Schema

Incompatibility

In Fujitsu Enterprise Postgres 17, rename the blk_read_time column to shared_blk_read_time and the blk_write_time column to shared_blk_write_time in the statement table of the statsrepo schema.

Action method

None.

3.11.4 Change the Default Value of the stattarget Column of the column Table in the statsrepo Schema

Incompatibility

In Fujitsu Enterprise Postgres 17, change the default value of the ststtarget column of the column table in the statsrepo schema from "-1" to "NULL".

Action method

None.

3.12 pgaudit Incompatibility

3.12.1 Repairing Unwanted Output in the Audit Log

Incompatibility

In Fujitsu Enterprise Postgres 16, we changed the audit log so that it no longer contains unwanted information at the end.

Fujitsu Enterprise Postgres 15 SP2 or earlier

Some audit logs contain unwanted content at the end.

[Example]

```
Input: INSERT INTO trig_test VALUES ('new value');
Part of the audit log: NOTICE:  AUDIT: SESSION,WRITE,,[local],,pg_regress/class,,baz,,
11,2,INSERT,,TABLE,public.trig_audit,,"INSERT INTO trig_audit SELECT 'I', now(), user, NULL,
NEW.*","(""new value"")  trig_audit AFTER ROW INSERT 16484 trig_test trig_test public 0  f"
```

Fujitsu Enterprise Postgres 16

Prevent unwanted from being output to the audit log.

[Example]

```
Input: INSERT INTO trig_test VALUES ('new value');
Part of the audit log: NOTICE:  AUDIT: SESSION,WRITE,,[local],,pg_regress/class,,baz,,
11,2,INSERT,,TABLE,public.trig_audit,,"INSERT INTO trig_audit SELECT 'I', now(), user, NULL,
NEW.*","(""new value"")"
```

Action method

None.

3.12.2 Changing to Output Extra NEW and OLD Values in the Audit Log when the Trigger Function Executes

Incompatibility

In FUJITSU Enterprise Postgres 13, the trigger function additionally outputs NEW and OLD values to the audit log when the pgaudit.log_parameter is set to on.

FUJITSU Enterprise Postgres 12 or earlier

The following (18) does not output the values of NEW, OLD.

[Example]

```
AUDIT: SESSION,WRITE,2020-09-03 07:07:39 UTC,
        (1)    (2)   (3)
[local],9775,psql,k5user,postgres,3/536, 1, 2, INSERT, ,
(4)     (5)  (6)  (7)    (8)      (9)   (10)(11)(12)(13)
TABLE,public.trig_audit, ,
(14)  (15)    (16)
 "INSERT INTO trig_audit SELECT 'U', now(), user, OLD.*, NEW.*",
(17)
trig_audit AFTER ROW UPDATE 92027 trig_test trig_test public 0  f aaaa
(18)
```

FUJITSU Enterprise Postgres 13 or later

NEW, OLD values are output.

[Example]

```
AUDIT: SESSION,WRITE,2020-09-03 07:07:39 UTC,
[local],9775,psql,k5user,postgres,3/536,1,2,INSERT,,TABLE,public.
trig_audit,,
"INSERT INTO trig_audit SELECT 'U', now(), user, OLD.*, NEW.*",
(bbb) (aaa) trig_audit AFTER ROW UPDATE 92027 trig_test trig_test
public 0  f aaaa
```

Action method

If you are using an application that works by monitoring the string that the trigger function output to the audit log, modify the application to work with the NEW and OLD values.

3.13 pg_dbms_stats Incompatibility

3.13.1 Change in Execution Plan due to Fixed Height of Btree index

Incompatibility

Fixing statistics with the following features may change the execution plan because the height of the Btree index is now fixed as well:

- dbms_stats.lock_*
- dbms_stats.restore_*
- dbms_stats.import_*

Action method

If you want to run compatibility with Fujitsu Enterprise Postgres 15 SP2 and earlier, configure the following:

- pg_dbms_stats.use_tree_height
- pg_dbms_stats.lock_tree_height

3.13.2 Incompatibility of Import Features with Fixed Height of Btree index

Incompatibility

Statistics exported by the export function in pg_dbms_stats prior to Fujitsu Enterprise Postgres 15 SP2 cannot be imported using the legacy import function.

Action method

When importing statistics exported by the export function in pg_dbms_stats prior to Fujitsu Enterprise Postgres 15 SP2, use a function with the suffix "_no_tree_height" appended to its name.

3.14 orafce Incompatibility

3.14.1 Interface changes due to enhancements to the DBMS_SQL package

Incompatibility

In Fujitsu Enterprise Postgres 17, includes enhancements to the DBMS_SQL package. The I/O interfaces of some functions have changed accordingly.

Refer to "Compatibility with Oracle Databases" in Application Development Guide.

Action method

If you are using the DBMS_SQL package, you will need to switch to the same procedures as Fujitsu Enterprise Postgres 16 SP1 or earlier for Oracle database compatibility enhancements, or modify your application.

Refer to "Compatibility with Oracle Databases" in Application Development Guide.

3.15 psycopg Incompatibility

3.15.1 Python Version Changes Required When Using psycopg

Incompatibility

In Fujitsu Enterprise Postgres 18 or later, the following Python required for using psycopg on Windows have been removed from the Python distribution.

- Python version 3.9
- Python version 3.10

Action method

None.

3.16 WebAdmin Incompatibility

3.16.1 Added SNI hostname verification functionality

Incompatibility

We now enforce validation that the SNI hostname matches the SSLHostConfig in the HTTP Host header.

Action method

Configure the SNI hostname to match the SSLHostConfig in the HTTP Host header.

3.16.2 Linux server behavior changes for login authentication

Incompatibility

In Fujitsu Enterprise Postgres 16 SP1, the security policy for accounts in the OS is now also in effect upon login authentication from WebAdmin.

As a result, the following events may occur:

- If the number of authentication failures exceeds the login failure limit, the OS account is also locked.

Action method

If your account is locked due to an authentication failure, ask your system administrator to unlock it.

To check whether a login failure occurred in WebAdmin, see the WebAdmin log in the following folder, and check whether a log containing "password is incorrect" was output.

/opt/fsepv<x>webadmin/log

3.16.3 Changing the default value of the item 'Number of digits for floating values' which is set in the section 'SQL options'

Incompatibility

In Fujitsu Enterprise Postgres 16, the default value of the item 'Number of digits for floating values' which is set in the section 'SQL options' in the view 'PostgreSQL configuration' is changed in order to match the default value of PostgreSQL.

Fujitsu Enterprise Postgres 15 SP2 or earlier

0

Fujitsu Enterprise Postgres 16 or later

1

Action method

Change the value of the item 'Number of digits for floating values', if necessary.

3.16.4 Cannot specify prefer-read for target_session_attrs

Incompatibility

FUJITSU Enterprise Postgres 14 will no longer allow prefer-read to target_session_attrs as a connection method to an upstream server that is specified when creating an instance of a standby server.

Action method

Specify prefer-standby.

3.17 Connection Manager Incompatibility

3.17.1 Behavior change when "read-write" is specified for the target_session_attrs parameter

Incompatibility

FUJITSU Enterprise Postgres 13 SP1 or earlier

May be connected to primary server (default_transaction_read_only = ON).

FUJITSU Enterprise Postgres 14 or later

It is not connected to the primary server (default_transaction_read_only = ON).

Action method

For FUJITSU Enterprise Postgres 13 SP1 and earlier, specify "primary" for the target_session_attrs parameter.

3.18 Confidentiality Management Incompatibility

3.18.1 Changes due to Changes in the pg_dump Specification

Incompatibility

If you are using multiple non-superuser sensitivity confidentiality management role to manage the sensitivity matrix, run the product-provided policy configuration script to define a row-level security feature policy on the table provided by the sensitivity support feature to make the sensitivity management roles independent of each other.

In Fujitsu Enterprise Postgres 15 SP2 or earlier, the effects of this script could be retained and backed up by pg_dump, but as of Fujitsu Enterprise Postgres 16, policy settings can no longer be backed up.

Action method

In Fujitsu Enterprise Postgres 16 or later, if you are managing a sensitivity matrix using more than one confidentiality management role other than superuser, then immediately after restoring a clear-text dump file using pg_dump, run the following command as superuser to reapply the confidentiality management feature policy:

```
psql -f ${install_dir}/share/extension/pgx_confidential_management_support_policy.sql
```

3.18.2 Changing Permission Settings by Changing the CREATEROLE Permission

Incompatibility

In Fujitsu Enterprise Postgres 16, if you want to use a non-superuser role as a confidentiality management role, you may need to set additional permissions for the confidentiality management role.

Action method

The confidentiality management role must already have the privileges it expects to operate on, other than the CREATEROLE privilege.

[Example]

If the confidentiality management role "manager_role" is also going to work with CREATEDB privileges, it will also set CREATEDB privileges when the role is created, like this:

```
CREATE ROLE manager_role LOGIN CREATEROLE CREATEDB;
```

If the required permissions are not set, the sensitivity management API terminates abnormally with a message similar to the following:

```
ERROR:  permission denied to create role
DETAIL:  Only roles with the CREATEDB attribute may create roles with the CREATEDB attribute.
```

3.18.3 Change due to Restriction of CREATEROLE Privilege

Incompatibility

In Fujitsu Enterprise Postgres 16, if you want to use a non-superuser role as a secret management role, the permissions on the roles that can be set in the secret group are different, and the roles that you set in the secret group must be granted ADMIN OPTION permission on the secret confidentiality management role before they can be used.

Action method

Take one of the following actions:

- A role created with the privileges of the confidentiality management role is to be managed in the confidential group. This creates a role that grants only the ADMIN OPTIN privilege to the sensitive confidentiality management role.
- Grant ADMIN OPTION permission on the role to the sensitive management role before setting the managed role to the sensitive group.

[Example]

You want to grant only the ADMIN OPTION privilege for role "user _role1" to the confidentiality management role "manager_role".

```
GRANT user_role1 TO manager_role WITH ADMIN TRUE, INHERIT FALSE, SET FALSE;
```

If the required permissions are not set, the sensitivity management API terminates abnormally with a message similar to the following:

```
ERROR:  permission denied to alter role
DETAIL:  Only roles with the CREATEROLE attribute and the ADMIN option on role "user_role1" may
alter this role.
```

Chapter 4 Program Updates

This version incorporates the following fixes:

- PostgreSQL 18
- PostgreSQL 18.1
- PostgreSQL 18.2
- PostgreSQL 18.3

See

Refer to the PostgreSQL Global Development Group website for information on the updates implemented in the following releases:

[PostgreSQL 18]

```
https://www.postgresql.org/docs/18/release-18.html
```

[PostgreSQL 18.1]

```
https://www.postgresql.org/docs/18/release-18-1.html
```

[PostgreSQL 18.2]

```
https://www.postgresql.org/docs/18/release-18-2.html
```

[PostgreSQL 18.3]

```
https://www.postgresql.org/docs/18/release-18-3.html
```

In addition, issues that occurred in previous versions are also fixed.

Refer to the following for details of the program fixes included in this version and level.

- 4.1 Fujitsu Enterprise Postgres 18 SP1 Program Updates
- 4.2 Fujitsu Enterprise Postgres 18 Program Updates

4.1 Fujitsu Enterprise Postgres 18 SP1 Program Updates

Table 4.1 Fujitsu Enterprise Postgres 18 SP1 Program Updates

P number	Update summary	AE	SE
PH24763	Buffer-related information in pg_stat_statements may sometimes display as 0 even when it is actually non 0.	Y	Y
PH25085	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pgAdmin4 9.9, 9.10, 9.11.	Y	Y
PH25086	Update Fujitsu Enterprise Postgres with bug fixes absorbed by PostgreSQL JDBC Driver 42.7.8.	Y	Y
PH25087	Provides a module to use JIT compilation for LLVM20.	Y	Y
PH25088	Update Fujitsu Enterprise Postgres with bug fixes absorbed by psycopg 3.2.10, 3.2.11, 3.2.12, and 3.2.13, as well as psycopg-pool 3.2.7 and 3.2.8.	Y	Y
PH25089	Update Fujitsu Enterprise Postgres with bug fixes absorbed by Apache AGE 1.6.0.	Y	Y
PH25090	Replace libedit with 3.1-20251016.	Y	Y
PH25091	Replace libxml2 with 2.15.1.	Y	Y
PH25092	Replace libxslt with 1.1.45.	Y	Y

P number	Update summary	AE	SE
PH25098	Update Fujitsu Enterprise Postgres with bug fixes absorbed by PostgreSQL 18.1, 18.2, and 18.3.	Y	Y
PH25110	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pg_repack 1.5.3.	Y	Y
PH25111	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pgBadger 13.2.	Y	Y
PH25119	Update Fujitsu Enterprise Postgres Client with bug fixes absorbed by Npgsql 8.0.8.	Y	Y
PH25125	Propagate defect fixes absorbed up to Apache Tomcat 9.0.115 to WebAdmin in Fujitsu Enterprise Postgres.	Y	Y
PH25129	Update Fujitsu Enterprise Postgres with bug fixes absorbed by orafce 4.14.5, 4.14.6, 4.16,0, 4.16.1, 4.16.2, 4.16.3.	Y	Y
PH25130	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pgBackRest 2.57.0.	Y	Y
PH25131	Update Fujitsu Enterprise Postgres with bug fixes absorbed by ldap2pg 6.5.0, 6.5.1.	Y	Y
PH25132	The version of the NuGet package in the .NET Data Provider does not match the major version of Fujitsu Enterprise Postgres.	Y	Y
PH25133	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pgvectorscale 0.9.0.	Y	Y
PH25134	Update with bug fixes absorbed by psqlodbc-17.00.0007.	Y	Y
PH25135	Update Fujitsu Enterprise Postgres with bug fixes absorbed by Pgpool-II 4.6.4, 4.6.5.	Y	Y
PH25138	Replace OpenSSL with 3.5.5.	Y	Y
PH25140	We provide EntityFrameworkCore.PG compatible with PostgreSQL 10 and PostgreSQL 10.	Y	Y
PH25141	When using audit logs, improper log output or abnormal termination due to a segfault may occur.	Y	-

Y : Fixed
- : Not relevant to this product

4.2 Fujitsu Enterprise Postgres 18 Program Updates

Table 4.2 Fujitsu Enterprise Postgres 18 Program Updates

P number	Update summary	AE	SE
PH24267	Even if a disk failure causing I/O errors occurs in the table space, WAL storage area, or database storage area, switching or disconnecting procedures may not occur.	Y	Y
PH24912	Replace OpenLDAP with 2.6.10.	Y	Y
PH24913	Replace libxml2 with 2.13.9.	Y	Y
PH24914	Replace OpenSSL with 3.5.4.	Y	Y
PH24916	Replace Kerberos with 1.22.1.	Y	Y
PH24917	Replace icu with 77.1.	Y	Y
PH24920	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pgBackRest 2.56.0.	Y	Y
PH24921	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pgAdmin4 9.6, 9.7, 9.8.	Y	Y
PH24922	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pg_bigm 1.2-20250903.	Y	Y
PH24923	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pgvector 0.8.1.	Y	Y
PH24924	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pg_cron 1.6.6, 1.6.7.	Y	Y
PH24926	Fujitsu Enterprise Postgres and the OSS Postgres have different public functions, causing issues for users such as errors during the build of peripheral OSS software.	Y	Y
PH24980	Update security bug fixes absorbed by PostgreSQL18.1 to Fujitsu Enterprise Postgres.	Y	Y

P number	Update summary	AE	SE
	- CVE-2025-12817 - CVE-2025-12818		
PH24985	When using the transparent data encryption feature, errors may occur.	Y	Y

Y : Fixed
- : Not relevant to this product

FUJITSU

Fujitsu Enterprise Postgres 18SP1 for x86

Release Notes

Windows

B1WS-1499-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document provides release information for Fujitsu Enterprise Postgres.

Structure of this document

This document is structured as follows:

Chapter 1 New Features and Improvements

Explains the new features and improvements in this version.

Chapter 2 Compatibility Information (List)

Provides a list of incompatible items when migrating from previous versions.

Chapter 3 Compatibility Information (Details)

Explains incompatibilities and corrective actions to be taken when migrating from previous versions.

Chapter 4 Program Updates

Explains updates incorporated in this version.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Issue date and version

```
Edition 2.0: March 2026
Edition 1.0: December 2025
```

Contents

Chapter 1 New Features and Improvements....1
1.1 Features Added in 18 SP1....1
1.1.1 Operation....1
1.1.1.1 Load Balancing Functionality Enhancement in HA Configuration....1
1.1.2 OSS....1
1.1.2.1 PostgreSQL Rebase....1
1.1.2.2 OSS Updates Provided....1
1.2 Features Added in 18....2
1.2.1 Application Development....2
1.2.1.1 COBOL Performance Improvement....2
1.2.2 Install....2
1.2.2.1 RPM-based Installation....2
1.2.3 OSS....2
1.2.3.1 PostgreSQL Rebase....2
1.2.3.2 OSS Updates Provided....2

Chapter 2 Compatibility Information (List)....4
2.1 If the version before migration is Fujitsu Enterprise Postgres 18....4
2.2 If the version before migration is Fujitsu Enterprise Postgres 17 SP2....4
2.3 If the Version Before Migration is Fujitsu Enterprise Postgres 17 SP1....5
2.4 If the Version Before Migration is Fujitsu Enterprise Postgres 17....5
2.5 If the Version Before Migration is Fujitsu Enterprise Postgres 16 SP1....6
2.6 If the Version Before Migration is Fujitsu Enterprise Postgres 16....7
2.7 If the Version Before Migration is Fujitsu Enterprise Postgres 15....7
2.8 If the Version Before Migration is FUJITSU Enterprise Postgres 14....8
2.9 If the Version Before Migration is FUJITSU Enterprise Postgres 13 SP1....9
2.10 If the Version Before Migration is FUJITSU Enterprise Postgres 13....11
2.11 If the Version Before Migration is FUJITSU Enterprise Postgres 12 SP1....12
2.12 If the Version Before Migration is FUJITSU Enterprise Postgres 12....13
2.13 If the Version Before Migration is FUJITSU Enterprise Postgres 11....15
2.14 If the Version Before Migration is FUJITSU Enterprise Postgres 10....16
2.15 If the Version Before Migration is FUJITSU Enterprise Postgres 9.6....18
2.16 If the Version Before Migration is FUJITSU Enterprise Postgres 9.5....19

Chapter 3 Compatibility Information (Details)....22
3.1 Installation/Setup Incompatibility....22
3.1.1 Perl Version Changes Required When Using PL/Perl....22
3.1.2 Removing Operating System Support for Client Feature....22
3.1.3 Removing Operating System Support for Client Feature....22
3.1.4 Removing Operating System Support for Server Assistant Feature....22
3.1.5 Perl Version Changes Required When Using PL/Perl....22
3.1.6 Tcl Version Changes Required When Using PL/Tcl....23
3.1.7 Removing Operating System Support for Client Feature....23
3.1.8 How max_wal_senders is calculated....23
3.1.9 How max_worker_processes is calculated....23
3.1.10 Removing Operating System Support for Client Feature....23
3.1.11 Removing Operating System Support for Server Feature....24
3.1.12 Removing Operating System Support for Client Feature....24
3.1.13 Removing Operating System Support for Client Feature....24
3.1.14 Removing Operating System Support for Server Feature....24
3.1.15 Changing the Way OSS is Set Up....25
3.1.16 Changing Core and Log File Paths when Instance is Created with WebAdmin....25
3.1.17 Renaming WebAdmin Services....25
3.1.18 Changing the Features Targeted for Installation in a 64-bit Environment....26
3.1.19 Changing the Access Permissions of the Windows Client Installation Folder....26
3.1.20 Changing the WebAdmin Installation Method....26

3.2 Application Migration Incompatibility....26
3.2.1 Output File Change....26
3.2.2 Changing the OID of the Data Type (NCHAR type) that Handles National Characters....27
3.2.3 Changed the Specification Method of the Application Connection Switch Feature....27
3.2.4 Changes in ecpg/ecobpg Handling of Zero-Length Unicode Identifiers....27
3.2.5 Changing the display result when data masking is applied to NaN, infinity, -infinity....27
3.2.6 Changing the Valid Range of Identifiers Defined by the DECLARE STATEMENT statement....28
3.2.7 Changing Precompile Results....28
3.2.8 Changing the Trigger Replacement Process....28
3.2.9 Change the "elif" Statement Behavior in ecobpg....29
3.2.10 Changed to Error when Running an Operator or Function that Returns non Data Types for Masking Type....29
3.2.11 Removing UTL_FILE for Oracle Database Compatibility Features....30
3.2.12 Changing the Method of Specifying the Application Connection Switch Feature....30
3.2.13 Changing the order of servers to be connected by the Application Connection Switch Feature....31
3.2.14 PostgreSQL Compatibility of Embedded SQL Applications in C and COBOL....31
3.2.15 Changing Vertical Clustered Index (VCI)....32
3.2.16 Changing how to Use the Features Compatible with Oracle Databases....32
3.3 Operation Migration Incompatibility....32
3.3.1 Disabling TLS1.0 and TLS1.1 Connections on the Mirroring Controller....32
3.3.2 Disabling Some Elliptic Curve Cryptography Algorithms in the Mirroring Controller....32
3.3.3 Changing the Default Protocol for SSL Connections on the Mirroring Controller....33
3.3.4 Disabling a portion of Root Certificates on the Mirroring Controller....34
3.3.5 Disabling the TLS_ECDH_* Cipher Suite on the Mirroring Controller....34
3.3.6 Deprecation of Some Encryption Algorithms in pgcrypto....34
3.3.7 Deprecation of Certificates Signed Using SHA1....35
3.3.8 Abolition of Message Numbers....35
3.3.9 Rename column "master_pid" in pgx_loader_state to "leader_pid"....35
3.3.10 Changing the Value of the Category Column in the pg_settings view....35
3.3.11 Changing pgx_stat_lwlock of the Statistics View....36
3.3.12 Changing the Behavior of pgx_rcvall....37
3.3.13 Mirroring Controller no Longer Retries to Monitor Database Processes when they are Detected as Down....37
3.3.14 Changing the Name and Parameter Name of the Mirroring Controller Post-Promote Command....38
3.3.15 Changing Mirroring Controller User Command Input Values....38
3.3.16 Changing the Maximum Number of Connections per Server....38
3.3.17 Changing the Encryption Settings Using the ALTER TABLESPACE Statement....39
3.3.18 Changing the Default Configuration of the Cluster System Using Database Multiplexing....39
3.3.19 Changing the Default Operation when mc_ctl Command Options are Omitted....39
3.3.20 Changing the Connection Settings when Mirroring Controller Connects to an Instance....40
3.3.21 Changing the Status Display of the Mirroring Controller Server....40
3.3.22 Changing the Operation when the synchronous_standby_names Parameter is Changed during Database Multiplexing Operation....41
3.3.23 Changing Masking Policy Definition for Unsupported Data Types....41
3.4 JDBC Driver Incompatibility....41
3.4.1 Changing the targetServerType Value....41
3.5 ODBC Driver Incompatibility....42
3.5.1 Cannot specify prefer-read for target_session_attrs....42
3.6 .NET Data Provider Incompatibility (Information for Using Npgsql 10 or Later)....42
3.7 .NET Data Provider Incompatibility (Information for using Npgsql 8 with Fujitsu Enterprise Postgres 18 SP1 or Later)....42
3.7.1 Npgsql NuGet Package Name and Version Change....42
3.8 .NET Data Provider Incompatibility (Information for Fujitsu Enterprise Postgres 18 and Earlier)....43
3.8.1 .NET Application Development and Operating Environment Changes....43
3.8.2 Changing the Specification Method and Specified Values for the Application Connection Switch Feature....43
3.8.3 Changing the Behavior of the Application Connection Switch Feature....44
3.8.4 Behavior Change when Multiple Host Information is Specified in the Connection String....44
3.8.5 Changing the TargetServerType Value....45
3.8.6 Changing the Server Explorer View in Visual Studio Integration with .NET Data Provider....45
3.9 C Library (libpq) Migration Incompatibility....45

3.9.1 Changing when "prefer-read" is Specified for the target_session_attrs Parameter ... 45
3.10 pgaudit Incompatibility ... 46
3.10.1 Repairing Unwanted Output in the Audit Log ... 46
3.10.2 Changing to Output Extra NEW and OLD Values in the Audit Log when the Trigger Function Executes ... 46
3.11 pg_dbms_stats Incompatibility ... 47
3.11.1 Change in Execution Plan due to Fixed Height of Btree index ... 47
3.11.2 Incompatibility of Import Features with Fixed Height of Btree index ... 47
3.12 orafce Incompatibility ... 48
3.12.1 Interface changes due to enhancements to the DBMS_SQL package ... 48
3.13 psycopg Incompatibility ... 48
3.13.1 Python Version Changes Required When Using psycopg ... 48
3.14 WebAdmin Incompatibility ... 48
3.14.1 Added SNI hostname verification functionality ... 48
3.14.2 Changing the TLS Version Limit for HTTPS Connections in WebAdmin ... 48
3.14.3 Changing the default value of the item 'Number of digits for floating values' which is set in the section 'SQL options' ... 49
3.14.4 Cannot specify prefer-read for target_session_attrs ... 49
3.15 Confidentiality Management Incompatibility ... 49
3.15.1 Changes due to Changes in the pg_dump Specification ... 49
3.15.2 Changing Permission Settings by Changing the CREATEROLE Permission ... 49
3.15.3 Change due to Restriction of CREATEROLE Privilege ... 50

Chapter 4 Program Updates ... 51
4.1 Fujitsu Enterprise Postgres 18 SP1 Program Updates ... 51
4.2 Fujitsu Enterprise Postgres 18 Program Updates ... 52

Index ... 53

Chapter 1 New Features and Improvements

This chapter explains Fujitsu Enterprise Postgres new features and improvements added in this version.

Table 1.1 New features and improvements

Version and level	Classification	Feature	Provided in AE	Provided in SE
18 SP1	Operation	Load Balancing Functionality Enhancement in HA Configuration	Y	-
	OSS	PostgreSQL Rebase	Y	Y
		OSS Updates Provided	Y	Y
18	Application Development	COBOL Performance Improvement	Y	Y
	Install	RPM-based Installation	Y	Y
	OSS	PostgreSQL Rebase	Y	Y
		OSS Updates Provided	Y	Y

1.1 Features Added in 18 SP1

This section explains new features and improvements in Fujitsu Enterprise Postgres 18 SP1.

1.1.1 Operation

This section explains the new feature related to Operation.

- Load Balancing Functionality Enhancement in HA Configuration

1.1.1.1 Load Balancing Functionality Enhancement in HA Configuration

Enhances load balancing functionality in HA configurations for Fujitsu Enterprise Postgres. The following Connection Manager features improve overall system stability and operational efficiency:

- Load balancing and read connection redistribution feature
- Initial data synchronization waiting feature for standby servers

See

Refer to "Connection Manager Features" in the Connection Manager User's Guide for details.

1.1.2 OSS

This section explains the new feature related to OSS.

- PostgreSQL Rebase
- OSS Updates Provided

1.1.2.1 PostgreSQL Rebase

The PostgreSQL version that Fujitsu Enterprise Postgres is based on is 18.3.

1.1.2.2 OSS Updates Provided

The OSS provided by Fujitsu Enterprise Postgres has been updated.

See

Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for details.

1.2 Features Added in 18

This section explains new features and improvements in Fujitsu Enterprise Postgres 18.

1.2.1 Application Development

This section explains the new features related to application development.

- COBOL Performance Improvement

1.2.1.1 COBOL Performance Improvement

Caching of host variables in the COBOL precompiler. This function is expected to improve the processing performance of embedded COBOL applications that use host variables.

See

Refer to "Embedded SQL in COBOL" in the Application Development Guide for details.

1.2.2 Install

This section explains the new feature related to install.

- RPM-based Installation

1.2.2.1 RPM-based Installation

You can now install from RPM packages.

See

Refer to Installation and Setup Guide for Client, and Installation and Setup Guide for Server Assistant for details.

1.2.3 OSS

This section explains the new feature related to OSS.

- PostgreSQL Rebase
- OSS Updates Provided

1.2.3.1 PostgreSQL Rebase

The PostgreSQL version that Fujitsu Enterprise Postgres is based on is 18.

1.2.3.2 OSS Updates Provided

The OSS provided by Fujitsu Enterprise Postgres has been updated.

See

Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for details.

Chapter 2 Compatibility Information (List)

Lists incompatible items when migrating from previous versions.

2.1 If the version before migration is Fujitsu Enterprise Postgres 18

Classification	Reference
Installation/Setup	There is no incompatibility.
Application	There is no incompatibility.
Operation	There is no incompatibility.
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	There is no incompatibility.
.NET Data Provider (When using .NET Framework)	3.7.1 Npgsql NuGet Package Name and Version Change
C Library (libpq)	There is no incompatibility.
pgaudit	There is no incompatibility.
pg_dbms_stats	There is no incompatibility.
orafce	There is no incompatibility.
psycopg	There is no incompatibility.
WebAdmin	3.14.1 Added SNI hostname verification functionality
Confidentiality Management	There is no incompatibility.

2.2 If the version before migration is Fujitsu Enterprise Postgres 17 SP2

Classification	Reference
Installation/Setup	3.1.1 Perl Version Changes Required When Using PL/Perl
Application	3.2.1 Output File Change
Operation	There is no incompatibility.
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	There is no incompatibility.
.NET Data Provider (When using .NET Framework)	There is no incompatibility.
C Library (libpq)	There is no incompatibility.
pgaudit	There is no incompatibility.
pg_dbms_stats	There is no incompatibility.
orafce	There is no incompatibility.
psycopg	3.13.1 Python Version Changes Required When Using psycopg

Classification	Reference
WebAdmin	3.14.1 Added SNI hostname verification functionality
Confidentiality Management	There is no incompatibility.

2.3 If the Version Before Migration is Fujitsu Enterprise Postgres 17 SP1

Classification	Reference
Installation/Setup	3.1.1 Perl Version Changes Required When Using PL/Perl
	3.1.2 Removing Operating System Support for Client Feature
Application	3.2.1 Output File Change
Operation	There is no incompatibility.
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	There is no incompatibility.
.NET Data Provider (When using .NET Framework)	There is no incompatibility.
C Library (libpq)	There is no incompatibility.
pgaudit	There is no incompatibility.
pg_dbms_stats	There is no incompatibility.
orafce	There is no incompatibility.
psycopg	3.13.1 Python Version Changes Required When Using psycopg
WebAdmin	3.14.1 Added SNI hostname verification functionality
Confidentiality Management	There is no incompatibility.

2.4 If the Version Before Migration is Fujitsu Enterprise Postgres 17

Classification	Reference
Installation/Setup	3.1.1 Perl Version Changes Required When Using PL/Perl
	3.1.2 Removing Operating System Support for Client Feature
Application	3.2.1 Output File Change
Operation	3.3.1 Disabling TLS1.0 and TLS1.1 Connections on the Mirroring Controller
	3.3.2 Disabling Some Elliptic Curve Cryptography Algorithms in the Mirroring Controller
	3.3.3 Changing the Default Protocol for SSL Connections on the Mirroring Controller
	3.3.4 Disabling a portion of Root Certificates on the Mirroring Controller
	3.3.5 Disabling the TLS_ECDH_* Cipher Suite on the Mirroring Controller
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.

Classification	Reference
.NET Data Provider (When using .NET)	3.8.1 .NET Application Development and Operating Environment Changes
.NET Data Provider (When using .NET Framework)	3.8.1 .NET Application Development and Operating Environment Changes
C Library (libpq)	There is no incompatibility.
pgaudit	There is no incompatibility.
pg_dbms_stats	There is no incompatibility.
orafce	There is no incompatibility.
WebAdmin	3.14.1 Added SNI hostname verification functionality
	3.14.2 Changing the TLS Version Limit for HTTPS Connections in WebAdmin
Confidentiality Management	There is no incompatibility.

2.5 If the Version Before Migration is Fujitsu Enterprise Postgres 16 SP1

Classification	Reference
Installation/Setup	3.1.1 Perl Version Changes Required When Using PL/Perl
	3.1.2 Removing Operating System Support for Client Feature
	3.1.3 Removing Operating System Support for Client Feature
	3.1.4 Removing Operating System Support for Server Assistant Feature
	3.1.5 Perl Version Changes Required When Using PL/Perl
	3.1.6 Tcl Version Changes Required When Using PL/Tcl
Application	3.2.1 Output File Change
Operation	3.3.1 Disabling TLS1.0 and TLS1.1 Connections on the Mirroring Controller
	3.3.2 Disabling Some Elliptic Curve Cryptography Algorithms in the Mirroring Controller
	3.3.3 Changing the Default Protocol for SSL Connections on the Mirroring Controller
	3.3.4 Disabling a portion of Root Certificates on the Mirroring Controller
	3.3.5 Disabling the TLS_ECDH_* Cipher Suite on the Mirroring Controller
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	3.8.1 .NET Application Development and Operating Environment Changes
.NET Data Provider (When using .NET Framework)	3.8.1 .NET Application Development and Operating Environment Changes
C Library (libpq)	There is no incompatibility.
pgaudit	There is no incompatibility.
pg_dbms_stats	There is no incompatibility.
orafce	3.12.1 Interface changes due to enhancements to the DBMS_SQL package
WebAdmin	3.14.1 Added SNI hostname verification functionality
	3.14.2 Changing the TLS Version Limit for HTTPS Connections in WebAdmin

Classification	Reference
Confidentiality Management	There is no incompatibility.

2.6 If the Version Before Migration is Fujitsu Enterprise Postgres 16

Classification	Reference
Installation/Setup	3.1.1 Perl Version Changes Required When Using PL/Perl
	3.1.2 Removing Operating System Support for Client Feature
	3.1.3 Removing Operating System Support for Client Feature
	3.1.4 Removing Operating System Support for Server Assistant Feature
	3.1.5 Perl Version Changes Required When Using PL/Perl
	3.1.6 Tcl Version Changes Required When Using PL/Tcl
Application	3.2.1 Output File Change
Operation	3.3.1 Disabling TLS1.0 and TLS1.1 Connections on the Mirroring Controller
	3.3.2 Disabling Some Elliptic Curve Cryptography Algorithms in the Mirroring Controller
	3.3.3 Changing the Default Protocol for SSL Connections on the Mirroring Controller
	3.3.4 Disabling a portion of Root Certificates on the Mirroring Controller
	3.3.5 Disabling the TLS_ECDH_* Cipher Suite on the Mirroring Controller
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	3.8.1 .NET Application Development and Operating Environment Changes
.NET Data Provider (When using .NET Framework)	3.8.1 .NET Application Development and Operating Environment Changes
C Library (libpq)	There is no incompatibility.
pgaudit	There is no incompatibility.
pg_dbms_stats	There is no incompatibility.
orafce	3.12.1 Interface changes due to enhancements to the DBMS_SQL package
WebAdmin	There is no incompatibility.
Confidentiality Management	There is no incompatibility.

2.7 If the Version Before Migration is Fujitsu Enterprise Postgres 15

Classification	Reference
Installation/Setup	3.1.1 Perl Version Changes Required When Using PL/Perl
	3.1.2 Removing Operating System Support for Client Feature
	3.1.3 Removing Operating System Support for Client Feature
	3.1.4 Removing Operating System Support for Server Assistant Feature

Classification	Reference
	3.1.5 Perl Version Changes Required When Using PL/Perl
	3.1.6 Tcl Version Changes Required When Using PL/Tcl
	3.1.7 Removing Operating System Support for Client Feature
	3.1.8 How max_wal_senders is calculated
	3.1.9 How max_worker_processes is calculated
Application	3.2.1 Output File Change
Operation	3.3.1 Disabling TLS1.0 and TLS1.1 Connections on the Mirroring Controller
	3.3.2 Disabling Some Elliptic Curve Cryptography Algorithms in the Mirroring Controller
	3.3.3 Changing the Default Protocol for SSL Connections on the Mirroring Controller
	3.3.4 Disabling a portion of Root Certificates on the Mirroring Controller
	3.3.5 Disabling the TLS_ECDH_* Cipher Suite on the Mirroring Controller
	3.3.6 Deprecation of Some Encryption Algorithms in pgcrypto
	3.3.7 Deprecation of Certificates Signed Using SHA1
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	3.8.1 .NET Application Development and Operating Environment Changes
.NET Data Provider (When using .NET Framework)	3.8.1 .NET Application Development and Operating Environment Changes
C Library (libpq)	There is no incompatibility.
pgaudit	3.10.1 Repairing Unwanted Output in the Audit Log
pg_dbms_stats	3.11.1 Change in Execution Plan due to Fixed Height of Btree index
	3.11.2 Incompatibility of Import Features with Fixed Height of Btree index
orafce	3.12.1 Interface changes due to enhancements to the DBMS_SQL package
WebAdmin	3.14.3 Changing the default value of the item 'Number of digits for floating values' which is set in the section 'SQL options'
Confidentiality Management	3.15.1 Changes due to Changes in the pg_dump Specification
	3.15.2 Changing Permission Settings by Changing the CREATEROLE Permission
	3.15.3 Change due to Restriction of CREATEROLE Privilege

2.8 If the Version Before Migration is FUJITSU Enterprise Postgres 14

Classification	Reference
Installation/Setup	3.1.1 Perl Version Changes Required When Using PL/Perl
	3.1.2 Removing Operating System Support for Client Feature
	3.1.3 Removing Operating System Support for Client Feature
	3.1.4 Removing Operating System Support for Server Assistant Feature
	3.1.5 Perl Version Changes Required When Using PL/Perl
	3.1.6 Tcl Version Changes Required When Using PL/Tcl

Classification	Reference
	3.1.7 Removing Operating System Support for Client Feature
	3.1.8 How max_wal_senders is calculated
	3.1.9 How max_worker_processes is calculated
Application	3.2.1 Output File Change
	3.2.2 Changing the OID of the Data Type (NCHAR type) that Handles National Characters
	3.2.3 Changed the Specification Method of the Application Connection Switch Feature
	3.2.4 Changes in ecpg/ecobpg Handling of Zero-Length Unicode Identifiers
Operation	3.3.1 Disabling TLS1.0 and TLS1.1 Connections on the Mirroring Controller
	3.3.2 Disabling Some Elliptic Curve Cryptography Algorithms in the Mirroring Controller
	3.3.3 Changing the Default Protocol for SSL Connections on the Mirroring Controller
	3.3.4 Disabling a portion of Root Certificates on the Mirroring Controller
	3.3.5 Disabling the TLS_ECDH_* Cipher Suite on the Mirroring Controller
	3.3.6 Deprecation of Some Encryption Algorithms in pgcrypto
	3.3.7 Deprecation of Certificates Signed Using SHA1
	3.3.8 Abolition of Message Numbers
JDBC Driver	There is no incompatibility.
ODBC Driver	There is no incompatibility.
.NET Data Provider (When using .NET)	3.8.2 Changing the Specification Method and Specified Values for the Application Connection Switch Feature
	3.8.3 Changing the Behavior of the Application Connection Switch Feature
	3.8.4 Behavior Change when Multiple Host Information is Specified in the Connection String
.NET Data Provider (When using .NET Framework)	3.8.2 Changing the Specification Method and Specified Values for the Application Connection Switch Feature
	3.8.3 Changing the Behavior of the Application Connection Switch Feature
	3.8.4 Behavior Change when Multiple Host Information is Specified in the Connection String
C Library (libpq)	There is no incompatibility.
pgaudit	3.10.1 Repairing Unwanted Output in the Audit Log
pg_dbms_stats	3.11.1 Change in Execution Plan due to Fixed Height of Btree index
	3.11.2 Incompatibility of Import Features with Fixed Height of Btree index
orafce	3.12.1 Interface changes due to enhancements to the DBMS_SQL package
WebAdmin	3.14.3 Changing the default value of the item 'Number of digits for floating values' which is set in the section 'SQL options'

2.9 If the Version Before Migration is FUJITSU Enterprise Postgres 13 SP1

Classification	Reference
Installation/Setup	3.1.1 Perl Version Changes Required When Using PL/Perl
	3.1.2 Removing Operating System Support for Client Feature
	3.1.3 Removing Operating System Support for Client Feature

Classification	Reference
	3.1.4 Removing Operating System Support for Server Assistant Feature
	3.1.5 Perl Version Changes Required When Using PL/Perl
	3.1.6 Tcl Version Changes Required When Using PL/Tcl
	3.1.7 Removing Operating System Support for Client Feature
	3.1.8 How max_wal_senders is calculated
	3.1.9 How max_worker_processes is calculated
Application	3.2.1 Output File Change
	3.2.2 Changing the OID of the Data Type (NCHAR type) that Handles National Characters
	3.2.3 Changed the Specification Method of the Application Connection Switch Feature
	3.2.4 Changes in ecpg/ecobpg Handling of Zero-Length Unicode Identifiers
	3.2.5 Changing the display result when data masking is applied to NaN, infinity, -infinity
	3.2.6 Changing the Valid Range of Identifiers Defined by the DECLARE STATEMENT statement
	3.2.7 Changing Precompile Results
	3.2.8 Changing the Trigger Replacement Process
Operation	3.3.1 Disabling TLS1.0 and TLS1.1 Connections on the Mirroring Controller
	3.3.2 Disabling Some Elliptic Curve Cryptography Algorithms in the Mirroring Controller
	3.3.3 Changing the Default Protocol for SSL Connections on the Mirroring Controller
	3.3.4 Disabling a portion of Root Certificates on the Mirroring Controller
	3.3.5 Disabling the TLS_ECDH_* Cipher Suite on the Mirroring Controller
	3.3.6 Deprecation of Some Encryption Algorithms in pgcrypto

	3.8.6 Changing the Server Explorer View in Visual Studio Integration with .NET Data Provider
C Library (libpq)	3.9.1 Changing when "prefer-read" is Specified for the target_session_attrs Parameter
pg_dbms_stats	3.11.1 Change in Execution Plan due to Fixed Height of Btree index
	3.11.2 Incompatibility of Import Features with Fixed Height of Btree index
orafce	3.12.1 Interface changes due to enhancements to the DBMS_SQL package
WebAdmin	3.14.4 Cannot specify prefer-read for target_session_attrs

Chapter 3 Compatibility Information (Details)

This chapter explains incompatible items and actions required when migrating from an earlier version to Fujitsu Enterprise Postgres 18. SP1
Check compatibility before migrating and take the appropriate action.

3.1 Installation/Setup Incompatibility

3.1.1 Perl Version Changes Required When Using PL/Perl

Incompatibility

In Fujitsu Enterprise Postgres 18 or later, change the required Perl version to 5.42.x when using PL/Perl.

Action method

None.

3.1.2 Removing Operating System Support for Client Feature

Incompatibility

In Fujitsu Enterprise Postgres 17 SP2 , the following operating systems have been removed.

- Windows(R) 10

Action method

None.

3.1.3 Removing Operating System Support for Client Feature

Incompatibility

In Fujitsu Enterprise Postgres 17 or later, the following operating systems have been removed.

- RHEL8.5 or earlier
- SLES 15 SP3 or earlier

Action method

None.

3.1.4 Removing Operating System Support for Server Assistant Feature

Incompatibility

In Fujitsu Enterprise Postgres 17 or later, the following operating systems have been removed.

- RHEL8.5 or earlier
- SLES 15 SP3 or earlier

Action method

None.

3.1.5 Perl Version Changes Required When Using PL/Perl

Incompatibility

In Fujitsu Enterprise Postgres 17 or later, change the required Perl version to 5.40.0 when using PL/Perl.

Action method

None.

3.1.6 Tcl Version Changes Required When Using PL/Tcl

Incompatibility

In Fujitsu Enterprise Postgres 17 or later, changes the required Tcl version to 9.0 when using PL/Tcl based on the Python 3 language.

Action method

None.

3.1.7 Removing Operating System Support for Client Feature

Incompatibility

In Fujitsu Enterprise Postgres 16 or later, the following operating systems have been removed.

- RHEL7
- SLES 12

Action method

None.

3.1.8 How max_wal_senders is calculated

Incompatibility

In Fujitsu Enterprise Postgres 16 or later, Fujitsu Enterprise Postgres uses the following values from the value set for the max_wal_senders parameter:

Policy-based password management in a streaming replication environment : Number of direct downstream hot standby servers

Action method

If necessary add a value for the max_wal_senders parameter.

3.1.9 How max_worker_processes is calculated

Incompatibility

In Fujitsu Enterprise Postgres 16 or later, Fujitsu Enterprise Postgres uses the following values from the value set for the max_worker_processes parameter:

Default value to use : 1

Policy-based password management in a streaming replication environment with a hot standby server : 1

Action method

If necessary add a value for the max_worker_processes parameter.

3.1.10 Removing Operating System Support for Client Feature

Incompatibility

In FUJITSU Enterprise Postgres 12 SP1 or later, the following operating systems have been removed.

- Windows Server(R) 2012
- Windows Server(R) 2012 R2

Action method

None.

3.1.11 Removing Operating System Support for Server Feature

Incompatibility

In FUJITSU Enterprise Postgres 12 SP1 or later, the following operating systems have been removed.

- Windows Server(R) 2012
- Windows Server(R) 2012 R2

Action method

None.

3.1.12 Removing Operating System Support for Client Feature

Incompatibility

In FUJITSU Enterprise Postgres 13 or later, the following operating systems have been removed.

- SLES 12 SP4 or earlier

Action method

None.

3.1.13 Removing Operating System Support for Client Feature

Incompatibility

In FUJITSU Enterprise Postgres 12 or later, the following operating systems have been removed.

- Windows(R) 7
- Windows Server(R) 2008
- RHEL6

Also, the 32 bit Linux client can no longer be installed because RHEL 6 has been removed from the operating system.

Action method

None.

3.1.14 Removing Operating System Support for Server Feature

Incompatibility

In FUJITSU Enterprise Postgres 12 or later, the following operating systems have been removed.

- Windows Server(R) 2008

Action method

None.

3.1.15 Changing the Way OSS is Set Up

Incompatibility

FUJITSU Enterprise Postgres 12 or later do not place OSS extension modules in the executable directory. The OSS extension modules must be placed in the executable directory when you set up OSS.

Refer to "Setting Up and Removing OSS" in the Installation and Setup Guide for Server for details.

Action method

None.

3.1.16 Changing Core and Log File Paths when Instance is Created with WebAdmin

Incompatibility

In FUJITSU Enterprise Postgres 12 or later, change the core and log file paths when creating an instance in WebAdmin.

FUJITSU Enterprise Postgres 11 or earlier

Log File Path: *userProfileFolder**localSettingsFolder*\Fujitsu\fsep_*version**instanceNamePortNumber*\log

Core File Path: *userProfileFolder**localSettingsFolder*\Fujitsu\fsep_*version**instanceNamePortNumber*\core

version: product version_edition_architecture

［Example］

Log File Path: C:\Users\naomi\AppData\Local\Fujitsu\fsep_110_AE_64\myinst27599\log

Core File Path: C:\Users\naomi\AppData\Local\Fujitsu\fsep_110_AE_64\myinst27599\core

FUJITSU Enterprise Postgres 12

*userProfileFolder**localSettingsFolder*\Fujitsu\fsep_*version**instanceNamePortNumber*\log

Core File Path: *userProfileFolder**localSettingsFolder*\Fujitsu\fsep_*version**instanceNamePortNumber*\core

version: product version_WA_architecture

［Example］

Log File Path: C:\Users\naomi\AppData\Local\Fujitsu\fsep_120_WA_64\myinst27599\log

Core File Path: C:\Users\naomi\AppData\Local\Fujitsu\fsep_120_WA_64\myinst27599\core

Action method

None.

3.1.17 Renaming WebAdmin Services

Incompatibility

In FUJITSU Enterprise Postgres 12 or later, change the service name registered when you set up WebAdmin.

FUJITSU Enterprise Postgres 11 or earlier

fsep_*x*SP*z*_*edition*_64_WebAdmin_Port1

fsep_*x*SP*z*_*edition*_64_WebAdmin_Port2

FUJITSU Enterprise Postgres 12 or later

fsep_xSPz_WA_64_WebAdmin_Port1

fsep_xSPz_WA_64_WebAdmin_Port2

Action method

None.

3.1.18 Changing the Features Targeted for Installation in a 64-bit Environment

Incompatibility

32 bit Linux client can no longer be installed on RHEL7 in FUJITSU Enterprise Postgres 10 or later.

Note: 32 bit Linux client can install on RHEL6 in FUJITSU Enterprise Postgres 11 or earlier.

Action method

None.

3.1.19 Changing the Access Permissions of the Windows Client Installation Folder

Incompatibility

In FUJITSU Enterprise Postgres 10 or later, when changed for install folder the Windows client from default, the access permissions of the installed files and folder changes to read and execute.

The above changes apply to non-administrators.

This incompatibility occurs with all supported Windows client operating systems. Refer to "Required Operating System" in the Installation and Setup Guide for Client for information on the operating environment.

Action method

This change was made simply to enhance security, therefore, no action is normally required.

However, if existing access permissions are required, this change can be reverted by running *installDir*\setup\revert_cacls.bat as an administrator after installation.

3.1.20 Changing the WebAdmin Installation Method

Incompatibility

In FUJITSU Enterprise Postgres 9.6 or later, WebAdmin is not installed automatically during server installation. Therefore, install WebAdmin separately.

Action method

None.

3.2 Application Migration Incompatibility

3.2.1 Output File Change

Incompatibility

In Fujitsu Enterprise Postgres 18, generates two temporary files during execution of the ecobpg command.

These temporary files are deleted upon successful or abnormal termination of the ecobpg command.

If an issue occurs during ecobpg command execution, these temporary files may remain. In such cases, delete them.

File names are output in the following format:

```
Output_filename.4-digit_random_number.{COB|IPB}.ecw
```

Action method

None.

3.2.2 Changing the OID of the Data Type (NCHAR type) that Handles National Characters

Incompatible

In Fujitsu Enterprise Postgres 15, OIDs for national character data types (NCHAR types) have changed.

Action method

If you are using a national character data type (NCHAR type), recompile the application and run it with Fujitsu Enterprise Postgres 15 or later clients.

3.2.3 Changed the Specification Method of the Application Connection Switch Feature

Incompatible

In Fujitsu Enterprise Postgres 15, the name of the "target server" specified by the application connection switch feature will be changed.

Action method

For applications that specify a target server as the application connection switch feature, change the target server according to the table below, recompile, and then execute using a client of Fujitsu Enterprise Postgres 15 or later.

Table 3.1 Specified name of the target server.

Target of use	Before modification	After modification
Leverage .NET Data Provider	TargetServerType	TargetSessionAttributes

3.2.4 Changes in ecpg/ecobpg Handling of Zero-Length Unicode Identifiers

Incompatible

In Fujitsu Enterprise Postgres 15, if the SQL statement contains a zero-length Unicode identifier, Change precompilation to fail.

Action method

None.

3.2.5 Changing the display result when data masking is applied to NaN, infinity, -infinity

Incompatibility

In FUJITSU Enterprise Postgres 14, the display result when data masking is applied to NaN, infinity, and -infinity will be changed.

FUJITSU Enterprise Postgres 13 SP1 or earlier

If the float type NaN, infinity, and -infinity are partially masking with (9,1,2), the following will be displayed.

```
NaN : 99
Infinity : 99
-Infinity : 99
```

FUJITSU Enterprise Postgres 14 or later

If the float type NaN, infinity, and -infinity are partially masking with (9,1,2), the following will be displayed.

```
NaN : NaN
Infinity : Infinity
-Infinity : -Infinity
```

Action method

If the application is analyzing the SQL masking output result, please consider the non-numeric output result and correct it.

3.2.6 Changing the Valid Range of Identifiers Defined by the DECLARE STATEMENT statement

Incompatibility

In FUJITSU Enterprise Postgres 14 will change the valid range of identifiers defined by a DECLARE STATEMENT statement in ecpg/ecobpg.

FUJITSU Enterprise Postgres 13 SP1 or earlier

The valid range is now per process.

FUJITSU Enterprise Postgres 14 or later

The valid range is now per file.

Action method

None.

3.2.7 Changing Precompile Results

Incompatibility

In FUJITSU Enterprise Postgres 14 removed the ECPGdeclare/ECPGopen function. Therefore, results precompiled from earlier versions of FUJITSU Enterprise Postgres will not be available in FUJITSU Enterprise Postgres 14.

Action method

Rebuild the application.

3.2.8 Changing the Trigger Replacement Process

Incompatibility

In FUJITSU Enterprise Postgres 14 will change restricted triggers to not be supported by replace operations (OR REPLACE).

FUJITSU Enterprise Postgres 13 SP1 or earlier

You can replace a constraint trigger.

[Example]

```
=# CREATE OR REPLACE CONSTRAINT TRIGGER my_constraint_trigger AFTER DELETE ON my_table
-# FOR EACH ROW
-# EXECUTE PROCEDURE funcA();
CREATE TRIGGER
```

FUJITSU Enterprise Postgres 14 or later

It does not support replacing a constraint trigger.

[Example]

```
=# CREATE OR REPLACE CONSTRAINT TRIGGER my_constraint_trigger AFTER DELETE ON my_table
-# FOR EACH ROW
-# EXECUTE PROCEDURE funcA();
ERROR:  CREATE OR REPLACE CONSTRAINT TRIGGER is not supported
```

Action method

None.

3.2.9 Change the "elif" Statement Behavior in ecobpg

Incompatibility

The "elif" statement now works correctly with FUJITSU Enterprise Postgres 13.

FUJITSU Enterprise Postgres 12 or earlier

The decision of the "elif" statement is made whether or not the "ifdef/ifndef" condition is met.

[Example]

```
000000     EXEC SQL ifdef DEF1 END-EXEC.
000000     Operation (1).
000000     EXEC SQL elif DEF2 END-EXEC.
000000     Operation (2).
000000     EXEC SQL else END-EXEC.
000000     Operation (3).
```

If "DEF1" and "DEF2" are true, both "Operation (1)" and "Operation (2)" are executed.

FUJITSU Enterprise Postgres 13 or later

If the condition "ifdef/ifndef" is met, the judgment of the "elif" statement is not enforced.

[Example]

```
000000     EXEC SQL ifdef DEF1 END-EXEC.
000000     Operation (1).
000000     EXEC SQL elif DEF2 END-EXEC.
000000     Operation (2).
000000     EXEC SQL else END-EXEC.
000000     Operation (3).
```

If "DEF1" and "DEF2" are true, only "Operation (1)" is executed.

Action method

Check your existing application and fix the elif statement to work correctly.

3.2.10 Changed to Error when Running an Operator or Function that Returns non Data Types for Masking Type

Incompatibility

In FUJITSU Enterprise Postgres 12, changed to error when running an operator or function that returns non Data Types for Masking type.

FUJITSU Enterprise Postgres 11 or earlier

In the following cases, the operator or function in 3) may be executed without masking.

This is an incorrect result because the data containing the masking column is performed without masking.

1) Create a Masking policy. and

2) Execute a SELECT statement. and

3) Execute an operator or function in the SELECT statement of 2). and

4) The operator or function argument of 3) includes a subquery. and

5) The operator or function argument of 3) contains the column to be protected created in 1). and

6) The operator or function of 3) returns a type not listed in "Data Types for Masking" in "Operation Guide".

FUJITSU Enterprise Postgres 12 or later

Operator or function results of 3) in the following error.

```
ERROR:  The output data type is incompatible with the confidential policy.
HINT:  Data type of the result value(s) produced by expression/function using confidential columns
is not supported by Data masking module. Consider removing confidential columns from such
expressions/functions.
```

This is correct because the operator or function returns a data type not listed in "Data Types for Masking" in "Operation Guide".

Action method

Do one of the following to ensure that the results are identical to those of FUJITSU Enterprise Postgres 11 and earlier:

1) Modify the Masking policy to prevent masking from being performed for the user executing the SQL.

2) Modify SQL to not use operators or functions that return types not listed in "Data Types for Masking" in "Operation Guide".

3.2.11 Removing UTL_FILE for Oracle Database Compatibility Features

Incompatibility

In FUJITSU Enterprise Postgres 12, remove the Oracle database compatibility UTL_FILE.

Action method

None.

3.2.12 Changing the Method of Specifying the Application Connection Switch Feature

Incompatibility

The target server specified using the application connection switch feature is changed to the same name as that of PostgreSQL.

Action method

Use the FUJITSU Enterprise Postgres 10 or later client to execute applications that have the target server specified as the application connection switch feature after changing the target server and specified value as listed below and recompiling.

Specified name of the target server

Usage target	Before correction	After correction
JDBC driver	No change	
ODBC driver	TargetServer	target_session_attrs
.NET Data Provider	target_server	TargetServerType
Connection service file	target_server	target_session_attrs
Library (libpq) for C	target_server	target_session_attrs Environment variable (PGTARGETSESSIONATTRS)

Usage target	Before correction	After correction
	Environment variable (PGXTARGETSERVER)	
Embedded SQL	target_server	target_session_attrs
psql	Environment variable (PGXTARGETSERVER)	Environment variable (PGTARGETSESSIONATTRS)

Specified value for the target server

Server selection order	JDBC driver	.NET Data Provider		Other driver	
		Before correction	After correction	Before correction	After correction
Primary server	No change	primary	master	primary	read-write
Standby server	No change	-	slave	-	-
Priority given to a standby server	No change	prefer_standby	preferSlave	prefer_standby	prefer-read
Any	No change	-	any	-	any

3.2.13 Changing the order of servers to be connected by the Application Connection Switch Feature

Incompatibility

Changes the order of the servers to be connected when you use the application connection switch feature.

FUJITSU Enterprise Postgres 9.6 or earlier

On subsequent connections within the same process, the server with the server attributes specified in target_session_attrs will try to connect first.

For example, if you specify host=host1, host2, host3 and target_session_attrs = read-write in a connection string in keyword/value format, and if host2 is the primary server during the first connection attempt, the connection attempts are made to host2, host3, and host1 in that order.

FUJITSU Enterprise Postgres 10 or later

Always attempt connections in the order specified in the connection string.

For example, if you specify host=host1, host2, host3 in a connection string in keyword/value format, connections are always attempted in the following order: host1, host2, host3.

Action method

None.

3.2.14 PostgreSQL Compatibility of Embedded SQL Applications in C and COBOL

Incompatibility

Embedded SQL applications in C and COBOL that were compiled with FUJITSU Enterprise Postgres 9.6 or earlier cannot be used in the FUJITSU Enterprise Postgres 10 client.

Action method

Use the FUJITSU Enterprise Postgres 10 or later client to execute the applications only after recompiling them with the FUJITSU Enterprise Postgres 10 or later client.

3.2.15 Changing Vertical Clustered Index (VCI)

Incompatibility

In FUJITSU Enterprise Postgres 10, the functions below have been added to the functions for which VCI is not used.

Type	Function
Date/time functions	age(timestamp) current_date current_timestamp current_time localtime localtimestamp
Session information functions	current_user current_role

Action method

To use VCI, specify the second argument when using the age function, and specify other functions as subqueries.

[Example]

Before: select age(column A), current_date from table

After: select age(column A, **now()**), **(select current_date)** from table

3.2.16 Changing how to Use the Features Compatible with Oracle Databases

Incompatibility

In FUJITSU Enterprise Postgres 9.6 or later, to use the features compatible with Oracle databases, create a new instance and execute the following command for the "postgres" and "template1" databases:

CREATE EXTENSION oracle_compatible

Action method

None.

3.3 Operation Migration Incompatibility

3.3.1 Disabling TLS1.0 and TLS1.1 Connections on the Mirroring Controller

Incompatibility

In Fujitsu Enterprise Postgres 17 SP1, the Mirroring Controller no longer supports SSL connections using TLS1.0 and TLS1.1.

Action method

If ssl_min_protocol or ssl_max_protocol is set to allow only TLS1.0 or TLS1.1, change it to allow TLS1.2 or later.

3.3.2 Disabling Some Elliptic Curve Cryptography Algorithms in the Mirroring Controller

Incompatibility

In Fujitsu Enterprise Postgres 17 SP1, the Mirroring Controller no longer supports SSL connections using the following elliptic curve cryptography algorithms:

- secp112r*
- secp128r*
- secp160*
- secp192*
- secp224*
- secp256k1
- sect113r*
- sect131r*
- sect163*
- sect193r*
- sect233*
- sect239k1
- sect283*
- sect409*
- sect571*
- X9.62 c2tnb191v*
- X9.62 c2tnb239v*
- X9.62 c2tnb359v1
- X9.62 c2tnb431r1
- X9.62 prime192v2
- X9.62 prime192v3
- X9.62 prime239v*
- brainpoolP256r1
- brainpoolP320r1
- brainpoolP384r1
- brainpoolP512r1

Action method

Change ssl_ecdh_curve to an allowed elliptic curve.

3.3.3 Changing the Default Protocol for SSL Connections on the Mirroring Controller

Incompatibility

In Fujitsu Enterprise Postgres 17 SP1, the default protocol for SSL connections on the Mirroring Controller has been changed to TLS1.3.

Action method

Set ssl_min_protocol or ssl_max_protocol to allow TLS1.3 connections.

3.3.4 Disabling a portion of Root Certificates on the Mirroring Controller

Incompatibility

In Fujitsu Enterprise Postgres 17 SP1, the following root certificates can no longer be used to establish an SSL connection with the Mirroring Controller:

- Alias name: entrustevca [jdk]
- Alias name: entrustrootcaec1 [jdk]
- Alias name: entrustrootcag2 [jdk]
- Alias name: entrustrootcag4 [jdk]
- Alias name: entrust2048ca [jdk]
- Alias name: affirmtrustcommercialca [jdk]
- Alias name: affirmtrustnetworkingca [jdk]
- Alias name: affirmtrustpremiumca [jdk]
- Alias name: affirmtrustpremiumeccca [jdk]
- Alias Name: thawtepremiumserverca [jdk]
- Alias Name: verisignclass2g2ca [jdk]
- Alias Name: verisignclass3ca [jdk]
- Alias Name: verisignclass3g2ca [jdk]
- Alias Name: verisigntsaca [jdk]
- Alias Name: soneraclass2ca
- Alias Name: identrustdstx3 [jdk]
- Alias Name: globalsignr2ca [jdk]
- Alias Name: secomscrootca1 [jdk]

Action method

If you are using an applicable root certificate, change it to a valid root certificate.

3.3.5 Disabling the TLS_ECDH_* Cipher Suite on the Mirroring Controller

Incompatibility

In Fujitsu Enterprise Postgres 17 SP1, the Mirroring Controller can no longer use the TLS_ECH_* cipher suite during SSL connections.

Action method

Change ssl_cipher to use a cipher suite other than TLS_ECDH_*.

3.3.6 Deprecation of Some Encryption Algorithms in pgcrypto

Incompatibility

In Fujitsu Enterprise Postgres 16 and later, the PostgreSQL extension pgcrypto does not support the use of the encryption algorithm, which has become a legacy algorithm in the OpenSSL3 family, by default.

The encryption algorithms that are no longer available by default are:

- BF
- CAST5

- DES-ECB
- DES-CBC
- MD4
- Whirlpool

Action method

If you use a legacy OpenSSL provider, create an OpenSSL configuration file and set the parameters in postgresql.conf. Refer to "Settings for Using Legacy OpenSSL Providers" in the Installation and Setup Guide for Server for information .

3.3.7 Deprecation of Certificates Signed Using SHA1

Incompatibility

In Fujitsu Enterprise Postgres 16 and later, you cannot connect to a database server using a certificate signed using SHA1.

Action method

Resubmit the certificate used for certificate authentication with SHA2 or higher.

3.3.8 Abolition of Message Numbers

Incompatibility

In Fujitsu Enterprise Postgres 15, the message number output at the end of the message is abolished.

Message numbers are output for messages output by Mirroring Controller.

For FUJITSU Enterprise Postgres 14 or earlier

The message number was printed at the end of the message.

[example]

```
3D000: 2017-07-10 19:41:05 JST[13899]: [1-1] user=fepuser,db=fep,remote=127.0.0.1(51902)
app=[unknown] FATAL: database "fep" does not exist (10571)
```

For Fujitsu Enterprise Postgres 15

No message number is output at the end of the message.

[example]

```
3D000: 2023-04-10 19:41:05 JST [13899]: [1-1] user = fepuser,db = fep,remote = 127.0.0.1(51902)
app = [unknown] FATAL: database "fep" does not exist
```

Action method

None.

3.3.9 Rename column "master_pid" in pgx_loader_state to "leader_pid"

Incompatibility

In FUJITSU Enterprise Postgres 14 renames column "master_pid" to "leader_pid" in the pgx_loade_state table.

Action method

None.

3.3.10 Changing the Value of the Category Column in the pg_settings view

Incompatibility

For FUJITSU Enterprise Postgres 13, change the value of the category column in the pg_settings view.

FUJITSU Enterprise Postgres 12 or earlier

Original value	wrong value
Preset Options	Fujitsu Enterprise Postgres Parameters
Customized Options	Preset Options
Developer Options	Customized Options

This is an incorrect result because it is different from the original value.

FUJITSU Enterprise Postgres 13 or later

The correct value is the category column in the pg_settings view.

Action method

Replaces the category column in the pg_settings view with the values before migration, so that the results are the same as before migration.

3.3.11 Changing pgx_stat_lwlock of the Statistics View

Incompatibility

In FUJITSU Enterprise Postgres 13, change the wait event name displayed in the lwlock_name column of the statistics view pgx_stat_lwlock.

Wait Event Name

FUJITSU Enterprise Postgres 12 or earlier	FUJITSU Enterprise Postgres 13
clog (*1)	XactBuffer
commit_timestamp (*1)	CommitTSBuffer
subtrans (*1)	SubtransBuffer
multixact_offset (*1)	MultiXactOffsetBuffer
multixact_member (*1)	MultiXactMemberBuffer
async (*1)	NotifyBuffer
oldserxid (*1)	SerialBuffer
wal_insert (*1)	WALInsert
buffer_content (*1)	BufferContent
buffer_io (*1)	BufferIO
replication_origin (*1)	ReplicationOriginState
replication_slot_io (*1)	ReplicationSlotIO
proc (*1)	LockFastPath
buffer_mapping (*1)	BufferMapping
lock_manager (*1)	LockManager
predicate_lock_manager (*1)	PredicateLockManager
parallel_hash_join (*3)	ParallelHashJoin
parallel_query_dsa (*2)	ParallelQueryDSA
session_dsa (*3)	PerSessionDSA
session_record_table (*3)	PerSessionRecordType

FUJITSU Enterprise Postgres 12 or earlier	FUJITSU Enterprise Postgres 13
session_typmod_table (*3)	PerSessionRecordTypmod
shared_tuplestore (*3)	SharedTupleStore
tbm (*2)	SharedTidBitmap
parallel_append (*3)	ParallelAppend
serializable_xact (*4)	PerXactPredicateList
shared_mcxt (*4)	SharedMcxt
meta_cache_map (*4)	MetaCacheMap
global_metacache (*4)	GlobalCatcache
cached_buf_tranche_id (*4)	CachedBufTranche

*1) Events added in FUJITSU Enterprise Postgres 9.6.

*2) Events added in FUJITSU Enterprise Postgres 10.

*3) Events added in FUJITSU Enterprise Postgres 11.

*4) Events added in FUJITSU Enterprise Postgres 12.

Action method

None.

3.3.12 Changing the Behavior of pgx_rcvall

Incompatibility

In FUJITSU Enterprise Postgres 13, change the pgx_rcvall command to fail if the -e option of the pgx_rcvall command specifies a future time or if the -n option specifies a list appointment that does not exist.

FUJITSU Enterprise Postgres 12 or earlier

All archived WALs are applied for recovery if the -e option of the pgx_rcvall command specifies a time in the future, or if the -n option specifies a list appointment that does not exist.

FUJITSU Enterprise Postgres 13 or later

The pgx_rcvall command fails if the -e option of the pgx_rcvall command specifies a time in the future, or if the -n option specifies a list appointment that does not exist.

Action method

Specify recovery objectives correctly, if necessary.

3.3.13 Mirroring Controller no Longer Retries to Monitor Database Processes when they are Detected as Down

Incompatibility

For the FUJITSU Enterprise Postgres 12 Mirroring Controller, change the heartbeat monitoring of the database process so that it does not retry monitoring when it detects down.

Action method

None.

3.3.14 Changing the Name and Parameter Name of the Mirroring Controller Post-Promote Command

Incompatibility

In the FUJITSU Enterprise Postgres 12 Mirroring Controller, change the name of the post-promote command, which is the state transition command, and the parameter name in the server configuration file that specifies the post-promote command.

FUJITSU Enterprise Postgres 11 or earlier

- Command Name

  post-promote command

- The parameter name in the server configuration file that specifies the post-promote command

  post_promote_command

FUJITSU Enterprise Postgres 12 or later

- Command Name

  post-switch command

- The parameter name in the server configuration file that specifies the post-promote command

  post_switch_command

Action method

The post_promote_command parameter in the server configuration file continues to be available in FUJITSU Enterprise Postgres 12 or later.If specified in the server configuration file, it acts as a post-switch command.You cannot specify the post_promote_command and post_switch_command parameters at the same time.

3.3.15 Changing Mirroring Controller User Command Input Values

Incompatibility

In FUJITSU Enterprise Postgres 12, arguments (Fixed value: primarycenter) have been added to the following user commands:

- Fencing command of the database server
- Arbitration command
- Post-switch command
- Pre-detach command
- Post-attach command

Action method

If you are checking the number of arguments in a user command, increase the number of arguments by one.

3.3.16 Changing the Maximum Number of Connections per Server

Incompatibility

In FUJITSU Enterprise Postgres 10, the maximum number of connections per server is changed from 262,143 to 65,535.

Action method

None.

3.3.17 Changing the Encryption Settings Using the ALTER TABLESPACE Statement

Incompatibility

In FUJITSU Enterprise Postgres 10, the ALTER TABLESPACE statement can be used to change the tablespace encryption settings if data is not stored in the tablespace.

Action method

None.

3.3.18 Changing the Default Configuration of the Cluster System Using Database Multiplexing

Incompatibility

In FUJITSU Enterprise Postgres 10, a split brain will not occur if heartbeat monitoring using an admin network times out, so the default is changed to a system configuration requiring an arbitration server acting as a third party.

FUJITSU Enterprise Postgres 9.6 or earlier

A cluster system comprises two database servers.

FUJITSU Enterprise Postgres 10 or later

By default, a cluster system comprises two database servers and an arbitration server.

Action method

If selecting the same system configuration as that in FUJITSU Enterprise Postgres 9.6 or earlier, set the parameters below in the server configuration file to perform automatic degradation unconditionally when a heartbeat abnormality is detected during OS/server heartbeat monitoring.

- Parameter: heartbeat_error_action
- Value: fallback

3.3.19 Changing the Default Operation when mc_ctl Command Options are Omitted

Incompatibility

In FUJITSU Enterprise Postgres 10, the default operation when the mc_ctl command options below are omitted has been changed:

- The -f option during start mode
- The -w option during start mode

FUJITSU Enterprise Postgres 9.6 or earlier

- If the -f option is omitted, automatic switching and disconnection immediately after the startup of Mirroring Controller will not be enabled.
- If the -w option is omitted, the system will not wait for operations to finish.

FUJITSU Enterprise Postgres 10 or later

- Even if the -f option is omitted, automatic switching and disconnection immediately after the startup of Mirroring Controller will be enabled.
- Even if the -w option is omitted, the system will wait for operations to finish.

Action method

If selecting the same operation as that in FUJITSU Enterprise Postgres 9.6 or earlier, take the action below when executing start mode of the mc_ctl command.

- If the -f option is omitted, specify the -F option.
- If the -w option is omitted, specify the -W option.

3.3.20 Changing the Connection Settings when Mirroring Controller Connects to an Instance

Incompatibility

In FUJITSU Enterprise Postgres 10, Mirroring Controller changes the connection setting below when connecting to an instance to detect failure of each database element.

- Application name

FUJITSU Enterprise Postgres 9.6 or earlier

- The application name is an empty string.

FUJITSU Enterprise Postgres 10 or later

- The application name is 'mc_agent'.

Action method

There is no method for changing the application name.

Therefore, if there is an application that identifies a database connection session of Mirroring Controller with the application name being an empty string, modify the process so that identification is performed using 'mc_agent'.

3.3.21 Changing the Status Display of the Mirroring Controller Server

Incompatibility

In FUJITSU Enterprise Postgres 10, the condition for displaying an abnormality for the process (WAL receive process) that receives transaction logs has been changed in regard to the server status display performed in status mode of the mc_ctl command of Mirroring Controller.

- Role of the applicable server (host_role): standby (standby)
- Display item: DBMS process status (db_proc_status)
- Display content: abnormal (abnormal process name)
  The applicability for incompatibility is determined based on whether 'wal_receiver' is included in the abnormality process name.

FUJITSU Enterprise Postgres 9.6 or earlier

Displays an abnormality when Mirroring Controller detects that the WAL send process has stopped.

FUJITSU Enterprise Postgres 10 or later

Displays an abnormality when Mirroring Controller detects that a streaming replication connection has not been established with the primary server using the WAL receive process.

Action method

If there is an application that determines the WAL receive process status from the display content retrieved using status mode of the mc_ctl command, modify as below to determine at the same level of accuracy as previously. However, this is not recommended due to incompatibilities accompanying the improvement in accuracy.

- If 'wal_sender' is included in the abnormal process name displayed in the 'abnormal' db_proc_status item of the 'primary' host_role, it is determined that an abnormality has occurred in the WAL receive process.

- If 'wal_sender' is not included in the abnormal process name displayed in the 'abnormal' db_proc_status item of the 'primary' host_role, it is determined that an abnormality has not occurred in the WAL receive process.

3.3.22 Changing the Operation when the synchronous_standby_names Parameter is Changed during Database Multiplexing Operation

Incompatibility

In FUJITSU Enterprise Postgres 9.6 or earlier, Mirroring Controller periodically accesses the database to retrieve the synchronous_standby_names parameter value using the SHOW command, and automatically recovers if changes are detected, in case the user accidentally changes the synchronous_standby_names parameter in postgresql.conf during database multiplexing mode. However, because this process uses the CPU of the database server for redundancy and SQL statements are executed with high frequency, these processes are not executed by default in FUJITSU Enterprise Postgres 10.

FUJITSU Enterprise Postgres 9.6 or earlier

Mirroring Controller checks if the synchronous_standby_names parameter in postgresql.conf has been mistakenly changed by the user.

FUJITSU Enterprise Postgres 10 or later

By default, Mirroring Controller does not check if the synchronous_standby_names parameter in postgresql.conf has been mistakenly changed by the user.

Action method

If selecting the same operation as that in FUJITSU Enterprise Postgres 9.6 or earlier, set the parameter below in the server definition file.

- Parameter: check_synchronous_standby_names_validation
- Value: 'on'

3.3.23 Changing Masking Policy Definition for Unsupported Data Types

Incompatibility

The data masking feature of FUJITSU Enterprise Postgres is updated so that an error occurs when a masking policy is defined for a column of an unsupported data type (array type or timestamp with timezone type).

FUJITSU Enterprise Postgres 9.5

The definition of a masking policy for a column of array type or timestamp with timezone type ends normally, but an error occurs when accessing a column of a table for which the policy is defined.

FUJITSU Enterprise Postgres 9.6 or later

An error occurs when defining a masking policy for a column of array type or timestamp with timezone type.

Action method

If a policy that was defined in FUJITSU Enterprise Postgres 9.5 includes masking of a column of an unsupported data type (array type or timestamp with timezone type), perform one of the following in FUJITSU Enterprise Postgres 9.6 or later:

- Ignore the error if the masking policy contains columns of only these data types, or delete the policy with the pgx_drop_confidential_policy system administration function.
- If the masking policy target contains columns of these data types and a supported data type, delete the problematic columns with the pgx_alter_confidential_policy system function.

3.4 JDBC Driver Incompatibility

3.4.1 Changing the targetServerType Value

Incompatibility

In FUJITSU Enterprise Postgres 13, the value of targetServerType specified in the connection string was changed. Therefore, the previously used values are no longer available.

Action method

If you specified a value for targetServerType, change the value as follows:

Table 3.2 Specified values for the target server

Server Selection Order	FUJITSU Enterprise Postgres 12 or earlier	FUJITSU Enterprise Postgres 13
Primary Server	master	primary
Standby Server	slave	secondary
Prefer Standby Server	preferSlave	preferSecondary
Any	any	any

3.5 ODBC Driver Incompatibility

3.5.1 Cannot specify prefer-read for target_session_attrs

Incompatibility

FUJITSU Enterprise Postgres 14 users will not see the "prefer-read" radio button in the "Target_Session_Attrs" item of the data source option selection screen.

Action method

Select prefer-standby.

3.6 .NET Data Provider Incompatibility (Information for Using Npgsql 10 or Later)

There is no incompatibility.

See

When migrating from Fujitsu Enterprise Postgres 18 or earlier, also refer to "3.8 .NET Data Provider Incompatibility (Information for Fujitsu Enterprise Postgres 18 and Earlier)".

3.7 .NET Data Provider Incompatibility (Information for using Npgsql 8 with Fujitsu Enterprise Postgres 18 SP1 or Later)

3.7.1 Npgsql NuGet Package Name and Version Change

Incompatibility

In Fujitsu Enterprise Postgres 18 SP1, the Npgsql NuGet package names will be changed as follows, and the package versions will be updated from 17.0.0 to 18.0.0.

Fujitsu Enterprise Postgres 18

```
Npgsql.17.0.0.nupkg
Npgsql.DependencyInjection.17.0.0.nupkg
Npgsql.GeoJSON.17.0.0.nupkg
Npgsql.Json.NET.17.0.0.nupkg
Npgsql.NetTopology.17.0.0.nupkg
Npgsql.NodaTime.17.0.0.nupkg
Npgsql.OpenTelemetry.17.0.0.nupkg
```

Fujitsu Enterprise Postgres 18 SP1

```
Npgsql.18.0.0.nupkg
Npgsql.DependencyInjection.18.0.0.nupkg
Npgsql.GeoJSON.18.0.0.nupkg
Npgsql.Json.NET.18.0.0.nupkg
Npgsql.NetTopology.18.0.0.nupkg
Npgsql.NodaTime.18.0.0.nupkg
Npgsql.OpenTelemetry.18.0.0.nupkg
```

Action method

Update or reinstall the package, then rebuild the application.

See

When migrating from Fujitsu Enterprise Postgres 18 or earlier, also refer to "3.8 .NET Data Provider Incompatibility (Information for Fujitsu Enterprise Postgres 18 and Earlier)".

3.8 .NET Data Provider Incompatibility (Information for Fujitsu Enterprise Postgres 18 and Earlier)

3.8.1 .NET Application Development and Operating Environment Changes

Incompatibility

In Fujitsu Enterprise Postgres 17 or later, the following .NET have been removed from the environment required to develop and run .NET applications:

- .NET 6.0
- .NET 7.0

Action method

None.

3.8.2 Changing the Specification Method and Specified Values for the Application Connection Switch Feature

Incompatibility

In Fujitsu Enterprise Postgres 15, the name of the "target server" specified by the connection switching function will be changed from "TargetServerType" to "TargetSessionAttributes", and the specified value will also be changed.

Action method

If the target server is specified, change the target server and specified value as follows.

Table 3.3 How to specify the connection destination switching function of the application and the specified value

Fujitsu Enterprise Postgres version		FUJITSU Enterprise Postgres 9.6 or earlier	FUJITSU Enterprise Postgres 10/11/12	FUJITSU Enterprise Postgres 13/14	Fujitsu Enterprise Postgres 15
Keywords to specify in the connection string		target_server	TargetServerType	TargetServerType	TargetSessionAttributes
Server selection order	Primary Server	primary(*1)	master(*1)	primary(*1)	read-write(*1) primary(*2)
	Standby Server	-	slave(*2)	standby(*2)	standby read-only(*2)
	Prefer Primary Server	-	-	-	prefer-primary
	Prefer Standby Server	prefer_standby	preferSlave	preferStandby	prefer-standby
	Any	-	any	any	any

*1: A primary server whose default transaction mode is read-only are not selected.

*2: A primary server whose default transaction mode is read-only is also selected.

3.8.3 Changing the Behavior of the Application Connection Switch Feature

Incompatibility

In Fujitsu Enterprise Postgres 15, when only one Host keyword is specified in the connection string, if a target server other than Any is specified, an exception will occur.

FUJITSU Enterprise Postgres 14 earlier

For example, if the connection string specifies "Host=host1, TargetServerType=primary", it will connect to host1 if host1 is the appropriate connection target.

Fujitsu Enterprise Postgres 15

For example, if "Host=host1, TargetSessionAttributes=primary" is specified in the connection string, an exception will always occur because the target server other than Any is specified for the specification of only one host information.

Action method

None.

3.8.4 Behavior Change when Multiple Host Information is Specified in the Connection String

Incompatibility

In Fujitsu Enterprise Postgres 15, when multiple hosts are specified in the connection string, even if one of them has an empty string specified, if another connectable connection destination is specified, that connection destination will be connected. In the old version, if there was even one host with an empty string, an exception would occur at that point.

FUJITSU Enterprise Postgres 14 earlier

For example, if "Host = host1," is specified in the connection string, an exception will always occur because the second host information is an empty string.

Fujitsu Enterprise Postgres 15

For example, if the connection string specifies "Host = host1," and if host1 is reachable, it will connect to host1 without throwing an exception.

Action method

None.

3.8.5 Changing the TargetServerType Value

Incompatibility

In FUJITSU Enterprise Postgres 13, the value of TargetServerType specified in the connection string was changed. Therefore, the previously used values are no longer available.

Action method

If you specified a value for TargetServerType, change the value as follows:

Table 3.4 Specified values for the target server

Server Selection Order	FUJITSU Enterprise Postgres 9.6 or earlier	FUJITSU Enterprise Postgres 10/11/12	FUJITSU Enterprise Postgres 13
Primary Server	primary	master	primary
Standby Server	-	slave	standby
Prefer Standby Server	prefer_standby	preferSlave	preferStandby
Any	-	any	any

3.8.6 Changing the Server Explorer View in Visual Studio Integration with .NET Data Provider

Incompatibility

FUJITSU Enterprise Postgres 10 or later, the following changes occur when you view database resources in Server Explorer.

- "Schema Name.Table Name" display under the Tables folder.
- The Indexes folder is not displayed.
- The Triggers folder does not displayed.
- The Sequences folder is not displayed.
- The Procedures folder does not displayed.

Action method

None.

3.9 C Library (libpq) Migration Incompatibility

3.9.1 Changing when "prefer-read" is Specified for the target_session_attrs Parameter

Incompatibility

In FUJITSU Enterprise Postgres 14 changes the attach server priority if any of the following servers are specified simultaneously with "prefer-read" as the target_session_attrs parameter:

- Primary server (default_transaction_read_only = ON)
- Standby server

FUJITSU Enterprise Postgres 13 SP1 or earlier

The primary server (default_transaction_read_only = ON) and standby servers have the same priority.

FUJITSU Enterprise Postgres 14 or later

Standby servers connect in preference to primary servers (default_transaction_read_only = ON).

Action method

None.

3.10 pgaudit Incompatibility

3.10.1 Repairing Unwanted Output in the Audit Log

Incompatibility

In Fujitsu Enterprise Postgres 16, we changed the audit log so that it no longer contains unwanted information at the end.

Fujitsu Enterprise Postgres 15 or earlier

Some audit logs contain unwanted content at the end.

[Example]

```
Input: INSERT INTO trig_test VALUES ('new value');
Part of the audit log: NOTICE:  AUDIT: SESSION,WRITE,,[local],,pg_regress/class,,baz,,
11,2,INSERT,,TABLE,public.trig_audit,,"INSERT INTO trig_audit SELECT 'I', now(), user, NULL,
NEW.*","(""new value"")  trig_audit AFTER ROW INSERT 16484 trig_test trig_test public 0  f"
```

Fujitsu Enterprise Postgres 16

Prevent unwanted from being output to the audit log.

[Example]

```
Input: INSERT INTO trig_test VALUES ('new value');
Part of the audit log: NOTICE:  AUDIT: SESSION,WRITE,,[local],,pg_regress/class,,baz,,
11,2,INSERT,,TABLE,public.trig_audit,,"INSERT INTO trig_audit SELECT 'I', now(), user, NULL,
NEW.*","(""new value"")"
```

Action method

None.

3.10.2 Changing to Output Extra NEW and OLD Values in the Audit Log when the Trigger Function Executes

Incompatibility

In FUJITSU Enterprise Postgres 13, the trigger function additionally outputs NEW and OLD values to the audit log when the pgaudit.log_parameter is set to on.

FUJITSU Enterprise Postgres 12 or earlier

The following (18) does not output the values of NEW, OLD.

[Example]

```
AUDIT: SESSION,WRITE,2020-09-03 07:07:39 UTC,
        (1)    (2)   (3)
[local],9775,psql,k5user,postgres,3/536, 1, 2, INSERT, ,
(4)     (5)  (6)  (7)    (8)      (9)   (10)(11)(12)(13)
TABLE,public.trig_audit, ,
(14)  (15)    (16)
 "INSERT INTO trig_audit SELECT 'U', now(), user, OLD.*, NEW.*",
(17)
trig_audit AFTER ROW UPDATE 92027 trig_test trig_test public 0  f aaaa
(18)
```

FUJITSU Enterprise Postgres 13 or later

NEW, OLD values are output.

[Example]

```
AUDIT: SESSION,WRITE,2020-09-03 07:07:39 UTC,
[local],9775,psql,k5user,postgres,3/536,1,2,INSERT,,TABLE,public.
trig_audit,,
"INSERT INTO trig_audit SELECT 'U', now(), user, OLD.*, NEW.*",
(bbb) (aaa) trig_audit AFTER ROW UPDATE 92027 trig_test trig_test
public 0  f aaaa
```

Action method

If you are using an application that works by monitoring the string that the trigger function output to the audit log, modify the application to work with the NEW and OLD values.

3.11 pg_dbms_stats Incompatibility

3.11.1 Change in Execution Plan due to Fixed Height of Btree index

Incompatibility

Fixing statistics with the following features may change the execution plan because the height of the Btree index is now fixed as well:

- dbms_stats.lock_*
- dbms_stats.restore_*
- dbms_stats.import_*

Action method

If you want to run compatibility with Fujitsu Enterprise Postgres 15 and earlier, configure the following:

- pg_dbms_stats.use_tree_height
- pg_dbms_stats.lock_tree_height

3.11.2 Incompatibility of Import Features with Fixed Height of Btree index

Incompatibility

Statistics exported by the export function in pg_dbms_stats prior to Fujitsu Enterprise Postgres 15 cannot be imported using the legacy import function.

Action method

When importing statistics exported by the export function in pg_dbms_stats prior to Fujitsu Enterprise Postgres 15, use a function with the suffix "_no_tree_height" appended to its name.

3.12 orafce Incompatibility

3.12.1 Interface changes due to enhancements to the DBMS_SQL package

Incompatibility

In Fujitsu Enterprise Postgres 17, includes enhancements to the DBMS_SQL package. The I/O interfaces of some functions have changed accordingly.

Refer to "Compatibility with Oracle Databases" in Application Development Guide.

Action method

If you are using the DBMS_SQL package, you will need to switch to the same procedures as Fujitsu Enterprise Postgres 16 SP1 or earlier for Oracle database compatibility enhancements, or modify your application.

Refer to "Compatibility with Oracle Databases" in Application Development Guide.

3.13 psycopg Incompatibility

3.13.1 Python Version Changes Required When Using psycopg

Incompatibility

In Fujitsu Enterprise Postgres 18 or later, the following Python required for using psycopg on Windows have been removed from the Python distribution.

- Python version 3.9
- Python version 3.10

Action method

None.

3.14 WebAdmin Incompatibility

3.14.1 Added SNI hostname verification functionality

Incompatibility

We now enforce validation that the SNI hostname matches the SSLHostConfig in the HTTP Host header.

Action method

Configure the SNI hostname to match the SSLHostConfig in the HTTP Host header.

3.14.2 Changing the TLS Version Limit for HTTPS Connections in WebAdmin

Incompatibility

In Fujitsu Enterprise Postgres 17 SP1, the use of TLS1.0 and TSL1.1 is disabled when WebAdmin is configured to use HTTPS connections.

Action method

To access WebAdmin, use a browser that supports TLS1.2 or later.

3.14.3 Changing the default value of the item 'Number of digits for floating values' which is set in the section 'SQL options'

Incompatibility

In Fujitsu Enterprise Postgres 16, the default value of the item 'Number of digits for floating values' which is set in the section 'SQL options' in the view 'PostgreSQL configuration' is changed in order to match the default value of PostgreSQL.

Fujitsu Enterprise Postgres 15 or earlier

0

Fujitsu Enterprise Postgres 16 or later

1

Action method

Change the value of the item 'Number of digits for floating values', if necessary.

3.14.4 Cannot specify prefer-read for target_session_attrs

Incompatibility

FUJITSU Enterprise Postgres 14 will no longer allow prefer-read to target_session_attrs as a connection method to an upstream server that is specified when creating an instance of a standby server.

Action method

Specify prefer-standby.

3.15 Confidentiality Management Incompatibility

3.15.1 Changes due to Changes in the pg_dump Specification

Incompatibility

If you are using multiple non-superuser sensitivity confidentiality management role to manage the sensitivity matrix, run the product-provided policy configuration script to define a row-level security feature policy on the table provided by the sensitivity support feature to make the sensitivity management roles independent of each other.

In Fujitsu Enterprise Postgres 15 or earlier, the effects of this script could be retained and backed up by pg_dump, but as of Fujitsu Enterprise Postgres 16, policy settings can no longer be backed up.

Action method

In Fujitsu Enterprise Postgres 16 or later, if you are managing a sensitivity matrix using more than one confidentiality management role other than superuser, then immediately after restoring a clear-text dump file using pg_dump, run the following command as superuser to reapply the confidentiality management feature policy:

```
psql -f ${install_dir}/share/extension/pgx_confidential_management_support_policy.sql
```

3.15.2 Changing Permission Settings by Changing the CREATEROLE Permission

Incompatibility

In Fujitsu Enterprise Postgres 16, if you want to use a non-superuser role as a confidentiality management role, you may need to set additional permissions for the confidentiality management role.

Action method

The confidentiality management role must already have the privileges it expects to operate on, other than the CREATEROLE privilege.

[Example]

If the confidentiality management role "manager_role" is also going to work with CREATEDB privileges, it will also set CREATEDB privileges when the role is created, like this:

```
CREATE ROLE manager_role LOGIN CREATEROLE CREATEDB;
```

If the required permissions are not set, the sensitivity management API terminates abnormally with a message similar to the following:

```
ERROR:  permission denied to create role
DETAIL:  Only roles with the CREATEDB attribute may create roles with the CREATEDB attribute.
```

3.15.3 Change due to Restriction of CREATEROLE Privilege

Incompatibility

In Fujitsu Enterprise Postgres 16, if you want to use a non-superuser role as a secret management role, the permissions on the roles that can be set in the secret group are different, and the roles that you set in the secret group must be granted ADMIN OPTION permission on the secret confidentiality management role before they can be used.

Action method

Take one of the following actions:

- A role created with the privileges of the confidentiality management role is to be managed in the confidential group. This creates a role that grants only the ADMIN OPTIN privilege to the sensitive confidentiality management role.
- Grant ADMIN OPTION permission on the role to the sensitive management role before setting the managed role to the sensitive group.

[Example]

You want to grant only the ADMIN OPTION privilege for role "user _role1" to the confidentiality management role "manager_role".

```
GRANT user_role1 TO manager_role WITH ADMIN TRUE, INHERIT FALSE, SET FALSE;
```

If the required permissions are not set, the sensitivity management API terminates abnormally with a message similar to the following:

```
ERROR:  permission denied to alter role
DETAIL:  Only roles with the CREATEROLE attribute and the ADMIN option on role "user_role1" may
alter this role.
```

Chapter 4 Program Updates

This version incorporates the following fixes:

- PostgreSQL 18
- PostgreSQL 18.1
- PostgreSQL 18.2
- PostgreSQL 18.3

See

Refer to the PostgreSQL Global Development Group website for information on the updates implemented in the following releases:

[PostgreSQL 18]

```
https://www.postgresql.org/docs/18/release-18.html
```

[PostgreSQL 18.1]

```
https://www.postgresql.org/docs/18/release-18-1.html
```

[PostgreSQL 18.2]

```
https://www.postgresql.org/docs/18/release-18-2.html
```

[PostgreSQL 18.3]

```
https://www.postgresql.org/docs/18/release-18-3.html
```

In addition, issues that occurred in previous versions are also fixed.

Refer to the following for details of the program fixes included in this version and level.

- 4.1 Fujitsu Enterprise Postgres 18 SP1 Program Updates
- 4.2 Fujitsu Enterprise Postgres 18 Program Updates

4.1 Fujitsu Enterprise Postgres 18 SP1 Program Updates

Table 4.1 Fujitsu Enterprise Postgres 18 SP1 Program Updates

P number	Update summary	AE	SE
PH24763	Buffer-related information in pg_stat_statements may sometimes display as 0 even when it is actually non 0.	Y	Y
PH25085	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pgAdmin4 9.9, 9.10, 9.11.	Y	Y
PH25086	Update Fujitsu Enterprise Postgres with bug fixes absorbed by PostgreSQL JDBC Driver 42.7.8.	Y	Y
PH25088	Update Fujitsu Enterprise Postgres with bug fixes absorbed by psycopg 3.2.10, 3.2.11, 3.2.12, and 3.2.13, as well as psycopg-pool 3.2.7 and 3.2.8.	Y	Y
PH25090	Replace libedit with 3.1-20251016.	Y	Y
PH25091	Replace libxml2 with 2.15.1.	Y	Y
PH25092	Replace libxslt with 1.1.45.	Y	Y
PH25098	Update Fujitsu Enterprise Postgres with bug fixes absorbed by PostgreSQL 18.1, 18.2, and 18.3.	Y	Y
PH25119	Update Fujitsu Enterprise Postgres Client with bug fixes absorbed by Npgsql 8.0.8.	Y	Y

P number	Update summary	AE	SE
PH25125	Propagate defect fixes absorbed up to Apache Tomcat 9.0.115 to WebAdmin in Fujitsu Enterprise Postgres.	Y	Y
PH25129	Update Fujitsu Enterprise Postgres with bug fixes absorbed by orafce 4.14.5, 4.14.6, 4.16,0, 4.16.1, 4.16.2, 4.16.3.	Y	Y
PH25132	The version of the NuGet package in the .NET Data Provider does not match the major version of Fujitsu Enterprise Postgres.	Y	Y
PH25134	Update with bug fixes absorbed by psqlodbc-17.00.0007.	Y	Y
PH25138	Replace OpenSSL with 3.5.5.	Y	Y
PH25140	We provide EntityFrameworkCore.PG compatible with PostgreSQL 10 and PostgreSQL 10.	Y	Y
PH25141	When using audit logs, improper log output or abnormal termination due to a segfault may occur.	Y	-

Y : Fixed
- : Not relevant to this product

4.2 Fujitsu Enterprise Postgres 18 Program Updates

Table 4.2 Fujitsu Enterprise Postgres 18 Program Updates

P number	Update summary	AE	SE
PH24267	Even if a disk failure causing I/O errors occurs in the table space, WAL storage area, or database storage area, switching or disconnecting procedures may not occur.	Y	Y
PH24912	Replace OpenLDAP with 2.6.10.	Y	Y
PH24913	Replace libxml2 with 2.13.9.	Y	Y
PH24914	Replace OpenSSL with 3.5.4.	Y	Y
PH24916	Replace Kerberos with 1.22.1.	Y	Y
PH24917	Replace icu with 77.1.	Y	Y
PH24921	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pgAdmin4 9.6, 9.7, 9.8.	Y	Y
PH24923	Update Fujitsu Enterprise Postgres with bug fixes absorbed by pgvector 0.8.1.	Y	Y
PH24926	Fujitsu Enterprise Postgres and the OSS Postgres have different public functions, causing issues for users such as errors during the build of peripheral OSS software.	Y	Y
PH24980	Update security bug fixes absorbed by PostgreSQL18.1 to Fujitsu Enterprise Postgres. - CVE-2025-12817 - CVE-2025-12818	Y	Y
PH24985	When using the transparent data encryption feature, errors may occur.	Y	Y

Y : Fixed
- : Not relevant to this product

FUJITSU

Fujitsu Enterprise Postgres 18 for x86 - Advanced Edition with Cryptographic Module

Read First

Linux

J2UL-3080-01ENZ0(00)

December-2025

Preface

Purpose of this document

This document provides an overview of the Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module, its features, and how to install it.

Read this before using Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module.

Intended readers

This document is intended for use with Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module.

Structure of this document

The structure and content of this manual is shown below.

Chapter 1 Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module Basics

Describes an overview of the Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module, its features, and how to install it.

Appendix A Installation and Uninstallation (Compatibility)

Describes how to install and uninstall in an interactive mode.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Issue date and version

Edition 1.0: December 2025

Chapter 1 Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module Basics

Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module is a product that is configured to use algorithms that are approved by the security requirements for cryptographic modules (FIPS 140), one of the FIPS (Federal Information Processing Standard) standards.

The Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module provides the same feature as the Fujitsu Enterprise Postgres Advanced Edition.

This chapter describes the differences between Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module and Fujitsu Enterprise Postgres Advanced Edition regarding the features, operating environment, installation, setup, and application development.

1.1 Feature Differences from Fujitsu Enterprise Postgres Advanced Edition

Encryption features

If you use a cryptographic module provided by Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module, you cannot use algorithms and parameters not approved for FIPS 140 , so the following cryptographic functionality differences exist:

- Saving Passwords in md5 format on the server
  Use the default scram-sha-256.
- Some algorithms and parameters used to connect and authenticate using SSL
  Not only are they not available as encryption algorithms for communication paths, but they are also not available as signature algorithms for certificates, encryption algorithms for encrypting and storing private keys, and so on. Additionally, X25519 cannot be used as the elliptic curve for ECDH key exchange (key establishment).
  Fujitsu Enterprise Postgres 18 adds X25519 as the default elliptic curve for ECDH key exchange. Therefore, when using SSL with Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module 18, specify a value for the "ssl_groups" parameter (which defines the elliptic curves used for ECDH key exchange) that does not include X25519.
- The following are not available
  - md5 in SQL functions
  - Some algorithms of the extension module pgcrypto
  - Some functions of the extension module uuid-ossp

Algorithms not approved for FIPS 140

Classification	Details
Algorithms	BF, CAST, DES, DESX, IDEA, RC2, RC4, RC5, SEED, ARIA, CAMELLIA, SM4
Digest	MD2, MD4, MDC2, DES, RIPEMD-160, WHIRLPOOL,BLAKE2, SM3, MD5, MD5-SHA1
MAC	BLAKE2, CMAC, KMAC, POLY1305, SIPHASH
KDF	KBKDF, KRB5KDF, SCRYPT, X942KDF, X963KDF
Asymmetric keys	RSA-PSS, RSA-OAEP, SM2
Asymmetric encryption	RSAES-OAEP

Application development

JDBC driver and .NET Data Provider

Prepare the Java or .NET runtime required for your application to work with the JDBC driver and the .NET Data Provider. The implementation of the encryption algorithms used to connect these applications to the database server is provided by the respective runtimes.

Features not provided

- Windows client(32bit)

1.2 Operating Environment

Describes the operating environment for Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module.

1.2.1 Required Operating System

One of the operating systems shown below is required in order to use Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module.

- RHEL8.6 or later minor version
- RHEL9.2 or later minor version
- SLES 15 SP4 or later minor version

Using RHEL

To use the JDBC driver, WebAdmin, and the database multiplexing feature, the following packages are required in addition to those listed in the "Required Operating System" in the Fujitsu Enterprise Postgres Installation and Setup Guide for Server.

- java-17-openjdk

  For the RHEL versions listed below, please install the version listed or later.

  - RHEL 8.6: 17.0.5.0.8-3.el8_6 or later
  - RHEL 8.7: 17.0.5.0.8-4.el8_7 or later

Using SLES

To use the JDBC driver, WebAdmin, and the database multiplexing feature, the following packages are required in addition to those listed in the "Required Operating System" in the Fujitsu Enterprise Postgres Installation and Setup Guide for Server.

- java-17-openjdk

When SELinux is enabled

If the boolean selinuxuser_execstack is off (allow_execstack is off) in an SELinux-enabled environment, programs that directly or indirectly link cryptographic modules provided by Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module may not work correctly. These programs include Fujitsu Enterprise Postgres server and client commands and application programs that link libpq or libecpg. Set up SELinux to grant execstack rights to these programs.

1.3 Install

Describes the install for Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module.

Install

To use Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module, you must install the cryptographic module. Install version 3 of the cryptographic module on each machine on which you want to install the following Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module features:

- Server feature
- Pgpool-II
- pgBackRest
- Client feature

The method for installing the encryption module varies depending on the platform on which the product is being implemented.

- Linux

  Install the encryption package (rpm).

  The path of the package and storage directory for the cryptographic module is shown below.

Package	Package storage directory
FJSVfsep-crypto-*.rpm	CRYPTO64/Linux/packages/*<os>*

  <os> is the operating system of the runtime environment. Depending on the runtime environment, refer to either RHEL8, RHEL9, or SLES15.

  * is the version, OS, etc.

- Windows

  Install using the installer.

The installation directory name for the encryption module is shown below.

Platform	Installation directory
Linux	/opt/fsepcryptov3
Windows	C:\Program Files\Fujitsu\fsepcryptov3

The disk space required to install the cryptographic module is 60 megabytes.

For more information on how to install, refer to the Fujitsu Enterprise Postgres Installation and Setup Guide for Server and the Fujitsu Enterprise Postgres Installation and Setup Guide for Client.

You should not specify the openssl_conf and openssl_modules parameters in postgresql.conf.

1.4 Setup

Describes the setup for Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module.

Using the WebAdmin

When using WebAdmin, you need to set up WebAdmin. Additionally, Java runtime is required when setting up WebAdmin. Prepare the Java runtime and set the JAVA_HOME environment variable to the installation location of the OpenJDK 17 Java runtime.

Example)

```
# export JAVA_HOME="Installation location of JRE 17"
```

For setup using the WebAdminSetup command, refer to "Setting Up WebAdmin" in the Fujitsu Enterprise Postgres Installation and Setup Guide for Server.

Using the database multiplexing feature

If you want to take advantage of the database multiplexing feature, you need a Java runtime.

Prepare the OpenJDK 17 Java runtime and set the JAVA_HOME environment variable to where the Java runtime environment will be installed.

Example)

```
# export JAVA_HOME="Installation location of JRE 17"
```

If Mirroring Controller connects to an instance with SSL, set the following in the server definition files of the primary server and standby server. For more information, refer to "Creating, Setting, and Registering the Primary Server Instance" in the Fujitsu Enterprise Postgres Cluster Operation Guide(Database Multiplexing).

- db_instance_ext_jdbc_conninfo

  If you are using a Red Hat build of OpenJDK on RHEL to connect via SSL, or if you are using the OpenJDK that comes with SLES to connect via SSL, add the following to your connection parameters:

```
sslfactory=org.postgresql.ssl.DefaultJavaSSLFactory
```

  Use the NSS database for storing certificates and private keys. To enable the JDBC driver to access the NSS database, specify the properties you want to specify for the JVM startup options in the environment variable JAVA_TOOL_OPTIONS.

1.5 Uninstall

Describes the uninstall for Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module.

Information

If installed in interactive mode, refer to "A.2 Uninstall" and uninstall in interactive mode.

After uninstalling the following features of Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module, uninstall the cryptographic module.

- Server feature
- Pgpool-II
- pgBackRest
- Client feature

For more information on how to uninstall, refer to the Fujitsu Enterprise Postgres Installation and Setup Guide for Server and the Fujitsu Enterprise Postgres Installation and Setup Guide for Client.

1.6 Application Development

Describes the application development for Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module.

Applications using the JDBC driver

If you are using a Red Hat build of OpenJDK on RHEL to connect via SSL, or if you are using the OpenJDK that comes with SLES to connect via SSL, add the following to your connection parameters:

```
sslfactory=org.postgresql.ssl.DefaultJavaSSLFactory
```

Use the NSS database as the keystore and truststore. Specify the JVM startup options so that the JDBC driver can access the NSS database.

Appendix A Installation and Uninstallation (Compatibility)

Describes how to install and uninstall Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module in an interactive mode.

See

For details on installation and uninstallation, refer to the following.

- "Installation and Uninstallation (Compatibility)" in the Fujitsu Enterprise Postgres Installation and Setup Guide for Server
- "Installation and Uninstallation of the Linux Client (Compatibility)" in the Fujitsu Enterprise Postgres Installation and Setup Guide for Client

A.1 Install

Describes the install for Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module.

Advance preparation (for RHEL)

If you use WebAdmin, you need the Java runtime to set up WebAdmin.

WebAdmin can be set up when installing Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module. Before installation, prepare the Java runtime and set the JAVA_HOME environment variable to the Java runtime installation location.

Example)

```
# export JAVA_HOME="JREInstallDir"
```

You can also be set up after installation using the WebAdminSetup command. Before setup, prepare the Java runtime and set the JAVA_HOME environment variable to the Java runtime installation location. For information about set up using the WebAdminSetup command, refer to "Setting Up WebAdmin" in the Fujitsu Enterprise Postgres Installation and Setup Guide for Server.

Advance preparation (for SLES)

Before installation, specify the installation directory of JRE 8 in the JAVA_HOME environment variable. If you specify OpenJDK 1.8 that comes with SLES, specify -Dcom.suse.fips=false in the JAVA_TOOL_OPTIONS environment variable, export it, and then install it. After installation, specify an empty string in the JAVA_TOOL_OPTIONS environment variable and export it.

Example)

```
# JAVA_TOOL_OPTIONS=-Dcom.suse.fips=false  ./install.sh
```

If you set up WebAdmin during installation, after installation, change the Java runtime used by WebAdmin to OpenJDK 17. For instructions on changing the JRE after installation, refer to "Procedure when Modifying the JRE Installation" in the Fujitsu Enterprise Postgres Installation and Setup Guide for Server.

Install

To use Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module, you must install the cryptographic module. Install version 3 of the cryptographic module on each machine on which you want to install the following Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module features:

- Server feature
- Pgpool-II
- pgBackRest
- Client feature

A.2 Uninstall

Describes the uninstall for Fujitsu Enterprise Postgres Advanced Edition with Cryptographic Module.

Advance preparation (for SLES)

Before uninstallation, make sure that JRE 8 is installed and export the JAVA_HOME environment variable. If you want to specify OpenJDK 1.8 that comes with SLES, specify -Dcom.suse.fips=false in the JAVA_TOOL_OPTIONS environment variable, export it, and then uninstall. After uninstalling, specify the JAVA_TOOL_OPTIONS environment variable as an empty string and export it.

Preface

Purpose of this document

The Fujitsu Enterprise Postgres database system extends the PostgreSQL features and runs on the Linux platform.

This document describes how to install and set up "Fujitsu Enterprise Postgres".

Intended readers

This document is intended for those who install and operate Fujitsu Enterprise Postgres.

Readers of this document are assumed to have general knowledge of:

- PostgreSQL
- SQL
- Linux

Structure of this document

This document is structured as follows:

Chapter 1 Overview of Installation

Describes the installation types and procedures

Chapter 2 Operating Environment

Describes the operating environment required to use Fujitsu Enterprise Postgres

IChapter 3 Installation

Describes how to perform a new installation of Fujitsu Enterprise Postgres

Chapter 4 Setup

Describes the setup to be performed after installation

Chapter 3 Installation

Describes how to uninstall Fujitsu Enterprise Postgres

Appendix A Recommended WebAdmin Environments

Describes the recommended WebAdmin environment.

Appendix B Setting Up and Removing WebAdmin

Describes how to set up and remove WebAdmin

Appendix C WebAdmin Disallow User Inputs Containing Hazardous Characters

Describes characters that are not allowed in WebAdmin.

Appendix D Configuring Parameters

Describes Fujitsu Enterprise Postgres parameters.

Appendix E Estimating Database Disk Space Requirements

Describes how to estimate database disk space requirements

Appendix F Estimating Memory Requirements

Describes the formulas for estimating memory requirements

Appendix G Quantitative Limits

Describes the quantity range

Appendix H Configuring Kernel Parameters

Describes the settings for kernel parameters

Appendix I Determining the Preferred WebAdmin Configuration

Describes the two different configurations in which WebAdmin can be used and how to select the most suitable configuration

Appendix J System Configuration when using Pgpool-II

Describes the system configuration when using Pgpool-II.

Appendix K Supported contrib Modules and Extensions Provided by External Projects

Lists the PostgreSQL contrib modules and the extensions provided by external projects supported by Fujitsu Enterprise Postgres.

Appendix L Procedure when Modifying the JRE Installation

Describes the procedures to follow when modifying the JRE installation.

Appendix M Access to Key Management System Using Plug-in

Describes how to access key management systems using plug-ins.

Appendix N Deploying Virtual Machines by Cloning

Describes installing Fujitsu Enterprise Postgres on a virtual machine, cloning the virtual machine, and deploying a new virtual machine.

Appendix O Collecting Failure Investigation Data

Explains how to collect data for initial investigation.

Appendix P Installation and Uninstallation (Compatibility)

Describes how to install (interactive mode/silent mode) the Fujitsu Enterprise Postgres.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Index....111

Chapter 1 Overview of Installation

This chapter provides an overview of Fujitsu Enterprise Postgres installation.

1.1 Features that can be Installed

Each Fujitsu Enterprise Postgres feature is installed on the machine that was used to build the database environment.

The following features can be installed.

- Server feature
- Client feature
- WebAdmin
- pgBackRest
- Pgpool-II

Chapter 2 Operating Environment

This chapter describes the operating environment required to use Fujitsu Enterprise Postgres.

See

Refer to "Operating Environment" in the Installation and Setup Guide for Client when installing the Fujitsu Enterprise Postgres client feature at the same time.

2.1 Required Operating System

One of the operating systems shown below is required in order to use Fujitsu Enterprise Postgres.

- RHEL8.6 or later minor version
- RHEL9.2 or later minor version
- SLES 15 SP4 or later minor version
  SLES cannot be used if performing failover operation integrated with PRIMECLUSTER.

Information

Asynchronous I/O using the io_uring I/O mode in PostgreSQL is available on RHEL 9.4 or later and on SLES.

2.1.1 Required Packages

Describes the required packages.

2.1.1.1 Packages Required for RHEL8

The following packages are required for operations on RHEL8.

Package name	Remarks
alsa-lib	-
audit-libs	-
bzip2-libs	Required when using pgBackRest.
cyrus-sasl-lib	-
pcp-system-tools	Required when using parallel scan.
glibc	-
iputils	Required for Mirroring Controller.
libcurl	Required when using OAuth authentication.
libnsl2	-
libicu	Provides collation support. Install 60.x.
libgcc	-
libmemcached	Required when using Pgpool-II.
libselinux	Required for sepgsql.
libstdc++	-
libtool-ltdl	Required when using ODBC drivers.

Package name	Remarks
libzstd	-
llvm	Versions 20.1.x, 19.1.x, 18.1.x, 17.0.x, 16.0.x, or 15.0.x,of llvm is required to run SQL with runtime compilation (just-in-time compilation). Install the package that contains libLLVM-20.so, libLLVM-19.so, libLLVM-18.so, libLLVM-17.so, llibLLVM-16.so, or llibLLVM-15.so. For example, version 19.1.x of "llvm-libs" published with Application Streams includes libLLVM-19.so. By default, version 19.1.x is used. If you use a version other than 19.1.x, specify the version you want to use in the jit_provider parameter in postgresql.conf. For example, use llvmjit-vsn20 when using version 20.1.x. Fujitsu Enterprise Postgres uses runtime compilation by default.If you do not want to use runtime compilation, turn off the jit parameter in postgresql.conf.You do not need to install llvm if you turn off the jit parameter. If the jit parameter is on and llvm is not installed, an error may occur during SQL execution. For more information about runtime compilation, see "Just-in-Time Compilation (JIT)" in "PostgreSQL Documentation".
libcgroup-tools	Required when using parallel scan.
lz4-libs	-
ncurses-libs	-
net-tools	-
nss-softokn-freebl	-
numactl-libs	-
pam	Required when using PAM authentication.
perl-libs	Required when using PL/Perl. Install 5.26.
protobuf-c	Required if using the Transparent Data Encryption feature when using a key management system as a keystore. Install 1.3.0.
python3	This is required when using PL/Python based on the Python 3 language, or when using semantic text search and automatic vectorization. Please install version 3.11.x.
rsync	Required when using Pgpool-II.
tcl	Required when using PL/Tcl. Install 8.6.
unzip	-
xz-libs	-
zlib	-

2.1.1.2 Packages Required for RHEL9

The following packages are required for operations on RHEL9.

Package name	Remarks
alsa-lib	-
audit-libs	-
bzip2-libs	Required when using pgBackRest.
cyrus-sasl-lib	-
pcp-system-tools	Required when using parallel scan.
glibc	-
iputils	Required for Mirroring Controller.
libcurl	Required when using OAuth authentication.
libnsl2	-
libicu	Provides collation support. Install 67.x.
libgcc	-
libmemcached-awesome	Required when using Pgpool-II.
libselinux	Required for sepgsql.
libstdc++	-
libtool-ltdl	Required when using ODBC drivers.
liburing	Install 2.x.
libzstd	-
llvm	Versions 20.1.x, 19.1.x, 18.1.x, 17.0.x, 16.0.x, or 15.0.x of llvm is required to run SQL with runtime compilation (just-in-time compilation). Install the package that contains libLLVM-20.so, libLLVM-19.so, llibLLVM-18.so, libLLVM-17.so, llibLLVM-16.so, or llibLLVM-15.so. For example, version 19.1.x of "llvm-libs " published with Application Streams includes libLLVM-19.so. By default, version 19.1.x is used. If you use a version other than 19.1.x, specify the version you want to use in the jit_provider parameter in postgresql.conf. For example, use llvmjit-vsn20 when using version 20.1.x. Fujitsu Enterprise Postgres is configured to use runtime compilation by default. If you do not want to use runtime compilation, turn off the jit parameter in postgresql.conf. If you turn off the jit parameter, you do not need to install llvm. If the jit parameter is on and llvm is not installed, an error may occur during SQL execution. For more information about runtime compilation, see "Just-in-Time Compilation (JIT) " in the PostgreSQL Documentation.
lz4-libs	-
ncurses-libs	-
net-tools	-
nss-softokn-freebl	-
numactl-libs	-

Package name	Remarks
pam	Required when using PAM authentication.
perl-libs	Required when using PL/Perl. Install 5.32.
protobuf-c	Required if using the Transparent Data Encryption feature when using a key management system as a keystore. Install 1.3.3.
python3	This is required when using PL/Python based on the Python 3 language, or when using semantic text search and automatic vectorization. Please install version 3.11.x.
rsync	Required when using Pgpool-II.
tcl	Required when using PL/Tcl. Install 8.6.
unzip	-
xz-libs	-
zlib	-

2.1.1.3 Packages Required for SLES 15

The following packages are required for operations on SLES 15.

Package name	Remarks
dstat	Required when using parallel scan.
gdb	-
glibc	-
glibc-32bit	-
iputils	Required for Mirroring Controller.
JRE 8	Required when using the installer, database multiplexing, and WebAdmin. The following JREs are available: - Oracle JRE Use the 64-bit version. - OpenJDK Past the Java TCK (Technology Compatibility Kit)
libasound2	-
libaudit1	-
libbz2-1	Required when using pgBackRest.
libcurl4	Required when using OAuth authentication.
libfreebl3	-
libicu-suse65_1	Provides collation support. Install 65.
libgcc	-
libltdl7	Required when using ODBC drivers.
liblz4-1	-
liblzma5	-
libmemcached	Required when using Pgpool-II.

Package name	Remarks
libncurses5	-
libnuma1	-
libprotobuf-c1	Required if using the Transparent Data Encryption feature when using a key management system as a keystore. Install 1.3.2.
libstdc++6	-
liburing2	-
libz1	-
libzstd1	-
llvm	Version 15.0.x of llvm is required to run SQL with runtime compilation (just-in-time compilation). Install the package that contains libLLVM.so.15. For example, the "libLLVM15" published in SUSE includes libLLVM.so.15. Fujitsu Enterprise Postgres uses runtime compilation by default.If you do not want to use runtime compilation, turn off the jit parameter in postgresql.conf.You do not need to install llvm if you turn off the jit parameter. If the jit parameter is on and llvm is not installed, an error may occur during SQL execution. For more information about runtime compilation, see "Just-in-Time Compilation (JIT)" in "PostgreSQL Documentation".
libLLVM15	Install 15.0.x.
net-tools	-
pam	Required when using PAM authentication.
perl	Required when using PL/Perl. Install 5.26.
python3	This is required when using PL/Python based on the Python 3 language, or when using semantic text search and automatic vectorization. Please install version 3.11.x.
rsync	Required when using Pgpool-II.
sysstat	Set up the sar command after installation.
tcl	Required when using PL/Tcl. Install 8.6.
unzip	-

2.2 Related Software

The following table lists the software required to use Fujitsu Enterprise Postgres.

Table 2.1 Related software

No.	Product name	Version	Fujitsu Enterprise Postgres product name		Remarks
			AE	SE	
1	PRIMECLUSTER (*1)	4.7A00 or later (*1)	Y	Y	Mandatory when performing failover operation integrated with PRIMECLUSTER.
2	Oracle Call Interface (OCI) libraries	19c or later	Y	Y	Required when using oracle_fdw.
3	Amazon Web Services Command Line Interface (AWS CLI)	2.x or later	Y	Y	Required for monitoring database operations using Amazon CloudWatch. Required for Autoscale of Replica Servers through Amazon EC2 Auto Scaling Integration. (*2)
4	amazon-cloudwatch-agent	v1.300064 or later	Y	N	Required for Autoscale of Replica Servers through Amazon EC2 Auto Scaling Integration.
5	amazon-ssm-agent	3.3 or later	Y	N	Required for Autoscale of Replica Servers through Amazon EC2 Auto Scaling Integration.
6	MCP Toolbox for Databases	v0.27.0 or later	Y	Y	Required when using MCP server feature for business data utilization.

Y: Can be used
N: Cannot be used

*1: The applicable products are shown below:

- PRIMECLUSTER Enterprise Edition
- PRIMECLUSTER HA Server

*2: This feature can only be used in AE.

If you want to use the semantic text search and automatic vectorization (including standalone use of model management within the database), you need the following Python packages:

Install to a location other than the default Python package installation destination (purelib) and set the environment variable PYTHONPATH.

Example of verifying the default Python package installation destination (purelib)

```
# python -c "import sysconfig;print(sysconfig.get_path('purelib'))"
/usr/local/lib/python3.11/site-packages
```

Example of installing Python packages using the pip command

```
pip install <package-name>==<version> -t <python package-install-destination>
```

Setting PYTHONPATH

```
export PYTHONPATH=<python package-install-destination>:$PYTHONPATH
```

Package name	Remarks
anthropic	Install 0.44.0.
backoff	Install 2.2.1.
boto3	Install 1.35 or higher and 2.0 or lower.
click	Install 8.0 or higher and 9.0 or lower.
cohere	Install 5.13.11.
datadog_lambda	Install 6.9 or higher and 7.0 or lower.
datasets	Install 3.1.0.
google-cloud-aiplatform	Install 1.78.0 or higher and 2.0 or lower.
langchain-openai	Install 0.1 or higher and 1.0 or lower.
langchain-text-splitters	Install 0.3.5 or higher and 1.0 or lower.
litellm	Install 1.58.2.
ollama	Required when using Ollama as the embedded provider. Install 0.4.5.
openai	Required when using OpenAI as the embedded provider. Install 1.56.0.
pgvector	Python library for handling the pgvector data type, separate from the pgvector Fujitsu Enterprise Postgres extension. Install 0.3 or higher and 1.0 or lower.
pydantic	Install 2.0 or higher and 3.0 or lower.
python-dotenv	Install 1.0 or higher and 2.0 or lower.
pytimeparse	Install 1.1 or higher and 2.0 or lower.
structlog	Install 24.0 or higher and 25.0 or lower.
tiktoken	Install 0.7 or higher and 1.0 or lower.
tritonclient[grpc]	Install 2.20.0 or higher. When performing vectorization using embedded models imported into the database, use the same version as the Triton Inference Server you set up as the inference server.
typing_extensions	Install 4.0 or higher and 5.0 or lower.
voyageai	Required when using VoyageAI as the embedded provider. Install 0.3.1.

The following table lists client that can be connected to the Fujitsu Enterprise Postgres server feature.

Table 2.2 Connectable client

OS	Product name
Windows Linux	Fujitsu Enterprise Postgres Client 18 or later

The following table lists server assistant that can be connected to the Fujitsu Enterprise Postgres server feature.

Table 2.3 Connectable server assistant

OS	Product name
Linux Windows	Fujitsu Enterprise Postgres Server Assistant 18 or later

2.3 Excluded Software

This section describes excluded software.

Fujitsu Enterprise Postgres

Fujitsu Enterprise Postgres cannot be installed if all the following conditions are met:

- The product version (indicated by "*x*" in "*x* SP*z*") of the product to be installed is the same as that of the installed product
- The editions are different

Example

In the following cases, Fujitsu Enterprise Postgres cannot be installed as an exclusive product:

- The installed product is Fujitsu Enterprise Postgres Standard Edition (64bit) 18
- The product to be installed is Fujitsu Enterprise Postgres Advanced Edition (64bit) 18 SP1

Other products

There are no exclusive products.

2.4 Required Patches

There are no required patches.

2.5 Hardware Environment

The following hardware is required to use Fujitsu Enterprise Postgres.

Memory

At least 512 MB of memory is required.

2.6 Disk Space Required for Installation

The following table shows the disk space requirements for new installation of Fujitsu Enterprise Postgres. If necessary, increase the size of the file system.

Disk space required for installation

Table 2.4 RHEL

Directory	Required disk space (Unit: MB)
/etc	1
/var	1
Installation destination of the server	800
Installation destination of WebAdmin	590
Installation destination of the client (64-bit)	180
Installation destination of Pgpool-II	30
Installation destination of pgBackRest	40

Table 2.5 SLES

Directory	Required disk space (Unit: MB)
/etc	1

Directory	Required disk space (Unit: MB)
/var	1
Installation destination of the server	290
Installation destination of WebAdmin	310
Installation destination of the client (64-bit)	170
Installation destination of Pgpool-II	30
Installation destination of pgBackRest	30

2.7 Supported System Environment

This section describes the supported system environment.

2.7.1 TCP/IP Protocol

Fujitsu Enterprise Postgres supports version 4 and 6 (IPv4 and IPv6) of TCP/IP protocols.

Do not use link-local addresses if TCP/IP protocol version 6 addresses are used.

2.7.2 File System

All file systems with a POSIX-compliant interface are supported.

However, for stable system operation, the disk where the database is deployed must use a highly reliable file system. Consider this aspect when selecting the file system to be used.

2.8 PostgreSQL Version Used for Fujitsu Enterprise Postgres

Fujitsu Enterprise Postgres is based on PostgreSQL 18.

2.9 Notes on Using Streaming Replication

To use streaming replication, build the primary server and all standby servers using the same Fujitsu Enterprise Postgres version. The same version refers to *x* SP*z* x, which is represented as the product version.

Streaming replication cannot be used in combination with Open Source PostgreSQL.

2.10 Key Management System Requirements

Describes the requirements for a key management system.

2.10.1 To Connect to a key Management System Using the KMIP Protocol

If you use a key management system as a keystore to use the Transparent Data Encryption feature, the following conditions must be met.

Protocol

Key management systems must use the Key Management Interoperability Protocol (KMIP) Version 1.4 protocol.

Encryption Key

The encryption key used must be able to be created or brought into the KMIP server under the following conditions.

- AES 256 bit symmetric key

  A Managed Object that meets the following criteria:

  - Cryptographic Algorithm : AES
  - Cryptographic Length : 256
- Key not wrapped

Operation

The following operations using the KMIP protocol must be supported:

- Get operation

  Encryption keys can be returned in Key Format Type: Raw format.

Client authentication

You must be able to authenticate and authorize clients in the following ways:

- The registered client certificate can authenticate the client and authorize access to the encryption key.

Quantitative Limits

Fujitsu Enterprise Postgres can receive a maximum response size of 8192 bytes from a key management system. Any further response results in an error.

If the private key file used for the client certificate is encrypted, the maximum length of the passphrase used for encryption is 1023 bytes.

2.10.2 To Connect to a Key Management System Using a Plug-in

If you are using a key management system that requires a connection using a protocol other than KMIP, you will need an adapter that converts the request from the Fujitsu Enterprise Postgres into a request format that the key management system can accept.

By preparing the adapter and registering it as a plug-in to the Fujitsu Enterprise Postgres, you can use the key management system as a keystore.

The adapter must be implemented to meet the requirements specified by the Fujitsu Enterprise Postgres.

The key management system must be capable of meeting the requirements of the adapter.

See "Appendix M Access to Key Management System Using Plug-in" for adapter requirements.

Quantitative Limits

The maximum length of the secret, used for example to pass passwords and other information to plug-ins, is 4095 bytes.

Chapter 3 Installation

This chapter explains the installation procedures of Fujitsu Enterprise Postgres.

Note

If you have antivirus software installed, the server may crash, fail to start, or stop responding, during installation or when starting up after installation. Set scan exception settings for the installation directory and resource allocation directory so that the files in these directories are not scanned for viruses.

Point

In this chapter, "< x >" in the path indicates the version ("SPz" is output when the product level is upgraded).

3.1 Pre-installation Tasks

Check the system environment below before installing Fujitsu Enterprise Postgres.

Check the disk space

Ensure that there is sufficient disk space to install Fujitsu Enterprise Postgres.

Refer to "2.6 Disk Space Required for Installation" for information on the required disk space.

Reconfigure the disk partition if disk space is insufficient.

Executable Users

Installation and uninstallation is performed by superuser.

On the system, run the following command to become superuser.

```
$ su -
Password:******
```

Determine the preferred WebAdmin configuration

WebAdmin can be installed in two configurations:

- Single-server
- Multiserver

See

Refer to "Appendix I Determining the Preferred WebAdmin Configuration" for details.

Determining the Pgpool-II System Configuration

The system configuration when using Pgpool-II is as follows:

- Place on database server
- Place on application server
- Place on dedicated server

See

Refer to "Appendix J System Configuration when using Pgpool-II".

3.2 Installation from RPM Package

Describes an interactive installation.

For Reinstallation

Back up the following folders that contain WebAdmin instance management information:

webAdminInstallFolder/data/fepwa

Follow the procedure below to perform the backup.

1. Stop the WebAdmin server. Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" for details.
2. Back up the following folder:

   webAdminInstallFolder/data/fepwa

Replace the above folder with the backed up folder when the reinstallation is complete.

Installation Instructions

Install according to the following procedure:

1. Stop applications and programs

Reinstallation requires stopping applications and programs.

Before starting the installation, stop the following:

- Applications that use the product
- Connection Manager
- Instance
- Web server feature of WebAdmin

  Execute the WebAdminStop command to stop the Web server feature of WebAdmin.

  Example

  If WebAdmin is installed in /opt/fsepv<*x*>webadmin:

  ```
  # cd /opt/fsepv<x>webadmin/sbin
  # ./WebAdminStop
  ```

- Mirroring Controller

  Execute the mc_ctl command with the stop mode option specified and stop the Mirroring Controller.

  Example

  ```
  $ mc_ctl stop -M /mcdir/inst1
  ```

- pgBadger
- Pgpool-II
- pgBackRest

2. Mount the DVD drive

Insert the server program DVD into the DVD drive, and run the command given below.

Example

```
# mount -t iso9660 -r -o loop /dev/dvd /media/dvd
```

Here /dev/dvd is the device name for the DVD drive (which may vary depending on your environment), and /media/dvd is the mount point (which may need to be created before calling the command).

3. Run the installation

The RPM packages required to install each product are stored under the mount point where you mounted the DVD.

The following shows a list of packages and the path of the storage directory.

Install all packages for the product you are installing.

Product name	Package storage directory	Package name
Server	SERVER/Linux/packages/<*os*>	FJSVfsep-server-*.rpm
WebAdmin	WEBADMIN/Linux/packages/<*os*>	FJSVfsep-webadmin-*.rpm
Client	CLIENT64/Linux/packages/<*os*>	FJSVfsep-client-*.rpm
Pgpool-II	PGPOOL2/Linux/packages/<*os*>	FJSVfsep-pgpool2-*.rpm
pgBackRest	PGBACKREST/Linux/packages/<*os*>	FJSVfsep-pgbackrest-*.rpm

<os> is the OS of the operating environment. Depending on your system requirements, refer to RHEL8, RHEL9, or SLES15.

*is the detailed name of the package, version, OS, etc.

The default installation directory names are:

To specify a path different from the default installation directory, you can use the following characters:

`[a-zA-Z0-9], -,, and /`

Product name	Installation directory name (default)
Server	/opt/fsepv<*x*>server64
WebAdmin	/opt/fsepv<*x*>webadmin
Client	/opt/fsepv<*x*>client64
Pgpool-II	/opt/fsepv<*x*>pgpool-II
pgBackRest	/opt/fsepv<*x*>pgbackrest

Point

We recommend that you install the packages for each product in a batch.

You can use "*" to specify a package name, or you can install all packages in a batch by specifying all package names side by side.

Example

To install the server product in a RHEL8 environment, run the following command:

```
# cd /media/dvd/SERVER/Linux/packages/RHEL8
# rpm -ivh FJSVfsep-server-*.rpm
```

Use --prefix to specify a path different from the default installation directory.

4. Check the installed product

Check the installed products by following the procedure below.

Example

Displays the name of the installed package.

```
# rpm -qa | grep FJSVfsep
```

For detailed package information, run the following command:

```
# rpm -qi package name
```

Example

In the path, "<x>" and "<x0z>" refer to the x and z of x SPz, which is expressed as the product version. For products without SPz, <x0z> is <x00>.

```
# rpm -qi FJSVfsep-server-essential-ae-<x>-<x0z>-0.el8.x86_64
Name        : FJSVfsep-server-essential-ae-<x>
Version     : <x0z>
Release     : 0.el8
Architecture: x86_64
Install Date: ddd MMM DD hh:mm:ss YYYY
Group       : Applications/Databases
Size        : XXX
License     : Fujitsu Limited
Signature   : (none)
Source RPM  : FJSVfsep-server-essential-ae-<x>-<x0z>-0.el8.src.rpm
Build Date  : ddd MMM DD hh:mm:ss YYYY
Build Host  : XXXXXXXXXX
Relocations : /opt/fsepv<x>server64
Packager    : Fujitsu Limited
Vendor      : Fujitsu Limited
URL         : https://www.fujitsu.com
Summary     : Fujitsu Enterprise Postgres Advanced Edition(64bit) <x>
Description :
Fujitsu Enterprise Postgres Advanced Edition Essential Package
```

5. Setting up WebAdmin

To use WebAdmin, you need to set up WebAdmin. Refer to "Appendix B Setting Up and Removing WebAdmin" for more information.

Chapter 4 Setup

This chapter describes the setup procedures to be performed after installation completes.

4.1 Operating Method Types and Selection

This section describes how to operate Fujitsu Enterprise Postgres.

There are two methods of managing Fujitsu Enterprise Postgres operations.

- Simple operation management using a WebAdmin (web-based GUI tool)

  Suitable when using frequently used basic settings and operations for operation management.

  This method allows you to perform simple daily tasks such as starting the system before beginning business, and stopping the system when business is over, using an intuitive operation.

- Advanced operation management using server commands

  Operations that use Fujitsu Enterprise Postgres or PostgreSQL server commands or server applications.

  When operating in a system that is automated by operation management middleware (Systemwalker Centric Manager, for example), this method allows you to use more detailed settings and operations and perform higher level operation management.

  Refer to Reference and the PostgreSQL Documentation for information on server commands and server applications.

Select one that suits your purposes.

How WebAdmin and Server Commands Work

Here are the differences between using WebAdmin and server commands:

Operation		Operation with the WebAdmin	Operation with commands
Setup	Creating an instance	The server machine capacity, and the optimum parameter for operations using WebAdmin, are set automatically. Instances that you create and manage in WebAdmin are registered in the WebAdmin administrative information, so you must delete the instance from WebAdmin.	The configuration file is edited directly using the initdb command.
	Creating a standby instance	WebAdmin performs a base backup of the source instance and creates a standby instance.	A standby instance is created using the pg_basebackup command.
	Changing the configuration files	You can change the values in the configuration file on the WebAdmin screen.	The configuration file is edited directly.
Starting and stopping an instance		You can start and stop with one click from the WebAdmin screen.	The pg_ctl command is used.
Creating a database		This is defined using pgAdmin of the GUI tool, or using the psql command or the application after specifying the DDL statement.	
Backing up the database		WebAdmin, or the pgx_dmpall command, is used. It cannot be used interchangeably with operation using server commands or server applications. If	It is recommended that the pgx_dmpall command be used. Recovery to the latest database can be performed.

Operation		Operation with the WebAdmin	Operation with commands
		used, WebAdmin will not be able to properly manage the instance. If you are backing up by using the copy command with the pgx_dmpall command, select the command operation method.	
Database recovery		You can recover using a backup taken with WebAdmin or the pgx_dmpall command.	To use the backup that was performed using the pgx_dmpall command, the pgx_rcvall command is used.
Monitoring	Database errors	The status in the WebAdmin window can be checked. (*1)	The messages that are output to the database server log are monitored (*1)
	Disk space	The status in the WebAdmin window can be checked. A warning will be displayed if the free space falls below 20%. (*1)	This is monitored using the df command of the operating system, for example. (*1)
	Connection status	This can be checked using pgAdmin of the GUI tool, or referencing pg_stat_activity of the standard statistics view from psql or the application.	

*1: This can be used together with system log monitoring using operations management middleware (Systemwalker Centric Manager, for example).

Refer to "Periodic Operations" and "Actions when an Error Occurs" in the Operation Guide for information on monitoring and database recovery.

4.2 Preparations for Setup

This section describes the preparation required before setting up Fujitsu Enterprise Postgres.

4.2.1 Creating an Instance Administrator

Decide which OS user account will be assigned the instance administrator role. You can assign it to a new user or to an existing one, but you cannot assign it to the OS superuser (root).

When operating with WebAdmin, if you change the password for the OS user account, use ALTER ROLE WITH PASSWORD to change the instance administrator password as well.

The following example shows an OS user account with the name "fsepuser" being assigned the instance administrator role.

Example

```
# useradd fsepuser
# passwd fsepuser
```

4.2.2 Preparing Directories for Resource Deployment

Prepare the directories required when creating instances.

Considerations when deploying resources

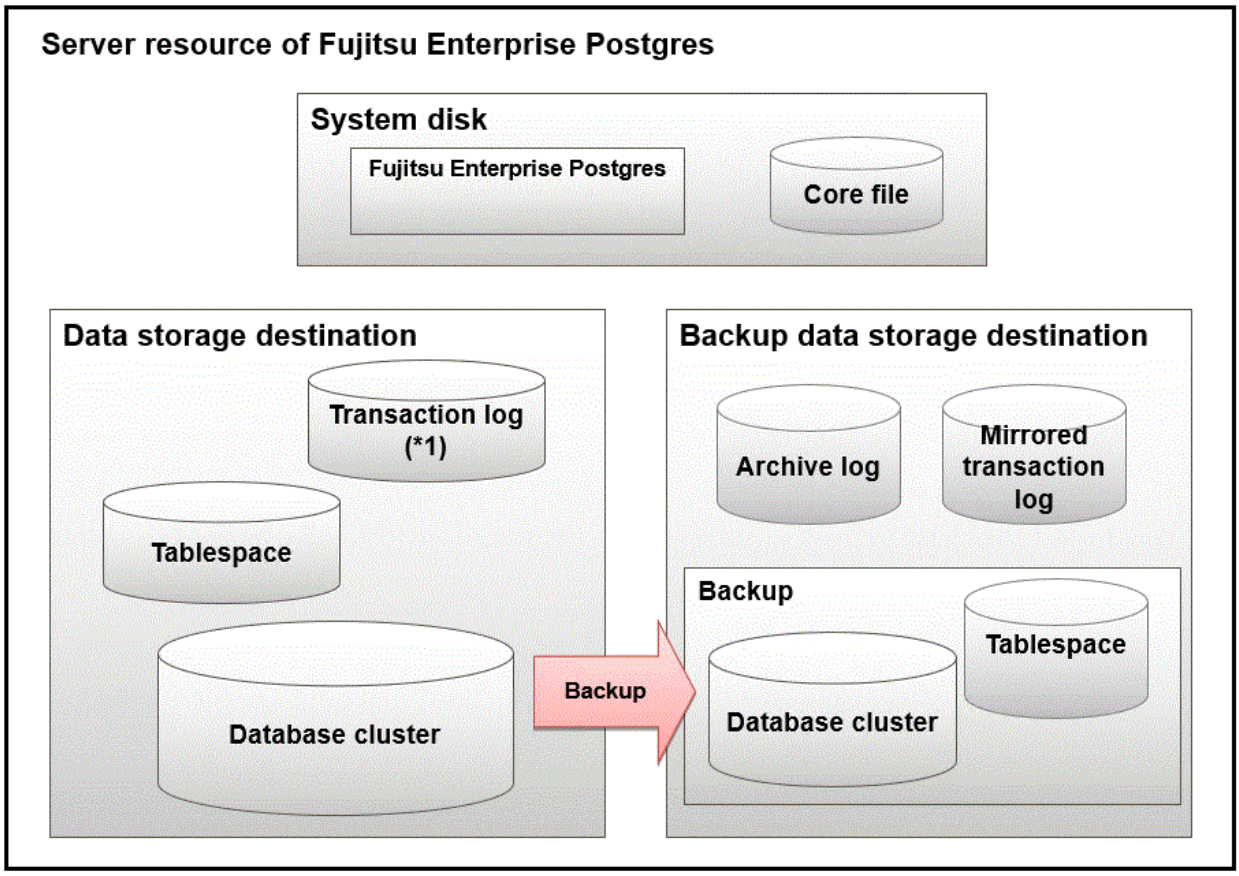
The disk configuration on the resource deployment destination is important, because it affects not only recovery following disk corruption, but normal operation as well. The points for determining the disk configuration are as follows:

1. If the backup data storage destination and the data storage destination are both lost, it will not be possible to recover the data, so deploy them to separate disks.
2. To shorten the recovery time following a single disk fault, deploy the system disk and data storage destination to separate disks.
3. The backup data storage destination requires at least double the capacity of the data storage destination, so deploy it to the disk with the most space available.
4. When large amounts of data are updated, the write-to load for the data storage destination, transaction log storage destination, and backup data storage destination (mirrored transaction log) will also be great. For this reason, deploy them to separate disks, out of consideration for performance.

Information

If you choose to place the archive log and mirrored transaction log (mirrored WAL) on a disk that is separate from the backup data storage destination, keep the following points in mind:

- Recovery requires not only the backup data, but also the archive log and mirrored transaction log (mirrored WAL). Therefore, make sure that these items can be stored together.
- Note that the permissions and mount state are the same at the time of the recovery as they were at the time of the backup. Make the archive log and mirrored transaction log (mirrored WAL) available before starting the recovery.



*1: To distribute the I/O load, place the transaction log on a different disk from the data storage destination.

Resource	Role
Database cluster	The area where the database is stored. It is a collection of databases managed by an instance.
Tablespace	Stores table files and index files in a separate area from the database cluster. Specify a space other than that under the database cluster.
Transaction log	Stores log information in preparation for a crash recovery or rollback. This is the same as the WAL (Write Ahead Log).
Archive log	Stores log information for recovery
Mirrored transaction log (mirrored WAL)	Enables a database cluster to be restored to the state immediately before an error even if both the database cluster and transaction log fail when performing backup/recovery operations using the pgx_dmpall command or WebAdmin.
Corefile	Fujitsu Enterprise Postgres process corefile output when an error occurs with a Fujitsu Enterprise Postgres process.

Examples of disk deployment

The following are examples of disk deployment:

Number of disks	Disk	Deployment
3	System disk	Fujitsu Enterprise Postgres program
		Corefile
	Connected physical disk	Data storage destination, transaction log storage destination
	Connected physical disk	Backup data storage destination
2	System disk	Fujitsu Enterprise Postgres program
		Corefile
		Data storage destination, transaction log storage destination
	Connected physical disk	Backup data storage destination

Preparing directories

You cannot use directories mounted over the network.
Examples include NFS (Network File System) and CIFS (Common Internet File System).
Do not use these directories unless you are creating tablespaces on a storage device on your network.

The directories to be prepared depend on the way that you create the instances.

Using WebAdmin

For WebAdmin, WebAdmin automatically creates the directory during instance creation.

Directory	Description
Data storage destination	Specify in the GUI.
Backup data storage destination	Specify in the GUI. Place them on a disk different from the data storage destination.
Transaction log storage destination	Specify in the GUI. The default is to create in a directory in the data storage destination. When

Directory	Description
	it is necessary to distribute the I/O load for the database data and the transaction log, consider putting the transaction log storage destination on a different disk from the data storage destination
Corefile output destination	WebAdmin generates it automatically, so no specification is required. For more information about directories, refer to "Directory for Core File Output when Using WebAdmin".

Directory for Core File Output when Using WebAdmin

The corefile path is as follows:

```
/var/tmp/fsep_productVersion_WA_architecture/instanceAdminUser_instanceNamePortNumber/core
```

product version

Contains the version of the [Server Product Type] that WebAdmin specifies when creating an instance.

If you manage multiple versions, the fsep_version directory is created for as many versions as you manage.

instanceAdminUser

Contains the user name of the OS.

PortNumber

Contains the port number of the database server specified when the instance was created.

Example:

```
/var/tmp/fsep_180_WA_64/naomi_myinst27599/core
```

To change the output destination, configure the core_directory and the core_contents parameters in postgresql.conf. Refer to "Parameters" in the Operation Guide for information on the settings for these parameters.

Note

Note that resources placed in /var/tmp that have not been accessed for 30 days or more will be deleted by the default settings of the operating system. Consider excluding them from deletion targets or changing the output destination in the operating system settings.

Using the initdb Command

For the inidb command, prepare the directory in advance.

The directories to prepare in advance are:

Directory to be prepared	Required / Optional
Data storage destination	Required
Backup data storage destination	Optional
Transaction log storage destination	Optional
Corefile output destination	Optional

4.2.3 Estimating Resources

Estimate the resources to be used on the Fujitsu Enterprise Postgres.

Refer to "Appendix E Estimating Database Disk Space Requirements" for information on estimating database disk space requirements.

Refer to "Parameters automatically set by WebAdmin according to the amount of memory" when creating multiple instances with WebAdmin.

Refer to "Appendix F Estimating Memory Requirements" when creating instances with the initdb command, to estimate memory usage.

4.2.4 Configuring Corefile Names

If a process crashes, a corefile for the process will be generated by the operating system. If a corefile is generated with the same name as an existing corefile generated for a different process, the newly-generated corefile will overwrite the previously dumped corefile. To prevent this, configure a unique corefile name for each crash by appending the process ID, program name, and datetime.

Corefile names can be configured using the "kernel.core_pattern" and "kernel.core_uses_pid" kernel parameters.
Refer to the "man page" in "core(5)" for information on how to use these parameters.

Note that with regard to the location for storing corefiles, the operating system settings take precedence over the core_directory parameter of postgresql.conf.

If you specify systemd-coredump as the core_pattern, the core file is not placed in the location specified by the core_directory parameter.See the systemd-coredump (8) man page for the location of core files.

Use coredumpctl to retrieve core files.For more information about using coredumpctl, see the coredumpctl (1) man page.

4.3 Creating Instances

There are two methods that can be used to create an instance:

- 4.3.1 Using WebAdmin
- 4.3.2 Using the initdb Command

4.3.1 Using WebAdmin

This section describes how to create an instance using WebAdmin.

WebAdmin must be set up correctly before it can be used. Refer to "B.1 Setting Up WebAdmin" for details. Additionally, if WebAdmin needs to be configured to use an external repository database, refer to "B.3 Using an External Repository for WebAdmin" for details.

4.3.1.1 Before Using WebAdmin

Learn what you need to know before using WebAdmin.

Recommended Browser

- Microsoft Edge

WebAdmin will work with other browsers, such as Firefox and Chrome, however, the look and feel may be different.

Configure your browser to allow cookies and pop-up requests from the server on which Fujitsu Enterprise Postgres is installed. Refer to "Appendix A Recommended WebAdmin Environments" for information on how to change the pop-up request settings and other recommended settings.

Notes on operations

- It will not work correctly if you operate the same instance from multiple WebAdmin screens at the same time.
- If you want to manage multiple versions of an instance, operate with the latest version of WebAdmin.
- It is recommended not to use the browser [Back] and [Forward] navigation buttons, the [Refresh] button, and context-sensitive menus, including equivalent keyboard shortcuts.
- Do not copy and paste or bookmark the URL of the WebAdmin login screen and skip directly.

Considerations for Using Transparent Data Encryption

After you create an instance in WebAdmin, follow the documentation for each feature in the Operation Guide for additional setup tasks.

About the PostgreSQL Configuration File Relationship

When creating or importing an instance in WebAdmin, set the log_directory parameter in postgresql.conf to '/var/tmp/fsep_version/instanceAdminUser_instanceNamePortNumber/log'.

Note

Note that resources placed in /var/tmp that have not been accessed for 30 days or more will be deleted by the default settings of the operating system. Therefore, consider excluding instances created using WebAdmin from deletion targets in the operating system settings if you need to stop those instances for a long time.

4.3.1.2 Logging in to WebAdmin

This section describes how to log in to WebAdmin.

Startup URL for WebAdmin

In the browser address bar, type the startup URL of the WebAdmin window in the following format:

```
http://hostNameOrIpAddress:portNumber/
```

- *hostNameOrIpAddress*: Host name or IP address of the server where WebAdmin is installed.
- *portNumber*: Port number of WebAdmin. The default port number is 27515.

The startup screen is displayed. From this window you can log in to WebAdmin or access the product documentation.

Logging in to WebAdmin

Click [Launch WebAdmin] in the startup URL window to start WebAdmin and display the login window. Enter the instance administrator user ID (operating system user account name) and password, and log in to WebAdmin. User credential (instance administrator user ID and password) should not contain hazardous characters. Refer to "Appendix C WebAdmin Disallow User Inputs Containing Hazardous Characters".

If you set the account lock for login failure, login failure from WebAdmin might lock the account and prevent you from logging in to the OS. Check the account lock settings in advance.

4.3.1.3 Creating an Instance

This section describes how to create an instance.

Information

- WebAdmin creates an instance configuration file, postgresql.conf, and sets kernel parameters to the optimal values for this configuration. Refer to "Appendix D Configuring Parameters" and "Appendix H Configuring Kernel Parameters" for more information.
- WebAdmin automatically sets the memory usage assuming you create one instance per machine. If you are creating multiple instances on a single machine, refer to "Parameters automatically set by WebAdmin according to the amount of memory" to adjust the memory usage after the instance is created.

1. Start WebAdmin, and log in to the database server.
2. In the [Instances] tab, click .
3. Enter the information for the instance to be created.

   Enter the following items:

[Host name] and [Operating system credential] should not contain hazardous characters. Refer to "Appendix C WebAdmin Disallow User Inputs Containing Hazardous Characters".

- [Configuration type]: Whether to create a standalone instance or an instance that is part of a cluster.
- [Server product type]: Sets which of the following instances to create:
  - Fujitsu Enterprise Postgres 9.5 Instances
  - Fujitsu Enterprise Postgres 9.6 Instances
  - Fujitsu Enterprise Postgres 10 Instances
  - Fujitsu Enterprise Postgres 11 Instances
  - Fujitsu Enterprise Postgres 12 Instances
  - Fujitsu Enterprise Postgres 13 Instances
  - Fujitsu Enterprise Postgres 14 Instances
  - Fujitsu Enterprise Postgres 15 Instances
  - Fujitsu Enterprise Postgres 16 Instances
  - Fujitsu Enterprise Postgres 17 Instances
  - Fujitsu Enterprise Postgres 18 Instances

  The default is "Fujitsu Enterprise Postgres 18".
- [Location]: Whether to create the instance in the server that the current user is logged into, or in a remote server. The default is "Local", which will create the instance in the server machine where WebAdmin is currently running.
- [Instance name]: Name of the database instance to manage

  The name must meet the conditions below:
  - Maximum of 16 characters
  - The first character must be an ASCII alphabetic character
  - The other characters must be ASCII alphanumeric characters
- [Instance port]: Port number of the database server
- [Data storage path]: Directory where the database data will be stored
- [Backup]: Whether to enable or disable the WebAdmin backup feature. The default is "Enabled". Select "Disabled" to disable all backup and restore functionality for the instance. If "Enabled" is selected, enter the following item:
  - [Backup storage path]: Directory where the database backup will be stored
- [Transaction log path]: Directory where the transaction log will be stored
- [Encoding]: Database encoding system
- [WAL file size]: Allow the WAL file size to be set when creating an instance. The default is 16 MB if the field is blank. The size specified must be a power of 2 between 1 and 1024. This option is not available for standby instances.

If "Remote" is selected for [Location], enter the following additional items:

- [Host name]: Name of the host where the instance is to be created
- [Operating system credential]: Operating system user name and password for the remote machine where the instance is to be created
- [Remote WebAdmin port for standalone]: Port in which WebAdmin is accessible in the remote machine

4. Click to create the instance.

   If the instance is created successfully, a message indicating the same will be displayed.

5. The instance will be started when it is created successfully.

6. Back up the basic information that was set

   Back up the WebAdmin management information periodically to ensure operational continuity when a fault occurs on the system disk. Follow the procedure below to perform the backup.

   a. Stop the WebAdmin server. Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" for details.

   b. Back up the following directory:

      webAdminInstallDir/data/fepwa

   Note that if you are using an external database as your WebAdmin repository, you must also back up the following:

   - *webAdminInstallDir*/data/remotemetadb.conf
   - Use the database features to back up external databases (if they are created on the system disk).

4.3.1.4 Changing Instance Settings

You can change the information that is set when an instance is created.

Change the following settings to suit the operating and management environment for Fujitsu Enterprise Postgres.

Note that this cannot be changed for instances of FUJITSU Enterprise Postgres 9.5.

- Instance configuration
  - Character encoding
  - Communication
  - SQL options
  - Memory
  - Streaming replication
- Changing client authentication information
- Editing instance information

Information

- These settings are the same as the parameters that can be set in the files shown below. Refer to "Appendix D Configuring Parameters" for information on the equivalence relationship between the item name and the parameter.
  - postgresql.conf
  - pg_hba.conf
- When [Instance name] or [Instance port] is modified, the log_directory and core_directory parameters in postgresql.conf are updated. Also, the specified directories are created if they do not exist. Refer to “4.3.1.5 Importing Instances” for information on the format of these directories.

4.3.1.4.1 Instance configuration

1. Start WebAdmin and log in to the database server.
2. In the [Instances] tab, click .
3. Click to change the configuration.
4. Click to save your changes.

See

Select a client-side encoding system that can be converted to/from the database encoding system. Refer to "Automatic Character Set Conversion Between Server and Client" in "Server Administration" in the PostgreSQL Documentation for information on the encoding system combinations that can be converted.

4.3.1.4.2 Changing client authentication information

1. Start WebAdmin and log in to the database server.
2. In the [Instances] tab, click .

   Click to register new authentication information.

   To change authentication information, select the information, and then click .

   To delete authentication information, select the information, and then click .

Notes on changing client authentication information

When creating the instance, do not delete the entry below, because it is a connection required for WebAdmin to monitor the operational status of the database:
Type=local, Database=all, User=all, and Method=md5

4.3.1.4.3 Editing instance information

Use the [Edit instance] page to modify the following items for an instance:

- Instance name
- Port number
- Backup storage path

1. In the [Instances] tab, click . The [Edit instance] page is displayed.
2. Modify the relevant items.

   If [Backup storage path] is changed, [Backup management] is enabled. Select the required option:

   - Retain existing backup: Create a backup in [Backup storage path] and retain the existing backup in its original location.
   - Copy existing backup to new path: Copy the existing backup to [Backup storage path]. A new backup will not be created. The existing backup will be retained in its original location.
   - Move existing backup to new path: Move the existing backup to [Backup storage path]. A new backup will not be created.
   - Remove existing backup: Create a backup in [Backup storage path]. The existing backup will be removed.
3. Click to save your changes.

4.3.1.5 Importing Instances

Instances can be created using WebAdmin, or via the command line using the initdb command. Instances created using the initdb command (command line instances) can be managed using WebAdmin, however, they must first be imported into WebAdmin.

You cannot import instances that use the Mirroring Controller.

Advance Preparation

- If the following file contains records that span multiple lines, change the record to a single line before importing.
  - pg_hba.conf
  - pg_ident.conf

- You must make the following changes to the parameters in postgresql.conf prior to importing the instance in WebAdmin.

Parameter	Requirements
port	The port parameter should be uncommented.

- Delete the values specified for the following parameters. Also, if you have changed the value of the parameter (where the file is stored) from the default, move the file to the data storage directory before importing it.
  - hba_file parameter (pg_hba.conf)
  - ident_file parameter (pg_ident.conf)

Import

This section explains how to import command line instances into WebAdmin.

1. In the [Instances] tab, click . The [Import instance] page is displayed.
2. Enter the information for the instance being imported. Refer to "4.3.1.3 Creating an Instance" for information on the items that need to be entered.
3. Click to import the instance.

Information

The log_directory and core_directory parameters in postgresql.conf are updated during import. Also, the specified directories are created if they do not exist.
The format of these directories is as follows:

```
log_directory: '/var/tmp/fsep_version/instanceAdminUser_instanceNamePortNumber/log'
core_directory: '/var/tmp/fsep_version/instanceAdminUser_instanceNamePortNumber/core'

    version: product version_WA_architecture
    instanceAdminUser: operating system user name
    PortNumber: port number specified when creating the instance
```

Examples:
log_directory: '/var/tmp/fsep_180_WA_64/naomi_myinst27599/log'
core_directory: '/var/tmp/fsep_180_WA_64/naomi_myinst27599/core'

4.3.2 Using the initdb Command

This section describes the procedure to create an instance using the initdb command.

Instances created using the initdb command (command line instances) can be managed using WebAdmin, however, they must first be imported into WebAdmin. Refer to "4.3.1.5 Importing Instances" for details.

4.3.2.1 Editing Kernel Parameters

Refer to "Appendix H Configuring Kernel Parameters" prior to editing these settings.

After the settings are complete, check the command specifications of the relevant operating system and restart the system if required.

4.3.2.2 Creating an Instance

Create an instance, with the database cluster storage destination specified in the PGDATA environment variable or in the -D option. Furthermore, the user that executed the initdb command becomes the instance administrator.

See

Refer to "initdb" in "Reference" in the PostgreSQL Documentation for information on the initdb command.

The procedure to create an instance is described below.

1. Use the OS user account that you want as the instance administrator.

   Connect with the server using the OS user account that you want as the instance administrator.

   You cannot use the OS superuser (root).

   The following example shows the OS superuser connected to the server being changed to the OS user account "fsepuser".

   Example

   ```
   # su fsepuser
   ```

2. Configure the environment variables

   Configure the environment variables in the server with the newly created instance.

   Set the following environment variables:

   - PATH environment variables

     Add the installation directory "/bin".

   - MANPATH environment variables

     Add the installation directory "/share/man".

   Example

   The following example configures environment variables when the installation directory is "/opt/fsepv<*x*>server64".

   Note that "<*x*>" indicates the product version.

   sh, bash

   ```
   $ PATH=/opt/fsepv<x>server64/bin:$PATH ; export PATH
   $ MANPATH=/opt/fsepv<x>server64/share/man:$MANPATH ; export MANPATH
   ```

   csh, tcsh

   ```
   $ setenv PATH /opt/fsepv<x>server64/bin:$PATH
   $ setenv MANPATH /opt/fsepv<x>server64/share/man:$MANPATH
   ```

3. Create a database cluster

   Create the database cluster with the initdb command, specifying the storage destination directory.

   Specify the transaction log storage destination and the locale setting option as required.

   If creating multiple instances, ensure that there is no duplication of directories that store database clusters.

   Example

   ```
   $ initdb -D /database/inst1 --waldir=/transaction/inst1 --lc-collate="C" --lc-ctype="C" --
   encoding=UTF8
   ```

   - In some features, instance names are requested, and those names are required to uniquely identify the instance within the system. These features allow names that conform to WebAdmin naming conventions, so refer to the following points when determining the names:

     - Maximum of 16 characters
     - The first character must be ASCII alphabetic character
     - The other characters must be ASCII alphanumeric characters

- Specify "C" or "POSIX" for collation and character category. Performance deteriorates if you specify a value other than "C" or "POSIX", although the behavior will follow the rules for particular languages, countries and regions. Furthermore, this may need to be revised when running applications on systems with different locales.
  For example, specify as follows:

  ```
  initdb --locale="C" --lc-messages="C"
  initdb --lc-collate="C" --lc-ctype="C"
  ```

- Specify the same string in the LANG environment variable of the terminal that starts Fujitsu Enterprise Postgres as was specified in lc-messages of initdb (lc_messages of postgresql.conf). If the same string is not specified, messages displayed on the terminal that was started, as well as messages output to the log file specified in the -l option of the pg_ctl command or the postgres command used for startup, may not be output correctly.
- Specify an encoding system other than SQL_ASCII for the database. If SQL_ASCII is used, there is no guarantee that the encryption system for data in the database will be consistent, depending on the application used to insert the data.

See

Refer to "Locale Support" in "Localization" in "Server Administration" in the PostgreSQL Documentation for information on locales.

4. Set port number.

   Specify a port number in the port parameter of postgresql.conf. Ensure that the specified port number is not already used for other software. If creating multiple instances, ensure that there is no duplication of port numbers.

   If a port number is not specified, "27500" is selected.

   Register the specified port numbers in the /etc/services file if WebAdmin is used to create other instances. WebAdmin uses the /etc/services file to check if port numbers specified as available candidates have been duplicated.

   Register any name as the service name.

5. Set the corefile output destination.

   Specify the output destination of the corefile, which can later be used to collect information for investigation, by setting the core_directory and core_contents parameters of postgresql.conf.

See

Refer to "Parameters" in the Operation Guide for information on the settings for these parameters.

6. Set the backup storage destination.

   Specify the backup data storage destination and other backup settings when backup is to be performed as a provision against database errors.

See

Refer to "Backup Methods" in the Operation Guide for information on specifying backup settings.

7. Start an instance.

   Start with the start mode of the pg_ctl command.

   Example

   ```
   $ pg_ctl start -D /database/inst1
   ```

   If either of the following conditions are met, the message "FATAL:the database system is starting up(11189)" may be output. This message is output by the pg_ctl command to check if the instance has started successfully. Therefore, ignore this message if there are no other applications, commands, or processes that connect to the database.

   - An application, command, or process connects to the database while the instance is starting

- An instance was started without the -W option specified

If the -W option is specified, the command will return without waiting for the instance to start. Therefore, it may be unclear as to whether instance startup was successful or failed.

See

Refer to "pg_ctl" in "Reference" in the PostgreSQL Documentation for information on the pg_ctl command.

4.4 Configuring Remote Connections

This section describes the settings required when connecting remotely to Fujitsu Enterprise Postgres from a database application or a client command.

4.4.1 When an Instance was Created with WebAdmin

Settings related to connection

The default is to accept connections from remote computers to the database.

Change "listen_addresses" in postgresql.conf to modify the default behavior.

Refer to "Appendix D Configuring Parameters" for information on postgresql.conf.

Client Authentication Information settings

The following content is set by default when WebAdmin is used to create an instance.

- Authentication of remote connections from local machines is performed.

When changing Client Authentication Information, select [Client Authentication] from [Setting], and then change the settings.

4.4.2 When an Instance was Created with the initdb Command

Connection settings

The default setting only permits local connections from the client to the database. Remote connections are not accepted.

Change "listen_addresses" in postgresql.conf to perform remote connection.

All remote connections will be allowed when changed as shown below.

Example

```
listen_addresses = '*'
```

Also, configure the parameters shown below in accordance with the applications and number of client command connections.

Parameter name	Parameter description
superuser_reserved_connections	Number of connections reserved for database maintenance, for example backup or index rebuilding. If you need to simultaneously perform a large number of processes that exceed the default value, change this value accordingly.
max_connections	Set the value as: *numberOfSimultaneousConnectionsToInstance* + superuser_reserved_connections

Client authentication information settings

When trying to connect from a client to a database, settings are required to determine whether the instance permits connections from the client - if it does, then it is possible to make settings to determine if authentication is required.

See

Refer to "The pg_hba.conf File" in "Server Administration" in the PostgreSQL Documentation for details.

4.5 Other Settings

This section describes settings that are useful for operations.

4.5.1 Error Log Settings

This section explains the settings necessary to monitor errors in applications and operations, and to make discovering the causes easier.

Make error log settings only when instances are created with the initdb command.

When creating instances with WebAdmin, these settings are already made and hence do not need to be set.

Furthermore, some parameters are used by WebAdmin, and if changed, may cause WebAdmin to no longer work properly. Refer to "Appendix D Configuring Parameters" for details.

Edit the following parameters in postgresql.conf:

Parameter name	Parameter description	How to enable the settings
syslog_ident	Used to specify labels to attach to messages, so that these can be identified when output to the system log if more than one Fujitsu Enterprise Postgres is used.	reload option of the pg_ctl mode
logging_collector	Specify "on" to ensure that messages are output by Fujitsu Enterprise Postgres to the server log file. The server log file is created in the log directory in the database cluster.	restart option of the pg_ctl mode
log_destination	Specify "stderr,syslog" to output messages from Fujitsu Enterprise Postgres to the screen and either the system log or the event log.	reload option of the pg_ctl mode
log_line_prefix	Specify information to be added at the start of messages output by an instance. This information is useful for automatic monitoring of messages. You can output the SQLSTATE value, output time, executing host, application name, and user ID. Refer to "What To Log" in the PostgreSQL Documentation for details. Example: log_line_prefix = '%e: %t [%p]: [%l-1] user = %u,db = %d,remote = %r app = %a '	reload option of the pg_ctl mode

Point

- Set the output destination for the system log to the server log so that it cannot be viewed by administrators of other instances. Application errors are output to the system log or server log. The output destination directory for the system log and server log should have access permissions set so that they cannot be viewed by people other than the instance administrator.
- If you want fewer application errors being output to the system log, refer to "When To Log" and "What To Log" in the PostgreSQL Documentation for information on how to reduce the output messages.
- If you want to separate errors output from other software, refer to "Where To Log" in the PostgreSQL Documentation to change the output destination to the server log file rather than the system log.

4.5.2 Configuring Automatic Start and Stop of an Instance

You can automatically start or stop an instance when the operating system on the database server is started or stopped.

Use the following procedure to configure automatic start and stop of an instance.

Note that, if an instance is started in a failover operation, the cluster system will control the start or stop, therefore this feature should not be used. Also, when performing database multiplexing, refer to "Enabling Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" in the Cluster Operation Guide (Database Multiplexing).

Note that "<*x*>" in paths indicates the product version.

1. Create a unit file

   Copy the unit file sample stored in the directory below, and revise it to match the target instance.

   ```
   fujitsuEnterprisePostgresInstallDir/share/fsepsvoi.service.sample
   ```

   Example

   In the following example, the installation directory is "/opt/fsepv<*x*>server64", and the instance name is "inst1".

   ```
   # cp /opt/fsepv<x>server64/share/fsepsvoi.service.sample /usr/lib/systemd/system/
   fsepsvoi_inst1.service
   ```

   Revise the underlined portions of the options below in the unit file.

   If necessary, correct the time correction, wait for the network environment to open, etc.

Section	Option	Specified value	Description
Unit	Description	Fujitsu Enterprise Postgres ***instanceName***	Specifies the feature overview. Specifies the name of the target instance. (*1)
Service	ExecStart	/bin/bash -c '***installDir***/bin/pgx_symstd start ***installDir dataStorageDestinationDir*** '	Command to be executed when the service is started.
	ExecStop	/bin/bash -c '***installDir***/bin/pgx_symstd stop ***installDir dataStorageDestinationDir*** '	Command to be executed when the service is stopped.
	ExecReload	/bin/bash -c '***installDir***/bin/pgx_symstd reload ***installDir dataStorageDestinationDir*** '	Command to be executed when the service is reloaded
	User	**User**	OS user account of the instance administrator.
	Group	**Group**	Group to which the instance administrator user belongs.

   *1: The instance name should be as follows:

   If WebAdmin is used to create the instance: *instanceName*

   If the initdb command is used to create the instance: *nameThatIdentifiesTheInstance*
   The naming conventions for the instance name or for identifying the instance are as follows:

   - Up to 16 bytes
   - The first character must be an ASCII alphabetic character
   - The other characters must be ASCII alphanumeric characters

2. Enable automatic start and stop

   As the OS superuser, use the systemctl command to enable automatic start and stop.

   Example

   ```
   # systemctl enable fsepsvoi_inst1.service
   ```

4.5.3 Settings when Using the Features Compatible with Oracle Databases

To use the features compatible with Oracle databases, create a new instance and execute the following command for the "postgres" and "template1" databases:

```
CREATE EXTENSION oracle_compatible;
```

Features compatible with Oracle databases are defined as user-defined functions in the "public" schema created by default when database clusters are created, so they can be available for all users without the need for special settings.

For this reason, ensure that "public" (without the double quotation marks) is included in the list of schema search paths specified in the search_path parameter.

There are also considerations for use the features compatible with Oracle databases. Refer to " Precautions when Using the Features Compatible with Oracle Databases" in the Application Development Guide for details.

4.5.4 LDAP Authentication File Settings

The LDAP authentication file refers to the following OS standard default file

/etc/openldap/ldap.conf

If you wish to use a different file, specify the LDAP authentication file you wish to set in an environment variable such as LDAPCONF, and then restart the Postgres instance. Refer to the OpenLDAP documentation for detailed configuration details.

4.5.5 Setting the server keytab file for GSSAPI authentication

When setting the server keytab file for GSSAPI authentication, be sure to set the "krb_server_keyfile" parameter, as the default value in postgresql.conf (FILE:/usr/local/pgsql/etc/krb5.keytab) will not take effect.

4.5.6 Settings for Using Legacy OpenSSL Providers

If you use a legacy OpenSSL provider, create an OpenSSL configuration file and set the parameters in postgresql.conf.

OpenSSL configuration file

Create an OpenSSL configuration file in any directory for legacy providers to use.

Example

```
openssl_conf = openssl_init

[openssl_init]
providers = provider_sect

[provider_sect]
default = default_sect
legacy = legacy_sect

[default_sect]
activate = 1

[legacy_sect]
activate = 1
```

Parameters

- openssl_conf

  Specify the OpenSSL configuration file created above.

  #### Example

  ```
  openssl_conf = '/path/to/openssl.conf'
  ```

- openssl_modules

  Specifies the installation directory for the server product that contains the additional OpenSSL modules.

  Example

  ```
  openssl_modules = '/opt/fsepv<x>server64/lib/ossl-modules'
  ```

  "< x >" indicates the product version.

See

Refer to "Parameters" in the Operation Guide for information for parameters.

4.6 Integration with Message-Monitoring Software

To monitor messages output by Fujitsu Enterprise Postgres using software, configure the product to monitor SQLSTATE, instead of the message text - this is because the latter may change when Fujitsu Enterprise Postgres is upgraded.

Configure Fujitsu Enterprise Postgres to output messages in a format that can be read by the message-monitoring software by specifying "%e" in the log_line_prefix parameter of postgresql.conf to output the SQLSTATE value.

A setting example is shown below - it outputs the output time, executing host, application name, and user ID, in addition to the SQLSTATE value.

Example

```
log_line_prefix = '%e: %t [%p]: [%l-1] user = %u,db = %d,remote = %r app = %a '
```

See

Refer to "What To Log" in the PostgreSQL Documentation for information on how to configure the settings.

4.7 Setting Up and Removing OSS

This section explains how to set up OSS supported by Fujitsu Enterprise Postgres.

If you want to use OSS supported by Fujitsu Enterprise Postgres, follow the setup procedure.

If you decide not to use the OSS supported by Fujitsu Enterprise Postgres, follow the removing procedure.

To build and use OSS obtained from the web, etc., instead of OSS supported by Fujitsu Enterprise Postgres, see "4.7.17 Build with PGXS".

Information

- In this section, the applicable database that enables the features of each OSS is described as "postgres".
- Execute CREATE EXTENSION for the "template1" database also, so that each OSS can be used by default when creating a new database.

Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for information on OSS other than those described below.

4.7.1 oracle_fdw

This feature is available only when the server command is used. It is not available for instances created with WebAdmin.

4.7.1.1 Setting Up oracle_fdw

1. Add the path of the OCI library to the environment variable.
   Add the installation path of the OCI library to the LD_LIBRARY_PATH environment variable.

2. As superuser, run the following command:

```
$ su -
Password:******
# cp -r /opt/fsepv<x>server64/OSS/oracle_fdw/* /opt/fsepv<x>server64
```

3. If a file named libclntsh.so.11.1 does not exist in your OCI library, create a symbolic link with the name libclntsh.so.11.1 to libclntsh.so.xx.1 (xx is the version of the OCI library).

```
# ln -s libclntsh.so.xx.1 libclntsh.so.11.1
```

4. Restart Fujitsu Enterprise Postgres.

5. Execute CREATE EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION oracle_fdw;
CREATE EXTENSION
```

Information

- If the OCI library is not installed on the server, install it using the Oracle client or Oracle Instant Client.
  Refer to the relevant Oracle manual for information on the installation procedure.
- If the version of the OCI library is updated, change the path of the OCI library in the LD_LIBRARY_PATH environment variable to the updated path. Also, re-create the symbolic link named libclntsh.so.11.1 if necessary.

4.7.1.2 Removing oracle_fdw

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# DROP EXTENSION oracle_fdw CASCADE;
DROP EXTENSION
```

2. As superuser, run the following command:

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/oracle_fdw
```

4.7.2 pg_bigm

4.7.2.1 Setting Up pg_bigm

1. Set the postgresql.conf file parameters.
   Add "pg_bigm" to the shared_preload_libraries parameter.

2. As superuser, run the following command:

```
$ su -
Password:******
# cp -r /opt/fsepv<x>server64/OSS/pg_bigm/* /opt/fsepv<x>server64
```

3. Restart Fujitsu Enterprise Postgres.

4. Execute CREATE EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION pg_bigm;
CREATE EXTENSION
```

4.7.2.2 Removing pg_bigm

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# DROP EXTENSION pg_bigm CASCADE;
DROP EXTENSION
```

2. Set the postgresql.conf file parameters.
   Delete "pg_bigm" to the shared_preload_libraries parameter.

3. Restart Fujitsu Enterprise Postgres.

4. As superuser, run the following command:

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/pg_bigm
```

4.7.3 pg_hint_plan

4.7.3.1 Setting Up pg_hint_plan

1. Set the postgresql.conf file parameters.
   Add "pg_hint_plan" to the "shared_preload_libraries" parameter.

2. As superuser, run the following command:

```
$ su -
Password:******
# cp -r /opt/fsepv<x>server64/OSS/pg_hint_plan/* /opt/fsepv<x>server64
```

3. Restart Fujitsu Enterprise Postgres.

4. Run CREATE EXTENSION for the database that uses this feature.
   The target database is described as "postgres" here.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION pg_hint_plan;
CREATE EXTENSION
```

See

Refer to "Enhanced Query Plan Stability" in the Operation Guide for details.

4.7.3.2 Removing pg_hint_plan

Unsetting pg_hint_plan will cause hints registered in the hint_plan.hints table to be lost. Therefore, if you might later use pg_hint_plan again, back up each database's hint_plan.hints table with pg_dump before unsetting it up.

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# DROP EXTENSION pg_hint_plan CASCADE;
DROP EXTENSION
```

2. Set the postgresql.conf file parameters.
   Delete "pg_hint_plan" to the shared_preload_libraries parameter.
3. Restart Fujitsu Enterprise Postgres.
4. As superuser, run the following command:

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/pg_hint_plan
```

4.7.4 pg_dbms_stats

4.7.4.1 Setting Up pg_dbms_stats

1. Set the postgresql.conf file parameter.
   Add "pg_dbms_stats" to the "shared_preload_libraries" parameter.
2. As superuser, run the following command:

```
$ su -
Password:******
# cp -r /opt/fsepv<x>server64/OSS/pg_dbms_stats/* /opt/fsepv<x>server64
```

3. Restart Fujitsu Enterprise Postgres.
4. Run CREATE EXTENSION for the database that will use this feature.
   The target database is described as "postgres" here.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION pg_dbms_stats;
CREATE EXTENSION
```

See

Refer to "Enhanced Query Plan Stability" in the Operation Guide for details.

4.7.4.2 Removing pg_dbms_stats

Unsetting pg_dbms_stats causes statistics managed by pg_dbms_stats to be lost. Therefore, if you plan to use pg_dbms_stats again later, back up each table in each database's dbms_stats schema in binary format, as shown below, and then perform unsetup.

```
postgres > # COPY <dbms_stats Schema's table name> TO '<Filename>' FORMAT binary;
```

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

   ```
   postgres=# DROP EXTENSION pg_dbms_stats CASCADE;
   DROP EXTENSION
   ```

2. Set the postgresql.conf file parameters.
   Delete "pg_dbms_stats" to the shared_preload_libraries parameter.

3. Restart Fujitsu Enterprise Postgres.

4. As superuser, run the following command:

   ```
   $ su -
   Password:******
   # rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
   ```

   Information

   The files copied during setup can be checked below.

   ```
   # find /opt/fsepv<x>server64/OSS/pg_dbms_stats
   ```

4.7.5 pg_repack

4.7.5.1 Setting Up pg_repack

1. As superuser, run the following command:

   ```
   $ su -
   Password:******
   # cp -r /opt/fsepv<x>server64/OSS/pg_repack/* /opt/fsepv<x>server64
   ```

2. Execute CREATE EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

   ```
   postgres=# CREATE EXTENSION pg_repack;
   CREATE EXTENSION
   ```

4.7.5.2 Removing pg_repack

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

   ```
   postgres=# DROP EXTENSION pg_repack CASCADE;
   DROP EXTENSION
   ```

2. As superuser, run the following command:

   ```
   $ su -
   Password:******
   # rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
   ```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/pg_repack
```

4.7.6 pg_rman

This feature is available only when the server command is used. It is not available for instances created with WebAdmin.

4.7.6.1 Setting Up pg_rman

1. As superuser, run the following command:

```
$ su -
Password:******
# cp -r /opt/fsepv<x>server64/OSS/pg_rman/* /opt/fsepv<x>server64
```

2. Restart Fujitsu Enterprise Postgres.

Information

Before initialization of the backup catalog, it is recommended to set the parameters below in postgresql.conf. Refer to the pg_rman manual (http://ossc-db.github.io/pg_rman/index-ja.html) for details.

- log_directory
- archive_mode
- archive_command

4.7.6.2 Removing pg_rman

1. As superuser, run the following command:

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/pg_rman
```

2. Restart Fujitsu Enterprise Postgres.

4.7.7 pg_statsinfo

This feature is available only when the server command is used. It is not available for instances created with WebAdmin.

4.7.7.1 Setting Up pg_statsinfo

1. Set the postgresql.conf file parameters.
   - Add "pg_statsinfo" to the shared_preload_libraries parameter.
   - Specify the log file name for the log_filename parameter.

- Specify "on" to the logging_collecto parameter.
- Add "csvlog" to the log_destination parameter.
- Delete "stderr" to the log_destination parameter.

For the parameters "logging_collector" and "log_destination", pg_statsinfo will change the settings in the postmaster process as above without rewriting postgresql.conf, even if you do not make the above changes.
Explicit rewriting is recommended because the configuration file and behavior will not match.

2. Perform the following setup as a superuser:

   Install the pg_statsinfo module:

```
# cp -r /opt/fsepv<x>server64/OSS/pg_statsinfo/* /opt/fsepv<x>server64
```

   Create the directories needed for pg_statsinfo to work.
   This directory is where the files for managing process IDs for pg_statsinfo processes are stored.
   The minimum required permissions for the directory are 700.
   Set the owner of the directory to the instance administrator user.
   This example sets the OS user “fsepuser” as the instance administrator.

```
# mkdir /run/pg_statsinfo
# chmod 700 /run/pg_statsinfo
# chown fsepuser:fsepuser /run/pg_statsinfo
```

   The directory created above is deleted when the OS stops.
   You can configure the above directories to be created automatically on reboot by running the following command:

```
# cat << EOF > /usr/lib/tmpfiles.d/pg_statsinfo-<x>.conf
d /run/pg_statsinfo 0755 fsepuser fsepuser -
EOF
```

3. Restart Fujitsu Enterprise Postgres.

Information

There are the following differences in postgresql.conf parameter settings required for statistics collection between OSS pg_statsinfo v16 and pg_statsinfo shipped with Fujitsu Enterprise Postgres:

OSS: You must specify "C" for the lc_messages parameter.

Fujitsu Enterprise Postgres: The lc_messages parameter can be any message locale supported by PostgreSQL.

4.7.7.2 Removing pg_statsinfo

1. Set the postgresql.conf file parameters.
   - Delete "pg_statsinfo" to the shared_preload_libraries parameter.
   - Delete the log file name for the log_filename parameter.
   - Specify "off" to the logging_collecto parameter.
   - Delete "csvlog" to the log_destination parameter.
   - Add "stderr" to the log_destination parameter.
2. Restart Fujitsu Enterprise Postgres.
3. As superuser, run the following command:

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
```

```
# rm -rf /run/pg_statsinfo
# rm -rf /usr/lib/tmpfiles.d/pg_statsinfo-<x>.conf
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/pg_statsinfo
```

4.7.8 pgBadger

4.7.8.1 Setting Up pgBadger

1. Set the postgresql.conf file parameters.
   Set the parameters so that the information required for analysis is output to the server log.
   Refer to "Documentation" in the pgBadger website (https://pgbadger.darold.net/) for details.
   The pgBadger material is stored under /opt/fsepv<x>server64/OSS/pgbadger.

2. Restart Fujitsu Enterprise Postgres.

4.7.8.2 Removing pgBadger

1. Set the postgresql.conf file parameters.
   Restores information you specified during Setup.

2. Restart Fujitsu Enterprise Postgres.

4.7.9 Pgpool-II

The online recovery feature of Pgpool-II is available only when the server command is used. It is not available for instances created with WebAdmin.

4.7.9.1 Setting Up Pgpool-II

1. As superuser, run the following command:

```
$ su -
Password:******
# cp -r /opt/fsepv<x>server64/OSS/Pgpool-II/* /opt/fsepv<x>server64
```

2. Execute CREATE EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION pgpool_recovery;
CREATE EXTENSION
```

3. Set the postgresql.conf file parameters.
   Specify the path to pg_ctl for the pgpool.pg_ctl parameter.

4. Restart Fujitsu Enterprise Postgres.

4.7.9.2 Removing Pgpool-II

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# DROP EXTENSION pgpool_recovery CASCADE;
DROP EXTENSION
```

2. As superuser, run the following command:

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/Pgpool-II
```

3. Set the postgresql.conf file parameters.
   Delete the pg_ctl path for the pgpool.pg_ctl parameter.
4. Restart Fujitsu Enterprise Postgres.

4.7.10 pgBackRest

This feature is available only when the server command is used. It is not available for instances created with WebAdmin.

The pg_rman, pgx_dmpall, and pgx_rcvall commands cannot be used when using pgBackRest because of conflicting shell commands to set archive_command.

4.7.10.1 Setting Up pgBackRest

1. Install pgBackRest.

   To use the pgbackrest command on the same host as the Fujitsu Enterprise Postgres server, install pgBackRest using the server program DVD. If you want to use the pgbackrest command on a different host than the Fujitsu Enterprise Postgres server, install pgBackRest using the client program DVD.

2. Set the environment variable PATH for pgBackRest.

   The pgBackRest material is stored under /opt/fsepv<x>pgbackrest. Set the environment variable PATH to the storage location/bin of the pgBackRest material to be used.

```
$ export PATH=/opt/fsepv<x>pgbackrest/bin:$PATH
```

3. Perform pgBackRest setup.

   Refer to " User Guides " in the pgBackRest website (https://pgbackrest.org/) for details.

4.7.10.2 Removing pgBackRest

1. Sets parameters in the postgresql.conf file.

   Reverses the information specified during setup

2. Restart Fujitsu Enterprise Postgres.
3. If it was set to perform periodic backups, unset it.

4.7.10.3 Servers to which pgBackRest can connect

The following table lists server that pgBackRest can connected to.

Table 4.1 Connectable server

OS	Product name
Linux	- Fujitsu Enterprise Postgres Advanced Edition 18, or 18 SP1 - Fujitsu Enterprise Postgres Standard Edition 18, or 18 SP1

4.7.11 pgvector

Note that while OSS is named "pgvector", the binaries and the extensions themselves are named "vector".

It is not possible to data masking data added by pgvector using data masking features.

When using in-memory features, data types and functions added in pgvector cannot be accelerated.

4.7.11.1 Setting Up pgvector

1. As superuser, run the following command:

```
$ su -
Password:******
# cp -r /opt/fsepv<x>server64/OSS/pgvector/* /opt/fsepv<x>server64
```

2. Execute CREATE EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION vector;
CREATE EXTENSION
```

4.7.11.2 Removing pgvector

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# DROP EXTENSION vector CASCADE;
DROP EXTENSION
```

2. As superuser, run the following command:

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/pgvector
```

4.7.12 pgvectorscale

Note that while OSS is named "pgvectorscale", the binaries and the extensions themselves are named "vectorscale".

4.7.12.1 Setting Up pgvectorscale

1. As superuser, run the following command:
   Since pgvectorscale depends on pgvector, it copies pgvector as well.

```
$ su -
Password:******
# cp -r /opt/fsepv<x>server64/OSS/pgvector/* /opt/fsepv<x>server64
# cp -r /opt/fsepv<x>server64/OSS/pgvectorscale/* /opt/fsepv<x>server64
```

2. Execute CREATE EXTENSION for the database that will use this feature.
   Adding the CASCADE option will also CREATE EXTENSION any dependent pgvectors.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION IF NOT EXISTS vectorscale CASCADE;
CREATE EXTENSION
```

4.7.12.2 Removing pgvectorscale

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# DROP EXTENSION vectorscale;
DROP EXTENSION
```

2. As superuser, run the following command:

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/pgvectorscale
```

4.7.13 Apache AGE

4.7.13.1 Setting Up Apache AGE

1. As superuser, run the following command:

```
$ su -
Password:******
# cp -r /opt/fsepv<x>server64/OSS/age/* /opt/fsepv<x>server64
```

2. Execute CREATE EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION age;
CREATE EXTENSION
```

3. To use Apache AGE, execute a LOAD statement for each session, or add "age" to session_preload_libraries parameter in postgresql.conf file.

```
postgres=# LOAD 'age';
LOAD
```

4.7.13.2 Removing Apache AGE

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# DROP EXTENSION age;
DROP EXTENSION
```

2. Set the postgresql.conf file parameters.
   Delete "age" to the session_preload_libraries parameter.

3. Restart Fujitsu Enterprise Postgres.
4. As superuser, run the following command:

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/age
```

4.7.14 pg_cron

4.7.14.1 Setting Up pg_cron

1. Set the postgresql.conf file parameter.
   Add "pg_cron" to the "shared_preload_libraries" parameter.
   When using streaming replication, the primary and standby servers must be on the same port number. If you cannot set the same port number, you will need to enable background workers in pg_cron.
   Specify "on" to the cron.use_background_workers parameter.
   Increase the max_worker_processes parameter as needed. In addition to one resident process of pg_cron, max_worker_processes must be increased depending on the number of concurrently running jobs.
2. As superuser, run the following command:

```
$ su -
Password:******
# cp -r /opt/fsepv<x>server64/OSS/pg_cron /* /opt/fsepv<x>server64
```

3. Restart Fujitsu Enterprise Postgres.
4. Run CREATE EXTENSION for the database that will use this feature.
   The target database is described as "postgres" here.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION pg_cron;
CREATE EXTENSION
```

4.7.14.2 Removing pg_cron

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# DROP EXTENSION pg_cron CASCADE;
DROP EXTENSION
```

2. Set the postgresql.conf file parameters.
   Delete "pg_cron" to the shared_preload_libraries parameter.
   Specify "off" to the cron.use_background_workers parameter.
   Returns the value of the max_worker_processes parameter.
3. Restart Fujitsu Enterprise Postgres.

4. As superuser, run the following command:

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>server64/filesCopiedDuringSetup
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>server64/OSS/pg_cron
```

4.7.15 Patroni

1. Install Patroni and its associated support libraries using Python.
   To avoid conflicts with libraries already installed on your system and for ease of uninstallation, this guide demonstrates setup using a Python virtual environment.
   The following example uses "/venv/opt/patroni" as the virtual environment.
   Execute this as a user with write permissions to the "/venv/opt/patroni" directory.
   Additionally, if any additional support libraries are required, install them in the virtual environment in the same manner.

```
python -m venv  /venv/opt/patroni
source /venv/opt/patroni/bin/activate
cd /opt/fsepv<x>server64/OSS/patroni
pip install --no-index --find-links=./wheel ./wheel/*.whl
#If additional installation is required
pip install <additional library name>
```

2. Add the path to the Patroni execution environment to the environment of the user running Patroni. The execution environment is "virtual environment/bin".

```
export PATH=/venv/opt/patroni/bin:$PATH
```

3. Configure Patroni to run as a service. As superuser, create the service system file (/etc/systemd/system/patroni.service).
   Below is an example configuration.
   Specify the virtual environment where Patroni is installed (/venv/opt/patroni) for "WorkingDirectory".
   <path> is the location of the Patroni configuration file required to run Patroni. The Patroni configuration file must be created beforehand.

```
[Unit]
Description=Patroni Master/Slave controller
After=network.target etcd.service
Wants=etcd.service

[Service]
Type=simple
User=fepuser
Group=fepuser

WorkingDirectory=/venv/opt/patroni
ExecStart=/venv/opt/patroni/bin/python3 -m patroni <path>/patroni.yml
Environment="PATRONI_REPLICATION_PASSWORD=patpass" "PATRONI_SUPERUSER_PASSWORD=patpass"
KillMode=process
TimeoutSec=30
Restart=no

[Install]
WantedBy=multi-user.target
```

4. Create the Patroni configuration file (<path>/patroni.yml).
   Please create it by referring to the OSS manual.
   Important points to note during creation are documented as comments here for your reference.

```
# Patroni configuration
scope: patroni_cluster # Cluster name. Set to the same value on all servers.
name: node1

[Text omitted]

# PostgreSQL configuration
postgresql:
  data_dir: /home/fepuser/pg_pt
  bin_dir:  /opt/ fsepv<x>server64/bin
  connect_address: xx.yyy.zzzz.www:27500 # This server's IP address and PostgreSQL port
  listen: xxx.yyy.zzz.www:27500          # This server's IP address and PostgreSQL port
  # User and password for Patroni to connect to PostgreSQL
  # Specify the patroni_user and its password created in the service system file
  authentication:
    replication:
      username: patroni_user
      password: ${PATRONI_REPLICATION_PASSWORD}
    superuser:
      username: patroni_user
      password: ${PATRONI_SUPERUSER_PASSWORD}

    [Text omitted]

  pg_hba:
    # Replication users and superusers must be specified.
    - host replication patroni_user xx.yyy.zzz.0/24 md5 # Replication user
    - host all patroni_user xx.yyy.zzz.0/24 md5         # superuser (patroni_user)
    - host all all xx.yyy.zzz.0/24 md5                  # Other users (as needed)
    - host replication patroni_user XX.YY.ZZZ.0/24 md5
    - host all patroni_user XX.YY.ZZZ.0/24 md5
    - host all all XX.YY.ZZZ.0/24 md5
    - host all all xx.zz.yy.0/24 md5

# initdb configuration
initdb:
  - encoding: UTF8
  - locale: ja_JP.UTF-8
  - data-checksums # Required when using pg_rewind, etc.

# Recovery operation settings
recovery_conf:
  [Text omitted]

# Etcd configuration
etcd3:
  [Text omitted]

# REST API Configuration (for Patroni health checks and management)
restapi:
  [Text omitted]

# Must be specified when running initdb with Patroni.
bootstrap:
  dcs:
    postgresql:
```

```
      use_pg_rewind: true
```

4.7.15.1 Removing Patroni

1. Delete the Python virtual environment.
   This example uses the virtual environment "/venv/opt/patroni".

```
# rm -rf /venv/opt/patroni
```

4.7.16 etcd

When using etcd commands on the same host as the Fujitsu Enterprise Postgres server, perform setup using the "Server Assistant Program" DVD.

Refer to "etcd" in the Installation and Setup Guide for Server Assistant for details.

4.7.17 Build with PGXS

Many PostgreSQL extensions are built using a build base for extensions called PGXS. Building with PGXS also generates files related to llvm. Depending on which version of llvm you are using, follow these steps:

PGXS builds also set DT_RUNPATH to the built binaries. See "4.7.17.4 Setting DT_RUNPATH" for more information.

4.7.17.1 Using the Default Version of llvm

The default version of llvm is described in "2.1 Required Operating System". If you want to use the default version of llvm, use the OSS documentation to build and install OSS.

4.7.17.2 Using a Non-Default Version of llvm

1. As superuser, copy the Makefile.global corresponding to the version of llvm you want to use. The following is an example of using llvm. Makefile.global is overwritten when an emergency fix is applied or removed from Fujitsu Enterpise Postgres, this procedure should be performed each time a build is performed.

```
$ su -
Password:******
# cp /opt/fsepv<x>server64/lib/pgxs/src/Makefile.global-vsn<The version of llvm> /opt/
fsepv<x>server64/lib/pgxs/src/Makefile.global
```

2. Follow the OSS documentation to build and install OSS.
3. As superuser, run the following command:. The following is an example of using llvm:.

```
$ su -
Password:******
# mv /opt/fsepv<x>server64/lib/bitcode/<OSS name>* /opt/fsepv<x>server64/lib/bitcode-vsn<The
version of llvm>/
```

4.7.17.3 Without llvm

If you do not use llvm, use the with _ llvm = no option when performing the build, as shown below. For other options, follow the OSS documentation.

```
# make USE_PGXS=1 with_llvm=no
```

4.7.17.4 Setting DT_RUNPATH

The default values for DT_RUNPATH are <Fujitsu Enterprise Postgres installation directory in the build environment>/lib, and $ORIGIN /../ lib.

If your build and production environments have the same Fujitsu Enterprise Postgres installation directory, you can run the built program without setting the environment variable LD_LIBRARY_PATH to <*Fujitsu Enterprise Postgres installationdirectory in the operating environment*>/lib.

If the installation directories of Fujitsu Enterprise Postgres for the build and production environments cannot be in the same location, or the production installation directory cannot be pre-determined, you can run a program built without <*Fujitsu Enterprise Postgres installationdirectory in the operating environment*>/lib in the LD_LIBRARY_PATH by doing the following:

Set the DT_RUNPATH attribute to any path.

In your production environment, create a symbolic link to <*Fujitsu Enterprise Postgres installationdirectory in the operating environment*>/lib in the appropriate path.

To do this, set the DT_RUNPATH attribute in the environment variable PG_LDFLAGS(*1).

If this is not possible, set LD_LIBRARY_PATH to <*Fujitsu Enterprise Postgres installationdirectory in the operating environment*>/lib when you run the program.

For notes on setting the environment variable LD_LIBRARY_PATH, see "When DT_RUNPATH cannot be set" in "How to Build and Run an Application that Uses Shared Libraries" in the Application Development Guide.

*1:For more information about the PG_LDFLAGS environment variable, see "Extension Building Infrastructure" in the PostgreSQL Documentation. For example, "make USE_PGXS = 1 PG_LDFLAGS =" -Wl, -rpath, '$$ORIGIN /../ libdummy', --enable-new-dtags ".

4.7.18 Build without PGXS

For extensions that do not utilize PGXS, but utilize the interface of Fujitsu Enterprise Postgres, build to explicitly set DT_RUNPATH, or set LD_LIBRARY_PATH to <Fujitsu Enterprise Postgres installation directory>/lib at runtime.

For information about how to set DT_RUNPATH, refer to "Setting DT_RUNPATH for Applications" in the Application Development Guide.

For notes on using LD_LIBRARY_PATH without setting DT_RUNPATH, refer to "When DT_RUNPATH cannot be set" in "How to Build and Run an Application that Uses Shared Libraries" in the Application Development Guide.

4.8 Deleting Instances

This section explains how to delete an instance.

- 4.8.1 Using WebAdmin
- 4.8.2 Using Server Commands

When automatic start and stop of an instance is set

Execute the following command to disable it, and then unregister it.

```
systemctl disable nameOfUnitFileThatPerformsAutomaticStartAndStop
rm /usr/lib/systemd/system/nameOfUnitFileThatPerformsAutomaticStartAndStop
```

Example

```
# systemctl disable fsepsvoi_inst1.service
# rm /usr/lib/systemd/system/fsepsvoi_inst1.service
```

4.8.1 Using WebAdmin

This section explains how to delete an instance using WebAdmin. Always use WebAdmin to delete instances that were created or imported using WebAdmin. Because WebAdmin managementinformation cannot be deleted, WebAdmin will determine that the instance is abnormal.

Use the following procedure to delete an instance.

1. Stop the instance

   In the [Instances] tab, select the instance to stop and click .

2. Back up files.

   Before deleting the instance, back up any required files under the data storage destination, the backup data storage destination, and the transaction log storage destination.

3. Delete the instance

   In the [Instances] tab, select the instance to delete and click .

Deleting Unnecessary Directories

Deleting an instance deletes only the following lowest-level directories. If they are not required, delete them manually.

- Data storage destination
- Backup data storage destination
- Transaction log storage destination (if different from the data storage destination)

4.8.2 Using Server Commands

This section explains how to delete an instance using server commands.

Use the following procedure to delete an instance.

1. Stop the instance

   Execute the stop mode of the pg_ctl command.

   An example is shown below:

   Example

   ```
   $ pg_ctl stop -D /data/inst1
   ```

2. Back up files.

   Before deleting the instance, back up any required files under the data storage destination, the backup data storage destination, and the transaction log storage destination.

3. Delete the instance

   Use a standard UNIX tool (the rm command) to delete the following directories:

   - Data storage destination
   - Backup data storage destination
   - Transaction log storage destination (if a directory different from the data storage directory was specified)

Chapter 5 Uninstallation

This chapter describes the procedure for uninstalling Fujitsu Enterprise Postgres.

Information

If you installed interactive mode/silent mode, uninstall interactive mode/silent mode. Refer to "P.3 Uninstallation" for more information.

5.1 Pre-uninstallation Tasks

Before uninstalling Fujitsu Enterprise Postgres, do the following:

When user files are placed in the installation directory

When you perform uninstallation, all files and directories under the installation directory are deleted. If necessary, back up the files before uninstalling them.

When SLES

On SLES, before uninstallation, ensure that JRE 8 is installed, and export the JAVA_HOME environment variable.

```
#export JAVA_HOME="Jre8InstallDir"
```

When WebAdmin is used for operation

To reinstall Fujitsu Enterprise Postgres after it was uninstalled, and reuse an instance that was already created so that it can be managed from WebAdmin, back up the directory shown below in which the WebAdmin instance management information had been defined before uninstalling Fujitsu Enterprise Postgres, and then restore the backed up directory to its original location once Fujitsu Enterprise Postgres has been reinstalled.

Follow the procedure below to perform the backup.

1. Stop the WebAdmin server.
   Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" for details.
2. Back up the following directory:

   ```
   webAdminInstallDir/data/fepwa
   ```

When using HTTPS or HTTPS client authentication with WebAdmin

All the certificates placed in "keystore" directory will be removed when uninstalling WebAdmin. Back up these certificates and its configuration file in advance if required.

```
webAdminInstallDir/tomcat/keystore
webAdminInstallDir/tomcat/conf/server.xml
```

They are backed up because the keystore contains certificates, and server.xml contains information for the keystorePass, keyAlias, and trustorePass attributes.

5.2 Uninstallation RPM Packages

Uninstall according to the following procedure:

1. Delete the operation information

If the Fujitsu Enterprise Postgres operation information has been registered in the operating system or another middleware product, for example, then it must be deleted. Cases in which deletion is required are as follows:

- For a cluster system using failover operation integrated with PRIMECLUSTER, stop the cluster applications and delete the cluster application resources and Fujitsu Enterprise Postgres resources. Refer to the Cluster Operation Guide (PRIMECLUSTER) and PRIMECLUSTER Installation and Administration Guide for details.
- If you have set automatic start and stop of the instance, execute the following commands to disable the script and cancel registration.

  ```
  systemctl disable nameOfUnitFileThatPerformsAutomaticStartAndStop
  rm /usr/lib/systemd/system/nameOfUnitFileThatPerformsAutomaticStartAndStop
  ```

  Example

  ```
  # systemctl disable fsepsvoi_inst1.service
  # rm /usr/lib/systemd/system/fsepsvoi_inst1.service
  ```

2. Stop applications and programs

Before starting the uninstallation, stop the following:

- Applications that use the product
- Connection Manager
- Instance

  Using WebAdmin

  In the [Instances] tab, select the instance to stop and click .

  Using server commands

  Execute the pg_ctl command in stop mode.

  ```
  $ /opt/fsepv<x>server64/bin/pg_ctl stop -D /database/inst1
  ```

- Web server feature of WebAdmin

  Execute the WebAdminStop command to stop the Web server feature of WebAdmin.

  Example

  If WebAdmin is installed in /opt/fsepv<*x*>webadmin:

  ```
  # cd /opt/fsepv<x>webadmin/sbin
  # ./WebAdminStop
  ```

- Mirroring Controller

  Execute the mc_ctl command with the stop mode option specified and stop the Mirroring Controller.

  Example

  ```
  $ mc_ctl stop -M /mcdir/inst1
  ```

- pgBadger
- Pgpool-II
- pgBackRest

3. Check the installed product

Check the installed products by following the procedure below.

Example

Displays the name of the installed package.

```
# rpm -qa | grep FJSVfsep
```

For detailed package information, run the following command:

```
# rpm -qi Package Name
```

4. Start the uninstaller

Uninstall all packages for the product to be uninstalled.

Refer to the table in "3.2 Installation from RPM Package" for the package set for each product.

The installation directory may remain after uninstallation. Delete them if they are not needed.

```
# rpm -e package name
```

Point

We recommend that you uninstall the packages of the products to be uninstalled in batches for each product.

Example

The following shows an example of uninstalling a server product.

```
# rpm -qa | grep FJSVfsep-server
FJSVfsep-server-essential-ae-*
FJSVfsep-server-openjdk-*
FJSVfsep-server-core-*
FJSVfsep-server-core-openssl-*
FJSVfsep-server-lmb-*
FJSVfsep-server-lmb-validation-*
FJSVfsep-server-pgaudit-*
FJSVfsep-server-conmgr-*
FJSVfsep-server-userlog-*
# rpm -e FJSVfsep-server-userlog-<x> FJSVfsep-server-conmgr-<x> FJSVfsep-server-pgaudit-<x> \
FJSVfsep-server-lmb-validation-<x> FJSVfsep-server-lmb-<x> FJSVfsep-server-core-openssl-<x> FJSVfsep-
server-core-<x> FJSVfsep-server-openjdk-<x> FJSVfsep-server-essential-ae-<x>
```

*is the version, OS, and so on.

"<x>" indicates the version.

Appendix A Recommended WebAdmin Environments

This appendix describes the recommended WebAdmin environment. The following explanation is based on the assumption that Microsoft Edge is used unless otherwise stated.

Note

The displayed screen varies depending on your environment, so check and set according to the screen.

A.1 Recommended Browser Settings

- Use a display resolution of 1280 x 768 or higher, and 256 colors or more.
- Select [Setting] >>[Appearance] >> [Font size] >> [Medium (Recommended)].
- Select [Setting] >>[Appearance] >> [Zoom] >> [100%].

A.2 How to Set Up the Pop-up Blocker

If the Pop-up Blocker is enabled, use the procedure below to configure settings to allow pop-ups from the server where Fujitsu Enterprise Postgres is installed.

1. Click [Setting] >> [Cookie and site permissions] >> [All Permissions] >> [Pop-ups and redirects].
   If the [Block (Recommended)] switch is not on (blue), the pop-up blocker is not working, and no further action is required.
2. Under [Pop-ups and Redirects], click the [Allow] >> [Add] button.
3. In [Add Site], in [Site], enter the address of the server where you installed Fujitsu Enterprise Postgres and click the [Add] button.
4. Close Microsoft Edge.

Appendix B Setting Up and Removing WebAdmin

This appendix describes how to set up and remove WebAdmin.

Note that "<*x*>" in paths indicates the product version.

B.1 Setting Up WebAdmin

This section explains how to set up WebAdmin.

B.1.1 Setting Up WebAdmin

In the case of a re-setup, the existing server.xml is overwritten with the default values. Therefore, back up the information in server.xml beforehand and update it manually after setting up WebAdmin.
No action is required because the certificate is not overwritten during re-setup.

Follow the procedure below to set up WebAdmin.

1. Change to the superuser

   Acquire superuser privileges on the system.

   Example

   ```
   $ su -
   Password:******
   ```

2. Set JAVA_HOME (SLES only)

   Ensure that JRE 8 is installed, and export the JAVA_HOME environment variable.

   Example

   ```
   #export JAVA_HOME="Jre8InstallDir"
   ```

   Refer to "Appendix L Procedure when Modifying the JRE Installation" for information on modifying JRE after installation.

3. Run Setup

   Run the WebAdminSetup command.

   Example

   If WebAdmin is installed in /opt/fsepv<*x*>webadmin:

   ```
   # cd /opt/fsepv<x>webadmin/sbin
   # ./WebAdminSetup
   ```

4. Specifying Setup Items

   Specify the following:

   Refer to the "/etc/services" file and only change to a different port number if there is overlap with a port number from another service.

   Make a note of the port number for the Web server, because it will be required for starting the WebAdmin window.

Item
HTTPS usage Do you want to use HTTPS (secure communication)? [y,n,q] (default: n)
Web server port number Enter port number of Web Server (default: 27515):
(Can be set only when HTTPS is used.)

Item
HTTPS Client Authentication usage Do you want to use HTTPS Client Authentication? [y,n,q] (default: n)
WebAdmin internal port number Enter Internal port number for WebAdmin (default: 27516):
WebAdmin automatic start Start WebAdmin automatically when system starting? [y,n] (default: y)

HTTPS usage

Specify whether to use HTTPS, for secure communication with the WebAdmin (and to be used internally by the WebAdmin).

To facilitate HTTPS deployment, WebAdmin automatically creates a self-signed server certificate. This certificate should only be used for testing purposes, such as connection verification, and should be replaced with an appropriate CA-signed certificate in production.

Refer to "B.1.2 Certificate Settings For Secure Connection Support" for detail certificate settings.

Point

If you continue to use the self-signed server certificate that WebAdmin created, your browser displays a warning screen when you access the WebAdmin page because you can access WebAdmin but the certificate is not signed by a known and trusted CA.

Web server port number

Specify a numeric value from 1024 to 32767 for the port number to be used for communication between the Web browser and the Web server.

The Web server port number will be registered as a port number with the following service name in the "/etc/services" file.

fsep_180_WA_64_WebAdmin_Port1

HTTPS Client Authentication usage

Specify whether to use HTTPS Client Authentication, to ensure that only authenticated clients can use the WebAdmin.

To facilitate the deployment of HTTPS client authentication, WebAdmin automatically creates two self-signed client certificates.

One is for browser-to-server authentication. and one for server-to-server authentication.

Server to server authentication is required because WebAdmins can have multiple server configurations and communicate between them. Refer to "Appendix I Determining the Preferred WebAdmin Configuration".

These certificate should only be used for testing purposes, such as connection verification, and should be replaced with an appropriate CA-signed certificate in production.

Refer to "B.1.2 Certificate Settings For Secure Connection Support" for detail certificate settings.

Point

If client authentication is selected, client certificate for browser must be registered in user's browser before accessing to WebAdmin. Otherwise, WebAdmin will not be accessible.

WebAdmin internal port number

Specify a numeric value from 1024 to 32767 for the port number to be used for communication between the Web server and the WebAdmin runtime environment.

The WebAdmin internal port number will be registered as a port number with the following service name in the /etc/services file.

fsep_180_WA_64_WebAdmin_Port2

WebAdmin automatic start

Select whether or not to start WebAdmin when the machine is started.

Note

- Unused port numbers
  Irrespective of the information specified in the "/etc/services" file, unused port numbers in the OS and other products can sometimes be automatically numbered and then used, or port numbers specified in environment files within products may also be used. Check the port numbers used by the OS and other products, and ensure that these are not duplicated.
- Access restrictions
  Prevent unauthorized access and maintain security by using a firewall product, or the packet filtering feature of a router device, to restrict access to the server IP address and the various specified port numbers.
- Port access permissions
  If a port is blocked (access permissions have not been granted) by a firewall, enable use of the port by granting access. Refer to the vendor document for information on how to grant port access permissions.
  Consider the security risks carefully when opening ports.
- Changing port numbers
  When using WebAdmin in multiserver mode, it is recommended not to change WebAdmin ports after creating instances. Otherwise, the created instances may not be accessible through WebAdmin after the port is changed.
- Building in a Multi-Server Environment
  Configure your environment so that all servers have the same settings for using HTTPS and using HTTPS client authentication.

B.1.2 Certificate Settings For Secure Connection Support

Describes how to support secure connections.

You must replace the certificate used for HTTPS and client authentication with a CA-signed certificate. To determine if it has been replaced, check the certificate in the "keystore" to ensure that it has been replaced with a CA-signed certificate.

Certificate Storage Directory

If you specify Use HTTPS or Use HTTPS Client Authentication during setup, a new subdirectory "keystore" for storing certificates is added to the WebAdmin Tomcat installation directory.

Example: If WebAdmin is installed in /opt/fsepv<x>webadmin:

```
Tomcat installation directory (/opt/fsepv<x>webadmin/tomcat/)
├─── bin
├─── Building.txt
├─── conf
├─── CONTRIBUTING.md
├─── keystore
|    ├─── keystore.p12            → For HTTPS
|    ├─── clientbrowser.p12       → For client authentication
|    ├─── clientkeystore.p12      → For client authentication
|    ├─── truststore.p12          → For client authentication
|    ├─── clientkeystore.conf     → For client authentication
├─── ...
```

Certificate Configuration

To configure a certificate:

1. Prepare CA-signed certificates

Certificate	Summary
keystore.p12 (private and public keys included)	One server certificate for HTTPS. Used for data encryption.
clientbrowser.p12 (private key included)	One client certificate to authenticate the browser between the browser and the server.

Certificate	Summary
	It is registered in the user's browser. The number of certificates generated corresponds to the number of clients (browsers) accessing WebAdmin.
clientkeystore.p12 (private key included)	One client certificate for server-to-server authentication. Used internally by WebAdmin.
truststore.p12 (clientbrowser.p12 and clientkeystore.p12)	Imported public keys for all client certificates.

2. Place certificates in keystore directory

Single-server configuration

1. Place keystore.p12, truststore.p12 and clientkeystore.p12 files in "keystore" directory
2. Import clientbrowser.p12 into your browser.
   If you use multiple clients (browsers), import the certificate into each browser.

Multi-server configuration

1. Place keystore.p12, truststore.p12 and clientkeystore.p12 files in "keystore" directory
2. Import clientbrowser.p12 into your browser.
   If you use multiple clients (browsers), import the certificate into each browser.
3. Import the public key corresponding to the private key in clientkeystore.p12 into truststore.p12 on the other server you want to connect to.

3. Update certificate information in server.xml and clientkeystore.conf files

- **keystore.p12 and truststore.p12**

Populate server.xml with the information from keystore.p12 and truststore.p12.

The server.xml file is located under/opt/fsepv<x>webadmin/tomcat/conf.

HTTPS

Set the keystorePass and keyAlias attributes to the password and alias for keystore.p12.

server.xml (/opt/fsepv<x>webadmin/tomcat/conf)

```
<Connector port="27515" sslProtocol="TLS"
    protocol="org.apache.coyote.http11.Http11NioProtocol"
    maxThreads="150" SSLEnabled="true" scheme="https" secure="true"
    clientAuth="false" keystoreType="PKCS12"
    keystoreFile="/opt/fsepv<x>webadmin/tomcat/keystore/keystore.p12"
    keystorePass="password" keyAlias="alias" />
```

HTTPS and client authentication

Set the keystorePass and keyAlias attributes to the password and alias for keystore.p12.

Set the truststorePass attribute to the password for truststore.p12.

server.xml (/opt/fsepv<x>webadmin/tomcat/conf)

```
<Connector port="27515" sslProtocol="TLS"
    protocol="org.apache.coyote.http11.Http11NioProtocol"
    maxThreads="150" SSLEnabled="true" scheme="https" secure="true"
    clientAuth="true" keystoreType="PKCS12"
    keystoreFile="/opt/fsepv<x>webadmin/tomcat/keystore/keystore.p12"
    keystorePass="password" keyAlias="alias"
    truststoreType="PKCS12"
    truststoreFile="/opt/fsepv<x>webadmin/tomcat/keystore/truststore.p12"
    truststorePass="password" />
```

- **clientkeystore.p12**

  Populate clientkeystore.conf with the information from clientkeystore.p12.

  clientkeystore.conf file is generated by WebAdmin and its filename cannot be modified.

  HTTPS and client authentication

  Sets the client certificate information for server authentication.

  Set the password for the private key imported into clientkeystore.p12 and the password and alias for clientkeystore.p12.

  clientkeystore.conf (/opt/fsepv<x>webadmin/tomcat/keystore/)

```
clientkeystore.key.pass=password
clientkeystore.store.pass=password
clientkeystore.alias=alias
```

4. Back up

   Back up the certificates and server.xml file.

   Point

   When you uninstall WebAdmin, all certificates in the keystore directory are deleted. Also, when you reinstall WebAdmin, the server.xml file is overwritten with the default settings. Back up your data in case of incorrect operation.

5. Restart WebAdmin

   Stop WebAdmin and start it again.

   Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" and "B.1.3 Starting the Web Server Feature of WebAdmin" for detailed instructions.

   Point

   If certificates or connection failures occur, refer to the Tomcat log directory (/opt/fsepv<x>webadmin/tomcat/logs/) for detailed error messages.

B.1.3 Starting the Web Server Feature of WebAdmin

Follow the procedure below to start the Web server feature of WebAdmin.

1. Change to the superuser

   Acquire superuser privileges on the system.

   Example

```
$ su -
Password:******
```

2. Start the Web server feature of WebAdmin

   Execute the WebAdminStart command to start the Web server feature of WebAdmin.

   Example

   If WebAdmin is installed in /opt/fsepv<*x*>webadmin:

```
# cd /opt/fsepv<x>webadmin/sbin
# ./WebAdminStart
```

B.1.4 Stopping the Web Server Feature of WebAdmin

Follow the procedure below to stop the Web server feature of WebAdmin.

1. Change to the superuser

   Acquire superuser privileges on the system.

   Example

   ```
   $ su -
   Password:******
   ```

2. Stop the Web server feature of WebAdmin

   Execute the WebAdminStop command to stop the Web server feature of WebAdmin.

   Example

   If WebAdmin is installed in /opt/fsepv<*x*>webadmin:

   ```
   # cd /opt/fsepv<x>webadmin/sbin
   # ./WebAdminStop
   ```

Note

- For efficient operation of WebAdmin, it is recommended that the Web server feature be stopped only during a scheduled maintenance period.
- When WebAdmin is used to create and manage instances in a multiserver configuration, the Web server feature must be started and running on all servers at the same time.

B.2 Removing WebAdmin

This section explains how to remove WebAdmin.

This removal procedure stops WebAdmin and ensures that it no longer starts automatically when the machine is restarted.

1. Change to the superuser

   Acquire superuser privileges on the system.

   Example

   ```
   $ su -
   Password:******
   ```

2. Export JAVA_HOME (SLES only)

   On SLES, before uninstallation, ensure that JRE 8 is installed, and export the JAVA_HOME environment variable.

   ```
   #export JAVA_HOME="Jre8InstallDir"
   ```

3. Remove WebAdmin setup

   Execute the WebAdminSetup command to remove WebAdmin setup.

   Example

   If WebAdmin is installed in /opt/fsepv<*x*>webadmin:

   ```
   # cd /opt/fsepv<x>webadmin/sbin
   # ./WebAdminSetup -d
   ```

B.3 Using an External Repository for WebAdmin

WebAdmin can be configured to use an external database, where it can store the various metadata information it uses. WebAdmin will use this database as a repository to store the information it uses to manage all the created instances. This can be a Fujitsu Enterprise Postgres database.

Using an external database as a WebAdmin repository provides you with more flexibility in managing WebAdmin. This repository can be managed, backed up and restored as needed using pgAdmin or command line tools, allowing users to have greater flexibility and control.

Follow the procedure below to set up the repository.

1. Start WebAdmin, and log in to the database server.
2. Click the [Settings] tab, and then click in the [WebAdmin repository configuration] section.
3. Enter the following items:
   - [Host name]: Host name of the database server
   - [Port]: Port number of the database server
   - [Database name]: Name of the database
   - [User name]: User name to access the database
   - [Password]: Password of the database user

   Note

   - Database type
     It is recommended to use a Fujitsu Enterprise Postgres database as a repository. A compatible PostgreSQL database can also be used as an alternative.
   - It is recommended to click [Test connection] to ensure that the details entered are valid and WebAdmin is able to connect to the target database.
   - Host name, Database name, User name, Password should not contain hazardous characters. Refer to "Appendix C WebAdmin Disallow User Inputs Containing Hazardous Characters".
4. Click to register the repository details.

Note

- Once the repository is set up, it can be changed any number of times by the user logged into WebAdmin. When a repository is changed:
  - It is recommended to preload the backup into this database.
  - If the data is not preloaded, WebAdmin will create a new repository.
- The database repository can be set up even after WebAdmin was already used to create instances. In that scenario, the instances already created are retained and can continue to be operated on.
- If the instance used as a repository is stopped, WebAdmin will be unusable. For this reason, it is recommended to be familiar with starting an instance from the command line. If the instance is stopped for any reason, start it from the command line and WebAdmin will be usable again.

B.4 Using the WebAdmin Auto-Refresh Feature

The WebAdmin auto-refresh feature automatically refreshes the operating status of all instances in the Instance list at the specified interval. It also refreshes the details of the selected instance. You can use the auto-refresh feature to prevent timeouts.

Follow the procedure below to configure the auto-refresh options.

1. Click the [Settings] tab, and then click in the [User preferences] section.
2. Enter the following items:
   - [Auto-refresh instance]: To use the auto-refresh feature, select "Enabled". The default is "Disabled".
   - [Refresh interval (seconds)]: Number of seconds between each refresh. This is a countdown timer, which is reset every time the instance status is refreshed by any operation. Specify a value from 30 to 3600 (seconds). The default is 30.
3. Click to save the auto-refresh settings.

Point

- Auto-refresh will run only if the [Instances] page is displayed and no user-initiated operation is in progress.
- A text indicator, which is independent of auto-refresh, is displayed at the top of the Instance list. It is dynamically updated to display when the page was last refreshed.

Appendix C WebAdmin Disallow User Inputs Containing Hazardous Characters

WebAdmin considers the following as hazardous characters, which are not allowed in user inputs.

```
| (pipe sign)

& (ampersand sign)

; (semicolon sign)

$ (dollar sign)

% (percent sign)

@ (at sign)

' (single apostrophe)

" (quotation mark)

\' (backslash-escaped apostrophe)

\" (backslash-escaped quotation mark)

<> (triangular parenthesis)

() (parenthesis)

+ (plus sign)

CR (Carriage return, ASCII 0x0d)

LF (Line feed, ASCII 0x0a)

, (comma sign)

\ (backslash)
```

Appendix D Configuring Parameters

WebAdmin operates and manages databases according to the contents of the following configuration files:

- postgresql.conf

  Contains various items of information that define the operating environment of Fujitsu Enterprise Postgres.

- pg_hba.conf

  Contains various items of information related to client authentication.

These configuration files are deployed to a data storage destination. Data is written to them when the instance is created by WebAdmin and when settings are changed, and data is read from them when the instance is started and when information from the [Setting] menu is displayed.

See

Refer to "Server Configuration" and "Client Authentication" in "Server Administration" in the PostgreSQL Documentation for information on the parameters.

Note

WebAdmin checks for port number and backup storage path anomalies when various operations are performed. An anomaly occurs when the value of [Port number] and/or [Backup storage path] in WebAdmin is different from the value of the corresponding parameter in postgresql.conf. Refer to "Anomaly Detection and Resolution" in the Operation Guide for details.

postgresql.conf

Parameters that can be changed in WebAdmin

The postgresql.conf parameters that can be changed in WebAdmin are shown below:

Section	WebAdmin item	postgresql.conf file parameter
Instance Configuration		
Character encoding	Character set	client_encoding
	Message locale	lc_messages
Communication	Max connections	max_connections
SQL options	Transform NULL format	transform_null_equals
	Date output format	DateStyle (*1)
	Interval output format	IntervalStyle
	Number of digits for floating values	extra_float_digits
	Transaction isolation levels	default_transaction_isolation
	Currency format	lc_monetary
	Date and time format	lc_time
	Numerical value format	lc_numeric
Memory	Sort memory (KB)	work_mem
	Shared buffers (KB)	shared_buffers
Streaming replication	WAL level	wal_level
	Maximum WAL senders	max_wal_senders

Section	WebAdmin item	postgresql.conf file parameter
	WAL save size (MB)	wal_keep_size
	Hot standby	hot_standby
	Synchronous standby names	synchronous_standby_names
	WAL receiver timeout (ms)	wal_receiver_timeout
Edit instance		
	Instance name	n/a
	Instance port	port
	Backup storage path	backup_destination

*1: If you specify "Postgres" as the output format, dates will be output in the "12-17-1997" format, not the "Wed Dec 17 1997" format used in the PostgreSQL Documentation.

Information

- Calculate the maximum number of connections using the formula below:

```
maximumNumberOfConnections = maximumNumberOfConnectionsFromApplications + 3 (*1)
```

*1: 3 is the default number of connections required by the system.
Calculate the maximum number of connections using the following formula when changing superuser_reserved_connections (connections reserved for use by the superuser) in postgresql.conf.

```
maximumNumberOfConnections = maximumNumberOfConnectionsFromApplications +
superuser_reserved_connections
```

- Also check if the memory used exceeds the memory installed (refer to "Parameters automatically set by WebAdmin according to the amount of memory").
- When modifying "Shared buffers" or "Max connections", edit the kernel parameter. Refer to "Appendix H Configuring Kernel Parameters", and "Managing Kernel Resources" in "Server Administration" in the PostgreSQL Documentation for details.

Parameters set by WebAdmin

The following postgresql.conf parameters are set by WebAdmin during instance startup (they will be ignored even if specified in postgresql.conf):

Parameter	Value
listen_addresses	*
log_destination	'stderr,syslog'
logging_collector	on
log_line_prefix	'%e: %t [%p]: [%l-1] user = %u,db = %d,remote = %r app = %a '
log_filename (*1) (*2)	'logfile-%a.log'
log_file_mode	0600
log_truncate_on_rotation	on
log_rotation_age	1d

*1: The server logs are split into files based on the day of the week, and are rotated after each week.

*2: If the date changes while the instance is stopped, old logs are not deleted and continue to exist.
Manually delete old logs that are no longer required to release disk space.

Parameters automatically set by WebAdmin according to the amount of memory

The postgresql.conf parameters automatically set according to the amount of installed memory, during the creation of instances by WebAdmin, are shown below:

Parameter	Value
shared_buffers	30% of the machine's installed memory
work_mem	30% of the machine's installed memory / max_connections / 2
effective_cache_size	75% of the machine's installed memory
maintenance_work_mem	10% of the machine's installed memory / (1 + autovacuum_max_workers) (*1)

*1: The value will be capped at 2097151 KB.

When determining the values to be configured in the above parameters, you must take into account any anticipated increases in access volume or effects on performance during business operations, such as the number of applications and commands that will access the instance, and the content of processes. Also, note that in addition to Fujitsu Enterprise Postgres, other software may be running on the actual database server. You will need to determine the degree of priority for the database and other software, as well as the memory allocation size.

WebAdmin automatically configures complex parameter settings such as those mentioned above, based on the size of the internal memory of the machine. This enables maximum leverage of the machine memory to facilitate resistance against fluctuations during business operations.

Accordingly, the effects of the above-mentioned factors must be estimated and taken into account when determining and configuring parameter values, so that memory resources can be effectively allocated among other software or instances, and so that adverse effects can be mutually avoided. Refer to "Memory" in "Resource Consumption", and "Planner Cost Constants" in "Query Planning", under "Server Administration" in the PostgreSQL Documentation for information on parameter values and required considerations.

Parameter values can be modified using the WebAdmin [Setting] menu, or edited directly using a text editor.

If adding an instance, determine the parameter values, including for existing instances, and make changes accordingly.

See

Kernel parameters need to be tuned according to the parameters being changed. Refer to "Appendix H Configuring Kernel Parameters", and "Managing Kernel Resources" in "Server Administration" in the PostgreSQL Documentation for information on tuning kernel parameters.

Note

- You can edit postgresql.conf directly with a text editor. However, do not edit the following parameters. If you edit incorrectly, WebAdmin will not work correctly.
  - archive_mode
  - archive_command
  - wal_level
  - log_line_prefix
  - log_destination
  - logging_collector
  - log_directory
  - log_file_mode
  - log_filename

    - log_truncate_on_rotation
    - log_rotation_age

- If you edit postgresql.conf directly, the records should be single line. WebAdmin will not work correctly if the record spans multiple lines.
- If you change superuser_reserved_connections, set the value you want to change plus the number of connections required by WebAdmin of 3.

pg_hba.conf

Refer to "Client Authentication" in "Server Administration" in the PostgreSQL Documentation for information on content that can be configured in pg_hba.conf.

- Configure the instance administrator permissions in the "local" connection format settings. WebAdmin may not work properly if permissions are not configured.
- You can also edit pg_hba.conf directly. However, do not modify items that cannot be configured in WebAdmin. WebAdmin does not work correctly.
- If you edit pg_hba.conf directly, the records should be single line. WebAdmin will not work correctly if the record spans multiple lines.

Appendix E Estimating Database Disk Space Requirements

This appendix describes how to estimate database disk space requirements.

E.1 Estimating Table Size Requirements

The following tables provide the formulas for estimating table size requirements.

Table E.1 Estimation formula when the record length is 2032 bytes or less

Item	Estimation formula (bytes)
(1) Record length	27(*1) + NULL map + OID + column data NULL map: Number of columns / 8 (*2) OID: 4 Column data: Sum of column lengths *1: Record header section *2: Round the result up to the next integer. - Because the column data is placed in boundaries of 8 bytes, you need to make an adjustment so that the sum of the record header section, NULL map and OID is a multiple of 8. For example, if the calculated length is 27 + 1 / 8 (rounded up) + 0 = 28 bytes, add 4 to make the length 32 bytes. - Because the data of each column is placed in boundaries of the defined data type, take the boundary of each data type into account for the length of the column data. For example, the length of the column data in the table below will not be the sum of the data types, which is 37 bytes, but will instead be 64 bytes following boundary adjustment. Definition: create table tb1(c1 char(1), c2 bigint, c3 int, c4 box) Estimation: CHAR type 1 byte + boundary adjustment of 7 bytes for BIGINT type 8 bytes + BIGINT type 8 bytes + INT type 4 bytes + boundary adjustment of 12 bytes for BOX type 32 bytes + BOX type 32 bytes = 64 bytes - Because each record is placed in boundaries of 8 bytes, you need to make an adjustment so that the length of the column data is a multiple of 8. - If the calculated record length exceeds 2,032 bytes, the variable length data in the record might be compressed automatically. If so, use the estimation formulas in "Table E.2 Estimation formula when the record length exceeds 2032 bytes" to estimate the table size.
(2) Page size requirement	8192 (*1) × fillfactor (*2) - 24 (*3) *1: Page length (8192) *2: Value of the fillfactor specified in the table definitions (if omitted, 100%) *3: Page header (24) - The calculated (2) page size requirement will be rounded down to the nearest integer.
(3) Number of records per page	(2) Page size requirement / ((1) record length + 4 (*1)) *1: Pointer length (4) - The result will be rounded down to the nearest integer.

Item	Estimation formula (bytes)
(4) Number of pages required for storing records	Total number of records / (3) number of records per page - The result will be rounded up to the next integer.
(5) Amount of space	(4) Number of pages required for storing records x page length x safety factor (*1) *1: Specify 2.0 or higher. - This is the safety factor assumed if vacuuming is performed for garbage collection in tables and indexes.

Table E.2 Estimation formula when the record length exceeds 2032 bytes

Item	Estimation formula (bytes)
(5) Amount of space	Total number of records x (1) record length x safety factor (*1) *1: Specify 2.0 or higher. - This is the safety factor assumed if vacuuming is performed for garbage collection in tables and indexes.

E.2 Estimating Index Size Requirements

This section provides the formulas for estimating index size requirements.

Fujitsu Enterprise Postgres provides six index types: B-tree, Hash, GiST, GIN, SP-GiST, and VCI. If you do not specify the index type in the CREATE INDEX statement, a B-tree index is generated.

The following describes how to estimate a B-tree index. Refer to "E.7 Estimating VCI Disk Space Requirements" for information on how to estimate VCI.

A B-tree index is saved as a fixed-size page of 8 KB. The page types are meta, root, leaf, internal, deleted, and empty. Since leaf pages usually account for the highest proportion of space required, you need to calculate the requirements for these only.

Table E.3 Estimation formula when the key data length is 512 bytes or less

Item	Estimation formula (bytes)
(1) Entry length	8 (*1) + key data length (*2) *1: Entry header *2: The key data length depends on its data type (refer to "E.3 Sizes of Data Types" for details). Because each entry is placed in boundaries of 8 bytes, you need to make an adjustment so that the length of the key data is a multiple of 8. For example, if the calculated length is 28 bytes, add 4 to make the length 32 bytes. - If the key data length exceeds 512 bytes, key data may be automatically compressed. In this case, use the estimation formula given in "Table E.4 Estimation formula when the key data length exceeds 512 bytes" to estimate the key data length.
(2) Page size requirement	8192 (*1) × fillfactor (*2) - 24 (*3) - 16 (*4) *1: Page length (8192) *2: Value of the fillfactor specified in the index definitions (if omitted, 90%) In the case of indexes of primary key constraints and unique constraints, the value of the fillfactor specified for each constraint in the table definitions (if omitted, 90%) *3: Page header (24) *4: Special data (16)

Item	Estimation formula (bytes)
	- The calculated (2) page size requirement will be rounded down to the nearest integer.
(3) Number of entries per page	(2) Page size requirement / ((1) entry length + 4 (*1)) *1: Pointer length - Result of (3) number of entries per page will be rounded down to the nearest integer.
(4) Number of pages required for storing indexes	Total number of records / (3) number of entries per page - Result of (4) number of pages required for storing indexes will be rounded up to the nearest integer.
(5) Space requirement	(4) Number of pages required for storing indexes x 8192 (*1) / usage rate (*2) *1: Page length *2: Specify 0.7 or lower.

Table E.4 Estimation formula when the key data length exceeds 512 bytes

Item	Estimation formula (bytes)
(5) Space requirement	Total number of records x key data length x compression ratio (*1) / usage rate (*2) *1: The compression ratio depends on the data value, so specify 1. *2: Specify 0.7 or lower as the usage rate.

E.3 Sizes of Data Types

This section lists the sizes of the data types.

E.3.1 Sizes of Fixed-Length Data Types

The following table lists the sizes of fixed-length data types.

Data type	Size (bytes)
SMALLINT (INT2)	2
INTEGER (INT4)	4
BIGINT (INT8)	8
REAL	4
DOUBLE PRECISION	8
SERIAL (SERIAL4)	4
BIGSERIAL (SERIAL8)	8
MONEY	8
FLOAT	8
FLOAT (1-24)	4
FLOAT (25-53)	8
TIMESTAMP WITHOUT TIME ZONE	8
TIMESTAMP WITH TIME ZONE	8
DATE	4
TIME WITHOUT TIME ZONE	8
TIME WITH TIME ZONE	12

Data type	Size (bytes)
INTERVAL	12
BOOLEAN	1
CIDR	IPv4: 7 IPv6: 19
INET	IPv4: 7 IPv6: 19
MACADDR	6
MACADDR8	8
POINT	16
LINE	32
LSEG	32
BOX	32
CIRCLE	24

E.3.2 Sizes of Variable-Length Data Types

The following table lists the sizes of variable-length data types.

Data type	Size (bytes)	Remarks
path	Length of size portion + 12 + 16 x number of vertices	1) When carrying out division, round to the next integer. 2) If the real data length is less than 127, then the length of the size portion is 1 byte, otherwise it is 4 bytes. 3) The number of bytes per character depends on the character set (refer to "E.3.4 Number of Bytes per Character" for details).
polygon	Length of size portion + 36 + 16 x number of vertices	
decimal	Length of size portion + 2 + (integer precision / 4 + decimal precision / 4) x 2	
numeric		
bytea	Length of size portion + real data length	
character varying(*n*), varchar(*n*)	Length of size portion + number of characters x number of bytes per character	
character(*n*), char(*n*)	Length of size portion + *n* x number of bytes per character	
text	Length of size portion + number of characters x number of bytes per character	

E.3.3 Sizes of Array Data Types

The following table lists the sizes of array data types.

Data type	Size (bytes)	Remarks
Array	Length of size portion + 12 + 8 x number of dimensions + data size of each item	If the real data length is less than 127, then the length of the size portion is 1 byte, otherwise it is 4 bytes. - Example of estimation when array data is "ARRAY[[1,2,3],[1,2,3]]" Number of dimensions: 2 INTEGER data size: 4 Total size = 1+12+8x2+6x4 = 53

E.3.4 Number of Bytes per Character

The following table lists the number of bytes per character.

The given values relate to the common character sets EUC-JP and UTF8.

Character type	Character set	Number of bytes per character
ASCII	EUC_JP	1
Halfwidth katakana	EUC_JP	2
JIS X 0208 kanji characters	EUC_JP	2
JIS X 0212 kanji characters	EUC_JP	3
ASCII	UTF8	1
Halfwidth katakana	UTF8	3
JIS X 0208 kanji characters	UTF8	3
JIS X 0212 kanji characters	UTF8	3

E.4 Estimating Transaction Log Space Requirements

This section provides the formula for estimating transaction log space requirements.

```
Transaction log space requirements = max_wal_size
```

However, if the update volume is extremely high (for example, due to a large data load and batch processing), disk writing at a checkpoint may not be able to keep up with the load, and a higher number of transaction logs than indicated here may temporarily be accumulated.

E.5 Estimating Archive Log Space Requirements

This section explains how to estimate archive log space requirements.

The archive log is an archive of the transaction logs from the time of a previous backup to the present, so it fluctuates depending on the backup period and the content of update transactions.

The longer the backup period and the more update transactions, the greater the space required for the archive log.

Therefore, measure the actual archive log space by using a test environment to simulate backup scheduling and database update in a real operating environment.

E.6 Estimating Backup Disk Space Requirements

This section provides the formula for estimating backup disk space requirements.

```
Backup disk space requirements = size of the database cluster x 2 + transaction log space requirements
                               + archive log space requirements
```

Note

If the pgx_dmpall command performs a backup using a user exit, the backup disk size differs according to the database resources targeted for backup and the copy method.

E.7 Estimating VCI Disk Space Requirements

This section provides the formula for estimating VCI disk space requirements.

```
Disk space = (number of rows in tables) x (number of bytes per row) x (compression ratio) + (WOS size)
```

Number of bytes per row

```
Number of bytes per row = (19 + (number of columns specified in CREATE INDEX) / 8
                                  + (number of bytes per single column value)) x 1.1
```

Note: Round up the result to the nearest integer.

Compression ratio

Specify a value between 0 and 1. Since compression ratio depends on the data being compressed, use actual data or test data that simulates it, then compare the value with the estimation result. As a guide, the compression ratio measured with the Fujitsu sample data is shown below:

- Data with high degree of randomness (difficult to compress): Up to approximately 0.9 times.
- Data with high degree of similarity (easy to compress): Up to approximately 0.5 times.

WOS size

```
WOS size = (number of WOS rows) / 185 x 8096
```

One row is added to the number of WOS rows for each INSERT and DELETE, and two rows are added for UPDATE. On the other hand, the number decreases to 520,000 rows or less during conversion to ROS performed by the ROS control daemon.

Note

VCI does not support retrieval of disk space usage using the database object size function pg_indexes_size. To find out the actual total VCI disk space, check the disk space of the storage directory using an OS command or other method.

E.8 Estimating pgvector Disk Space Requirements

When using pgvector, refer to the pgvector documentation for the size of each data type and index. Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for the documentation URL.

Information

For pgvector 0.7.4, refer to the documentation "Reference" for details on each data type, and the source code for index sizes.

E.9 Estimating Hybrid Search Trace Information Disk Space Requirements

The bulk of the size of the hybrid search trace information is the text chunks that are the search results.

Describes the formula for estimating the amount of text chunks recorded per hybrid search.

```
Total size of text chunks recorded per hybrid search = average size of text chunks x (n_0 + n_1 + n_2)
```

n_0: Number of hybrid search returned

n_1: Number of semantic text search returned

n_2: Number of full-text search returned

Appendix F Estimating Memory Requirements

This appendix explains how to estimate the memory.

F.1 Fujitsu Enterprise Postgres Memory Requirements

This section describes the formulas for estimating Fujitsu Enterprise Postgres memory requirements.

Use the following formula to obtain a rough estimate of memory required for Fujitsu Enterprise Postgres:

```
fujitsuEnterprisePostgresRequiredMemory = sharedMemoryAmount + localMemoryAmount
```

Shared memory amount

```
sharedMemoryAmount = 1523444
                        + 8518 x x
                        + 7154 x (a + b + c + d + 1)
                        + 405 x (a + b + c + d + e) x f
                        + (1208 + g) x (a + b + c + d + 9)
                        + 64 x b
                        + 568 x c
                        + 104 x d
                        + 5666 x e
                        + 112 x h
                        + 8200 x i
                        + 512 x j
                        + 4 x (k + 10)
                        + 1097984 x m
                        + 258 x (a + b + c + d + 1 + e) x o
                        + (1024 x 1024) x p
                        + n
                        + 128 x q
```

The above units are Byte.

Parameter Details:

```
x = shared_buffer/8
    Note : Units of shared_buffer (kB)
    Example : x = 16384 (128 x 1024/8) when shared_buffer = 128 MB
        Convert MB to KB to calculate x.
a = max_connections
b = autovacuum_max_workers
c = max_worker_processes
d = max_wal_senders
e = max_prepared_transactions
f = max_locks_per_transaction
g = track_activity_query_size (byte)
h = max_logical_replication_workers
i = wal_buffers/8
  Note: If wal_buffers is the default value (-1), calculate i = x/32.
        However, if it becomes 2048 or more, set the maximum value to 2048.
        If i = x/32, there is a limit on the maximum value of i.
        Max i = WAL segment size/8
        The WAL segment size can be set with the initdb option --wal-segsize.
        The WAL segment size is in kilobytes.
        (The default WAL segment size is 16 MB. Convert to KB when calculating i)
  Example: If shared_buffer = 128 MB and wal_buffers = -1, i = 512 (16384/32)
           If shared_buffer = 2 GB and wal_buffers = -1, i = 2048 (2 x 1024 x 1024/8/32 = 8192,
           but the maximum value of i is 2048)
           If wal_buffers = 512 kB, i = 64 (512/8)
           i = 4096 (32 x 1024/8) when wal_buffers = 32 MB
```

```
                  Converts MB to KB to calculate i.
j = max_replication_slots
k = old_snapshot_threshold
  Note: If old_snapshot_threshold is the default value (-1), there is no need to add "4 x (k + 10)"
to the quote formula.
           old_snapshot_threshold units (min)
  Example: k = 60 (1 x 60) if old_snapshot_threshold = 1 h
               Convert h to min to get k.
m = pgx_global_metacache (megabytes)
n = memory size requested by the plug-in (determined by the plug-in)
o = max_pred_locks_per_transaction
p = min_dynamic_shared_memory (MB)
q = number of database roles
```

However, note that if instances have been created using WebAdmin, the parameters below will be configured automatically when the instances are created. Take this into account when calculating the shared memory size.

Parameter name	Set value
shared_buffers	30 percent of the internal memory of the machine.
max_connections	100
max_prepared_transactions	100

Local memory amount

```
localMemoryAmount = processStackArea
                  + memoryUsedInDbSessionsThatUseTempTables
                  + memoryUsedInDbSessionsThatPerformSortAndHashTableOperations
                  + memoryUsedInMaintenanceOperations
                  + baseMemoryUsedInEachProcess
                  + memoryUsedPreparingForDataAccess
```

Process stack area

```
processStackArea
  = max_stack_depth x (max_connections + autovacuum_max_workers + 9)
```

This formula evaluates to the maximum value.
Actually it is used according to the growth of the stack.
In the formula above, 9 is the number of processes that perform roles specific to servers.

Memory used in database sessions that use temporary tables

```
memoryUsedInDbSessionsThatUseTempTables
  = temp_buffers x max_connections
```

This formula evaluates to the maximum value.
Memory is gradually used as temporary buffers are used, and is released when the session ends.

Memory used in database sessions that perform sort and hash table operations

```
memoryUsedInDbSessionsThatPerformSortAndHashTableOperations
  = work_mem (*1) x max_connections
```

*1) For hash table operations, multiply work_mem by hash_mem_multiplier.
This formula evaluates to the maximum value.
Memory is gradually used as operations such as sort are performed, and is released when the query ends.

Memory used in maintenance operations

```
memoryUsedInMaintenanceOperations
  = maintenance_work_mem x (numOfSessionsPerformingMaintenance + autovacuum_max_workers)
```

Note that 'maintenance operations' are operations such as VACUUM, CREATE INDEX, and ALTER TABLE ADD FOREIGN KEY.

Base memory used in each process

```
baseMemoryUsedInEachProcess
  = baseMemoryUsedInOneProcess x (max_connections + autovacuum_max_workers + 9)
```

Use the result of the following formula for memory consumed per process. This formula evaluates to the memory used when server processes are running.
In the formula above, 9 is the number of processes that perform roles specific to servers.

The amount of memory consumed per process is determined by the number of tables, indexes, and all columns of all tables that the process accesses. If your system has about 100 tables, you can estimate it to be 3 MB, but otherwise use the following estimate:

```
baseMemoryUsedInOneProcess
  = (1.9KB x All user tables + 2.9KB x All user indexes + 1.0KB x All user columns) x 1.5(*1)

If you enable the Global Meta Cache feature, use the following formula:
baseMemoryUsedInOneProcess
 = (All user tables + All user indexes + All user columns) x 1.0KB x 1.5 (*1)
    + (All user tables x 1.4KB + All user indexes x 2.4KB)
```

*1) Safety Factor (1.5)
There are variable length information. This value takes that into account.

Memory used preparing for data access

```
memoryUsedPreparingForDataAccess
 = variationAmount x (max_connections + autovacuum_max_workers + 4)

  where variationAmount = shared_buffers / 8KB x 4 bytes
      (note that 8KB is the page length, and 4 bytes is the size of page management data)
```

This formula evaluates to the memory required to access the database cache in the shared memory.
In the formula above, among the processes that perform roles specific to servers, 4 is the number of processes that access the database.

F.2 Database Multiplexing Memory Requirements

This section describes the formula for estimating database multiplexing memory requirements for the database server.

Use the following formula to obtain a rough estimate of memory required for database multiplexing:

```
Memory usage of the database multiplexing feature for the database server
           = Peak memory usage of the Mirroring Controller processes
           + Peak memory usage of the Mirroring Controller commands

Peak memory usage of the Mirroring Controller processes=150 MB

Peak memory usage of the Mirroring Controller commands=50 MB x Number of commands executed
simultaneously
```

F.3 VCI Memory Requirements

This section describes the formula for estimating VCI memory requirements.

Use the following formula to obtain a rough estimate of memory requirements:

```
memUsedByVci = memForData + memForEachProcess
```

Memory required to store data in memory

Secure the space estimated using the formula below on the stable buffer (part of shared_buffers).

```
memForData = (numOfRowsInTables) x (numOfBytesPerRow) + (wosSize)
```

Number of bytes per row

```
numOfBytesPerRow
 = (19 + (numOfColsInCreateIndexStatement) / 8 + (numOfBytesPerSingleColValue)) x 1.1
```

Note: Round up the result to the nearest integer.

WOS size

```
wosSize = (numOfWosRows) / 185 x 8096
```

One row is added to the number of WOS rows for each INSERT and DELETE, and two rows are added for UPDATE. On the other hand, the number decreases to 520,000 rows or less during conversion to ROS performed by the ROS control daemon.

Memory required for each process

```
memForEachProcess
 = memUsedPerScanning
 + memUsedForVciMaintenace
 + memUsedByCreateIndexStatement
```

Memory used per scanning

- Parallel scan

```
memUsedPerScanning
 = vci.shared_work_mem + (numOfParallelWorkers + 1) x vci.maintenance_work_mem
```

Note: The number of parallel workers used by VCI simultaneously in the entire instance is equal to or less than vci.max_parallel_degree.

- Non-parallel scan

```
memUsedPerScanning = vci.max_local_ros + vci.maintenance_work_mem
```

Note

- vci.shared_work_mem, and vci.max_local_ros are used to create local ROS. If local ROS exceeds these sizes, execute a query without using VCI according to the conventional plan.
- vci.maintenance_work_mem specifies the memory size to be secured dynamically. If it exceeds the specified value, a disk temporary file is used for operation.

Memory used for VCI maintenance

```
memUsedForVciMaintenace = vci.maintenance_work_mem x vci.control_max_workers
```

Memory used by CREATE INDEX

```
memUsedByCreateIndexStatement = vci.maintenance_work_mem
```

Note

vci.maintenance_work_mem specifies the memory to be secured dynamically. If it exceeds the specified value, a disk temporary file is used for operation.

F.4 High-Speed Data Load Memory Requirements

This section describes the formula for estimating memory requirements for the high-speed data load feature.

Use the following formula to obtain a rough estimate of memory requirements:

```
Memory usage of high speed data load
 = (Peak memory usage of pgx_loader processes + Peak memory usage of the pgx_loader commands)
 x Number of commands executed simultaneously

Peak memory usage of pgx_loader processes
 = Peak memory usage of the backend process   (6 MB)
 + Peak memory usage of parallel workers       (6 MB x number of parallel workers)
 + Peak memory usage of dynamic shared memory (80 MB x number of parallel workers)

Peak memory usage of the pgx_loader commands=9 MB
```

Point

In addition to the size calculated using the formula above, the database cache on the shared memory estimated using the shared_buffers parameter is consumed according to the size of the data (table and index keys) loaded using this feature. Refer to "E.1 Estimating Table Size Requirements" and "E.2 Estimating Index Size Requirements" for information on estimating an appropriate shared buffers value.

F.5 Global Meta Cache Memory Requirements

This section describes the formula for estimating Global Meta Cache memory requirements.

The memory calculated by "Size of the GMC area" is allocated to the shared memory. The memory calculated by the per-process meta cache management information is allocated to the local memory. Refer to the graphic in "Architecture of Global Meta Cache Feature" in the "Memory usage reduction by Global Meta Cache" in the General Description for more information.

Use the following formula to obtain a rough estimate of memory requirements:

```
Amount of memory used by the Global Meta Cache feature
  = Size of GMC area + Per-process meta cache management information

Size of GMC area = (All user tables x 0.4 KB
     + All user indexes x 0.3 KB
     + All user columns x 0.8 KB) x 1.5 (*1)

Per-process meta cache management information
  = (All user tables + All user indexes + All user columns) x 0.1KB x max_connections x 1.5 (*1)
```

*1) Safety Factor (1.5)
This value takes into account the case where both GMC before and after the change temporarily exist at the same time in shared memory when the table definition is changed or the row of the system catalog is changed.

Appendix G Quantitative Limits

This appendix lists the quantitative limits of Fujitsu Enterprise Postgres.

Refer to the pgvector documentation for quantitative limits on the capabilities provided by pgvector. Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for the documentation URL.

Table G.1 Length of identifier

Item	Limit
Database name	Up to 63 bytes (*1) (*2)
Schema name	Up to 63 bytes (*1) (*2)
Table name	Up to 63 bytes (*1) (*2)
View name	Up to 63 bytes (*1) (*2)
Index name	Up to 63 bytes (*1) (*2)
Tablespace name	Up to 63 bytes (*1) (*2)
Cursor name	Up to 63 bytes (*1) (*2)
Function name	Up to 63 bytes (*1) (*2)
Aggregate function name	Up to 63 bytes (*1) (*2)
Trigger name	Up to 63 bytes (*1) (*2)
Constraint name	Up to 63 bytes (*1) (*2)
Conversion name	Up to 63 bytes (*1) (*2)
Role name	Up to 63 bytes (*1) (*2)
Cast name	Up to 63 bytes (*1) (*2)
Collation sequence name	Up to 63 bytes (*1) (*2)
Encoding method conversion name	Up to 63 bytes (*1) (*2)
Domain name	Up to 63 bytes (*1) (*2)
Extension name	Up to 63 bytes (*1) (*2)
Operator name	Up to 63 bytes (*1) (*2)
Operator class name	Up to 63 bytes (*1) (*2)
Operator family name	Up to 63 bytes (*1) (*2)
Rewrite rule name	Up to 63 bytes (*1) (*2)
Sequence name	Up to 63 bytes (*1) (*2)
Text search settings name	Up to 63 bytes (*1) (*2)
Text search dictionary name	Up to 63 bytes (*1) (*2)
Text search parser name	Up to 63 bytes (*1) (*2)
Text search template name	Up to 63 bytes (*1) (*2)
Data type name	Up to 63 bytes (*1) (*2)
Enumerator type label	Up to 63 bytes (*1) (*2)
Profile name	Up to 63 bytes (*1) (*2)

*1: This is the character string byte length when converted by the server character set character code.

*2: If an identifier that exceeds 63 bytes in length is specified, the excess characters are truncated and it is processed.

Table G.2 Database object

Item	Limit
Number of databases	Less than 4,294,967,296 (*1)
Number of schemas	Less than 4,294,967,296 (*1)
Number of tables	Less than 4,294,967,296 (*1)
Number of views	Less than 4,294,967,296 (*1)
Number of indexes	Less than 4,294,967,296 (*1)
Number of tablespaces	Less than 4,294,967,296 (*1)
Number of functions	Less than 4,294,967,296 (*1)
Number of aggregate functions	Less than 4,294,967,296 (*1)
Number of triggers	Less than 4,294,967,296 (*1)
Number of constraints	Less than 4,294,967,296 (*1)
Number of conversion	Less than 4,294,967,296 (*1)
Number of roles	Less than 4,294,967,296 (*1)
Number of casts	Less than 4,294,967,296 (*1)
Number of collation sequences	Less than 4,294,967,296 (*1)
Number of encoding method conversions	Less than 4,294,967,296 (*1)
Number of domains	Less than 4,294,967,296 (*1)
Number of extensions	Less than 4,294,967,296 (*1)
Number of operators	Less than 4,294,967,296 (*1)
Number of operator classes	Less than 4,294,967,296 (*1)
Number of operator families	Less than 4,294,967,296 (*1)
Number of rewrite rules	Less than 4,294,967,296 (*1)
Number of sequences	Less than 4,294,967,296 (*1)
Number of text search settings	Less than 4,294,967,296 (*1)
Number of text search dictionaries	Less than 4,294,967,296 (*1)
Number of text search parsers	Less than 4,294,967,296 (*1)
Number of text search templates	Less than 4,294,967,296 (*1)
Number of data types	Less than 4,294,967,296 (*1)
Number of enumerator type labels	Less than 4,294,967,296 (*1)
Number of default access privileges defined in the ALTER DEFAULT PRIVILEGES statement	Less than 4,294,967,296 (*1)
Number of large objects	Less than 4,294,967,296 (*1)
Number of index access methods	Less than 4,294,967,296 (*1)
Number of profile	Less than 4,294,967,296 (*1)

*1: The total number of all database objects must be less than 4,294,967,296.

Table G.3 Schema element

Item	Limit
Number of columns that can be defined in one table	From 250 to 1600 (according to the data type)
Table row length	Up to 400 gigabytes

Item	Limit
Number of columns comprising a unique constraint	Up to 32 columns
Data length comprising a unique constraint	Less than 2,000 bytes (*1) (*2)
Table size	Up to 32 terabyte
Search condition character string length in a trigger definition statement	Up to 800 megabytes (*1) (*2)
Item size	Up to 1 gigabyte

*1: Operation might proceed correctly even if operations are performed with a quantity outside the limits.

*2: This is the character string byte length when converted by the server character set character code.

Table G.4 Index

Item	Limit
Number of columns comprising a key (including VCI)	Up to 32 columns
Key length (other than VCI)	Less than 2,000 bytes (*1)

*1: This is the character string byte length when converted by the server character set character code.

Table G.5 Data types and attributes that can be handled

Item			Limit
Character	Data length		Data types and attributes that can be handled (*1)
	Specification length (n)		Up to 10,485,760 characters (*1)
Numeric	External decimal expression		Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point
	Internal binary expression	2 bytes	From -32,768 to 32,767
		4 bytes	From -2,147,483,648 to 2,147,483,647
		8 bytes	From -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807
	Internal decimal expression		Up to 13,1072 digits before the decimal point, and up to 16,383 digits after the decimal point
	Floating point expression	4 bytes	From -3.4E+38 to -7.1E-46, 0, or from 7.1E-46 to 3.4E+38
		8 bytes	From -1.7E+308 to -2.5E-324, 0, or from 2.5E-324 to 1.7E+308
bytea			Up to one gigabyte minus 53 bytes
Large object			Up to 4 terabyte

*1: This is the character string byte length when converted by the server character set character code.

Table G.6 Function definition

Item	Limit
Number of arguments that can be specified	Up to 100
Number of variable names that can be specified in the declarations section	No limit

Item	Limit
Number of SQL statements or control statements that can be specified in a function processing implementation	No limit

Table G.7 Data operation statement

Item	Limit
Maximum number of connections for one process in an application (remote access)	4,000 connections
Number of expressions that can be specified in a selection list	Up to 1,664
Number of tables that can be specified in a FROM clause	No limit
Number of unique expressions that can be specified in a selection list/ DISTINCT clause/ORDER BY clause/GROUP BY clause within one SELECT statement	Up to 1,664
Number of expressions that can be specified in a GROUP BY clause	No limit
Number of expressions that can be specified in an ORDER BY clause	No limit
Number of SELECT statements that can be specified in a UNION clause/INTERSECT clause/EXCEPT clause	Up to 4,000 (*1)
Number of nestings in joined tables that can be specified in one view	Up to 4,000 (*1)
Number of functions or operator expressions that can be specified in one expression	Up to 4,000 (*1)
Number of expressions that can be specified in one row constructor	Up to 1,664
Number of expressions that can be specified in an UPDATE statement SET clause	Up to 1,664
Number of expressions that can be specified in one row of a VALUES list	Up to 1,664
Number of expressions that can be specified in a RETURNING clause	Up to 1,664
Total expression length that can be specified in the argument list of one function specification	Up to 800 megabytes (*2)
Number of cursors that can be processed simultaneously by one session	No limit
Character string length of one SQL statement	Up to 800 megabytes (*1) (*3)
Number of input parameter specifications that can be specified in one dynamic SQL statement	No limit
Number of tokens that can be specified in one SQL statement	Up to 10,000
Number of values that can be specified as a list in a WHERE clause IN syntax	No limit
Number of expressions that can be specified in a USING clause	No limit
Number of JOINs that can be specified in a joined table	Up to 4,000 (*1)
Number of expressions that can be specified in COALESCE	No limit
Number of WHEN clauses that can be specified for CASE in a simple format or a searched format	No limit
Data size per record that can be updated or inserted by one SQL statement	Up to one gigabyte minus 53 bytes
Number of objects that can share a lock simultaneously	Up to 256,000 (*1)

*1: Operation might proceed correctly even if operations are performed with a quantity outside the limits.

*2: The total number of all database objects must be less than 4,294,967,296.

*3: This is the character string byte length when converted by the server character set character code.

Table G.8 Data size

Item	Limit
Data size per record for input data files (COPY statement, psql command \copy meta command)	Up to 800 megabytes (*1)
Data size per record for output data files (COPY statement, psql command \copy meta command)	Up to 800 megabytes (*1)

*1: Operation might proceed correctly even if operations are performed with a quantity outside the limits.

Appendix H Configuring Kernel Parameters

Use the "System V IPC Parameters" table in "Managing Kernel Resources" in the PostgreSQL Documentation for the relationship between configuration parameters and kernel parameters, as well as calculation formulas.
Refer to the "Managing Kernel Resources" in the PostgreSQL Documentation to calculate shared memory usage.

For multiple instances, the kernel parameters should be evaluated for all instances. For example, in the case of the maximum number of shared memory segments for the entire system (SHMMNI), the total number of segments obtained by all instances should be added to the kernel parameters. In the case of the maximum number of semaphores for each process (SEMMSL), the largest of all sizes obtained by all instances should be compared to the current value prior to configuring the settings.

Note

If there is insufficient shared memory due to miscalculation of SHMMAX, a message will be output indicating that the shmget system call failed at "errno=22 (EINVAL)". Review the calculation, and reconfigure.

The relationship between System V IPC parameters and kernel parameters in various operating systems is shown below.

System	V IPC parameter	Kernel parameter action
SHMMAX	kernel.shmmax	If *currentValue* < *calculatedValue*, configure the calculated value
SHMMIN	No compatible parameter	
SHMALL	kernel.shmall	Specify *currentValue* + *calculatedValue*
SHMSEG	No compatible parameter	
SHMMNI	kernel.shmmni	Specify *currentValue* + *calculatedValue*
SEMMNI	Fourth parameter of kernel.sem	Specify *currentValue* + *calculatedValue*
SEMMNS	Second parameter of kernel.sem	Specify *currentValue* + *calculatedValue*
SEMMSL	First parameter of kernel.sem	If *currentValue* < *calculatedValue*, configure the calculated value
SEMMAP	No compatible parameter	
SEMVMX	No compatible parameter	

Remark 1: kernel.shmall specifies the number of pages.
Remark 2: Specify all four parameters for kernel.sem. At this time, the value specified in the third parameter should be the same value as before configuration.

Appendix I Determining the Preferred WebAdmin Configuration

This appendix describes the two different configurations in which WebAdmin can be used and how to select the most suitable configuration.

I.1 WebAdmin Configurations

WebAdmin can be installed in two configurations:

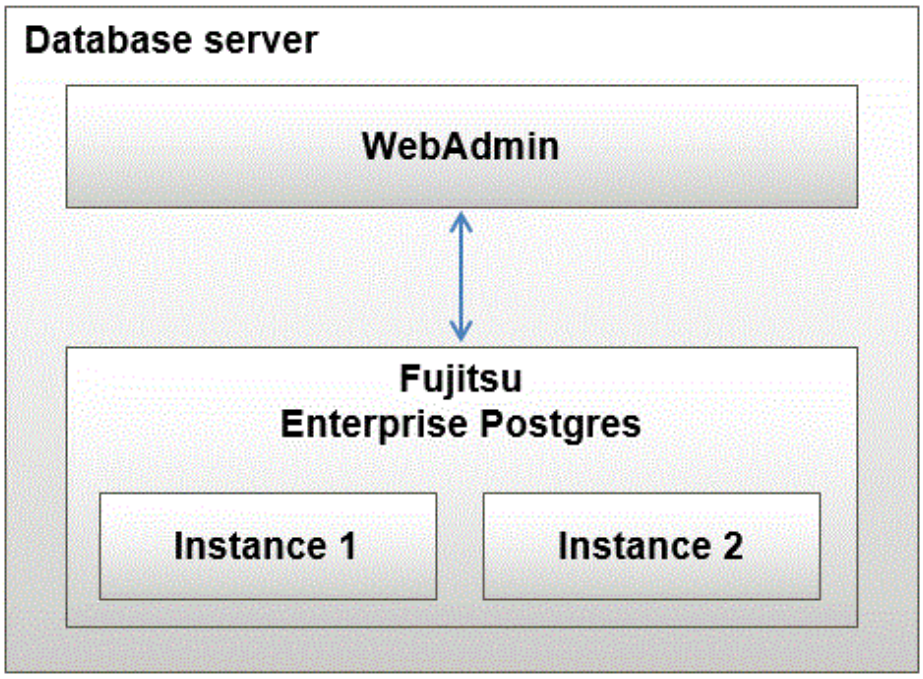
- Single-server
- Multiserver

WebAdmin supports the option to select http or secure https between browsers and servers and between servers. If you have a multi-server environment with a mix of older versions, select http (the default) during setup to continue using the HTTP protocol. This is because older versions do not support HTTPS and all HTTPS settings must be the same on the configuration server.

I.1.1 Single-Server Configuration

A single-server configuration enables you to create and operate instances on a single server. In this configuration, WebAdmin must be installed on the same database server as the Fujitsu Enterprise Postgres Server component.

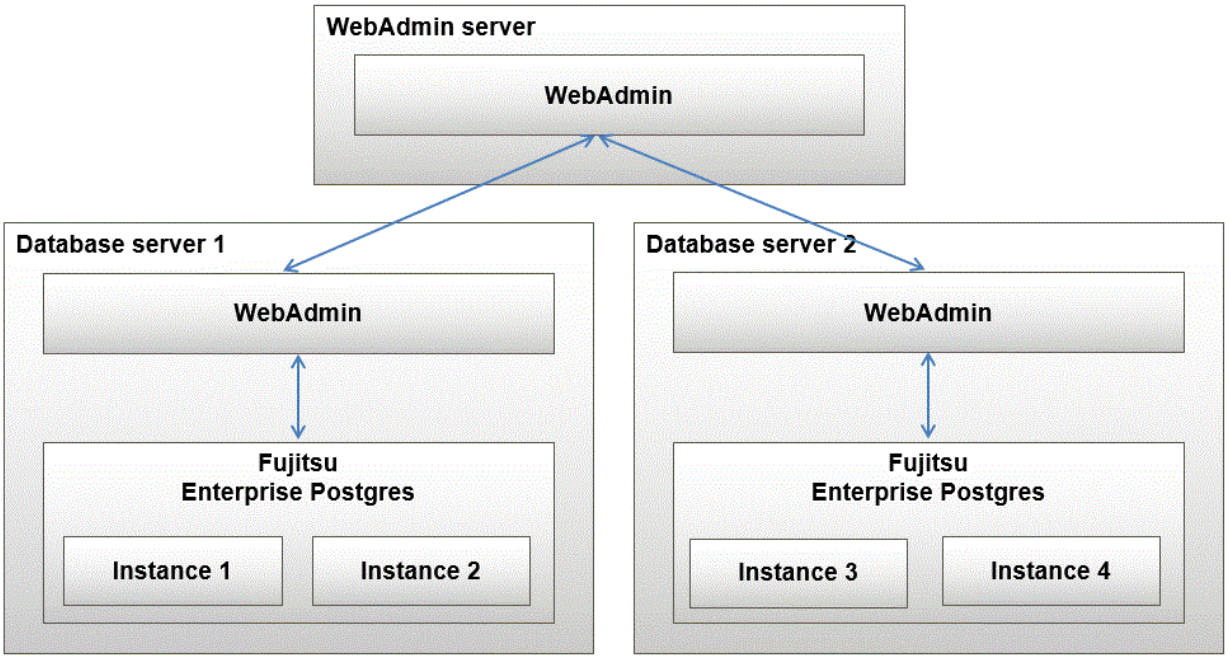
Single-server configuration



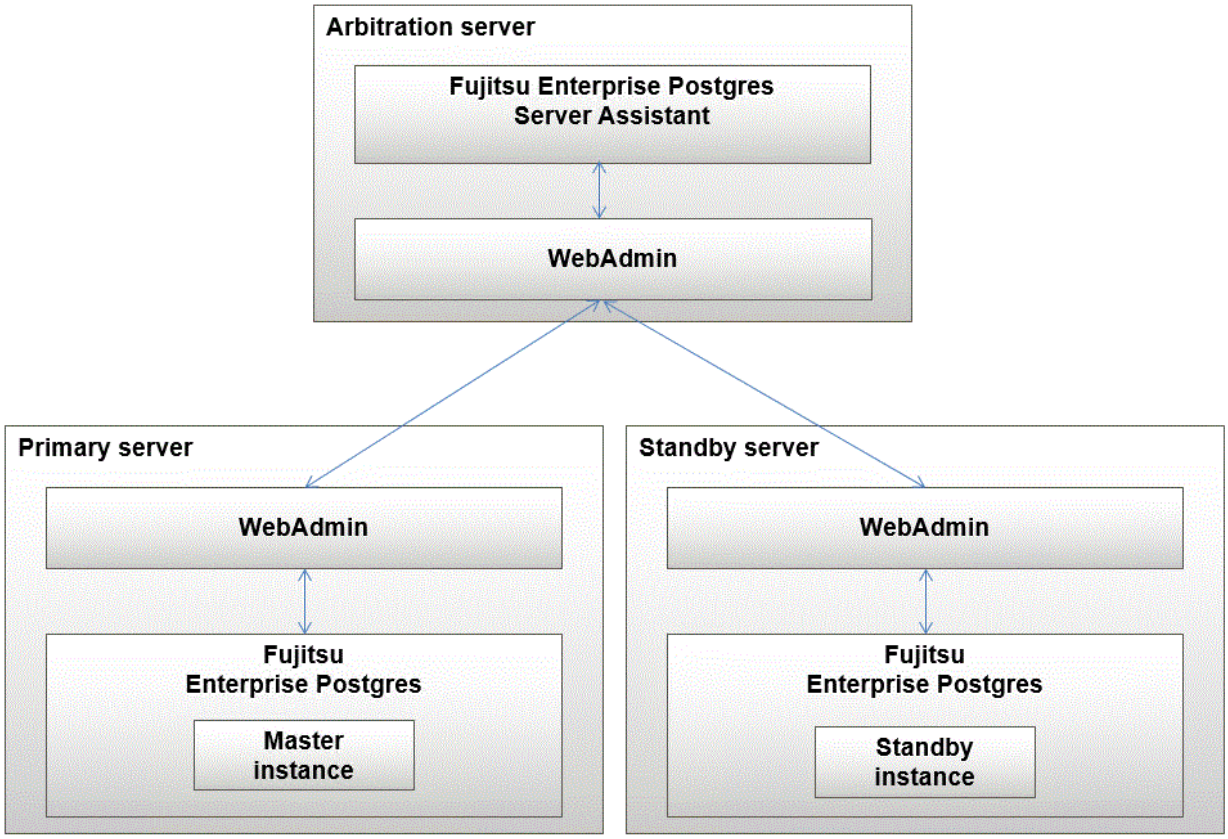
I.1.2 Multiserver Configuration

A multiserver configuration enables you to create and operate instances stored on multiple database servers. As shown in the figure below, WebAdmin can be installed on a dedicated WebAdmin server and used to collectively manage the instances stored on the database servers.

Multiserver configuration



Also, when setting up the arbitration server by WebAdmin during database multiplexing mode, install WebAdmin on the arbitration server.



I.2 Installing WebAdmin in a Single-Server Configuration

To install WebAdmin in a single-server configuration, the Fujitsu Enterprise Postgres Server component and WebAdmin must be installed on the same machine.

Select the following items when installing Fujitsu Enterprise Postgres in a single-server configuration:

- Fujitsu Enterprise Postgres Advanced Edition or Fujitsu Enterprise Postgres Standard Edition
- WebAdmin

I.3 Installing WebAdmin in a Multiserver Configuration

In a multiserver configuration, install WebAdmin on one server, and both WebAdmin and the Fujitsu Enterprise Postgres Server component on any number of database servers.

Select the following items when installing Fujitsu Enterprise Postgres in a multiserver configuration:

- WebAdmin server:
  - WebAdmin
- Database server:
  - Fujitsu Enterprise Postgres Advanced Edition or Fujitsu Enterprise Postgres Standard Edition
  - WebAdmin

Also, when setting up the arbitration server by WebAdmin during database multiplexing mode, select the following when installing Fujitsu Enterprise Postgres.

- Arbitration server
  - Fujitsu Enterprise Postgres Server Assistant
  - WebAdmin

See

Refer to the Installation and Setup Guide for Server Assistant for details on how to install the Server Assistant.

Appendix J System Configuration when using Pgpool-II

Describes the system configuration when using Pgpool-II.

The system configuration when using Pgpool-II is as follows:

Place on database server

System configuration to coexist the database server with Pgpool-II.

Place on application server

System configuration to coexist the application server with Pgpool-II.

Place on dedicated server

System configuration in which Pgpool-II resides on a dedicated server (Pgpool-II Server) that is separate from the database and application servers.

Select the system configuration that best meets your operational requirements.

J.1 Pgpool-II Configuration

In this example, Pgpool-II is deployed on a different Pgpool-II server than the database and application servers.

There are three configurations of Pgpool-II:

- Single-machine configuration
- Two-machine configuration
- Three-machine configuration

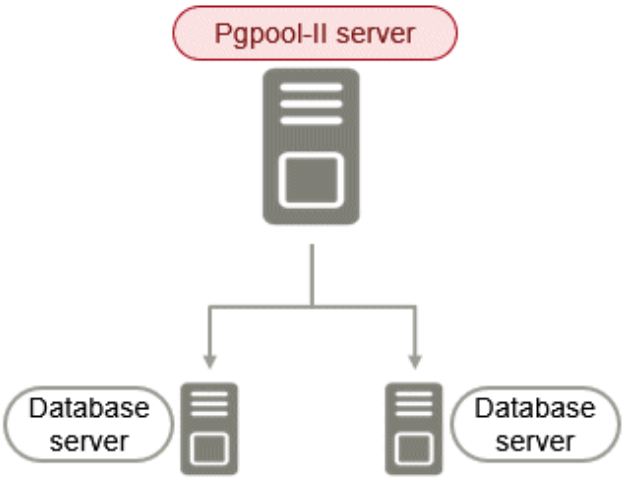
Although the Pgpool-II server can be operated on a single machine, to ensure business continuity, it is recommended to operate the Pgpool-II server using a three-machine configuration in Fujitsu Enterprise Postgres.

If employing a configuration of three or more machines, use an odd number of machines in the configuration.

J.1.1 Single-Machine Configuration

This is the basic configuration when running Pgpool-II.

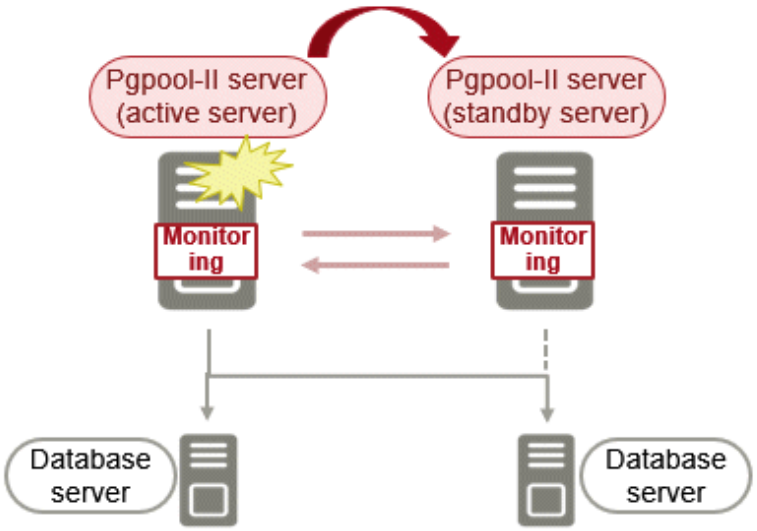
Although the database server has redundancy, if an error occurs on the Pgpool-II server that accesses the database server, the job will stop.



J.1.2 Two-Machine Configuration

When an error occurs on the active server, the Pgpool-II monitoring feature that mutually monitors the status of the Pgpool-II servers enables jobs to continue uninterrupted by switching to the standby server.

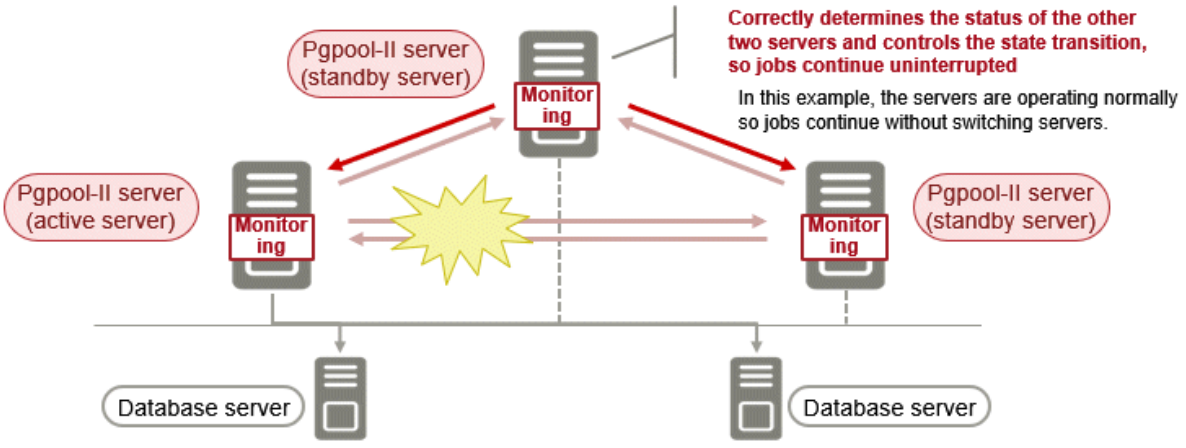
If the network between Pgpool-II servers is disconnected, even if the Pgpool-II servers are running correctly, which may lead to stoppage of jobs.



J.1.3 Three-Machine Configuration

The Pgpool-II monitoring feature enables a Pgpool-II server to monitor the other two Pgpool-II servers.

Even if any of the networks monitoring the Pgpool-II servers are disconnected, the status of servers on a network that is operating normally can be checked correctly, enabling accurate continuation of jobs.



J.2 Installing Pgpool-II

Pgpool-II is bundled with the server program and the client program. To use Pgpool-II, use the server program or the client program to install and set up Pgpool-II.

Depending on where Pgpool-II is installed, select the appropriate DVD for deployment:

Installing on Database Server (coexist)

Install the Pgpool-II program along with the server program from the server program DVD.

Installing on Application Server (coexist)

Install the Pgpool-II program along with the client program from the client program DVD.

Installing on Dedicated server different from the above (Pgpool-II server)

Install the Pgpool-II program along with the client program from the client program DVD.

J.3 Pgpool-II Setup

Describes how to set up Pgpool-II.

J.3.1 Setting Environment Variables

If you use the Pgpool-II command, set the following environment variables:

PATH environment variable

Add "Install Directory/bin".

The following is an example of setting environment variables:

Example

The following is an example of setting environment variables when the installation directory is "/ opt/fsepv < x > pgpool-II".

"< x >"” indicates the product version.

```
$ PATH=/opt/fsepv<x>pgpool-II/bin:$PATH ; export PATH
```

J.3.2 Configuration file

Describes Pgpool-II configuration files.

J.3.2.1 Configuring pgpool.conf

To configure pgpool.conf, see the Pgpool-II documentation.

A sample configuration file is located under the installation directory/etc.

J.3.2.2 Using Configuration Files

The pgpool command makes use of configuration files such as pgpool.conf, pcp.conf, and pool_hba.conf.

To take advantage of these configuration files, specify the path to the files in the pgpool command options.

The following example shows how to configure options for the pgpool command:

Example

```
$ pgpool -f /usr/local/etc/pgpool.conf -F /usr/local/etc/pcp.conf -a / usr/local/etc/pool_hba.conf
```

Appendix K Supported contrib Modules and Extensions Provided by External Projects

Fujitsu Enterprise Postgres supports PostgreSQL contrib modules, and extensions provided by external projects.

Refer to the following for details on the supported contrib modules:

- "Additional Supplied Modules" in the PostgreSQL Documentation
- "Additional Supplied Programs" in the PostgreSQL Documentation

Information

You can also check the list of available extensions using the pg_available_extensions view.

Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for information on supported extensions provided by external projects.

Appendix L Procedure when Modifying the JRE Installation

This appendix describes the procedures to follow when modifying the JRE installation.

The JRE, of which the installation destination is specified in the JAVA_HOME environment variable when installing Fujitsu Enterprise Postgres, is used by features such as WebAdmin and database multiplexing.

Therefore, when updating or reinstalling JRE after installing Fujitsu Enterprise Postgres, the procedures below must be performed.

L.1 When Using WebAdmin

WebAdmin must be set up again.

Follow the procedure below to modify the JRE installation:

1. Stop the Web server feature of WebAdmin

   Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" for details.

2. Remove WebAdmin

   Refer to "B.2 Removing WebAdmin" for details.

3. Modify the JRE installation

4. Set the JAVA_HOME environment variable

   Set the JAVA_HOME environment variable to the installation destination of JRE 8.

   Example

   ```
   # export JAVA_HOME="Jre8InstallDir"
   ```

5. Set up WebAdmin

   Refer to "B.1.1 Setting Up WebAdmin" for details.

6. Start the Web server feature of WebAdmin

   Refer to "B.1.3 Starting the Web Server Feature of WebAdmin" for details.

L.2 When Performing Database Multiplexing

Mirroring Controller must be restarted.

Follow the procedure below to modify the JRE installation:

1. Stop Mirroring Controller

   Refer to the Cluster Operation Guide (Database Multiplexing) for details.

2. Modify the JRE installation

3. Change the installation environment to be used by Mirroring Controller

   Note

   If database multiplexing is performed using WebAdmin, perform the procedure described in this procedure after performing step 4 "Set the JAVA_HOME environment variable" in "L.1 When Using WebAdmin".

   Set the JAVA_HOME environment variable to the installation destination of JRE 8, and use the mc_update_jre_env command to change the installation environment to be used by Mirroring Controller.
   This procedure must be executed by the superuser.

Example

/opt/fsepv<*x*>server64/bin is the installation directory where the server product is installed.

```
$ su -
Password:******
# export JAVA_HOME="Jre8InstallDir"
# /opt/fsepv<x>server64/bin/mc_update_jre_env
```

4. Start Mirroring Controller

   Refer to the Cluster Operation Guide (Database Multiplexing) for details.

Appendix M Access to Key Management System Using Plug-in

M.1 What to do with Plug-ins

Plug-ins are called to verify, encrypt, and decrypt keys.

Key validation, encryption, and decryption requests are required.

M.2 Where the Plug-in is Stored

Plug-ins are stored as executables with the same name as the plug-in name in the directory specified in the tde_kms.plugin.path parameter. It is the responsibility of the database administrator to ensure that only secure plugins are stored in this directory.

M.3 Invoking the Plug-in

The plug-in runs with the same ownership as the user running the FEP server. The plug-in is passed information that should be kept secret. It is the database administrator's responsibility to ensure that the plug-in is trustworthy.

Plug-ins can be invoked at the same time (multiple).

The plug-in must complete the operation in a timely manner and return a response.

M.4 Passing Confidential Information to Plug-ins

Confidential credentials passed to the FEP instance using the FEP keystore open facility (pgx _ open _ keystore function, opening at server startup prompt, opening using obfuscated files) are passed to the plug-in as environment variables.

You can pass arbitrary values as arguments when calling the plug-in, but do not use this feature to pass sensitive information.

The authentication and authorization of access to the key management system depends on the implementation of the plug-in.

M.5 Calling Convention

M.5.1 Key Verification

Arguments

The following arguments are supplied:

	Argument value	Notes
First argument	validate-key	Fixed
second argument	--keyid	Fixed
third argument	*keyid*	Variable; the key ID specified in the pgx_declare_external_master_key function is passed
After the fourth argument	*extraarg*	Arguments specified in the connection information file, if any, are given in the specified order

Environment variable

The following environment variables are supplied:

Name of the environment variable	Value of the environment variable	Notes
TDE_KMS_SECRET	KMS Secret	String entered in the FEP to open the keystore

Return value

The command ends with the following return values:

Return value	Condition
0	If the processing is successful
Other than 0	When processing does not complete normally

delivery of data

Data is delivered to the plug-in in the following way.The plug-in also returns results in the following ways:

Classification	Data Content	Delivery method	Notes
Input	Key ID	Arguments	
Output	Process Status	Plug-in return code	
Output	Message	Plugin standard error output	Expected to be printable

Calling opportunity

Called before starting to use the encryption key.

Processing contents

Verifies the existence of the encryption key identified by the key ID and whether the user is authorized to use the encryption key.

M.5.2 Encryption

Arguments

The following arguments are supplied:

	Argument value	Notes
First argument	encrypt	Fixed
second argument	--keyid	Fixed
third argument	*keyid*	Variable; the key ID specified in the pgx_declare_external_master_key function is passed
After the fourth argument	*extraarg*	The values specified in extra-args in the key management system connection information file, if any, are passed in the specified order

Environment variable

The following environment variables are supplied:

Name of the environment variable	Value of the environment variable	Notes
TDE_KMS_SECRET	KMS Secret	String entered in the FEP to open the keystore

Return value

The command ends with the following return values:

Return value	Condition
0	If the processing is successful
Other than 0	When processing does not complete normally

delivery of data

Data is delivered to the plug-in in the following way.The plug-in also returns results in the following ways:

Classification	Data Content	Delivery method	Notes
Input	Data to be encrypted	Standard input for the plug-in	As Is (not Base 64 encoding, etc)
Input	Key ID	Arguments	
Input	Encryption parameter	-	Not passed by the FEP
Output	Encryption result	Standard output of the plug-in	As Is (not Base 64 encoding, etc)
Output	Status of the action	plug-in return code	
Output	Message	Standard error output of the plug-in	It is expected to be printable

Calling opportunity

Called when encryption with the master encryption key is required.

Processing Contents

Encrypts the given data to be encrypted with the encryption key identified by the specified key ID, and returns the result. The returned encryption result must be decryptable with the same key ID.

Caution

- Implement so that data to be encrypted is not leaked. For example, temporarily storing encrypted data that is plaintext in a file poses a risk of disclosure.
- Fujitsu Enterprise Postgres only guarantees the following during decryption:
  - The same key ID is handed over during decryption as during encryption.
  - The data received as a result of the "encryption" operation is passed as-is when decrypting.
- The maximum amount of data to be encrypted passed from the Fujitsu Enterprise Postgres is 2048 bytes.

M.5.3 Decryption

Arguments

The following arguments are supplied:

	Argument value	Notes
First argument	decrypt	Fixed
second argument	--keyid	Fixed
third argument	*keyid*	Variable; the key ID specified in the pgx_declare_external_master_key function is passed
After the fourth argument	*extraarg*	The values specified in extra-args in the key management system connection information file, if any, are passed in the specified order.

Environment variable

The following environment variables are supplied:

Name of the environment variable	Value of the environment variable	Notes
TDE_KMS_SECRET	KMS Secret	String entered in the FEP to open the keystore

Return value

The command ends with the following return values:

Return value	Condition
0	If the processing is successful
Other than 0	When processing does not complete normally

delivery of data

Data is delivered to the plug-in in the following way.The plug-in also returns results in the following ways:

Classification	Data Content	Delivery method	Notes
Input	Data to be decrypted	Standard input for the plug-in	As Is (not Base 64 encoding, etc.)
Input	Key ID	Arguments	
Input	Encryption parameter	-	Not passed by the FEP
Output	Decoding result	Standard output of the plug-in	As Is (not Base 64 encoding, etc.)
Output	Status of the action	plug-in return code	
Output	Message	Standard error output of the plug-in	It is expected to be printable

Calling opportunity

Called when decryption with the master encryption key is required.

Processing Contents

Decrypts the given encrypted data with the encryption key identified by the given key ID and returns the result.

Caution

- Implement so that the decrypted data is not leaked. For example, there is a risk of leakage if the decryption result data, which is clear text, is temporarily stored in a file.
- If decryption requires the same encryption parameters as encryption, it is the plug-in's responsibility to ensure this. During decryption, the FEP only ensures that the plug-in receives the same key ID and encrypted data as was encrypted.
- The data to be decrypted is passed as is the data returned by the plug-in in response to the encryption request.

Appendix N Deploying Virtual Machines by Cloning

Learn how to install Fujitsu Enterprise Postgres on a virtual machine, clone the virtual machine, and deploy a new virtual machine.

N.1 If you are installing only

There are no guidelines for installing Fujitsu Enterprise Postgres on a virtual machine only and cloning a virtual machine.

N.2 If you are creating an instance

When creating an instance on a virtual machine and cloning the virtual machine, the following precautions must be taken:

- Clone the virtual machine while the instance and WebAdmin are stopped.
- Modify the IP address and host name settings in files such as postgresql.conf and pg_hba.conf if they are different for each replicated machine.
- Use transparent data encryption on the replicated machine. Instances that use transparent data encryption cannot be cloned for use.
- If you cloned the virtual machine that contains the WebAdmin server, reinstall WebAdmin and import the instance that WebAdmin created.

Appendix O Collecting Failure Investigation Data

If the cause of an error that occurs while building the environment or during operations is unclear, data must be collected for initial investigation.

This subsection describes how to collect information for the initial check of the database server.

Use the pgx_fjqssinf command to collect data for initial investigation.

See

- Refer to "pgx_fjqssinf" in the Reference for informations about the pgx_fjqssinf command.
- To collect information about the arbitration server in a database multiplexing, refer to "Collecting Failure Investigation Data" in the Installation and Setup Guide for Server Assistant.

Appendix P Installation and Uninstallation (Compatibility)

This chapter explains how to install and uninstall (interactive mode/silent mode) the Fujitsu Enterprise Postgres.

P.1 Operating Environment

The following describes the system requirements for using Fujitsu Enterprise Postgres.

P.1.1 Packages Required for RHEL8

In addition to the "2.1.1.1 Packages Required for RHEL8", you need:

Package name	Remarks
gdb	Required to run FJQSS.
glibc.i686	Required by installer.
redhat-lsb	Required by installer.
sudo	Required by installer.
sysstat	Required when using FJQSS. Set up the sar command after installation.

P.1.2 Packages Required for RHEL9

In addition to the "2.1.1.2 Packages Required for RHEL9", you need:

Package name	Remarks
gdb	Required to run FJQSS.
glibc.i686	Required by installer.
sudo	Required by installer.
sysstat	Required when using FJQSS. Set up the sar command after installation.

P.1.3 Packages Required for SLES 15

In addition to the "2.1.1.3 Packages Required for SLES 15", you need:

Package name	Remarks
JRE 8	Required by installer. The following JREs are available: - Oracle JRE Use the 64-bit version. - OpenJDK Past the Java TCK (Technology Compatibility Kit)
libstdc++6-32bit	Required for silent installation.
sudo	Required by installer.

P.1.4 Disk Space Required for Installation

The following table shows the disk space requirements for new installation of Fujitsu Enterprise Postgres. If necessary, increase the size of the file system.

Disk space required for installation

Table P.1 RHEL

Directory	Required disk space (Unit: MB)
/etc	1 + 1 (*1)
/var	1 + 2 (*1) +1 (*2)
/opt	300 (*1) +10 (*2)
Installation destination of the server	1120
Installation destination of WebAdmin	880
Installation destination of the client (64-bit)	220
Installation destination of Pgpool-II	40
Installation destination of pgBackRest	40

*1: Required for the installation of the Uninstall (middleware) tool.

*2: Required for the installation of FJQSS.

Table P.2 SLES

Directory	Required disk space (Unit: MB)
/etc	1 + 1 (*1)
/var	1 + 2 (*1)
/opt	10 (*1)
Installation destination of the server	370
Installation destination of WebAdmin	470
Installation destination of the client (64-bit)	210
Installation destination of Pgpool-II	40
Installation destination of pgBackRest	40

*1: Required for the installation of the Uninstall (middleware) tool.

P.2 Installation

This section explains each of the installation procedures of Fujitsu Enterprise Postgres.

Note

If you have antivirus software installed, the server may crash, fail to start, or stop responding, during installation or when starting up after installation. Set scan exception settings for the installation directory and resource allocation directory so that the files in these directories are not scanned for viruses.

Point

In this chapter, "< x >" in the path indicates the version ("SPz" is output when the product level is upgraded).

P.2.1 Pre-installation Tasks

Check the system environment below before installing Fujitsu Enterprise Postgres.

Check the disk space

Ensure that there is sufficient disk space to install Fujitsu Enterprise Postgres.

Refer to "P.1.4 Disk Space Required for Installation" for information on the required disk space.

Reconfigure the disk partition if disk space is insufficient.

Set JAVA_HOME (SLES only)

Ensure that JRE 8 is installed, and export the JAVA_HOME environment variable.

```
#export JAVA_HOME="Jre8InstallDir"
```

Executable Users

Installation and uninstallation is performed by superuser.

On the system, run the following command to become superuser.

```
$ su -
Password:******
```

Check the installed products and determine the installation method

Using the operation shown below, start Uninstall (middleware), and check the installed products.

Example

```
# /opt/FJSVcir/cimanager.sh -c
Loading Uninstaller...

Currently installed products
1. productName
2. productName
3. productName
4. productName
5: productName

Type [number] to select the software you want to uninstall.
[number,q]
=>q

Exiting Uninstaller.
```

If Fujitsu Enterprise Postgres is already installed, determine which installation method to use:

- Reinstallation
- Multi-version installation

Remove applied updates(For Reinstallation)

Use the following procedure to remove applied fixes.

If you install the product without removing the fix, you will apply the same version of the fix with the same fix number, resulting in an error that has already been applied. Remove the fix and then reinstall.

1. Checking the environment variable LD_LIBRARY_PATH

   If the installation directory/lib is set in the environment variable LD_LIBRARY_PATH for the running user, remove the installation directory/lib from LD_LIBRARY_PATH.

2. Display the applied updates

   Execute the following command to display the applied updates:

```
# /opt/FJSVfupde/bin/uam showup
```

3. Remove the updates

   Execute the command below to remove the updates. If an update with the same update number was applied more than once, the updates are removed in order, starting from the highest version number.

```
# /opt/FJSVfupde/bin/uam remove -i update-number
```

Determine the preferred WebAdmin configuration

WebAdmin can be installed in two configurations:

- Single-server
- Multiserver

Refer to "Appendix I Determining the Preferred WebAdmin Configuration" for details.

Determining the Pgpool-II System Configuration

The system configuration when using Pgpool-II is as follows:

- Place on database server
- Place on application server
- Place on dedicated server

Refer to "Appendix J System Configuration when using Pgpool-II".

P.2.2 Installation in Interactive Mode

Describes an interactive installation.

Available Characters

The following characters can be used as input values:

```
Alphanumeric characters, hyphens, commas and forward slashes
```

For a new or multi-version installation

In an interactive installation, default values are set for the installation information, but you can change the following settings:

- Installation directory
- WebAdmin setup information, if WebAdmin is selected

  To change the port number, confirm that it is an unused port number between 1024 and 32767.

For Reinstallation

Back up the following folders that contain WebAdmin instance management information:

webAdminInstallFolder/data/fepwa

Follow the procedure below to perform the backup.

1. Stop the WebAdmin server. Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" for details.
2. Back up the following folder:

   webAdminInstallFolder/data/fepwa

Replace the above folder with the backed up folder when the reinstallation is complete.

Installation Instructions

Install according to the following procedure:

You can set up WebAdmin during installation, but if you want WebAdmin to use the HTTPS protocol and perform client authentication, you must set it up again using the WebAdminSetup command. After the installation is complete, refer to "B.1 Setting Up WebAdmin" to set up WenAdmin again.

1. Stop applications and programs

If the installation method is the following, all applications and programs that use the product must be stopped:

- Reinstallation

Before starting the installation, stop the following:

- Applications that use the product
- Connection Manager
- Instance
- Web server feature of WebAdmin

  Execute the WebAdminStop command to stop the Web server feature of WebAdmin.

  Example

  If WebAdmin is installed in /opt/fsepv<*x*>webadmin:

  ```
  # cd /opt/fsepv<x>webadmin/sbin
  # ./WebAdminStop
  ```

- Mirroring Controller

  Execute the mc_ctl command with the stop mode option specified and stop the Mirroring Controller.

  Example

  ```
  $ mc_ctl stop -M /mcdir/inst1
  ```

- pgBadger
- Pgpool-II
- pgBackRest

2. Mount the DVD drive

Insert the server program DVD into the DVD drive, and run the command given below.

Example

```
# mount -t iso9660 -r -o loop /dev/dvd /media/dvd
```

Here /dev/dvd is the device name for the DVD drive (which may vary depending on your environment), and /media/dvd is the mount point (which may need to be created before calling the command).

If the DVD was mounted automatically using the automatic mount daemon (autofs), "noexec" is set as the mount option, so the installer may fail to start. In this case, use the mount command to remount the DVD correctly, and then run the installation. Note that the mount options of a mounted DVD can be checked by executing the mount command without any arguments.

3. Run the installation

Execute the following command:

Example

```
# cd /media/dvd
# ./install.sh
```

In the example above, /media/dvd is the DVD mount point.

4. Select the product for installation

The list of installation target products is displayed.
Type the number for the product to be installed, or "all", and press Enter.

Information

- The Fujitsu Enterprise Postgres server component and WebAdmin can be installed on the same machine by selecting the "Fujitsu Enterprise Postgres server component" and the "WebAdmin component".
- Pgpool-II to be installed on the same server as the database server, you can install it on the same machine by selecting "Fujitsu Enterprise Postgres Server Component" and "Pgpool-II component". Pgpool-II to be installed on the same server as the application server, or on a dedicated server that is different from the database server and application server, see "Appendix J System Configuration when using Pgpool-II".
- If the selected product has been installed, a window for selecting reinstallation or multi-version installation is displayed for each product. Follow the on-screen instructions to select the installation method.

5. Check the settings

The window for checking the installation information is displayed.
Type "y" and press Enter to start the installation.
To change the settings, type "c", press Enter, and follow the on-screen instructions. This option is not displayed if there is no information that can be modified.

If you have not set up WebAdmin during installation, refer to "Appendix B Setting Up and Removing WebAdmin" for details.

6. Check the changed settings

If the installation information has been modified, the new installation information is displayed.
Type "y" and press Enter to start the installation.
To change the settings again, type "c" and press Enter.

7. Display the installation status

When the installation is started, the installation status is displayed.

Note that even if WebAdmin setup fails, the process will continue.

If the following message is displayed, manually execute WebAdmin setup after installation is completed.
Refer to "B.1 Setting Up WebAdmin" for information on the WebAdmin setup procedure.

```
Starting setup.

Setting up WebAdmin.

ERROR: WebAdmin setup failed.
```

8. Finish the installation

When the installation is complete, a message is displayed showing the status.
If installation was successful, a message like the one shown below is displayed:

```
Installed successfully.
```

If an error occurs during the installation, read the error message and remove the cause of the error, and then reexecute the install.sh command.

P.2.3 Installation in Silent Mode

Installation in silent mode can be performed only when the installation method is one of the following:

- New installation
- Multi-version installation

See

Refer to the Fujitsu Enterprise Postgres product website for information on installation in silent mode, such as the installation parameters and error messages.

Installation Instructions

The installation procedure is described below.

You can set up WebAdmin during installation, but if you want WebAdmin to use the HTTPS protocol and perform client authentication, you must set it up again using the WebAdminSetup command. After the installation is complete, refer to "B.1 Setting Up WebAdmin" to set up WenAdmin again.

1. Mount the DVD drive

Insert the server program DVD into the DVD drive, and run the command given below.

Example

```
# mount -t iso9660 -r -o loop /dev/dvd /media/dvd
```

Here /dev/dvd is the device name for the DVD drive (which may vary depending on your environment), and /media/dvd is the mount point (which may need to be created before calling the command).

If the DVD was mounted automatically using the automatic mount daemon (autofs), "noexec" is set as the mount option, so the installer may fail to start. In this case, use the mount command to remount the DVD correctly, and then run the installation. Note that the mount options of a mounted DVD can be checked by executing the mount command without any arguments.

2. Create an installation parameters CSV file

Consider the features that will be required for system operations, and then create an installation parameters CSV file that uses the following specification format.

```
sectionName, parameterName, value
sectionName, parameterName, value
    :
```

Information

The template for the installation parameters CSV file is "*mountPoint*/sample/sample.csv".

3. Run the installation

Execute the following command:

Example

```
# cd /media/dvd
# ./silent.sh /home/work/inspara.csv
```

In the example above, /media/dvd is the DVD mount point, and /home/work/inspara.csv is the installation parameter CSV.

If the installer ends in an error, a message is output to the log file and return values are returned.

P.3 Uninstallation

This section describes the procedure for uninstalling Fujitsu Enterprise Postgres.

P.3.1 Pre-uninstallation Tasks

Before uninstalling Fujitsu Enterprise Postgres, do the following:

When user files are placed in the installation directory

When you perform uninstallation, all files and directories under the installation directory are deleted. If necessary, back up the files before uninstalling them.

When SLES

On SLES, before uninstallation, ensure that JRE 8 is installed, and export the JAVA_HOME environment variable.

```
#export JAVA_HOME="Jre8InstallDir"
```

When WebAdmin is used for operation

To reinstall Fujitsu Enterprise Postgres after it was uninstalled, and reuse an instance that was already created so that it can be managed from WebAdmin, back up the directory shown below in which the WebAdmin instance management information had been defined before uninstalling Fujitsu Enterprise Postgres, and then restore the backed up directory to its original location once Fujitsu Enterprise Postgres has been reinstalled.

Follow the procedure below to perform the backup.

1. Stop the WebAdmin server.
   Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" for details.
2. Back up the following directory:

   ```
   webAdminInstallDir/data/fepwa
   ```

When using HTTPS or HTTPS client authentication with WebAdmin

All the certificates placed in "keystore" directory will be removed when uninstalling WebAdmin. Back up these certificates and its configuration file in advance if required.

```
webAdminInstallDir/tomcat/keystore
webAdminInstallDir/tomcat/conf/server.xml
```

They are backed up because the keystore contains certificates, and server.xml contains information for the keystorePass, keyAlias, and truststorePass attributes.

P.3.2 Uninstallation in Interactive Mode

Uninstall according to the following procedure:

If an error occurs while the product is being uninstalled, refer to "Uninstall (middleware) Messages" in the Fujitsu Enterprise Postgres product website, and take the required action.

1. Delete the operation information

If the Fujitsu Enterprise Postgres operation information has been registered in the operating system or another middleware product, for example, then it must be deleted. Cases in which deletion is required are as follows:

- For a cluster system using failover operation integrated with PRIMECLUSTER, stop the cluster applications and delete the cluster application resources and Fujitsu Enterprise Postgres resources. Refer to the Cluster Operation Guide (PRIMECLUSTER) and PRIMECLUSTER Installation and Administration Guide for details.
- If you have set automatic start and stop of the instance, execute the following commands to disable the script and cancel registration.

  ```
  systemctl disable nameOfUnitFileThatPerformsAutomaticStartAndStop
  rm /usr/lib/systemd/system/nameOfUnitFileThatPerformsAutomaticStartAndStop
  ```

  Example

  ```
  # systemctl disable fsepsvoi_inst1.service
  # rm /usr/lib/systemd/system/fsepsvoi_inst1.service
  ```

2. Stop applications and programs

Before starting the uninstallation, stop the following:

- Applications that use the product
- Connection Manager
- Instance

  Using WebAdmin

  In the [Instances] tab, select the instance to stop and click .

  Using server commands

  Execute the pg_ctl command in stop mode.

  ```
  $ /opt/fsepv<x>server64/bin/pg_ctl stop -D /database/inst1
  ```

- Web server feature of WebAdmin

  Execute the WebAdminStop command to stop the Web server feature of WebAdmin.

  Example

  If WebAdmin is installed in /opt/fsepv<*x*>webadmin:

  ```
  # cd /opt/fsepv<x>webadmin/sbin
  # ./WebAdminStop
  ```

- Mirroring Controller

  Execute the mc_ctl command with the stop mode option specified and stop the Mirroring Controller.

  Example

  ```
  $ mc_ctl stop -M /mcdir/inst1
  ```

- pgBadger
- Pgpool-II
- pgBackRest

3. Start the Uninstall (middleware)

Execute the following command:

```
# /opt/FJSVcir/cimanager.sh -c
```

4. Select the software

Type the number for the product to be uninstalled, and press Enter.

5. Start the uninstallation

To start the uninstallation, type "y" and press Enter.

To display the list of products again, type "b" and press Enter.

6. Finish the uninstallation

Upon successful completion, the window below is displayed.

The installation directory may remain after uninstallation. If it is not required, delete it.

```
Uninstalling...

productName is being uninstalled now.
    100% ##############################

The following products have been uninstalled successfully:
    productName

Uninstallation of "productName" has completed successfully.

Exiting Uninstaller.
```

P.3.3 Uninstallation in Silent Mode

Uninstall according to the following procedure:

Refer to the Fujitsu Enterprise Postgres product website for information on uninstallation in silent mode, such as the error messages.

1. Delete the operation information

If the Fujitsu Enterprise Postgres operation information has been registered in the operating system or another middleware product, for example, then it must be deleted. Cases in which deletion is required are as follows:

- For a cluster system using failover operation integrated with PRIMECLUSTER, stop the cluster applications and delete the cluster applications resources and Fujitsu Enterprise Postgres resources. Refer to the Cluster Operation Guide (PRIMECLUSTER) and PRIMECLUSTER Installation and Administration Guide for details.
- If you have set automatic start and stop of the instance, execute the following commands to disable the script and cancel registration.

  ```
  systemctl disable nameOfUnitFileThatPerformsAutomaticStartAndStop
  rm /usr/lib/systemd/system/nameOfUnitFileThatPerformsAutomaticStartAndStop
  ```

  Example

  ```
  # systemctl disable fsepsvoi_inst1.service
  # rm /usr/lib/systemd/system/fsepsvoi_inst1.service
  ```

2. Stop applications and programs

Before starting the uninstallation, stop the following:

- Applications that use the product
- Connection Manager

- Instance

  Using WebAdmin

  In the [Instances] tab, select the instance to stop and click .

  Using server commands

  Execute the pg_ctl command with the stop mode option specified.

```
$ /opt/fsepv<x>server64/bin/pg_ctl stop -D /database/inst1
```

- Web server feature of WebAdmin

  Execute the WebAdminStop command to stop the Web server feature of WebAdmin.

  Example

  If WebAdmin is installed in /opt/fsepv<*x*>webadmin:

```
# cd /opt/fsepv<x>webadmin/sbin
# ./WebAdminStop
```

- Mirroring Controller

  Execute the mc_ctl command with the stop mode option specified and stop the Mirroring Controller.

  Example

```
$ mc_ctl stop -M /mcdir/inst1
```

- pgBadger
- Pgpool-II
- pgBackRest

3. Run the uninstallation

Execute the command below.

The installation directory may remain after uninstallation. If it is not required, delete it.

Example

```
# /opt/fsepv<x>server64/setup/suninst.sh
```

In the example above, /opt/fsepv<*x*>server64/setup is the name of the installation directory in which the server product is installed.

```
# /opt/fsepv<x>webadmin/setup/suninst.sh
```

In the example above, /opt/fsepv<*x*>webadmin/setup is the name of the installation directory in which the WebAdmin is installed.

```
# /opt/fsepv<x>pgpool-II/setup/suninst.sh
```

In the example above, /opt/fsepv<*x*>pgpool-II/setup is the name of the installation directory in which the Pgpool-II is installed.

```
# /opt/fsepv<x>pgbackrest/setup/suninst.sh
```

In the example above, /opt/fsepv<x>pgbackrest/setup is the name of the installation directory in which the pgBackRest is installed.

P.4 Collecting Failure Investigation Data

If the cause of an error that occurs while building the environment or during operations is unclear, data must be collected for initial investigation.

This subsection describes how to collect information for the initial check of the database server.

RHEL8 and RHEL9

Use FJQSS (Information Collection Tool) to collect data for initial investigation. However, if you are asked by a Fujitsu technical support representative to collect investigation information, use the pgx_fjqssinf command to collect the information.

SLES 15

Use the pgx_fjqssinf command to collect data for initial investigation.

See

- Refer to the FJQSS manual for information on how to use FJQSS.
- Refer to "pgx_fjqssinf" in the Reference for informations about the pgx_fjqssinf command.
- To collect information about the arbitration server in a database multiplexing, refer to "Collecting Failure Investigation Data" in the Installation and Setup Guide for Server Assistant.

Setting environment variables

When using FJQSS to collect data for initial investigation, you must set the following environment variables:

- Environment variables required for using Fujitsu Enterprise Postgres

  Refer to "Configure the environment variables" in "4.3.2.2 Creating an Instance".

- PGDATA

  Set the data storage destination.

- PGDATABASE

  Set the database name from which you want to collect data for initial investigation.

- PGPORT

  Set the instance port number. This does not need to be set if the default port number (27500) has not been changed.

- PGUSER

  Set the database superuser.
  Set the database superuser so that client authentication is possible.
  FJQSS establishes a TCP/IP connection with the template1 database and collects data from the database.

- FSEP_HOME

  Set the Fujitsu Enterprise Postgres installation directory.

If you are using database multiplexing, you must set the following environment variables:

- MCCONTROLDIR

  Specify the Mirroring Controller management directory.
  For details about the Mirroring Controller management directory, refer to "Mirroring Controller Resources" in the Cluster Operation Guide (Database Multiplexing).

Installation and Setup Guide for Server

Windows

B1WS-1496-02ENZ0(00)

March-2026

Preface

Purpose of this document

The Fujitsu Enterprise Postgres database system extends the PostgreSQL features and runs on the Windows platform.

This document describes how to install and set up "Fujitsu Enterprise Postgres".

Intended readers

This document is intended for those who install and operate Fujitsu Enterprise Postgres.

Readers of this document are assumed to have general knowledge of:

- PostgreSQL
- SQL
- Windows

Structure of this document

This document is structured as follows:

Chapter 1 Overview of Installation

Describes the installation types and procedures

Chapter 2 Operating Environment

Describes the operating environment required to use Fujitsu Enterprise Postgres

Chapter 3 Installation

Describes how to perform a new installation of Fujitsu Enterprise Postgres

Chapter 4 Setup

Describes the setup to be performed after installation

Chapter 5 Uninstallation

Describes how to uninstall Fujitsu Enterprise Postgres

Appendix A Recommended WebAdmin Environments

Describes the recommended WebAdmin environment

Appendix B Setting Up and Removing WebAdmin

Describes how to set up and remove WebAdmin

Appendix C WebAdmin Disallow User Inputs Containing Hazardous Characters

Describes characters that are not allowed in WebAdmin.

Appendix D Configuring Parameters

Describes Fujitsu Enterprise Postgres parameters

Appendix E Estimating Database Disk Space Requirements

Describes how to estimate database disk space requirements

Appendix F Estimating Memory Requirements

Describes the formulas for estimating memory requirements

Appendix G Quantitative Limits

Describes the quantity range

Appendix H Determining the Preferred WebAdmin Configuration

Describes the two different configurations in which WebAdmin can be used and how to select the most suitable configuration

Appendix I Supported contrib Modules and Extensions Provided by External Projects

Lists the PostgreSQL contrib modules and the extensions provided by external projects supported by Fujitsu Enterprise Postgres.

Appendix J Deploying Virtual Machines by Cloning

Describes installing Fujitsu Enterprise Postgres on a virtual machine, cloning the virtual machine, and deploying a new virtual machine.

Appendix K Collecting Failure Investigation Data

Explains how to collect data for initial investigation.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Chapter 1 Overview of Installation

This chapter provides an overview of Fujitsu Enterprise Postgres installation.

1.1 Features that can be Installed

Each Fujitsu Enterprise Postgres feature is installed on the machine that was used to build the database environment.

The following features can be installed.

- Server feature
- Client feature
- WebAdmin

Chapter 2 Operating Environment

This chapter describes the operating environment required to use Fujitsu Enterprise Postgres.

See

Refer to "Operating Environment" in the Installation and Setup Guide for Client when installing the Fujitsu Enterprise Postgres client feature at the same time.

2.1 Required Operating System

One of the operating systems shown below is required in order to use Fujitsu Enterprise Postgres.

Table 2.1 Operating systems

Operating system name
- Microsoft(R) Windows Server(R) 2016 Datacenter - Microsoft(R) Windows Server(R) 2016 Standard - Microsoft(R) Windows Server(R) 2016 Essentials
- Microsoft(R) Windows Server(R) 2019 Datacenter - Microsoft(R) Windows Server(R) 2019 Standard - Microsoft(R) Windows Server(R) 2019 Essentials
- Microsoft(R) Windows Server(R) 2022 Datacenter - Microsoft(R) Windows Server(R) 2022 Standard - Microsoft(R) Windows Server(R) 2022 Essentials
- Microsoft(R) Windows Server(R) 2025 Datacenter - Microsoft(R) Windows Server(R) 2025 Standard - Microsoft(R) Windows Server(R) 2025 Essentials

The following components of Windows Server(R) 2016, Windows Server(R) 2019, Windows Server(R) 2022 and Windows Server(R) 2025 are not supported:

- Server Core
- Nano Server
- Windows Server Container

2.2 Related Software

The following table lists the software required to use Fujitsu Enterprise Postgres.

Table 2.2 Related software

No.	Software name	Version	Product name of Fujitsu Enterprise Postgres		Remarks
			AE	SE	
1	Perl	5.42.x	Y	Y	Required when using PL/Perl.
2	Python	3.12.x	Y	Y	Required when using PL/Python based on Python 3.
3	Tcl	9.0.x	Y	Y	Required when using PL/Tcl.

No.	Software name	Version	Product name of Fujitsu Enterprise Postgres		Remarks
			AE	SE	
4	Oracle Call Interface (OCI) libraries	19c or later	Y	Y	Required when using oracle_fdw.
5	Amazon Web Services Command Line Interface (AWS CLI)	2.x or later	Y	Y	Required for monitoring database operations using Amazon CloudWatch.

Y: Can be used

Note

The following programs are installed during installation of Fujitsu Enterprise Postgres. Do not uninstall it because it is required for Fujitsu Enterprise Postgres to work.

- Microsoft Visual C++ 2015-2022 Redistributable version 14.44.35211.0

The following table lists client that can be connected to the Fujitsu Enterprise Postgres server feature.

Table 2.3 Connectable client

OS	Product name
Windows Linux	Fujitsu Enterprise Postgres Client 18 or later

The following table lists server assistant that can be connected to the Fujitsu Enterprise Postgres server feature.

Table 2.4 Connectable server assistant

OS	Product name
Windows Linux	Fujitsu Enterprise Postgres Server Assistant 18 or later

2.3 Excluded Software

This section describes excluded software.

Fujitsu Enterprise Postgres

Fujitsu Enterprise Postgres cannot be installed if all the following conditions are met:

- The product version (indicated by "*x*" in "*x* SP*z*") of the product to be installed is the same as that of the installed product
- The editions are different

Example

In the following cases, Fujitsu Enterprise Postgres cannot be installed as an exclusive product:

- The installed product is Fujitsu Enterprise Postgres Standard Edition (64bit) 18
- The product to be installed is Fujitsu Enterprise Postgres Advanced Edition (64bit) 18 SP1

Other products

There are no exclusive products.

2.4 Required Patches

There are no required patches.

2.5 Hardware Environment

The following hardware is required to use Fujitsu Enterprise Postgres.

Memory

256 MB or more is recommended (at least 128 MB is required).

2.6 Disk Space Required for Installation

The following table shows the disk space requirements for new installation of Fujitsu Enterprise Postgres. If necessary, increase the size of the file system.

Table 2.5 Disk space required for installation

Directory	Required disk space (Unit: MB)
Windows system drive	7 + 310 (*1) + 40 (*2)
Installation destination of the Server	990
Installation destination of the WebAdmin	810
Installation destination of the Client (32bit)	370
Installation destination of the Client (64 bit)	2100

*1: Required for the installation of the Uninstall (middleware) tool.

*2: Required for the installation of FJQSS.

2.7 Supported System Environment

This section describes the supported system environment.

2.7.1 TCP/IP Protocol

Fujitsu Enterprise Postgres supports version 4 and 6 (IPv4 and IPv6) of TCP/IP protocols.

Do not use link-local addresses if TCP/IP protocol version 6 addresses are used.

2.7.2 File System

You can install Fujitsu Enterprise Postgres only if the system folder is an NTFS volume.

2.8 PostgreSQL Version Used for Fujitsu Enterprise Postgres

Fujitsu Enterprise Postgres is based on PostgreSQL 18.

2.9 Notes on Using Streaming Replication

To use streaming replication, build the primary server and all standby servers using the same Fujitsu Enterprise Postgres version. The same version refers to *x* SP*z* x, which is represented as the product version.

Streaming replication cannot be used in combination with Open Source PostgreSQL.

Chapter 3 Installation

This chapter describes the procedures for the installation of Fujitsu Enterprise Postgres.

Note

If you have antivirus software installed, the server may crash, fail to start, or stop responding, during installation or when starting up after installation. Set scan exception settings for the installation directory and resource allocation directory so that the files in these directories are not scanned for viruses.

3.1 Pre-installation Tasks

Check the system environment below before installing Fujitsu Enterprise Postgres.

Check the disk space

Ensure that there is sufficient disk space to install Fujitsu Enterprise Postgres.

Refer to "2.6 Disk Space Required for Installation" for information on the required disk space.

Check the installed products and determine the installation method

In [Start] menu, click [All apps], then [Fujitsu], and then [Uninstall (middleware)]. In the displayed window, check the installed products.

If Fujitsu Enterprise Postgres is already installed, determine which installation method to use:

- Reinstallation
- Multi-version installation

The shortcuts displayed on the [Start] menu might be arranged differently depending on the operating system.

Remove applied updates(For Reinstallation)

Use the following procedure to remove applied fixes.

If you install the product without removing the fix, you will apply the same version of the fix with the same fix number, resulting in an error that has already been applied. Remove the fix and then reinstall.

1. Display the applied updates

   Execute the following command to display the applied updates:

```
C:\>uam showup
```

2. Remove the updates

   Execute the command below to remove the updates. If an update with the same update number was applied more than once, the updates are removed in order, starting from the highest version number.

```
C:\>uam remove -i update-number
```

Confirm service

The Windows Installer service must be running.

Determine the preferred WebAdmin configuration

WebAdmin can be installed in two configurations:

- Single-server
- Multiserver

See

Refer to "Appendix H Determining the Preferred WebAdmin Configuration" for details.

3.2 Pre-installation Considerations

The following describes the precautions before installation.

- The remote desktop service is installed in application server mode, it is necessary to switch to install mode by executing the command shown below before installation. Also, after the installation is completed, execute the command shown below to switch back to execute mode.

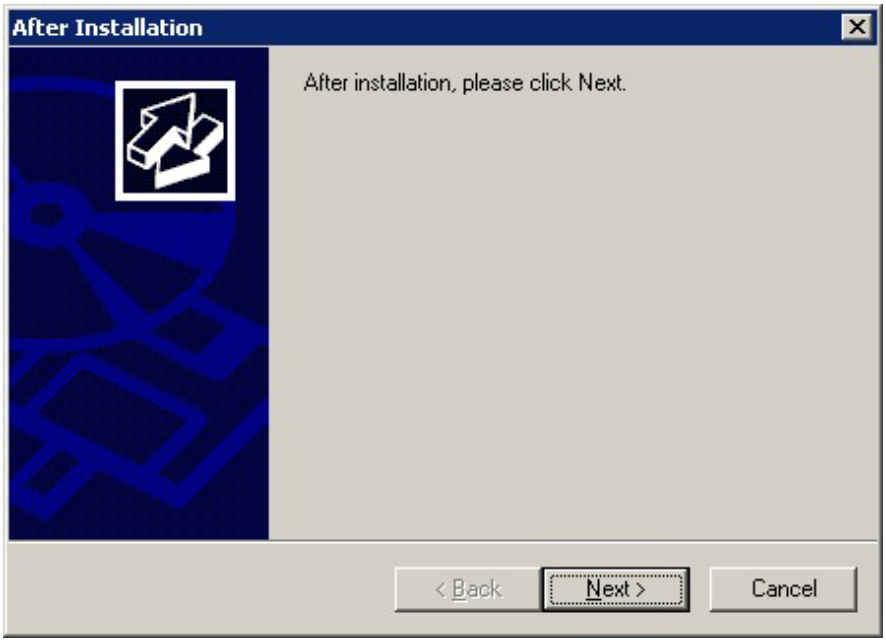
  [Before the installation]

```
CHANGE USER /INSTALL
```

  [After the installation]

```
CHANGE USER /EXECUTE
```

- The following window may be displayed when executing the installation program:



If this window is displayed, perform the following operations:

1. Perform the installation steps until the [Finish Install] window is displayed.
2. At the window shown above, click [Next].

3. The window shown below is displayed. Click [Finish].

Information

- If a [User Account Control] dialog box is displayed at the start of the installation, click [Yes] to continue processing:

  If [No] is clicked, permission to continue is denied and an [Error] dialog box will be displayed.
  To continue the installation, click [Retry] at the [Error] dialog box. To end the installation, click [Cancel].

- If installation is suspended or processing terminates abnormally, the [Program Compatibility Assistant] dialog box may be displayed. Click [This program installed correctly] and continue operation.

3.3 Installation in Interactive Mode

Describes an interactive installation.

For a new or multi-version installation

For installation in interactive mode, default values are set for the installation information. The following settings can be changed for a new installation or a multi-version installation:

- Installation destination
  - It is necessary to specify a local disk as the installation destination of Fujitsu Enterprise Postgres.
  - If using WebAdmin, do not use fullwidth characters or halfwidth katakana characters in [Installation destination folder].
- WebAdmin setup information, if WebAdmin is selected
  To change the port number, confirm that it is an unused port number between 1024 and 49151. Additionally, take note of the Web server port number for the Windows Firewall settings.

For Reinstallation

Back up the following folders that contain WebAdmin instance management information:

webAdminInstallFolder\data\fepwa

Follow the procedure below to perform the backup.

1. Stop the WebAdmin server. Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" for details.

2. Back up the following folder:

   webAdminInstallFolder\data\fepwa

Replace the above folder with the backed up folder when the reinstallation is complete.

Installation Instructions

The installation procedure is described below.

The installation must be performed by a user with administrator privileges (a user ID that belongs to the Administrators group).

You can set up WebAdmin during installation, but if you want WebAdmin to use the HTTPS protocol and perform client authentication, you must set it up again after installation is complete. Refer to "B.1 Setting Up WebAdmin" and perform WenAdmin setup again.

1. Stop applications and programs

When reinstalling the product, all applications and programs that use the product must be stopped.

Before starting the installation, stop the following:

- Applications that use the product
- Connection Manager
- Instance
- Web server feature of WebAdmin

  If you are using WebAdmin, stop WebAdmin.

  Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" for details.
- Mirroring Controller

  Execute the mc_ctl command with the stop mode option specified and stop the Mirroring Controller.

  Example

  ```
  > mc_ctl stop -M D:\mcdir\inst1
  ```
- pgAdmin

2. Inserting the DVD

Insert the Fujitsu Enterprise Postgres DVD into the drive.

3. Run the installation

The installation menu will be displayed. Click [Installation].

If the Autorun feature of Windows is disabled, or a remote desktop service (terminal service) is used, the installation program is not automatically started. Execute the following file using [Run] or Windows Explorer.

```
Z:\autorun.exe
```

Z: The drive into which the DVD is inserted.

4. Select the products to install

The [Installation product] window will be displayed.

Select the products to install, and then click [Next].

If a selected product can only be reinstalled, refer to "6. Check the settings".

Information

- To develop or execute a 32-bit application in a 64-bit environment, Fujitsu Enterprise Postgres Client (32bit) is required. When installing the Fujitsu Enterprise Postgres Client (32 bit), do not specify a destination folder under the environment ProgramFiles variable.
- The Fujitsu Enterprise Postgres server component and WebAdmin can be installed on the same machine by selecting the "Fujitsu Enterprise Postgres server component" and the "WebAdmin component".
- If the selected product has been installed, the [Select installation method] window is displayed for each product. To perform a multi-version installation, click [Next].

5. Checking the installation content

The [Confirm installation] window will be displayed.

Click [Next] to start the installation.

To modify the settings, select [Modify], and then click [Next]. Follow the on-screen instructions.

If using WebAdmin for operation, make a note of the Web server port number displayed in the settings, for use in the Windows firewall settings.

If you have not set up WebAdmin during installation, refer to "Appendix B Setting Up and Removing WebAdmin for details.

6. Check the settings

The [Confirm installation] window is displayed for reinstallation, or if the installation information is modified.

Click [Install] to start the installation.

To change any settings, click [Back].

7. Completing installation

The [Installation complete] window is displayed.

Click [Finish].

In [Start] menu, click [All apps], then [Fujitsu], and then [Uninstall (middleware)]. If the installed product names have been added under [Software Name], installation is complete.

The shortcuts displayed on the [Start] menu might be arranged differently depending on the operating system.

3.4 Installation in Silent Mode

Installation in silent mode can be performed only when the installation method is one of the following:

- New installation
- Multi-version installation

See

Refer to the Fujitsu Enterprise Postgres product website for information on installation in silent mode, such as the installation parameters and error messages.

Installation Instructions

The installation procedure is described below.

The installation must be performed by a user with administrator privileges (a user ID that belongs to the Administrators group).

You can set up WebAdmin during installation, but if you want WebAdmin to use the HTTPS protocol and perform client authentication, you must set it up again after installation is complete. Refer to "B.1 Setting Up WebAdmin" and perform WenAdmin setup again.

1. Insert the DVD

Insert the "server program" DVD in the DVD drive.

The [Install Menu] window will be displayed automatically. Click [Finish].

2. Create an installation parameters CSV file

Consider the features that will be required for system operations, and then create an installation parameters CSV file that uses the following specification format.

When installing the Fujitsu Enterprise Postgres Client (32 bit), do not specify a destination folder under the environment ProgramFiles variable.

If using WebAdmin for operation, make a note of the Web server port number displayed in the settings (the port number defined in WebPortNumber1), for use in the Windows firewall settings.

```
sectionName, parameterName, value
sectionName, parameterName, value
    :
```

Information

The template for the installation parameters CSV file is "*Z*:\sample\sample.csv" (*Z* is the drive into which the DVD is insered).

3. Start the command prompt

In Windows, right-click [Command Prompt] and then select [Run as administrator].

4. Run the installation

Execute the command below.

```
Z:\>silent.bat c:\temp\inspara.csv
```

Z: The drive into which the DVD is inserted.

Also in the example above, c:\temp\inspara.csv is the installation parameter CSV file name.

If the installer ends in an error, a message is output to the log file and return values are returned.

Chapter 4 Setup

This chapter describes the setup procedures to be performed after installation completes.

4.1 Operating Method Types and Selection

This section describes how to operate Fujitsu Enterprise Postgres.

There are two methods of managing Fujitsu Enterprise Postgres operations.

- Simple operation management using a WebAdmin (web-based GUI tool)

  Suitable when using frequently used basic settings and operations for operation management.

  This method allows you to perform simple daily tasks such as starting the system before beginning business, and stopping the system when business is over, using an intuitive operation.

- Advanced operation management using server commands

  Operations that use Fujitsu Enterprise Postgres or PostgreSQL server commands or server applications.

  When operating in a system that is automated by operation management middleware (Systemwalker Centric Manager, for example), this method allows you to use more detailed settings and operations and perform higher level operation management.

  Refer to Reference and the PostgreSQL Documentation for information on server commands and server applications.

Select one that suits your purposes.

How WebAdmin and Server Commands Work

Here are the differences between using WebAdmin and server commands:

Operation		Operation with the WebAdmin	Operation with commands
Setup	Creating an instance	The server machine capacity, and the optimum parameter for operations using WebAdmin, are set automatically. Instances that you create and manage in WebAdmin are registered in the WebAdmin administrative information, so you must delete the instance from WebAdmin.	The configuration file is edited directly using the initdb command.
	Creating a standby instance	WebAdmin performs a base backup of the source instance and creates a standby instance.	A standby instance is created using the pg_basebackup command.
	Changing the configuration files	You can change the values in the configuration file on the WebAdmin screen.	The configuration file is edited directly.
Starting and stopping an instance		You can start and stop with one click from the WebAdmin screen.	The net command or sc command of the operating system is used.
Creating a database		This is defined using pgAdmin of the GUI tool, or using the psql command or the application after specifying the DDL statement.	
Backing up the database		WebAdmin, or the pgx_dmpall command, is used. It cannot be used interchangeably with operation using server commands or server applications. If	It is recommended that the pgx_dmpall command be used. Recovery to the latest database can be performed.

Operation		Operation with the WebAdmin	Operation with commands
		used, WebAdmin will not be able to properly manage the instance. If you are backing up by using the copy command with the pgx_dmpall command, select the command operation method.	
Database recovery		You can recover using a backup taken with WebAdmin or the pgx_dmpall command.	To use the backup that was performed using the pgx_dmpall command, the pgx_rcvall command is used.
Monitoring	Database errors	The status in the WebAdmin window can be checked. (*1)	The messages that are output to the database server log are monitored (*1)
	Disk space	The status in the WebAdmin window can be checked. A warning will be displayed if the free space falls below 20%. (*1)	This is monitored using the fsutil command (check free space), and the dir command (check used space), of the operating system, for example. (*1)
	Connection status	This can be checked using pgAdmin of the GUI tool, or referencing pg_stat_activity of the standard statistics view from psql or the application.	

*1: This can be used together with system log monitoring using operations management middleware (Systemwalker Centric Manager, for example).

See

Refer to "Periodic Operations" and "Actions when an Error Occurs" in the Operation Guide for information on monitoring and database recovery.

4.2 Preparations for Setup

This section describes the preparation required before setting up Fujitsu Enterprise Postgres.

4.2.1 Creating an Instance Administrator

Decide the OS user account that will become the instance administrator. Use either a new user, or a user that already exists.To create a user in Windows, select [Administrative Tools], [Computer Management], and then create the user in [Local Users and Groups]. Refer to "Help and Support" for details.

The following characters can be used for user names:

- - (hyphen)
- _ (underscore)
- Space
- A-Z, a-z, 0-9 (alphanumeric)

When using WebAdmin

- The instance administrator must have a local OS user account.
- After creating the user account of the instance administrator, log in to the operating system. A profile directory is created for the user when logging in to the operating system for the first time. This directory will be used by WebAdmin.

- If changing the password for the user account of the instance administrator, always ensure to stop the instance and log out of WebAdmin before making the change. If you mistakenly change the password while logged in to WebAdmin or while the instance is running, log out from WebAdmin, and then log in again, and stop and start the instance.
- If you change the password for the OS user account, use ALTER ROLE WITH PASSWORD to change the instance administrator password as well.

4.2.1.1 Security policy settings

If using commands for operation, security settings that allow logon as a service are required for the operating system user account of the instance administrator in order to start and stop an instance using a Windows service.

Information

If using WebAdmin for operation, these settings are not required as WebAdmin performs the settings automatically for the user ID (operating system user account) that logged in to the database server.

The following explains how to perform the security settings to allow logon as a service:

1. Displaying the Local Security Policy window

   In Windows, select [Administrative Tools], and then click [Local Security Policy].

2. Setting up security

   1. In the [Local Security Policy] window, select [Security Settings], select [Local Policies], and then click [User Rights Assignment].
   2. Under [Policy] in the [User Rights Assignment] window, double-click [Log on as a service].
   3. In the [Log on as a service Properties] window, set the following:
      a. Select the [Local Security Setting] tab.
      b. On the [Local Security Setting] tab, click [Add User or Group].
      c. In the [Select Users or Groups] window, enter the operating system user account of the instance administrator in [Enter the object names to select].
      d. Click [OK].
   4. In the [Log on as a service Properties] window, click [OK].

4.2.2 Preparing Directories for Resource Deployment

Prepare the directories required when creating instances.

If anti-virus software is used, set scan exception settings for folders so that none of the server resources that comprise Fujitsu Enterprise Postgres are scanned for viruses. Alternatively, if the server resources that comprise Fujitsu Enterprise Postgres are to be scanned for viruses, stop the instance and perform the scan when tasks that use Fujitsu Enterprise Postgres are not operating.

Considerations when deploying resources

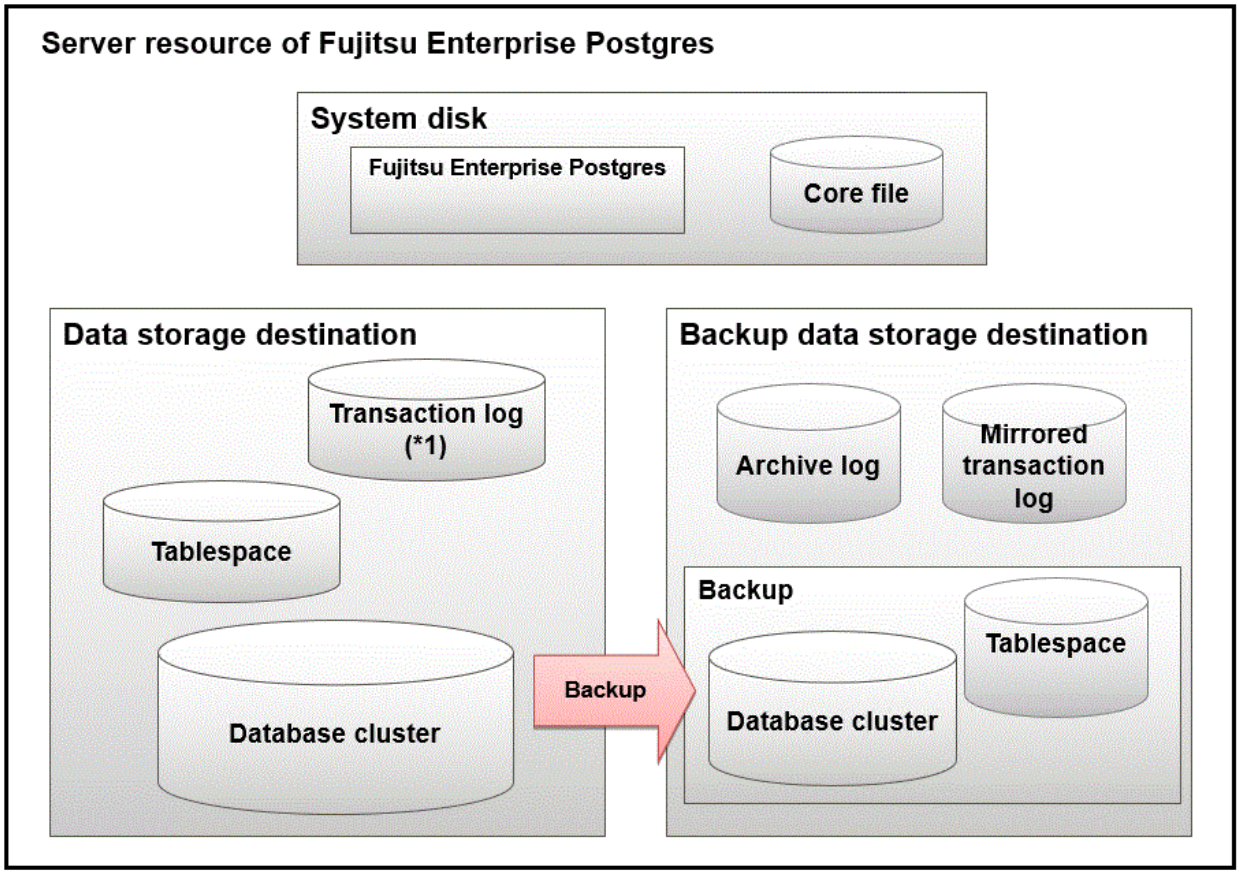
The disk configuration on the resource deployment destination is important, because it affects not only recovery following disk corruption, but normal operation as well. The points for determining the disk configuration are as follows:

1. If the backup data storage destination and the data storage destination are both lost, it will not be possible to recover the data, so deploy them to separate disks.
2. To shorten the recovery time following a single disk fault, deploy the system disk and data storage destination to separate disks.
3. The backup data storage destination requires at least double the capacity of the data storage destination, so deploy it to the disk with the most space available.
4. When large amounts of data are updated, the write-to load for the data storage destination, transaction log storage destination, and backup data storage destination (mirrored transaction log) will also be great. For this reason, deploy them to separate disks, out of consideration for performance.

Information

If you choose to place the archive log and mirrored transaction log (mirrored WAL) on a disk that is separate from the backup data storage destination, keep the following points in mind:

- Recovery requires not only the backup data, but also the archive log and mirrored transaction log (mirrored WAL). Therefore, make sure that these items can be stored together.
- Note that the permissions and mount state are the same at the time of the recovery as they were at the time of the backup. Make the archive log and mirrored transaction log (mirrored WAL) available before starting the recovery.



*1: To distribute the I/O load, place the transaction log on a different disk from the data storage destination.

Resource	Role
Database cluster	The area where the database is stored. It is a collection of databases managed by an instance.
Tablespace	Stores table files and index files in a separate area from the database cluster. Specify a space other than that under the database cluster.
Transaction log	Stores log information in preparation for a crash recovery or rollback. This is the same as the WAL (Write Ahead Log).
Archive log	Stores log information for recovery
Mirrored transaction log (mirrored WAL)	Enables a database cluster to be restored to the state immediately before an error even if both the database cluster and transaction log fail when

Resource	Role
	performing backup/recovery operations using the pgx_dmpall command or WebAdmin.
Corefile	Fujitsu Enterprise Postgres process corefile output when an error occurs with a Fujitsu Enterprise Postgres process.

Examples of disk deployment

The following are examples of disk deployment:

Number of disks	Disk	Deployment
3	System disk	Fujitsu Enterprise Postgres program
		Corefile
	Connected physical disk	Data storage destination, transaction log storage destination
	Connected physical disk	Backup data storage destination
2	System disk	Fujitsu Enterprise Postgres program
		Corefile
		Data storage destination, transaction log storage destination
	Connected physical disk	Backup data storage destination

Preparing directories

You cannot use directories mounted over the network.
Examples include NFS (Network File System) and CIFS (Common Internet File System).
Do not use these directories unless you are creating tablespaces on a storage device on your network.

The directories to be prepared depend on the way that you create the instances.

Using WebAdmin

For WebAdmin, WebAdmin automatically creates the directory during instance creation.

Directory	Description
Data storage destination	Specify in the GUI.
Backup data storage destination	Specify in the GUI. Place them on a disk different from the data storage destination.
Transaction log storage destination	Specify in the GUI. The default is to create in a directory in the data storage destination. When it is necessary to distribute the I/O load for the database data and the transaction log, consider putting the transaction log storage destination on a different disk from the data storage destination
Corefile output destination	WebAdmin generates it automatically, so no specification is required. For more information about directories, refer to "Directory for Core File Output when Using WebAdmin".

Directory for Core File Output when Using WebAdmin

The corefile path is as follows:

```
userProfileFolder\localSettingsFolder\Fujitsu\fsep_productVersion_WA_architecture
\instanceNamePortNumber\core
```

product version

Contains the version of the Server Product Type that WebAdmin specifies when creating an instance.

If you manage multiple versions, the fsep_version directory is created for as many versions as you manage.

PortNumber

Contains the port number of the database server specified when the instance was created.

Example:

```
C:\Users\naomi\AppData\Local\Fujitsu\fsep_180_WA_64\myinst27599\core
```

To change the output destination, specify in the core_directory parameter and core_contents parameter in postgresql.conf. Refer to "Parameters" in the Operation Guide for information on the settings for these parameters.

Using the initdb Command

For the inidb command, prepare the directory in advance.

The directories to prepare in advance are:

Directory to be prepared	Required / Optional
Data storage destination	Required
Backup data storage destination	Optional
Transaction log storage destination	Optional
Corefile output destination	Optional

Confirm and configure directory access permissions

If the instance administrator user has "Administrator" permissions (user ID belonging to the Administrators group), it is necessary to configure the settings so that each directory inherits the file and directory access permissions for the instance administrator user.

Therefore, ensure that the setting to inherit permissions has been configured.

The following is an explanation on how to confirm and configure the settings.

How to confirm access permissions

Perform the following operations in Windows Explorer on the directories to be prepared in advance:

1. Right-click on the applicable directory, and then click [Properties] from the menu that is displayed.
2. In the [*applicableDir* Properties] window, select [Security] >> [Advanced].
3. In the [Advanced Security Settings for *applicableDir*] window, and in the [Permission entries] list under the [Permissions] tab, confirm that [Applies to] for the instance administrator user is "This folder, subfolders and files".
4. Click [OK].

How to configure the access permissions

Perform the following operations in Windows Explorer if there are any directories that have not been configured for the access permissions to be inherited.

1. Right-click on the applicable directory, and then click [Properties] from the menu that is displayed.
2. In the [*applicableDir* Properties] window, select [Security] >> [Advanced].
3. In the [Advanced Security Settings for *applicableDir*] window, click [Add].
4. In the [Permission Entry for *applicableDir*] window, click [Select a principal].
5. In the [Select User or Group] window, enter the instance administrator user name as the object name to select, and then click [OK].
6. In the [Permission Entry for *applicableDir*] window, set [This folder, subfolders and files] for [Applies to:], and under [Basic permissions], allow read and write permissions, and then click [OK].

7. In the [Advanced Security Settings for *applicableDir*] window, confirm that the instance administrator user has been added, with [This folder, subfolders and files] set for [Applies to] in the [Permission entries] list.

8. Click [OK].

The access permissions can also be configured using the icacls command provided by the operating system.

The following is an execution example in which the application destination is set to "(OI)(CI)" and the access permissions are set to "(F) (Full access permissions)" when the data storage destination is "D:\database\inst1" and the instance administrator user is "fsepuser":

```
>icacls D:\database\inst1 /grant fsepuser:(OI)(CI)(F)
processed file: D:\database\inst1
Successfully processed 1 files; Failed processing 0 files
```

4.2.3 Estimating Resources

Estimate the resources to be used on the Fujitsu Enterprise Postgres.

Refer to "Appendix E Estimating Database Disk Space Requirements" for information on estimating database disk space requirements.

Refer to "Parameters automatically set by WebAdmin according to the amount of memory" when creating multiple instances with WebAdmin.

Refer to "Appendix F Estimating Memory Requirements" when creating instances with the initdb command, to estimate memory usage.

4.2.4 Windows Firewall Settings

This section explains the Windows firewall settings required if using WebAdmin for operation.

These settings are not required if using server commands for operation.

If the Windows firewall feature is to be enabled, you should enable a port number on the Web server. The following explains how to enable a port number:

Windows Server(R) 2016:

1. Select [Systems and Security] from [Control Panel] and click [Windows Firewall].
2. In the [Windows Firewall] window, click [Advanced settings].
3. In the [Windows Firewall with Advanced Security] window, click [Inbound Rules] on the left side of the window.
4. Click [New Rule] on the right side of the window.
5. In the [New Inbound Rule Wizard] window, select [Port], and then click [Next].
6. Select [TCP] and [Specific local ports], then specify the Web server port number specified during the WebAdmin setup, and then click [Next].
7. Select [Allow the connection], and then click [Next].
8. Select the profiles for which this rule applies, and then click [Next].
9. In [Name], specify the desired name, and then click [Finish].
10. In the [Windows Firewall with Advanced Security] window, check if the added rule is enabled under [Inbound Rules] in the center of the window.

In cases other than the above:

1. Select [Systems and Security] from [Control Panel] and click [Windows Defender Firewall].
2. In the [Windows Defender Firewall] window, click [Advanced settings].

3. In the [Windows Defender Firewall with Advanced Security] window, click [Inbound Rules] on the left side of the window.
4. Click [New Rule] on the right side of the window.
5. In the [New Inbound Rule Wizard] window, select [Port], and then click [Next].
6. Select [TCP] and [Specific local ports], then specify the Web server port number specified during the WebAdmin setup, and then click [Next].
7. Select [Allow the connection], and then click [Next].
8. Select the profiles for which this rule applies, and then click [Next].
9. In [Name], specify the desired name, and then click [Finish].
10. In the [Windows Defender Firewall with Advanced Security] window, check if the added rule is enabled under [Inbound Rules] in the center of the window.

4.2.5 Preparing for Output to the Event Log

This subsection describes the preparation operations for using commands and outputting error logs to the event log.If outputting error logs to the event log, you should register an event source name beforehand.

If you do not register an event source name, the message content output to the event log may be incomplete.

Due to the default event source name "FUJITSU Enterprise Postgres Server" being output to the event log when using the following commands, you should register this default event source name beforehand:

- pg_ctl command
- pgx_dmpall command
- pgx_rcvall command

The following is an example in which the DLL of a 64-bit product is registered under the default event source name:

```
> regsvr32  "C:\Program Files\Fujitsu\fsepv<x>server64\lib\pgevent.dll"
```

If using multiple instances

You can output messages corresponding to the event source name assigned by the user, so that messages output to the event log can be identified by instance.

The following is an example in which the DLL of a 64-bit product is registered under the event source name "Fujitsu Enterprise Postgres inst1":

```
> regsvr32 /n /i:"Fujitsu Enterprise Postgres inst1" "C:\Program Files\Fujitsu\fsepv<x>server64\lib
\pgevent.dll"
```

You will need to edit the parameters for each instance, therefore, after creating an instance, refer to "4.5.1 Error Log Settings" when performing this setting.

If installing multiple versions

If Fujitsu Enterprise Postgres is already installed on the same machine, search for the key below in Registry Editor, and make a note of the path of the registered DLL. Afterwards, register a new DLL under the default event source name.

Use the DLL path that you made a note of in the above step when re-registering the default event source name during an uninstall.

FUJITSU Enterprise Postgres Server

See

Refer to "Registering Event Log on Windows" in "Server Setup and Operation" in the PostgreSQL Documentation for information on how to register event source names.

4.3 Creating Instances

There are two methods that can be used to create an instance:

- 4.3.1 Using WebAdmin
- 4.3.2 Using the initdb Command

Refer to "4.5.2 Configuring Automatic Start and Stop of an Instance" for information on how to start and stop the operating system of the database server, and how to start and stop linked instances.

4.3.1 Using WebAdmin

This section describes how to create an instance using WebAdmin.

WebAdmin must be set up correctly before it can be used. Refer to "B.1 Setting Up WebAdmin" for details. Additionally, if WebAdmin needs to be configured to use an external repository database, refer to "B.3 Using an External Repository for WebAdmin" for details.

4.3.1.1 Before Using WebAdmin

Learn what you need to know before using WebAdmin.

Recommended Browser

- Microsoft Edge

WebAdmin will work with other browsers, such as Firefox and Chrome, however, the look and feel may be different.

Configure your browser to allow cookies and pop-up requests from the server on which Fujitsu Enterprise Postgres is installed. Refer to "Appendix A Recommended WebAdmin Environments" for information on how to change the pop-up request settings and other recommended settings.

Notes on operations

- It will not work correctly if you operate the same instance from multiple WebAdmin screens at the same time.
- If you want to manage multiple versions of an instance, operate with the latest version of WebAdmin.
- It is recommended not to use the browser [Back] and [Forward] navigation buttons, the [Refresh] button, and context-sensitive menus, including equivalent keyboard shortcuts.
- Do not copy and paste or bookmark the URL of the WebAdmin login screen and skip directly.

Considerations for Using Transparent Data Encryption

After you create an instance in WebAdmin, follow the documentation for each feature in the Operation Guide for additional setup tasks.

About the PostgreSQL Configuration File Relationship

When creating or importing an instance in WebAdmin, set the log_directory parameter in postgresql.conf in the following format:

log_directory='userProfileFolder\\localSettingsFolder\\Fujitsu\\fsep_version\\instanceNamePortNumber\\log'

Example: userProfileFolder\\localSettingsFolder will be C:\\Users\\userName\\AppData\\Local.

4.3.1.2 Logging in to WebAdmin

This section describes how to log in to WebAdmin.

Startup URL for WebAdmin

In the browser address bar, type the startup URL of the WebAdmin window in the following format:

```
http://hostNameOrIpAddress:portNumber/
```

- *hostNameOrIpAddress*: Host name or IP address of the server where WebAdmin is installed
- *portNumber*: Port number of WebAdmin. The default port number is 27515.

The startup screen is displayed. From this window you can log in to WebAdmin or access the product documentation.

Logging in to WebAdmin

Click [Launch WebAdmin] in the startup URL window to start WebAdmin and display the login window. Enter the instance administrator user name (operating system user account name) and password, and log in to WebAdmin. User credential (instance administrator user ID and password) should not contain hazardous characters. Refer to "Appendix C WebAdmin Disallow User Inputs Containing Hazardous Characters".

If you set the account lock for login failure, login failure from WebAdmin might lock the account and prevent you from logging in to the OS. Check the account lock settings in advance.

4.3.1.3 Creating an Instance

This section describes how to create an instance.

Information

WebAdmin automatically sets the memory usage assuming you create one instance per machine. If you are creating multiple instances on a single machine, refer to "Parameters automatically set by WebAdmin according to the amount of memory" to adjust the memory usage after the instance is created.

1. Start WebAdmin, and log in to the database server.
2. In the [Instances] tab, click .
3. Enter the information for the instance to be created.

   Enter the following items:

   [Host name] and [Operating system credential] should not contain hazardous characters. Refer to "Appendix C WebAdmin Disallow User Inputs Containing Hazardous Characters".

   - [Configuration type]: Whether to create a standalone instance or an instance that is part of a cluster.
   - [Server product type]: Sets which of the following instances to create:
     - Fujitsu Enterprise Postgres 9.5 Instances
     - Fujitsu Enterprise Postgres 9.6 Instances
     - Fujitsu Enterprise Postgres 10 Instances
     - Fujitsu Enterprise Postgres 11 Instances
     - Fujitsu Enterprise Postgres 12 Instances
     - Fujitsu Enterprise Postgres 13 Instances
     - Fujitsu Enterprise Postgres 14 Instances
     - Fujitsu Enterprise Postgres 15 Instances
     - Fujitsu Enterprise Postgres 16 Instances
     - Fujitsu Enterprise Postgres 17 Instances
     - Fujitsu Enterprise Postgres 18 Instances

   The default is "Fujitsu Enterprise Postgres 18".

- [Location]: Whether to create the instance in the server that the current user is logged into, or in a remote server. The default is "Local", which will create the instance in the server machine where WebAdmin is currently running.
- [Instance name]: Name of the database instance to manage

  The name must meet the conditions below:

  - Maximum of 16 characters
  - The first character must be an ASCII alphabetic character
  - The other characters must be ASCII alphanumeric characters
- [Instance port]: Port number of the database server
- [Data storage path]: Directory where the database data will be stored
- [Backup]: Whether to enable or disable the WebAdmin backup feature. The default is "Enabled". Select "Disabled" to disable all backup and restore functionality for the instance. If "Enabled" is selected, enter the following item:
  - [Backup storage path]: Directory where the database backup will be stored
- [Transaction log path]: Directory where the transaction log will be stored
- [Encoding]: Database encoding system
- [WAL file size]: Allow the WAL file size to be set when creating an instance. The default is 16 MB if the field is blank. The size specified must be a power of 2 between 1 and 1024. This option is not available for standby instances.

If "Remote" is selected for [Location], enter the following additional items:

- [Host name]: Name of the host where the instance is to be created
- [Operating system credential]: Operating system user name and password for the remote machine where the instance is to be created
- [Remote WebAdmin port for standalone]: Port in which WebAdmin is accessible in the remote machine

4. Click to create the instance.

   If the instance is created successfully, a message indicating the same will be displayed.

5. The instance will be started when it is created successfully.

   The following message is output during startup of an instance when the startup process is operating normally, therefore, the user does not need to be aware of this message.

   ```
   FATAL:  the database system is starting up
   ```

6. Back up the basic information that was set

   Back up the WebAdmin management information periodically to ensure operational continuity when a fault occurs on the system disk. Follow the procedure below to perform the backup.

   a. Stop the WebAdmin server. Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" for details.

   b. Back up the following directory:

      webAdminInstallDir\data\fepwa

   Note that if you are using an external database as your WebAdmin repository, you must also back up the following:

   - *webAdminInstallDir*\data\remotemetadb.conf
   - Use the database features to back up external databases (if they are created on the system disk).

If the instance create was successful

When an instance that uses WebAdmin is created successfully, the following Windows service is registered:

`fsep_version_WA_architecture_userName_instanceNamePortNumber`

The account and password of the instance administrator are registered in the Windows service.
If the password for this account is changed, you must also change the password registered in the service.
Change this at the Properties window registered in the Windows service.

4.3.1.4 Changing Instance Settings

You can change the information that is set when an instance is created.

Change the following settings to suit the operating and management environment for Fujitsu Enterprise Postgres. Note that this cannot be changed for instances of FUJITSU Enterprise Postgres 9.5.

- Instance configuration
  - Character encoding
  - Communication
  - SQL options
  - Memory
  - Streaming replication
- Changing client authentication information
- Editing instance information

Information

- These settings are the same as the parameters that can be set in the files shown below. Refer to "Appendix D Configuring Parameters" for information on the equivalence relationship between the item name and the parameter.
  - postgresql.conf
  - pg_hba.conf
- When [Instance name] or [Instance port] is modified, the log_directory and core_directory parameters in postgresql.conf are updated. Also, the specified directories are created if they do not exist. Refer to "4.3.1.5 Importing Instances" for information on the format of these directories.

4.3.1.4.1 Instance configuration

1. Start WebAdmin and log in to the database server.
2. In the [Instances] tab, click .
3. Click to change the configuration.
4. Click to save your changes.

See

Select a client-side encoding system that can be converted to/from the database encoding system. Refer to "Automatic Character Set Conversion Between Server and Client" in "Server Administration" in the "PostgreSQL Documentation" for information on the encoding system combinations that can be converted.

4.3.1.4.2 Changing client authentication information

1. Start WebAdmin and log in to the database server.
2. In the [Instances] tab, click .

   Click to register new authentication information.

To change authentication information, select the information, and then click .

To delete authentication information, select the information, and then click .

Notes on changing client authentication information

When creating the instance, do not delete the entry below, because it is a connection required for WebAdmin to monitor the operational status of the database:
Type= host, Database=all, User=all, and Method=md5

4.3.1.4.3 Editing instance information

Use the [Edit instance] page to modify the following items for an instance:

- Instance name
- Port number
- Backup storage path

1. In the [Instances] tab, click . The [Edit instance] page is displayed.
2. Modify the relevant items.

   If [Backup storage path] is changed, [Backup management] is enabled. Select the required option:

   - Retain existing backup: Create a backup in [Backup storage path] and retain the existing backup in its original location.
   - Copy existing backup to new path: Copy the existing backup to [Backup storage path]. A new backup will not be created. The existing backup will be retained in its original location.
   - Move existing backup to new path: Move the existing backup to [Backup storage path]. A new backup will not be created.
   - Remove existing backup: Create a backup in [Backup storage path]. The existing backup will be removed.
3. Click to save your changes.

4.3.1.5 Importing Instances

Instances can be created using WebAdmin, or via the command line using the initdb command. Instances created using the initdb command (command line instances) can be managed using WebAdmin, however, they must first be imported into WebAdmin.

You cannot import instances that use the Mirroring Controller.

Advance Preparation

- If the following file contains records that span multiple lines, change the record to a single line before importing.
  - pg_hba.conf
  - pg_ident.conf
- You must make the following changes to the parameters in postgresql.conf prior to importing the instance in WebAdmin.

Parameter	Requirements
port	The port parameter should be uncommented.

- Delete the values specified for the following parameters. Also, if you have changed the value of the parameter (where the file is stored) from the default, move the file to the data storage directory before importing it.
  - hba_file parameter (pg_hba.conf)
  - ident_file parameter (pg_ident.conf)

Import

This section explains how to import command line instances into WebAdmin.

1. In the [Instances] tab, click . The [Import instance] page is displayed.
2. Enter the information for the instance being imported. Refer to "4.3.1.3 Creating an Instance" for information on the items that need to be entered.
3. Click to import the instance.

If the instance import was successful

A Windows service is automatically registered when an instance is imported into WebAdmin. If a Windows service was registered by the user prior to importing the instance, that service will not be deleted. After importing the instance into WebAdmin, it is recommended to discontinue the use of the user-created service.

Information

The log_directory and core_directory parameters in postgresql.conf are updated during import. Also, the specified directories are created if they do not exist.
The format of these directories is as follows:

```
log_directory: 'userProfileFolder\\localSettingsFolder\\Fujitsu\\fsep_version\\instanceNamePortNumber
\\log'

core_directory:
userProfileFolder\\localSettingsFolder\\Fujitsu\\fsep_version\\instanceNamePortNumber\\core'

    version: product version_WA_architecture
    PortNumber: port number specified when creating the instance
```

Examples:
log_directory: 'C:\\Users\\naomi\\AppData\\Local\\Fujitsu\\fsep_180_WA_64\\myinst27599\\log'
core_directory: 'C:\\Users\\naomi\\AppData\\Local\\Fujitsu\\fsep_180_WA_64\\myinst27599\\core'

4.3.2 Using the initdb Command

This section describes the procedure to create an instance using the initdb command.

Instances created using the initdb command (command line instances) can be managed using WebAdmin, however, they must first be imported into WebAdmin. Refer to "4.3.1.5 Importing Instances" for details.

4.3.2.1 Creating an Instance

Create an instance, with the database cluster storage destination specified in the PGDATA environment variable or in the -D option. Furthermore, the user that executed the initdb command becomes the instance administrator.

See

Refer to "initdb" in "Reference" in the PostgreSQL Documentation for information on the initdb command.

The procedure to create an instance is described below.

1. Use the OS user account that you want as the instance administrator.

   Connect with the server using the OS user account that you want as the instance administrator.

2. Configure the environment variables

   Configure the environment variables in the server with the newly created instance.

Set the following environment variables:

- PATH environment variables

  Add installDir\bin and installDir\lib.

Example

The following is a setting example for environment variables in which "C:\Program Files\Fujitsu\fsepv<*x*>server64" is used as the installation folder:

Note that "<*x*>" indicates the product version.

```
> SET PATH=C:\Program Files\Fujitsu\fsepv<x>server64\bin;C:\Program Files\Fujitsu
\fsepv<x>server64\lib;%PATH%
```

3. Create a database cluster

Create the database cluster with the initdb command, specifying the storage destination directory.

Specify the transaction log storage destination and the locale setting option as required.

If creating multiple instances, ensure that there is no duplication of directories that store database clusters.

Example

```
> initdb -D D:\database\inst1 --waldir=E:\transaction\inst1 --lc-collate="C" --lc-ctype="C" --
encoding=UTF8
```

- In some features, instance names are requested, and those names are required to uniquely identify the instance within the system. These features allow names that conform to WebAdmin naming conventions, so refer to the following points when determining the names:
  - Maximum of 16 characters
  - The first character must be ASCII alphabetic character
  - The other characters must be ASCII alphanumeric characters
- Messages may not display correctly if a value other than "C" is specified as the display language for messages.
- Specify "C" for collation and character category. Performance deteriorates if you specify a value other than "C" , although the behavior will follow the rules for particular languages, countries and regions. Furthermore, this may need to be revised when running applications on systems with different locales.
  For example, specify as follows:

  ```
  initdb --locale="C" --lc-messages="C"
  initdb --lc-collate="C" --lc-ctype="C"
  ```

- Specify an encoding system other than SQL_ASCII for the database. If SQL_ASCII is used, there is no guarantee that the encryption system for data in the database will be consistent, depending on the application used to insert the data.

See

Refer to "Locale Support" in "Localization" in "Server Administration" in the PostgreSQL Documentation for information on locales.

4. Set port number.

Specify a port number in the port parameter of postgresql.conf. Ensure that the specified port number is not already used for other software. If creating multiple instances, ensure that there is no duplication of port numbers.

If a port number is not specified, "27500" is selected.

Register the specified port numbers in the C:\Windows\System32\drivers\etc\services file if WebAdmin is used to create other instances. WebAdmin uses the services file to check if port numbers specified as available candidates have been duplicated.

Register any name as the service name.

Make a note of the port number for use in the Windows firewall settings.

5. Set the corefile output destination.

   Specify the output destination of the corefile, which can later be used to collect information for investigation, by setting the core_directory and core_contents parameters of postgresql.conf.

   See

   Refer to "Parameters" in the Operation Guide for information on the settings for these parameters.

6. Set the backup storage destination.

   Specify the backup data storage destination and other backup settings when backup is to be performed as a provision against database errors.

   See

   Refer to "Backup Methods" in the Operation Guide for information on specifying backup settings.

7. Register an instance in the Windows service

   Use the register mode of the pg_ctl command to register an instance in the Windows service.

   Specify the service name, user name, password and path to the instance in the pg_ctl command, and register the instance in the Windows service.

   This command must be executed by an instance administrator user with administrator privileges. Execute the command from the [Administrator: Command Prompt] window. Right-click [Command Prompt], and then select [Run as administrator] from the menu to display the [Administrator: Command Prompt] window.

   Example

   The following is a setting example, in which the service name to register is "inst1", the user name is "fepuser", and the storage destination directory of the database cluster is "D:\database\inst1":

   ```
   > pg_ctl register -N "inst1" -U fepuser -P ******** -D D:\database\inst1
   ```

   For the following reasons, a user name and password must always be specified:

   - Because the Windows service is started up by the Network Service account, all user resources are created as resources of that account. This can result in error events such as failing to access database resources and not being able to perform backups/recovery.
     Note that if not specifying a user name and password for security reasons, you should specify the account from the Windows services list immediately after registering the instance in Windows services.

   Commands such as sc query can be used to check the registration status.

8. Start an instance

   Use the following procedure to start the service:

   a. Display the [Services] window.

      In Windows, select [Administrative Tools], and then click [Services].

   b. Start the service

      From the services list, select the instance name that you wish to start, and click [Start Service].

If using commands to start the service, specify the service name using either the net start command or sc start command from the command prompt.

4.4 Configuring Remote Connections

This section describes the settings required when connecting remotely to Fujitsu Enterprise Postgres from a database application or a client command.

4.4.1 When an Instance was Created with WebAdmin

Settings related to connection

The default is to accept connections from remote computers to the database.

Change "listen_addresses" in postgresql.conf to modify the default behavior.

Refer to "Appendix D Configuring Parameters" for information on postgresql.conf.

Client Authentication Information settings

The following content is set by default when WebAdmin is used to create an instance.

- Authentication of remote connections from local machines is performed.

When changing Client Authentication Information, select [Client Authentication] from [Setting], and then change the settings.

4.4.2 When an Instance was Created with the initdb Command

Connection settings

The default setting only permits local connections from the client to the database. Remote connections are not accepted.

Change "listen_addresses" in postgresql.conf to perform remote connection.

All remote connections will be allowed when changed as shown below.

Example

```
listen_addresses = '*'
```

Also, configure the parameters shown below in accordance with the applications and number of client command connections.

Parameter name	Parameter description
superuser_reserved_connections	Number of connections reserved for database maintenance, for example backup or index rebuilding. If you need to simultaneously perform a large number of processes that exceed the default value, change this value accordingly.
max_connections	Set the value as: *numberOfSimultaneousConnectionsToInstance* + superuser_reserved_connections

Client authentication information settings

When trying to connect from a client to a database, settings are required to determine whether the instance permits connections from the client - if it does, then it is possible to make settings to determine if authentication is required.

See

Refer to "The pg_hba.conf File" in "Server Administration" in the PostgreSQL Documentation for details.

4.4.3 Windows Firewall Settings

If the Windows firewall feature is to be enabled, you should enable a port number on the database server. The following explains how to enable a port number:

Windows Server(R) 2016:

1. Select [Systems and Security] from [Control Panel] and click [Windows Firewall].
2. In the [Windows Firewall] window, click [Advanced settings].
3. In the [Windows Firewall with Advanced Security] window, click [Inbound Rules] on the left side of the window.
4. Click [New Rule] on the right side of the window.
5. In the [New Inbound Rule Wizard] window, select [Port], and then click [Next].
6. Select [TCP] and [Specific local ports], then specify the Web server port number specified during the WebAdmin setup, and then click [Next].
7. Select [Allow the connection], and then click [Next].
8. Select the profiles for which this rule applies, and then click [Next].
9. In [Name], specify the desired name, and then click [Finish].
10. In the [Windows Firewall with Advanced Security] window, check if the added rule is enabled under [Inbound Rules] in the center of the window.

In cases other than the above:

1. Select [Systems and Security] from [Control Panel] and click [Windows Defender Firewall].
2. In the [Windows Defender Firewall] window, click [Advanced settings].
3. In the [Windows Defender Firewall with Advanced Security] window, click [Inbound Rules] on the left side of the window.
4. Click [New Rule] on the right side of the window.
5. In the [New Inbound Rule Wizard] window, select [Port], and then click [Next].
6. Select [TCP] and [Specific local ports], then specify the Web server port number specified during the WebAdmin setup, and then click [Next].
7. Select [Allow the connection], and then click [Next].
8. Select the profiles for which this rule applies, and then click [Next].
9. In [Name], specify the desired name, and then click [Finish].
10. In the [Windows Defender Firewall with Advanced Security] window, check if the added rule is enabled under [Inbound Rules] in the center of the window.

4.5 Other Settings

This section describes settings that are useful for operations.

4.5.1 Error Log Settings

This section explains the settings necessary to monitor errors in applications and operations, and to make discovering the causes easier.

Make error log settings only when instances are created with the initdb command.

When creating instances with WebAdmin, these settings are already made and hence do not need to be set. Furthermore, some parameters are used by WebAdmin, and if changed, may cause WebAdmin to no longer work properly. Refer to "Appendix D Configuring Parameters" for details.

Edit the following parameters in postgresql.conf:

Parameter name	Parameter description	How to enable the settings
event_source	Specify the event source name to be attached to messages, for identifying messages output to the event log when using multiple instances.	- Restart services from the Windows services window. - Use the net command or sc command to stop and start services.
logging_collector	Specify "on" to ensure that messages are output by Fujitsu Enterprise Postgres to the server log file. The server log file is created in the log directory in the database cluster.	- Restart services from the Windows services window. - Use the net command or sc command to stop and start services.
log_destination	Specify " stderr, eventlog" to output messages from Fujitsu Enterprise Postgres to the screen and either the system log or the event log.	reload option of the pg_ctl mode
log_line_prefix	Specify information to be added at the start of messages output by an instance. This information is useful for automatic monitoring of messages. You can output the SQLSTATE value, output time, executing host, application name, and user ID. Refer to "What To Log" in the PostgreSQL Documentation for details. Example: log_line_prefix = '%e: %t [%p]: [%l-1] user = %u,db = %d,remote = %r app = %a '	reload option of the pg_ctl mode

Point

- If you want fewer application errors being output to the eventlog, refer to "When To Log" and "What To Log" in the PostgreSQL Documentation for information on how to reduce the output messages.
- If you want to separate errors output from other software, refer to "Where To Log" in the PostgreSQL Documentation to change the output destination to the server log file rather than the system log.

4.5.2 Configuring Automatic Start and Stop of an Instance

You can automatically start or stop an instance when the operating system on the database server is started or stopped.

Use the following procedure to configure automatic start and stop of an instance.

Note that, if an instance is started in a failover operation, the cluster system will control the start or stop, therefore this feature should not be used. Also, when performing database multiplexing, refer to "Enabling Automatic Start and Stop of Mirroring Controller and Multiplexed Instances" in the Cluster Operation Guide (Database Multiplexing).

When an instance was created with WebAdmin

When an instance is created with WebAdmin, the instance is registered in the Windows service and automatic start and stop is set for the instance.

To change the automatic start and stop setting for an instance, select the service for the applicable instance in the Windows services window, and in [Startup Type], select [Automatic] or [Manual].

When an instance was created with the initdb command

When the startup type of the service is set to [Manual], change it to [Automatic]. By setting the startup type to [Automatic], the service will start up automatically when the Windows(R) system is started up, and will stop automatically when the Windows(R) system is shut down.

The settings should be performed by a user with administrator privileges.

Use the following procedure to switch the service:

1. Display the [Services] window.

   In Windows, select [Administrative Tools], and then click [Services].

2. Switch the startup type

   Select the Fujitsu Enterprise Postgres service name, display the [Properties] dialog box, and then switch the startup type from [Manual] to [Automatic].

The above setting can also be changed using the sc config command.

4.5.3 Settings when Using the Features Compatible with Oracle Databases

To use the features compatible with Oracle databases, create a new instance and execute the following command for the "postgres" and "template1" databases:

```
CREATE EXTENSION oracle_compatible;
```

Features compatible with Oracle databases are defined as user-defined functions in the "public" schema created by default when database clusters are created, so they can be available for all users without the need for special settings.

For this reason, ensure that "public" (without the double quotation marks) is included in the list of schema search paths specified in the search_path parameter.

There are also considerations for use the features compatible with Oracle databases. Refer to "Precautions when Using the Features Compatible with Oracle Databases" in the Application Development Guide for details.

4.5.4 LDAP Authentication File Settings

You can use Active Directory as the LDAP server.

Refer to the Active Directory documentation for detailed settings.

4.5.5 Setting the server keytab file for GSSAPI authentication

When setting the server keytab file for GSSAPI authentication, be sure to set the "krb_server_keyfile" parameter, as the default value in postgresql.conf (FILE:/usr/local/pgsql/etc/krb5.keytab) will not take effect.

4.6 Integration with Message-Monitoring Software

To monitor messages output by Fujitsu Enterprise Postgres using software, configure the product to monitor SQLSTATE, instead of the message text - this is because the latter may change when Fujitsu Enterprise Postgres is upgraded.

Configure Fujitsu Enterprise Postgres to output messages in a format that can be read by the message-monitoring software by specifying "%e" in the log_line_prefix parameter of postgresql.conf to output the SQLSTATE value.

A setting example is shown below - it outputs the output time, executing host, application name, and user ID, in addition to the SQLSTATE value.

Example

```
log_line_prefix = '%e: %t [%p]: [%l-1] user = %u,db = %d,remote = %r app = %a '
```

See

Refer to "What To Log" in the PostgreSQL Documentation for information on how to configure the settings.

4.7 Setting Up and Removing OSS

This section explains how to set up OSS supported by Fujitsu Enterprise Postgres.

If you want to use OSS supported by Fujitsu Enterprise Postgres, follow the setup procedure.

If you decide not to use the OSS supported by Fujitsu Enterprise Postgres, follow the removing procedure.

Information

- In this section, the applicable database that enables the features of each OSS is described as "postgres".
- Execute CREATE EXTENSION for the "template1" database also, so that each OSS can be used by default when creating a new database.

Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for information on OSS other than those described below.

4.7.1 oracle_fdw

This feature is available only when the server command is used. It is not available for instances created with WebAdmin.

4.7.1.1 Setting Up oracle_fdw

1. Add the path of the OCI library to the environment variable.
   Add the installation path of the OCI library to the PATH environment variable.
2. Open a command prompt with administrator privileges and run the following command:

```
> xcopy /E "c:\Program Files\Fujitsu\fsepv<x>server64\OSS\oracle_fdw\*"
        "c:\Program Files\Fujitsu\fsepv<x>server64"
```

3. Restart Fujitsu Enterprise Postgres.
4. Execute CREATE EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION oracle_fdw;
CREATE EXTENSION
```

Information

- If the OCI library is not installed on the server, install it using the Oracle client or Oracle Instant Client.
  Refer to the relevant Oracle manual for information on the installation procedure.
- If the version of the OCI library is updated, change the path of the OCI library in the PATH environment variable to the updated path.

4.7.1.2 Removing oracle_fdw

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# DROP EXTENSION oracle_fdw CASCADE;
DROP EXTENSION
```

2. Open a command prompt with administrator privileges and run the following command:

```
> del "c:\Program Files\Fujitsu\fsepv<x>server64\filesCopiedDuringSetup"
```

Information

The files copied during setup can be checked below.

```
> dir /b /s "c:\Program Files\Fujitsu\fsepv<x>server64\OSS\oracle_fdw"
```

4.7.2 pg_hint_plan

4.7.2.1 Setting Up pg_hint_plan

1. Set the postgresql.conf file parameters.
   Add "pg_hint_plan" to the "shared_preload_libraries" parameter.
2. Open a command prompt with administrator privileges and run the following command:

```
> xcopy /E "c:\Program Files\Fujitsu\fsepv<x>server64\OSS\pg_hint_plan\*"
        "c:\Program Files\Fujitsu\fsepv<x>server64"
```

3. Restart Fujitsu Enterprise Postgres.
4. Run CREATE EXTENSION for the database that uses this feature.
   The target database is described as "postgres" here.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION pg_hint_plan;
CREATE EXTENSION
```

See

Refer to "Enhanced Query Plan Stability" in the Operation Guide for details.

4.7.2.2 Removing pg_hint_plan

Unsetting pg_hint_plan will cause hints registered in the hint_plan.hints table to be lost. Therefore, if you might later use pg_hint_plan again, back up each database's hint_plan.hints table with pg_dump before unsetting it up.

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# DROP EXTENSION pg_hint_plan CASCADE;
DROP EXTENSION
```

2. Set the postgresql.conf file parameters.
   Delete "pg_hint_plan" to the shared_preload_libraries parameter.
3. Restart Fujitsu Enterprise Postgres.
4. Open a command prompt with administrator privileges and run the following command:

```
> del "c:\Program Files\Fujitsu\fsepv<x>server64\filesCopiedDuringSetup"
```

Information

The files copied during setup can be checked below.

```
> dir /b /s "c:\Program Files\Fujitsu\fsepv<x>server64\OSS\pg_hint_plan"
```

4.7.3 pg_dbms_stats

4.7.3.1 Setting Up pg_dbms_stats

1. Set the postgresql.conf file parameter.
   Add "pg_dbms_stats" to the "shared_preload_libraries" parameter.

2. Open a command prompt with administrator privileges and run the following command:

```
> xcopy /E "c:\Program Files\Fujitsu\fsepv<x>server64\OSS\pg_dbms_stats\*"
       "c:\Program Files\Fujitsu\fsepv<x>server64"
```

3. Restart Fujitsu Enterprise Postgres.

4. Run CREATE EXTENSION for the database that will use this feature.
   The target database is described as "postgres" here.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION pg_dbms_stats;
CREATE EXTENSION
```

See

Refer to "Enhanced Query Plan Stability" in the Operation Guide for details.

4.7.3.2 Removing pg_dbms_stats

Unsetting pg_dbms_stats causes statistics managed by pg_dbms_stats to be lost. Therefore, if you plan to use pg_dbms_stats again later, back up each table in each database's dbms_stats schema in binary format, as shown below, and then perform unsetup.

```
postgres > # COPY <dbms_stats Schema's table name> TO '<Filename>' FORMAT binary;
```

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# DROP EXTENSION pg_dbms_stats CASCADE;
DROP EXTENSION
```

2. Set the postgresql.conf file parameters.
   Delete "pg_dbms_stats" to the shared_preload_libraries parameter.

3. Restart Fujitsu Enterprise Postgres.

4. Open a command prompt with administrator privileges and run the following command:

```
> del "c:\Program Files\Fujitsu\fsepv<x>server64\filesCopiedDuringSetup"
```

Information

The files copied during setup can be checked below.

```
> dir /b /s "c:\Program Files\Fujitsu\fsepv<x>server64\OSS\pg_dbms_stats"
```

4.7.4 pgvector

Note that while OSS is named "pgvector", the binaries and the extensions themselves are named "vector".

It is not possible to data masking data added by pgvector using data masking features.

When using in-memory features, data types and functions added in pgvector cannot be accelerated.

4.7.4.1 Setting Up pgvector

1. Open a command prompt with administrator privileges and run the following command:

```
> xcopy /E "c:\Program Files\Fujitsu\fsepv<x>server64\OSS\pgvector\*"
        "c:\Program Files\Fujitsu\fsepv<x>server64"
```

2. Execute CREATE EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# CREATE EXTENSION vector;
CREATE EXTENSION
```

4.7.4.2 Removing pgvector

1. Execute DROP EXTENSION for the database that will use this feature.
   Use the psql command to connect to the "postgres" database.

```
postgres=# DROP EXTENSION vector CASCADE;
DROP EXTENSION
```

2. Open a command prompt with administrator privileges and run the following command:

```
> del "c:\Program Files\Fujitsu\fsepv<x>server64\filesCopiedDuringSetup"
```

Information

The files copied during setup can be checked below.

```
> dir /b /s "c:\Program Files\Fujitsu\fsepv<x>server64\OSS\pgvector"
```

4.8 Deleting Instances

This section explains how to delete an instance.

- 4.8.1 Using WebAdmin
- 4.8.2 Using Server Commands

4.8.1 Using WebAdmin

This section explains how to delete an instance using WebAdmin. Always use WebAdmin to delete instances that were created or imported using WebAdmin. Because WebAdmin managementinformation cannot be deleted, WebAdmin will determine that the instance is abnormal.

Use the following procedure to delete an instance.

1. Stop the instance

   In the [Instances] tab, select the instance to stop and click .

2. Back up files.

   Before deleting the instance, back up any required files under the data storage destination, the backup data storage destination, and the transaction log storage destination.

3. Delete the instance

   In the [Instances] tab, select the instance to delete and click .

Deleting Unnecessary Directories

Deleting an instance deletes only the following lowest-level directories. If they are not required, delete them manually.

- Data storage destination
- Backup data storage destination
- Transaction log storage destination (if different from the data storage destination)

4.8.2 Using Server Commands

This section explains how to delete an instance using server commands.

Use the following procedure to delete an instance.

1. Stop the instance

   Stop the instance in Windows services, or use the pg_ctl command stop mode.

   Use the following procedure to stop a service in Windows services:

   a. Display the [Services] window.

      In Windows, select [Administrative Tools], and then click [Services].

   b. Stop the service

      Select the instance name that you wish to stop from the services list, and click [Stop Service]. If you stop a service while applications and commands are running, Fujitsu Enterprise Postgres will force those applications and commands to close and will stop normally.

   You can also stop a service by specifying the service name in the net stop command or sc stop command.

2. Back up files

   Before deleting the instance, you should back up all necessary files contained in the data storage destination, backup data storage destination, and transaction log storage destination.

3. Delete the instance

   Use a command such as rmdir to delete the following directories:

   - Data storage destination directory
   - Backup data storage destination directory
   - Transaction log storage destination directory (if a different directory to the data storage destination directory was specified)

Chapter 5 Uninstallation

This chapter explains the uninstallation of Fujitsu Enterprise Postgres.

Note that "*x* SP*z*" indicates the version and level of the installed product and "<*x*>" in paths indicates the product version.

Information

- If a [User Account Control] dialog box is displayed at the start of the uninstallation, click [Yes] to continue processing.

  If [No] is clicked, permission to continue is denied and an [Error] dialog box will be displayed.
  To continue the uninstallation, click [Retry] in the [Error] dialog box. To end the operation, click [Cancel].

- If uninstallation is suspended or processing terminates abnormally, the [Program Compatibility Assistant] dialog box may be displayed. Click [This program uninstalled correctly] and continue operation.

5.1 Pre-uninstallation Tasks

Before uninstalling Fujitsu Enterprise Postgres, do the following:

When user files are placed in the installation directory

When you perform uninstallation, all files and directories under the installation directory are deleted. If necessary, back up the files before uninstalling them.

When WebAdmin is used for operation

If performing operation with WebAdmin, back up the following folder before uninstallation.
Instances will not be recognized by WebAdmin even if Fujitsu Enterprise Postgres is reinstalled after uninstallation.
If performing operation with WebAdmin after reinstalling Fujitsu Enterprise Postgres, replace the following backed up file after installation.

Follow the procedure below to perform the backup.

1. Stop the WebAdmin server. Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" for details.
2. Back up the following folder:

   webAdminInstallFolder\data\fepwa

By replacing the above folder in the installation folder after installation, the instance will be recognized by WebAdmin, and the recognized instance will be set to automatically start and stop.
To disable the automatic start and stop setting for an instance, select the service for the applicable instance in the Windows services window, and in [Startup Type], select [Manual].

When using HTTPS or HTTPS client authentication with WebAdmin

In case of secure connection, all the certificates placed in "keystore" directory will be removed when uninstalling WebAdmin. Back up these certificates and its configuration file in advance if required.

webAdminInstallDir\tomcat\keystore
webAdminInstallDir\tomcat\conf\server.xml

They are backed up because the keystore contains certificates, and server.xml contains information for the keystorePass, keyAlias, and trustorePass attributes.

When database multiplexing is performed

If using database multiplexing, refer to "Uninstalling in Database Multiplexing Mode" in the Fujitsu Enterprise Postgres Cluster Operation Guide (Database Multiplexing) before performing the uninstallation.

5.2 Uninstallation in Interactive Mode

The uninstallation procedure is described below.

If an error occurs while the product is being uninstalled, refer to "Uninstall (middleware) Messages" in the Fujitsu Enterprise Postgres product website, and take the required action.

1. Stop applications and programs

Before starting the uninstallation, stop the following:

- Applications that use the product
- Connection Manager
- pgAdmin

2. Stop instances

Stop all instances that are using the product to be uninstalled.

Stopping of instances should be performed by the appropriate instance administrator.

When an instance was created with WebAdmin

In the [Instances] tab, select the instance to stop and click .

When an instance was created with the initdb command

Use the following procedure to stop a service:

a. Display the [Services] window

   In Windows, select [Administrative Tools], and then click [Services].

b. Stop the service

   Select the instance name that you wish to stop from the services list, and click [Stop Service]. If you stop a service while applications and commands are running, Fujitsu Enterprise Postgres will force those applications and commands to close and will stop normally.

You can also stop a service by specifying the service name in the net stop command or sc stop command.

3. Stop WebAdmin

If you are using WebAdmin, stop WebAdmin.

Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" for details.

4. Unregister Windows services(When an instance is created with the initdb command)

Unregister the instance registered in Windows services.

Use the unregister mode of the pg_ctl command to specify the registered service name and unregister the instance from Windows services.

This command must be executed by an instance administrator user with administrator privileges. Execute the command from the [Administrator: Command Prompt] window. Right-click [Command Prompt], and then select [Run as administrator] from the menu to display the [Administrator: Command Prompt] window.

Example

The following is an example showing execution of this command on the registered service name "inst1".

```
> pg_ctl unregister -N "inst1"
```

Information

You should unregister services before uninstalling Fujitsu Enterprise Postgres. If you uninstall Fujitsu Enterprise Postgres while services are running, several files will remain after the uninstallation.

If you have carried out the uninstallation without unregistering services beforehand, use the server command sc delete to unregister the services.

5. Delete registrations related to the event log

If you are outputting to the event log, a DLL registration mentioned in "4.2.5 Preparing for Output to the Event Log" has been performed.

To prevent unnecessary issues from occurring, you should delete this registration. Refer to "Server Setup and Operation", "Registering Event Log on Windows" in the PostgreSQL Documentation for details.

Ensure to delete DLLs before the uninstallation. If you perform the uninstallation without doing so, you may not be able to delete the DLLs at a later time.

The following is an example showing deletion of the DLL registration for a 64-bit product under the default event source name.

```
> regsvr32 /u "c:\Program Files\Fujitsu\fsepv<x>server64\lib\pgevent.dll"
```

If using multiple instances

DLL registration is performed so that you can output messages corresponding to the event source name assigned by the user, allowing you to identify messages output to the event log by instance.

Since it is necessary to delete the DLL registration for each instance, delete the DLL registration by event source name.

The following is an example showing deletion of the DLL of a 64-bit product registered under the event source name "Enterprise Postgres inst1".

```
> regsvr32 /u /i:"Enterprise Postgres inst1" "C:\Program Files\Fujitsu\fsepv<x>server64\lib
\pgevent.dll"
```

Note that this step is not required if the instance was created with WebAdmin.

If installing multiple versions

If the instances you created using this package have been set to output error logs to the event log, use the DLL path name that you took note of previously as explained in "4.2.5 Preparing for Output to the Event Log" to reregister the default event source name.

6. Start Uninstall (middleware)

In [Start] menu, click [All apps], then [Fujitsu], and then [Uninstall (middleware)].

The shortcuts displayed on the [Start] menu might be arranged differently depending on the operating system.

7. Select the software

Select the product to be uninstalled from [Software Name], and then click [Remove].

8. Start the uninstallation

Click [Uninstall].

9. Finish the uninstallation

The uninstallation completion window will be displayed. Click [Finish].

The installation folder may remain after uninstallation. If it is not required, delete it.

10. Stop Uninstall (middleware)

In Uninstall (middleware), click [Close].

5.3 Uninstallation in Silent Mode

The uninstallation procedure is described below.

Refer to the Fujitsu Enterprise Postgres product website for information on uninstallation in silent mode, such as the error messages.

1. Stop applications and programs

Before starting the uninstallation, stop the following:

- Applications that use the product
- Connection Manager
- pgAdmin

2. Stop all instances

Stop all instances that are using the product to be uninstalled.

When an instance was created with WebAdmin

In the [Instances] tab, select the instance to stop and click .

When an instance was created with the initdb command

Use the following procedure to stop a service:

a. Display the [Services] window.

   In Windows, select [Administrative Tools], and then click [Services].

b. Stop the service

   Select the instance name that you wish to stop from the services list, and click [Stop Service]. If you stop a service while applications and commands are running, Fujitsu Enterprise Postgres will force those applications and commands to close and will stop normally.

You can also stop a service by specifying the service name in the net stop command or sc stop command.

3. Stop WebAdmin

If you are using WebAdmin, stop WebAdmin.

Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" for details.

4. Unregister Windows services(When an instance is created with the initdb command)

Unregister the instance registered in Windows services.

Use the unregister mode of the pg_ctl command to specify the registered service name and unregister the instance from Windows services.

This command must be executed by an instance administrator user with administrator privileges. Execute the command from the [Administrator: Command Prompt] window. Right-click [Command Prompt], and then select [Run as administrator] from the menu to display the [Administrator: Command Prompt] window.

Example

The following is an example showing execution of this command for the registered service name "inst1".

```
> pg_ctl unregister -N "inst1"
```

Information

You should unregister services before uninstalling Fujitsu Enterprise Postgres. If you uninstall Fujitsu Enterprise Postgres while services are running, several files will remain after the uninstallation.

If you have carried out the uninstallation without unregistering services beforehand, use the server command sc delete to unregister the services.

5. Delete registrations related to the event log

If you are outputting to the event log, a DLL registration mentioned in "4.2.5 Preparing for Output to the Event Log" has been performed.

To prevent unnecessary issues from occurring, you should delete this registration. Refer to "Server Setup and Operation", "Registering Event Log on Windows" in the PostgreSQL Documentation for details.

Ensure to delete DLLs before the uninstallation. If you perform the uninstallation without doing so, you may not be able to delete the DLLs at a later time.

The following is an example showing deletion of the DLL registration for a 64-bit product under the default event source name.

```
> regsvr32 /u "c:\Program Files\Fujitsu\fsepv<x>server64\lib\pgevent.dll"
```

If using multiple instances

DLL registration is performed so that you can output messages corresponding to the event source name assigned by the user, allowing you to identify messages output to the event log by instance.

Since it is necessary to delete the DLL registration for each instance, delete the DLL registration by event source name.

The following is an example showing deletion of the DLL of a 64-bit product registered under the event source name "Enterprise Postgres inst1".

```
> regsvr32 /u /i:"Enterprise Postgres inst1" "c:\Program Files\Fujitsu\fsepv<x>server64\lib
\pgevent.dll"
```

Note that this step is not required if the instance was created with WebAdmin.

If installing multiple versions

If the instances you created using this package have been set to output error logs to the event log, use the DLL path name that you took note of previously as explained in "4.2.5 Preparing for Output to the Event Log" to reregister the default event source name.

6. Start the command prompt

In Windows, right-click [Command Prompt] and then select [Run as administrator].

7. Run the uninstaller

Execute the command below.

The installation folder may remain after uninstallation. If it is not required, delete it.

Example

```
X:> installFolder\suninst.bat
```

X: Drive on which the product is installed

Appendix A Recommended WebAdmin Environments

This appendix describes the recommended WebAdmin environment. The following explanation is based on the assumption that Microsoft Edge is used unless otherwise stated.

Note

The displayed screen varies depending on your environment, so check and set according to the screen.

A.1 Recommended Browser Settings

- Use a display resolution of 1280 x 768 or higher, and 256 colors or more.
- Select [Setting] >>[Appearance] >> [Font size] >> [Medium (Recommended)].
- Select [Setting] >>[Appearance] >> [Zoom] >> [100%].

A.2 How to Set Up the Pop-up Blocker

If the Pop-up Blocker is enabled, use the procedure below to configure settings to allow pop-ups from the server where Fujitsu Enterprise Postgres is installed.

1. Click [Setting] >> [Cookie and site permissions] >> [All Permissions] >> [Pop-ups and redirects].
   If the [Block (Recommended)] switch is not on (blue), the pop-up blocker is not working, and no further action is required.
2. Under [Pop-ups and Redirects], click the [Allow] >> [Add] button.
3. In [Add Site], in [Site], enter the address of the server where you installed Fujitsu Enterprise Postgres and click the [Add] button.
4. Close Microsoft Edge.

Appendix B Setting Up and Removing WebAdmin

This appendix describes how to set up and remove WebAdmin.

Note that "<*x*>" in paths indicates the product version.

B.1 Setting Up WebAdmin

This section explains how to set up WebAdmin.

B.1.1 Setting Up WebAdmin

In the case of a re-setup, the existing server.xml is overwritten with the default values. Therefore, back up the information in server.xml beforehand and update it manually after setting up WebAdmin.

No action is required because the certificate is not overwritten during re-setup.

Follow the procedure below to set up WebAdmin.

1. Log in

   Log in as a user that belongs to the Administrators group.

2. Display the setup window

   From the [Start] menu, select All Apps, select Fujitsu Enterprise Postgres WebAdmin (64bit) <x>, and then start WebAdmin Setup.

   "<x>" indicates the product version.

   The shortcuts displayed on the [Start] menu might be arranged differently depending on the operating system.

   Note

   If the same [User Account Control] dialog box as that shown below is displayed, click [Yes] to continue processing.

3. Specifying Setup Items

   Specify the following:

   Refer to the services file. Only change to a different port number if the same port number is being used by another service.

   Make a note of the Web server port number, because it will be required for starting the WebAdmin window.

Item	Default value
WebAdmin secure connection support	HTTP
Web server port number	27515
WebAdmin internal port number	27516
WebAdmin automatic start	Selected

   WebAdmin secure connection support

   - **HTTP**

     Specifies that HTTP is used.

   - **HTTPS**

     Specifies to use HTTPS for secure communication with WebAdmin.

     To facilitate HTTPS deployment, WebAdmin automatically creates a self-signed server certificate. This certificate should only be used for testing purposes, such as connection verification, and should be replaced with an appropriate CA-signed certificate in production.

Refer to "B.1.2 Certificate Settings For Secure Connection Support" for detail certificate settings.

Point

If you continue to use the self-signed server certificate that WebAdmin created, your browser displays a warning screen when you access the WebAdmin page because you can access WebAdmin but the certificate is not signed by a known and trusted CA.

- **HTTPS with client authentication**

  Specifies to use HTTPS for secure communication with WebAdmin and to use HTTPS client authentication so that only authenticated clients can use WebAdmin.

  See “HTTPS” for instructions to facilitate HTTPS deployment.

  To facilitate the deployment of HTTPS client authentication, WebAdmin automatically creates two self-signed client certificates.

  One is for browser-to-server authentication. and one for server-to-server authentication.

  Server to server authentication is required because WebAdmins can have multiple server configurations and communicate between them. Refer to "Appendix H Determining the Preferred WebAdmin Configuration".

  These certificate should only be used for testing purposes, such as connection verification, and should be replaced with an appropriate CA-signed certificate in production.

  Refer to "B.1.2 Certificate Settings For Secure Connection Support" for detail certificate settings.

Point

If client authentication is selected, client certificate for browser must be registered in user’s browser before accessing to WebAdmin. Otherwise, WebAdmin will not be accessible.

Web server port number

Specify an unused port number in the following range for the port number used for communication between the Web browser and Web server:

- 1024 to 49151

The Web server port number is registered as a port number of the following service name in the services file.

fep_180_WA_64_WebAdmin_Port1

WebAdmin internal port number

Specify an unused port number in the following range for the port number used for communication between the Web server and WebAdmin runtime environment:

- 1024 to 49151

The WebAdmin internal port number is registered as a port number of the following service name in the services file.

fep_180_WA_64_WebAdmin_Port2

WebAdmin automatic start

Select whether or not to start WebAdmin when the machine is started.

Note

- Make a note of the Web server port number for use in the Windows firewall settings.
- Unused port numbers
  In the operating system and other products, regardless of the information in the service file, unused port numbers may be automatically numbered and then used, or port numbers specified in environment files within products may also be used. Check the port numbers used by the OS and other products, and ensure that these are not duplicated.

- Access restrictions
  Prevent unauthorized access and maintain security by using a firewall product, or the packet filtering feature of a router device, to restrict access to the server IP address and the various specified port numbers.

- Port access permissions
  If a port is blocked (access permissions have not been granted) by a firewall, enable use of the port by granting access. Refer to the vendor document for information on how to grant port access permissions.
  Consider the security risks carefully when opening ports.

- Changing port numbers
  When using WebAdmin in multiserver mode, it is recommended not to change WebAdmin ports after creating instances. Otherwise, the created instances may not be accessible through WebAdmin after the port is changed.

4. Prepare for setup

Click [OK] in the setup window, and after completing the WebAdmin setup, refer to "4.2 Preparations for Setup" and perform the required preparations for setting up Fujitsu Enterprise Postgres if using WebAdmin for operation.

B.1.2 Certificate Settings For Secure Connection Support

Describes how to support secure connections.

You must replace the certificate used for HTTPS and client authentication with a CA-signed certificate. To determine if it has been replaced, check the certificate in the "keystore" to ensure that it has been replaced with a CA-signed certificate.

Certificate Storage Directory

If you specify Use HTTPS or Use HTTPS Client Authentication during setup, a new subdirectory "keystore" for storing certificates is added to the WebAdmin Tomcat installation directory.

Example: If WebAdmin is installed in C:\Program Files\Fujitsu\fsepv<x>webadmin:

```
Tomcat installation directory (C:\Program Files\Fujitsu\fsepv<x>webadmin\tomcat\)
├─── bin
├─── Building.txt
├─── conf
├─── CONTRIBUTING.md
├─── keystore
│    ├─── keystore.p12            → For HTTPS
│    ├─── clientbrowser.p12       → For client authentication
│    ├─── clientkeystore.p12      → For client authentication
│    ├─── truststore.p12          → For client authentication
│    ├─── clientkeystore.conf     → For client authentication
├─── ...
```

Certificate Configuration

To configure a certificate:

1. Prepare CA-signed certificates

Certificate	Summary
keystore.p12 (private and public keys included)	One server certificate for HTTPS. Used for data encryption.
clientbrowser.p12 (private key included)	One client certificate to authenticate the browser between the browser and the server. It is registered in the user's browser. The number of certificates generated corresponds to the number of clients (browsers) accessing WebAdmin.
clientkeystore.p12 (private key included)	One client certificate for server-to-server authentication. Used internally by WebAdmin.

Certificate	Summary
truststore.p12 (clientbrowser.p12 and clientkeystore.p12)	Imported public keys for all client certificates.

2. Place certificates in keystore directory

Single-server configuration

1. Place keystore.p12, truststore.p12 and clientkeystore.p12 files in "keystore" directory
2. Import clientbrowser.p12 into your browser.
   If you use multiple clients (browsers), import the certificate into each browser.

Multi-server configuration

1. Place keystore.p12, truststore.p12 and clientkeystore.p12 files in "keystore" directory
2. Import clientbrowser.p12 into your browser.
   If you use multiple clients (browsers), import the certificate into each browser.
3. Import the public key corresponding to the private key in clientkeystore.p12 into truststore.p12 on the other server you want to connect to.

3. Update certificate information in server.xml and clientkeystore.conf files

- **keystore.p12 and truststore.p12**

  Populate server.xml with the information from keystore.p12 and truststore.p12.

  The server.xml file is located under C:\Program Files\Fujitsu\fsepv<x>webadmin\tomcat\conf.

  HTTPS

  Set the keystorePass and keyAlias attributes to the password and alias for keystore.p12.

  server.xml (C:\Program Files\Fujitsu\fsepv<x>webadmin\tomcat\conf)

```
<Connector port="27515" sslProtocol="TLS"
    protocol="org.apache.coyote.http11.Http11NioProtocol"
    maxThreads="150" SSLEnabled="true" scheme="https" secure="true"
    clientAuth="false" keystoreType="PKCS12"
    keystoreFile="C:\Program Files\Fujitsu\fsepv<x>webadmin\tomcat\keystore\keystore.p12"
    keystorePass="password" keyAlias="alias" />
```

  HTTPS and client authentication

  Set the keystorePass and keyAlias attributes to the password and alias for keystore.p12.

  Set the truststorePass attribute to the password for truststore.p12.

  server.xml (C:\Program Files\Fujitsu\fsepv<x>webadmin\tomcat\conf)

```
<Connector port="27515" sslProtocol="TLS"
    protocol="org.apache.coyote.http11.Http11NioProtocol"
    maxThreads="150" SSLEnabled="true" scheme="https" secure="true"
    clientAuth="true" keystoreType="PKCS12"
    keystoreFile="C:\Program Files\Fujitsu\fsepv<x>webadmin\tomcat\keystore\keystore.p12"
    keystorePass="password" keyAlias="alias"
    truststoreType="PKCS12"
    truststoreFile="C:\Program Files\Fujitsu\fsepv<x>webadmin\tomcat\keystore\truststore.p12"
    truststorePass="password" />
```

- **clientkeystore.p12**

  Populate clientkeystore.conf with the information from clientkeystore.p12.

  clientkeystore.conf file is generated by WebAdmin and its filename cannot be modified.

HTTPS and client authentication

Sets the client certificate information for server authentication.

Set the password for the private key imported into clientkeystore.p12 and the password and alias for clientkeystore.p12.

clientkeystore.conf (C:\Program Files\Fujitsu\fsepv<x>webadmin\tomcat\keystore\)

```
clientkeystore.key.pass=password
clientkeystore.store.pass=password
clientkeystore.alias=alias
```

4. Back up

Back up the certificates and server.xml file.

Point

When you uninstall WebAdmin, all certificates in the keystore directory are deleted. Also, when you reinstall WebAdmin, the server.xml file is overwritten with the default settings. Back up your data in case of incorrect operation.

5. Restart WebAdmin

Stop WebAdmin and start it again.

Refer to "B.1.4 Stopping the Web Server Feature of WebAdmin" and "B.1.3 Starting the Web Server Feature of WebAdmin" for detailed instructions.

Point

If certificates or connection failures occur, refer to the Tomcat log directory (C:\Program Files\Fujitsu\fsepv<x>webadmin\tomcat\logs\) for detailed error messages.

B.1.3 Starting the Web Server Feature of WebAdmin

Follow the procedure below to start the Web server feature of WebAdmin.

1. Display the Services window

In Windows, select [Administrative Tools], and then click [Services].

2. Start the service

Select the displayed name "Fujitsu Enterprise Postgres WebAdmin *version*", and then click [Start Service].

You can also start the service by specifying the service name of the Web server feature of WebAdmin in the net start command or sc start command.

B.1.4 Stopping the Web Server Feature of WebAdmin

Follow the procedure below to stop the Web server feature of WebAdmin.

1. Display the Services window

In Windows, select [Administrative Tools], and then click [Services].

2. Stop the service

Select the displayed name "Fujitsu Enterprise Postgres WebAdmin *version*", and then click [Stop Service].

You can also stop the service by specifying the service name of the Web server feature of WebAdmin in the net stop command or sc stop command.

Note

- For efficient operation of WebAdmin, it is recommended to stop the Web server feature only during a scheduled maintenance period.
- When WebAdmin is used to create and manage instances in a multiserver configuration, the Web server feature must be started and running on all servers at the same time.

B.2 Removing WebAdmin

This section explains how to remove WebAdmin.

This removal procedure stops WebAdmin and ensures that it no longer starts automatically when the machine is restarted.

To remove the setup, execute the command shown below.

Example

When WebAdmin is installed in "C:\Program Files\Fujitsu\fsepv<*x*>webadmin":

```
> C:
> cd C:\Program Files\Fujitsu\fsepv<x>webadmin\sbin
> WebAdminSetup --delete
```

Note

- The removal of the WebAdmin setup must be performed by a user with administrator privileges (a user ID that belongs to the Administrators group).
- Commands that require administrator privileges must be executed from the [Administrator: Command Prompt] window. Right-click [Command Prompt], and then select [Run as administrator] from the menu to display the [Administrator: Command Prompt] window.

B.3 Using an External Repository for WebAdmin

WebAdmin can be configured to use an external database, where it can store the various metadata information it uses. WebAdmin will use this database as a repository to store the information it uses to manage all the created instances. This can be a Fujitsu Enterprise Postgres database.

Using an external database as a WebAdmin repository provides you with more flexibility in managing WebAdmin. This repository can be managed, backed up and restored as needed using pgAdmin or command line tools, allowing users to have greater flexibility and control.

Follow the procedure below to set up the repository.

1. Start WebAdmin, and log in to the database server.
2. Click the [Settings] tab, and then click in the [WebAdmin repository configuration] section.

   Enter the following items:

   - [Host name]: Host name of the database server
   - [Port]: Port number of the database server
   - [Database name]: Name of the database
   - [User name]: User name to access the database
   - [Password]: Password of the database user

Note

- Database type
  It is recommended to use a Fujitsu Enterprise Postgres database as a repository. A compatible PostgreSQL database can also be used as an alternative.
- It is recommended to click [Test connection] to ensure that the details entered are valid and WebAdmin is able to connect to the target database.
- Host name, Database name, User name, Password should not contain hazardous characters. Refer to "Appendix C WebAdmin Disallow User Inputs Containing Hazardous Characters".

3. Click to register the repository details.

Note

- Once the repository is set up, it can be changed any number of times by the user logged into WebAdmin. When a repository is changed:
  - It is recommended to preload the backup into this database.
  - If the data is not preloaded, WebAdmin will create a new repository.
- The database repository can be set up even after WebAdmin was already used to create instances. In that scenario, the instances already created are retained and can continue to be operated on.
- If the instance used as a repository is stopped, WebAdmin will be unusable. For this reason, it is recommended to be familiar with starting an instance from the command line. If the instance is stopped for any reason, start it from the command line and WebAdmin will be usable again.

B.4 Using the WebAdmin Auto-Refresh Feature

The WebAdmin auto-refresh feature automatically refreshes the operating status of all instances in the Instance list at the specified interval. It also refreshes the details of the selected instance. You can use the auto-refresh feature to prevent timeouts.

Follow the procedure below to configure the auto-refresh options.

1. Click the [Settings] tab, and then click in the [User preferences] section.
2. Enter the following items:
   - [Auto-refresh instance]: To use the auto-refresh feature, select "Enabled". The default is "Disabled".
   - [Refresh interval (seconds)]: Number of seconds between each refresh. This is a countdown timer, which is reset every time the instance status is refreshed by any operation. Specify a value from 30 to 3600 (seconds). The default is 30.
3. Click to save the auto-refresh settings.

Point

- Auto-refresh will run only if the [Instances] page is displayed and no user-initiated operation is in progress.
- A text indicator, which is independent of auto-refresh, is displayed at the top of the Instance list. It is dynamically updated to display when the page was last refreshed.

Appendix C WebAdmin Disallow User Inputs Containing Hazardous Characters

WebAdmin considers the following as hazardous characters, which are not allowed in user inputs.

```
| (pipe sign)

& (ampersand sign)

; (semicolon sign)

$ (dollar sign)

% (percent sign)

@ (at sign)

' (single apostrophe)

" (quotation mark)

\' (backslash-escaped apostrophe)

\" (backslash-escaped quotation mark)

<> (triangular parenthesis)

() (parenthesis)

+ (plus sign)

CR (Carriage return, ASCII 0x0d)

LF (Line feed, ASCII 0x0a)

, (comma sign)

\ (backslash)
```

Appendix D Configuring Parameters

WebAdmin operates and manages databases according to the contents of the following configuration files:

- postgresql.conf

  Contains various items of information that define the operating environment of Fujitsu Enterprise Postgres.

- pg_hba.conf

  Contains various items of information related to client authentication.

These configuration files are deployed to a data storage destination. Data is written to them when the instance is created by WebAdmin and when settings are changed, and data is read from them when the instance is started and when information from the [Setting] menu is displayed.

See

Refer to "Server Configuration" and "Client Authentication" in "Server Administration" in the PostgreSQL Documentation for information on the parameters.

Note

WebAdmin checks for port number and backup storage path anomalies when various operations are performed. An anomaly occurs when the value of [Port number] and/or [Backup storage path] in WebAdmin is different from the value of the corresponding parameter in postgresql.conf. Refer to "Anomaly Detection and Resolution" in the Operation Guide for details.

postgresql.conf

Parameters that can be changed in WebAdmin

The postgresql.conf parameters that can be changed in WebAdmin are shown below:

Section	WebAdmin item	postgresql.conf file parameter
Instance Configuration		
Character encoding	Character set	client_encoding
	Message locale	lc_messages
Communication	Max connections	max_connections
SQL options	Transform NULL format	transform_null_equals
	Date output format	DateStyle (*1)
	Interval output format	IntervalStyle
	Number of digits for floating values	extra_float_digits
	Transaction isolation levels	default_transaction_isolation
	Currency format	lc_monetary
	Date and time format	lc_time
	Numerical value format	lc_numeric
Memory	Sort memory (KB)	work_mem
	Shared buffers (KB)	shared_buffers
Streaming replication	WAL level	wal_level
	Maximum WAL senders	max_wal_senders

Section	WebAdmin item	postgresql.conf file parameter
	WAL save size (MB)	wal_keep_size
	Hot standby	hot_standby
	Synchronous standby names	synchronous_standby_names
	WAL receiver timeout (ms)	wal_receiver_timeout
Edit instance		
	Instance name	n/a
	Instance port	port
	Backup storage path	backup_destination

*1: If you specify "Postgres" as the output format, dates will be output in the "12-17-1997" format, not the "Wed Dec 17 1997" format used in the PostgreSQL Documentation.

Information

- Calculate the maximum number of connections using the formula below:

```
maximumNumberOfConnections = maximumNumberOfConnectionsFromApplications + 3 (*1)
```

*1: 3 is the default number of connections required by the system.
Calculate the maximum number of connections using the following formula when changing superuser_reserved_connections (connections reserved for use by the superuser) in postgresql.conf.

```
maximumNumberOfConnections = maximumNumberOfConnectionsFromApplications +
superuser_reserved_connections
```

- Also check if the memory used exceeds the memory installed (refer to "Parameters automatically set by WebAdmin according to the amount of memory").

Parameters set by WebAdmin

The following postgresql.conf parameters are set by WebAdmin during instance startup (they will be ignored even if specified in postgresql.conf):

Parameter	Value
event_source (*1)	'fsep_*version_userName_instanceNamePortNumber*'
listen_addresses	*
log_destination	'stderr,eventlog'
logging_collector	on
log_line_prefix	'%e: %t [%p]: [%l-1] user = %u,db = %d,remote = %r app = %a '
log_filename (*2) (*3)	'logfile-%a.log'
log_truncate_on_rotation	on
log_rotation_age	1d

*1: *PortNumber* is the port number of the database server specified when creating the instance.

*2: The server logs are split into files based on the day of the week, and are rotated after each week.

*3: If the date changes while the instance is stopped, old logs are not deleted and continue to exist.
Manually delete old logs that are no longer required to release disk space.

Parameters automatically set by WebAdmin according to the amount of memory

The postgresql.conf parameters automatically set according to the amount of installed memory, during the creation of instances by WebAdmin, are shown below:

Parameter	Value
shared_buffers	30% of the machine's installed memory
work_mem	30% of the machine's installed memory / max_connections / 2
effective_cache_size	75% of the machine's installed memory
maintenance_work_mem	10% of the machine's installed memory / (1 + autovacuum_max_workers) (*1)

*1: The value will be capped at 2097151 KB.

When determining the values to be configured in the above parameters, you must take into account any anticipated increases in access volume or effects on performance during business operations, such as the number of applications and commands that will access the instance, and the content of processes. Also, note that in addition to Fujitsu Enterprise Postgres, other software may be running on the actual database server. You will need to determine the degree of priority for the database and other software, as well as the memory allocation size.

WebAdmin automatically configures complex parameter settings such as those mentioned above, based on the size of the internal memory of the machine. This enables maximum leverage of the machine memory to facilitate resistance against fluctuations during business operations.

Accordingly, the effects of the above-mentioned factors must be estimated and taken into account when determining and configuring parameter values, so that memory resources can be effectively allocated among other software or instances, and so that adverse effects can be mutually avoided. Refer to "Memory" in "Resource Consumption", and "Planner Cost Constants" in "Query Planning", under "Server Administration" in the PostgreSQL Documentation for information on parameter values and required considerations.

Parameter values can be modified using the WebAdmin [Setting] menu, or edited directly using a text editor.

If adding an instance, determine the parameter values, including for existing instances, and make changes accordingly.

Note

- You can edit postgresql.conf directly with a text editor. However, do not edit the following parameters. If you edit incorrectly, WebAdmin will not work correctly.
  - archive_mode
  - archive_command
  - wal_level
  - wal_sync_method
  - log_line_prefix
  - log_destination
  - logging_collector
  - log_directory
  - log_file_mode
  - log_filename
  - log_truncate_on_rotation
  - log_rotation_age
  - event_source
- If you edit postgresql.conf directly, the records should be single line. WebAdmin will not work correctly if the record spans multiple lines.

- If you change superuser_reserved_connections, set the value you want to change plus the number of connections required by WebAdmin of 3.

pg_hba.conf

Refer to "Client Authentication" in "Server Administration" in the PostgreSQL Documentation for information on content that can be configured in pg_hba.conf.

- Use the following client authentication settings to allow the instance administrator to connect to the database using WebAdmin:
  - The connection type: "host"
  - The IP address is a loopback address ("127.0.0.1/32")
- You can also edit pg_hba.conf directly. However, do not modify items that cannot be configured in WebAdmin. WebAdmin does not work correctly.
- If you edit pg_hba.conf directly, the records should be single line. WebAdmin will not work correctly if the record spans multiple lines.

Appendix E Estimating Database Disk Space Requirements

This appendix describes how to estimate database disk space requirements.

E.1 Estimating Table Size Requirements

The following tables provide the formulas for estimating table size requirements.

Table E.1 Estimation formula when the record length is 2032 bytes or less

Item	Estimation formula (bytes)
(1) Record length	27(*1) + NULL map + OID + column data NULL map: Number of columns / 8 (*2) OID: 4 Column data: Sum of column lengths *1: Record header section *2: Round the result up to the next integer. - Because the column data is placed in boundaries of 8 bytes, you need to make an adjustment so that the sum of the record header section, NULL map and OID is a multiple of 8. For example, if the calculated length is 27 + 1 / 8 (rounded up) + 0 = 28 bytes, add 4 to make the length 32 bytes. - Because the data of each column is placed in boundaries of the defined data type, take the boundary of each data type into account for the length of the column data. For example, the length of the column data in the table below will not be the sum of the data types, which is 37 bytes, but will instead be 64 bytes following boundary adjustment. Definition: create table tb1(c1 char(1), c2 bigint, c3 int, c4 box) Estimation: CHAR type 1 byte + boundary adjustment of 7 bytes for BIGINT type 8 bytes + BIGINT type 8 bytes + INT type 4 bytes + boundary adjustment of 12 bytes for BOX type 32 bytes + BOX type 32 bytes = 64 bytes - Because each record is placed in boundaries of 8 bytes, you need to make an adjustment so that the length of the column data is a multiple of 8. - If the calculated record length exceeds 2,032 bytes, the variable length data in the record might be compressed automatically. If so, use the estimation formulas in "Table E.2 Estimation formula when the record length exceeds 2032 bytes" to estimate the table size.
(2) Page size requirement	8192 (*1) × fillfactor (*2) - 24 (*3) *1: Page length (8192) *2: Value of the fillfactor specified in the table definitions (if omitted, 100%) *3: Page header (24) - The calculated (2) page size requirement will be rounded down to the nearest integer.
(3) Number of records per page	(2) Page size requirement / ((1) record length + 4 (*1)) *1: Pointer length (4) - The result will be rounded down to the nearest integer.

Item	Estimation formula (bytes)
(4) Number of pages required for storing records	Total number of records / (3) number of records per page - The result will be rounded up to the next integer.
(5) Amount of space	(4) Number of pages required for storing records x page length x safety factor (*1) *1: Specify 2.0 or higher. - This is the safety factor assumed if vacuuming is performed for garbage collection in tables and indexes.

Table E.2 Estimation formula when the record length exceeds 2032 bytes

Item	Estimation formula (bytes)
(5) Amount of space	Total number of records x (1) record length x safety factor (*1) *1: Specify 2.0 or higher. - This is the safety factor assumed if vacuuming is performed for garbage collection in tables and indexes.

E.2 Estimating Index Size Requirements

This section provides the formulas for estimating index size requirements.

Fujitsu Enterprise Postgres provides six index types: B-tree, Hash, GiST, GIN, SP-GiST, and VCI. If you do not specify the index type in the CREATE INDEX statement, a B-tree index is generated.

The following describes how to estimate a B-tree index. Refer to "E.7 Estimating VCI Disk Space Requirements" for information on how to estimate VCI.

A B-tree index is saved as a fixed-size page of 8 KB. The page types are meta, root, leaf, internal, deleted, and empty. Since leaf pages usually account for the highest proportion of space required, you need to calculate the requirements for these only.

Table E.3 Estimation formula when the key data length is 512 bytes or less

Item	Estimation formula (bytes)
(1) Entry length	8 (*1) + key data length (*2) *1: Entry header *2: The key data length depends on its data type (refer to "E.3 Sizes of Data Types" for details). Because each entry is placed in boundaries of 8 bytes, you need to make an adjustment so that the length of the key data is a multiple of 8. For example, if the calculated length is 28 bytes, add 4 to make the length 32 bytes. - If the key data length exceeds 512 bytes, key data may be automatically compressed. In this case, use the estimation formula given in "Table E.4 Estimation formula when the key data length exceeds 512 bytes" to estimate the key data length.
(2) Page size requirement	8192 (*1) × fillfactor (*2) - 24 (*3) - 16 (*4) *1: Page length (8192) *2: Value of the fillfactor specified in the index definitions (if omitted, 90%) In the case of indexes of primary key constraints and unique constraints, the value of the fillfactor specified for each constraint in the table definitions (if omitted, 90%) *3: Page header (24) *4: Special data (16)

Item	Estimation formula (bytes)
	- The calculated (2) page size requirement will be rounded down to the nearest integer.
(3) Number of entries per page	(2) Page size requirement / ((1) entry length + 4 (*1)) *1: Pointer length - Result of (3) number of entries per page will be rounded down to the nearest integer.
(4) Number of pages required for storing indexes	Total number of records / (3) number of entries per page - Result of (4) number of pages required for storing indexes will be rounded up to the nearest integer.
(5) Space requirement	(4) Number of pages required for storing indexes x 8192 (*1) / usage rate (*2) *1: Page length *2: Specify 0.7 or lower.

Table E.4 Estimation formula when the key data length exceeds 512 bytes

Item	Estimation formula (bytes)
(5) Space requirement	Total number of records x key data length x compression ratio (*1) / usage rate (*2) *1: The compression ratio depends on the data value, so specify 1. *2: Specify 0.7 or lower as the usage rate.

E.3 Sizes of Data Types

This section lists the sizes of the data types.

E.3.1 Sizes of Fixed-Length Data Types

The following table lists the sizes of fixed-length data types.

Data type	Size (bytes)
SMALLINT (INT2)	2
INTEGER (INT4)	4
BIGINT (INT8)	8
REAL	4
DOUBLE PRECISION	8
SERIAL (SERIAL4)	4
BIGSERIAL (SERIAL8)	8
MONEY	8
FLOAT	8
FLOAT (1-24)	4
FLOAT (25-53)	8
TIMESTAMP WITHOUT TIME ZONE	8
TIMESTAMP WITH TIME ZONE	8
DATE	4
TIME WITHOUT TIME ZONE	8
TIME WITH TIME ZONE	12

Data type	Size (bytes)
INTERVAL	12
BOOLEAN	1
CIDR	IPv4: 7 IPv6: 19
INET	IPv4: 7 IPv6: 19
MACADDR	6
MACADDR8	8
POINT	16
LINE	32
LSEG	32
BOX	32
CIRCLE	24

E.3.2 Sizes of Variable-Length Data Types

The following table lists the sizes of variable-length data types.

Data type	Size (bytes)	Remarks
path	Length of size portion + 12 + 16 x number of vertices	1) When carrying out division, round to the next integer. 2) If the real data length is less than 127, then the length of the size portion is 1 byte, otherwise it is 4 bytes. 3) The number of bytes per character depends on the character set (refer to "E.3.4 Number of Bytes per Character" for details).
polygon	Length of size portion + 36 + 16 x number of vertices	
decimal	Length of size portion + 2 + (integer precision / 4 + decimal precision / 4) x 2	
numeric		
bytea	Length of size portion + real data length	
character varying(*n*), varchar(*n*)	Length of size portion + number of characters x number of bytes per character	
character(*n*), char(*n*)	Length of size portion + *n* x number of bytes per character	
text	Length of size portion + number of characters x number of bytes per character	

E.3.3 Sizes of Array Data Types

The following table lists the sizes of array data types.

Data type	Size (bytes)	Remarks
Array	Length of size portion + 12 + 8 x number of dimensions + data size of each item	If the real data length is less than 127, then the length of the size portion is 1 byte, otherwise it is 4 bytes. - Example of estimation when array data is "ARRAY[[1,2,3],[1,2,3]]" Number of dimensions: 2 INTEGER data size: 4 Total size = 1+12+8x2+6x4 = 53

E.3.4 Number of Bytes per Character

The following table lists the number of bytes per character.

The given values relate to the common character sets EUC-JP and UTF8.

Character type	Character set	Number of bytes per character
ASCII	EUC_JP	1
Halfwidth katakana	EUC_JP	2
JIS X 0208 kanji characters	EUC_JP	2
JIS X 0212 kanji characters	EUC_JP	3
ASCII	UTF8	1
Halfwidth katakana	UTF8	3
JIS X 0208 kanji characters	UTF8	3
JIS X 0212 kanji characters	UTF8	3

E.4 Estimating Transaction Log Space Requirements

This section provides the formula for estimating transaction log space requirements.

```
Transaction log space requirements = max_wal_size
```

However, if the update volume is extremely high (for example, due to a large data load and batch processing), disk writing at a checkpoint may not be able to keep up with the load, and a higher number of transaction logs than indicated here may temporarily be accumulated.

E.5 Estimating Archive Log Space Requirements

This section explains how to estimate archive log space requirements.

The archive log is an archive of the transaction logs from the time of a previous backup to the present, so it fluctuates depending on the backup period and the content of update transactions.

The longer the backup period and the more update transactions, the greater the space required for the archive log.

Therefore, measure the actual archive log space by using a test environment to simulate backup scheduling and database update in a real operating environment.

E.6 Estimating Backup Disk Space Requirements

This section provides the formula for estimating backup disk space requirements.

```
Backup disk space requirements = size of the database cluster x 2 + transaction log space requirements
                               + archive log space requirements
```

Note

If the pgx_dmpall command performs a backup using a user exit, the backup disk size differs according to the database resources targeted for backup and the copy method.

E.7 Estimating VCI Disk Space Requirements

This section provides the formula for estimating VCI disk space requirements.

```
Disk space = (number of rows in tables) x (number of bytes per row) x (compression ratio) + (WOS size)
```

Number of bytes per row

```
Number of bytes per row = (19 + (number of columns specified in CREATE INDEX) / 8
                                  + (number of bytes per single column value)) x 1.1
```

Note: Round up the result to the nearest integer.

Compression ratio

Specify a value between 0 and 1. Since compression ratio depends on the data being compressed, use actual data or test data that simulates it, then compare the value with the estimation result. As a guide, the compression ratio measured with the Fujitsu sample data is shown below:

- Data with high degree of randomness (difficult to compress): Up to approximately 0.9 times.
- Data with high degree of similarity (easy to compress): Up to approximately 0.5 times.

WOS size

```
WOS size = (number of WOS rows) / 185 x 8096
```

One row is added to the number of WOS rows for each INSERT and DELETE, and two rows are added for UPDATE. On the other hand, the number decreases to 520,000 rows or less during conversion to ROS performed by the ROS control daemon.

Note

VCI does not support retrieval of disk space usage using the database object size function pg_indexes_size. To find out the actual total VCI disk space, check the disk space of the storage directory using an OS command or other method.

E.8 Estimating pgvector Disk Space Requirements

When using pgvector, refer to the pgvector documentation for the size of each data type and index. Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for the documentation URL.

Information

For pgvector 0.7.4, refer to the documentation "Reference" for details on each data type, and the source code for index sizes.

Appendix F Estimating Memory Requirements

This appendix explains how to estimate the memory.

F.1 Fujitsu Enterprise Postgres Memory Requirements

This section describes the formulas for estimating Fujitsu Enterprise Postgres memory requirements.

Use the following formula to obtain a rough estimate of memory required for Fujitsu Enterprise Postgres:

```
fujitsuEnterprisePostgresRequiredMemory = sharedMemoryAmount + localMemoryAmount
```

Shared memory amount

```
sharedMemoryAmount = 1523444
                        + 8518 x x
                        + 7154 x (a + b + c + d + 1)
                        + 405 x (a + b + c + d + e) x f
                        + (1208 + g) x (a + b + c + d + 9)
                        + 64 x b
                        + 568 x c
                        + 104 x d
                        + 5666 x e
                        + 112 x h
                        + 8200 x i
                        + 512 x j
                        + 4 x (k + 10)
                        + 1097984 x m
                        + 258 x (a + b + c + d + 1 + e) x o
                        + (1024 x 1024) x p
                        + n
                        + 128 x q
```

The above units are Byte.

Parameter Details:

```
x = shared_buffer/8
    Note : Units of shared_buffer (kB)
    Example : x = 16384 (128 x 1024/8) when shared_buffer = 128 MB
        Convert MB to KB to calculate x.
a = max_connections
b = autovacuum_max_workers
c = max_worker_processes
d = max_wal_senders
e = max_prepared_transactions
f = max_locks_per_transaction
g = track_activity_query_size (byte)
h = max_logical_replication_workers
i = wal_buffers/8
  Note: If wal_buffers is the default value (-1), calculate i = x/32.
        However, if it becomes 2048 or more, set the maximum value to 2048.
        If i = x/32, there is a limit on the maximum value of i.
        Max i = WAL segment size/8
        The WAL segment size can be set with the initdb option --wal-segsize.
        The WAL segment size is in kilobytes.
        (The default WAL segment size is 16 MB. Convert to KB when calculating i)
  Example: If shared_buffer = 128 MB and wal_buffers = -1, i = 512 (16384/32)
           If shared_buffer = 2 GB and wal_buffers = -1, i = 2048 (2 x 1024 x 1024/8/32 = 8192,
           but the maximum value of i is 2048)
           If wal_buffers = 512 kB, i = 64 (512/8)
           i = 4096 (32 x 1024/8) when wal_buffers = 32 MB
```

```
                  Converts MB to KB to calculate i.
j = max_replication_slots
k = old_snapshot_threshold
  Note: If old_snapshot_threshold is the default value (-1), there is no need to add "4 x (k + 10)"
to the quote formula.
           old_snapshot_threshold units (min)
  Example: k = 60 (1 x 60) if old_snapshot_threshold = 1 h
               Convert h to min to get k.
m = pgx_global_metacache (megabytes)
n = memory size requested by the plug-in (determined by the plug-in)
o = max_pred_locks_per_transaction
p = min_dynamic_shared_memory (MB)
q = number of database roles
```

However, note that if instances have been created using WebAdmin, the parameters below will be configured automatically when the instances are created. Take this into account when calculating the shared memory size.

Parameter name	Set value
shared_buffers	30 percent of the internal memory of the machine.
max_connections	100
max_prepared_transactions	100

Local memory amount

```
localMemoryAmount = processStackArea
                  + memoryUsedInDbSessionsThatUseTempTables
                  + memoryUsedInDbSessionsThatPerformSortAndHashTableOperations
                  + memoryUsedInMaintenanceOperations
                  + baseMemoryUsedInEachProcess
                  + memoryUsedPreparingForDataAccess
```

Process stack area

```
processStackArea
  = max_stack_depth x (max_connections + autovacuum_max_workers + 9)
```

This formula evaluates to the maximum value.
Actually it is used according to the growth of the stack.
In the formula above, 9 is the number of processes that perform roles specific to servers.

Memory used in database sessions that use temporary tables

```
memoryUsedInDbSessionsThatUseTempTables
  = temp_buffers x max_connections
```

This formula evaluates to the maximum value.
Memory is gradually used as temporary buffers are used, and is released when the session ends.

Memory used in database sessions that perform sort and hash table operations

```
memoryUsedInDbSessionsThatPerformSortAndHashTableOperations
  = work_mem (*1) x max_connections
```

*1) For hash table operations, multiply work_mem by hash_mem_multiplier.
This formula evaluates to the maximum value.
Memory is gradually used as operations such as sort are performed, and is released when the query ends.

Memory used in maintenance operations

```
memoryUsedInMaintenanceOperations
  = maintenance_work_mem x (numOfSessionsPerformingMaintenance + autovacuum_max_workers)
```

Note that 'maintenance operations' are operations such as VACUUM, CREATE INDEX, and ALTER TABLE ADD FOREIGN KEY.

Base memory used in each process

```
baseMemoryUsedInEachProcess
  = baseMemoryUsedInOneProcess x (max_connections + autovacuum_max_workers + 9)
```

Use the result of the following formula for memory consumed per process. This formula evaluates to the memory used when server processes are running.
In the formula above, 9 is the number of processes that perform roles specific to servers.

The amount of memory consumed per process is determined by the number of tables, indexes, and all columns of all tables that the process accesses. If your system has about 100 tables, you can estimate it to be 3 MB, but otherwise use the following estimate:

```
baseMemoryUsedInOneProcess
  = (1.9KB x All user tables + 2.9KB x All user indexes + 1.0KB x All user columns) x 1.5(*1)

If you enable the Global Meta Cache feature, use the following formula:
baseMemoryUsedInOneProcess
 = (All user tables + All user indexes + All user columns) x 1.0KB x 1.5 (*1)
    + (All user tables x 1.4KB + All user indexes x 2.4KB)
```

*1) Safety Factor (1.5)
There are variable length information. This value takes that into account.

Memory used preparing for data access

```
memoryUsedPreparingForDataAccess
 = variationAmount x (max_connections + autovacuum_max_workers + 4)

  where variationAmount = shared_buffers / 8KB x 4 bytes
      (note that 8KB is the page length, and 4 bytes is the size of page management data)
```

This formula evaluates to the memory required to access the database cache in the shared memory.
In the formula above, among the processes that perform roles specific to servers, 4 is the number of processes that access the database.

F.2 Database Multiplexing Memory Requirements

This section describes the formula for estimating database multiplexing memory requirements for the database server.

Use the following formula to obtain a rough estimate of memory required for database multiplexing:

```
Memory usage of the database multiplexing feature for the database server
           = Peak memory usage of the Mirroring Controller processes
           + Peak memory usage of the Mirroring Controller commands

Peak memory usage of the Mirroring Controller processes=150 MB

Peak memory usage of the Mirroring Controller commands=50 MB x Number of commands executed
simultaneously
```

F.3 VCI Memory Requirements

This section describes the formula for estimating VCI memory requirements.

Use the following formula to obtain a rough estimate of memory requirements:

```
memUsedByVci = memForData + memForEachProcess
```

Memory required to store data in memory

Secure the space estimated using the formula below on the stable buffer (part of shared_buffers).

```
memForData = (numOfRowsInTables) x (numOfBytesPerRow) + (wosSize)
```

Number of bytes per row

```
numOfBytesPerRow
 = (19 + (numOfColsInCreateIndexStatement) / 8 + (numOfBytesPerSingleColValue)) x 1.1
```

Note: Round up the result to the nearest integer.

WOS size

```
wosSize = (numOfWosRows) / 185 x 8096
```

One row is added to the number of WOS rows for each INSERT and DELETE, and two rows are added for UPDATE. On the other hand, the number decreases to 520,000 rows or less during conversion to ROS performed by the ROS control daemon.

Memory required for each process

```
memForEachProcess
 = memUsedPerScanning
 + memUsedForVciMaintenace
 + memUsedByCreateIndexStatement
```

Memory used per scanning

- Parallel scan

```
memUsedPerScanning
 = vci.shared_work_mem + (numOfParallelWorkers + 1) x vci.maintenance_work_mem
```

Note: The number of parallel workers used by VCI simultaneously in the entire instance is equal to or less than vci.max_parallel_degree.

- Non-parallel scan

```
memUsedPerScanning = vci.max_local_ros + vci.maintenance_work_mem
```

Note

- vci.shared_work_mem, and vci.max_local_ros are used to create local ROS. If local ROS exceeds these sizes, execute a query without using VCI according to the conventional plan.
- vci.maintenance_work_mem specifies the memory size to be secured dynamically. If it exceeds the specified value, a disk temporary file is used for operation.

Memory used for VCI maintenance

```
memUsedForVciMaintenace = vci.maintenance_work_mem x vci.control_max_workers
```

Memory used by CREATE INDEX

```
memUsedByCreateIndexStatement = vci.maintenance_work_mem
```

Note

vci.maintenance_work_mem specifies the memory to be secured dynamically. If it exceeds the specified value, a disk temporary file is used for operation.

F.4 High-Speed Data Load Memory Requirements

This section describes the formula for estimating memory requirements for the high-speed data load feature.

Use the following formula to obtain a rough estimate of memory requirements:

```
Memory usage of high speed data load
 = (Peak memory usage of pgx_loader processes + Peak memory usage of the pgx_loader commands)
 x Number of commands executed simultaneously

Peak memory usage of pgx_loader processes
 = Peak memory usage of the backend process   (6 MB)
 + Peak memory usage of parallel workers       (6 MB x number of parallel workers)
 + Peak memory usage of dynamic shared memory (80 MB x number of parallel workers)

Peak memory usage of the pgx_loader commands=9 MB
```

Point

In addition to the size calculated using the formula above, the database cache on the shared memory estimated using the shared_buffers parameter is consumed according to the size of the data (table and index keys) loaded using this feature. Refer to "E.1 Estimating Table Size Requirements" and "E.2 Estimating Index Size Requirements" for information on estimating an appropriate shared buffers value.

F.5 Global Meta Cache Memory Requirements

This section describes the formula for estimating Global Meta Cache memory requirements.

The memory calculated by "Size of the GMC area" is allocated to the shared memory. The memory calculated by the per-process meta cache management information is allocated to the local memory. Refer to the graphic in "Architecture of Global Meta Cache Feature" in the "Memory usage reduction by Global Meta Cache" in the General Description for more information.

Use the following formula to obtain a rough estimate of memory requirements:

```
Amount of memory used by the Global Meta Cache feature
  = Size of GMC area + Per-process meta cache management information

Size of GMC area = (All user tables x 0.4 KB
     + All user indexes x 0.3 KB
     + All user columns x 0.8 KB) x 1.5 (*1)

Per-process meta cache management information
  = (All user tables + All user indexes + All user columns) x 0.1KB x max_connections x 1.5 (*1)
```

*1) Safety Factor (1.5)
This value takes into account the case where both GMC before and after the change temporarily exist at the same time in shared memory when the table definition is changed or the row of the system catalog is changed.

Appendix G Quantitative Limits

This appendix lists the quantitative limits of Fujitsu Enterprise Postgres.

Refer to the pgvector documentation for quantitative limits on the capabilities provided by pgvector. Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for the documentation URL.

Table G.1 Length of identifier

Item	Limit
Database name	Up to 63 bytes (*1) (*2)
Schema name	Up to 63 bytes (*1) (*2)
Table name	Up to 63 bytes (*1) (*2)
View name	Up to 63 bytes (*1) (*2)
Index name	Up to 63 bytes (*1) (*2)
Tablespace name	Up to 63 bytes (*1) (*2)
Cursor name	Up to 63 bytes (*1) (*2)
Function name	Up to 63 bytes (*1) (*2)
Aggregate function name	Up to 63 bytes (*1) (*2)
Trigger name	Up to 63 bytes (*1) (*2)
Constraint name	Up to 63 bytes (*1) (*2)
Conversion name	Up to 63 bytes (*1) (*2)
Role name	Up to 63 bytes (*1) (*2)
Cast name	Up to 63 bytes (*1) (*2)
Collation sequence name	Up to 63 bytes (*1) (*2)
Encoding method conversion name	Up to 63 bytes (*1) (*2)
Domain name	Up to 63 bytes (*1) (*2)
Extension name	Up to 63 bytes (*1) (*2)
Operator name	Up to 63 bytes (*1) (*2)
Operator class name	Up to 63 bytes (*1) (*2)
Operator family name	Up to 63 bytes (*1) (*2)
Rewrite rule name	Up to 63 bytes (*1) (*2)
Sequence name	Up to 63 bytes (*1) (*2)
Text search settings name	Up to 63 bytes (*1) (*2)
Text search dictionary name	Up to 63 bytes (*1) (*2)
Text search parser name	Up to 63 bytes (*1) (*2)
Text search template name	Up to 63 bytes (*1) (*2)
Data type name	Up to 63 bytes (*1) (*2)
Enumerator type label	Up to 63 bytes (*1) (*2)
Profile name	Up to 63 bytes (*1) (*2)

*1: This is the character string byte length when converted by the server character set character code.

*2: If an identifier that exceeds 63 bytes in length is specified, the excess characters are truncated and it is processed.

Table G.2 Database object

Item	Limit
Number of databases	Less than 4,294,967,296 (*1)
Number of schemas	Less than 4,294,967,296 (*1)
Number of tables	Less than 4,294,967,296 (*1)
Number of views	Less than 4,294,967,296 (*1)
Number of indexes	Less than 4,294,967,296 (*1)
Number of tablespaces	Less than 4,294,967,296 (*1)
Number of functions	Less than 4,294,967,296 (*1)
Number of aggregate functions	Less than 4,294,967,296 (*1)
Number of triggers	Less than 4,294,967,296 (*1)
Number of constraints	Less than 4,294,967,296 (*1)
Number of conversion	Less than 4,294,967,296 (*1)
Number of roles	Less than 4,294,967,296 (*1)
Number of casts	Less than 4,294,967,296 (*1)
Number of collation sequences	Less than 4,294,967,296 (*1)
Number of encoding method conversions	Less than 4,294,967,296 (*1)
Number of domains	Less than 4,294,967,296 (*1)
Number of extensions	Less than 4,294,967,296 (*1)
Number of operators	Less than 4,294,967,296 (*1)
Number of operator classes	Less than 4,294,967,296 (*1)
Number of operator families	Less than 4,294,967,296 (*1)
Number of rewrite rules	Less than 4,294,967,296 (*1)
Number of sequences	Less than 4,294,967,296 (*1)
Number of text search settings	Less than 4,294,967,296 (*1)
Number of text search dictionaries	Less than 4,294,967,296 (*1)
Number of text search parsers	Less than 4,294,967,296 (*1)
Number of text search templates	Less than 4,294,967,296 (*1)
Number of data types	Less than 4,294,967,296 (*1)
Number of enumerator type labels	Less than 4,294,967,296 (*1)
Number of default access privileges defined in the ALTER DEFAULT PRIVILEGES statement	Less than 4,294,967,296 (*1)
Number of large objects	Less than 4,294,967,296 (*1)
Number of index access methods	Less than 4,294,967,296 (*1)
Number of profile	Less than 4,294,967,296 (*1)

*1: The total number of all database objects must be less than 4,294,967,296.

Table G.3 Schema element

Item	Limit
Number of columns that can be defined in one table	From 250 to 1600 (according to the data type)
Table row length	Up to 400 gigabytes

Item	Limit
Number of columns comprising a unique constraint	Up to 32 columns
Data length comprising a unique constraint	Less than 2,000 bytes (*1) (*2)
Table size	Up to 32 terabyte
Search condition character string length in a trigger definition statement	Up to 800 megabytes (*1) (*2)
Item size	Up to 1 gigabyte

*1: Operation might proceed correctly even if operations are performed with a quantity outside the limits.

*2: This is the character string byte length when converted by the server character set character code.

Table G.4 Index

Item	Limit
Number of columns comprising a key (including VCI)	Up to 32 columns
Key length (other than VCI)	Less than 2,000 bytes (*1)

*1: This is the character string byte length when converted by the server character set character code.

Table G.5 Data types and attributes that can be handled

Item			Limit
Character	Data length		Data types and attributes that can be handled (*1)
	Specification length (n)		Up to 10,485,760 characters (*1)
Numeric	External decimal expression		Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point
	Internal binary expression	2 bytes	From -32,768 to 32,767
		4 bytes	From -2,147,483,648 to 2,147,483,647
		8 bytes	From -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807
	Internal decimal expression		Up to 13,1072 digits before the decimal point, and up to 16,383 digits after the decimal point
	Floating point expression	4 bytes	From -3.4E+38 to -7.1E-46, 0, or from 7.1E-46 to 3.4E+38
		8 bytes	From -1.7E+308 to -2.5E-324, 0, or from 2.5E-324 to 1.7E+308
bytea			Up to one gigabyte minus 53 bytes
Large object			Up to 4 terabyte

*1: This is the character string byte length when converted by the server character set character code.

Table G.6 Function definition

Item	Limit
Number of arguments that can be specified	Up to 100
Number of variable names that can be specified in the declarations section	No limit

Item	Limit
Number of SQL statements or control statements that can be specified in a function processing implementation	No limit

Table G.7 Data operation statement

Item	Limit
Maximum number of connections for one process in an application (remote access)	4,000 connections
Number of expressions that can be specified in a selection list	Up to 1,664
Number of tables that can be specified in a FROM clause	No limit
Number of unique expressions that can be specified in a selection list/ DISTINCT clause/ORDER BY clause/GROUP BY clause within one SELECT statement	Up to 1,664
Number of expressions that can be specified in a GROUP BY clause	No limit
Number of expressions that can be specified in an ORDER BY clause	No limit
Number of SELECT statements that can be specified in a UNION clause/INTERSECT clause/EXCEPT clause	Up to 4,000 (*1)
Number of nestings in joined tables that can be specified in one view	Up to 4,000 (*1)
Number of functions or operator expressions that can be specified in one expression	Up to 4,000 (*1)
Number of expressions that can be specified in one row constructor	Up to 1,664
Number of expressions that can be specified in an UPDATE statement SET clause	Up to 1,664
Number of expressions that can be specified in one row of a VALUES list	Up to 1,664
Number of expressions that can be specified in a RETURNING clause	Up to 1,664
Total expression length that can be specified in the argument list of one function specification	Up to 800 megabytes (*2)
Number of cursors that can be processed simultaneously by one session	No limit
Character string length of one SQL statement	Up to 800 megabytes (*1) (*3)
Number of input parameter specifications that can be specified in one dynamic SQL statement	No limit
Number of tokens that can be specified in one SQL statement	Up to 10,000
Number of values that can be specified as a list in a WHERE clause IN syntax	No limit
Number of expressions that can be specified in a USING clause	No limit
Number of JOINs that can be specified in a joined table	Up to 4,000 (*1)
Number of expressions that can be specified in COALESCE	No limit
Number of WHEN clauses that can be specified for CASE in a simple format or a searched format	No limit
Data size per record that can be updated or inserted by one SQL statement	Up to one gigabyte minus 53 bytes
Number of objects that can share a lock simultaneously	Up to 256,000 (*1)

*1: Operation might proceed correctly even if operations are performed with a quantity outside the limits.

*2: The total number of all database objects must be less than 4,294,967,296.

*3: This is the character string byte length when converted by the server character set character code.

Table G.8 Data size

Item	Limit
Data size per record for input data files (COPY statement, psql command \copy meta command)	Up to 800 megabytes (*1)
Data size per record for output data files (COPY statement, psql command \copy meta command)	Up to 800 megabytes (*1)

*1: Operation might proceed correctly even if operations are performed with a quantity outside the limits.

Appendix H Determining the Preferred WebAdmin Configuration

This appendix describes the two different configurations in which WebAdmin can be used and how to select the most suitable configuration.

H.1 WebAdmin Configurations

WebAdmin can be installed in two configurations:

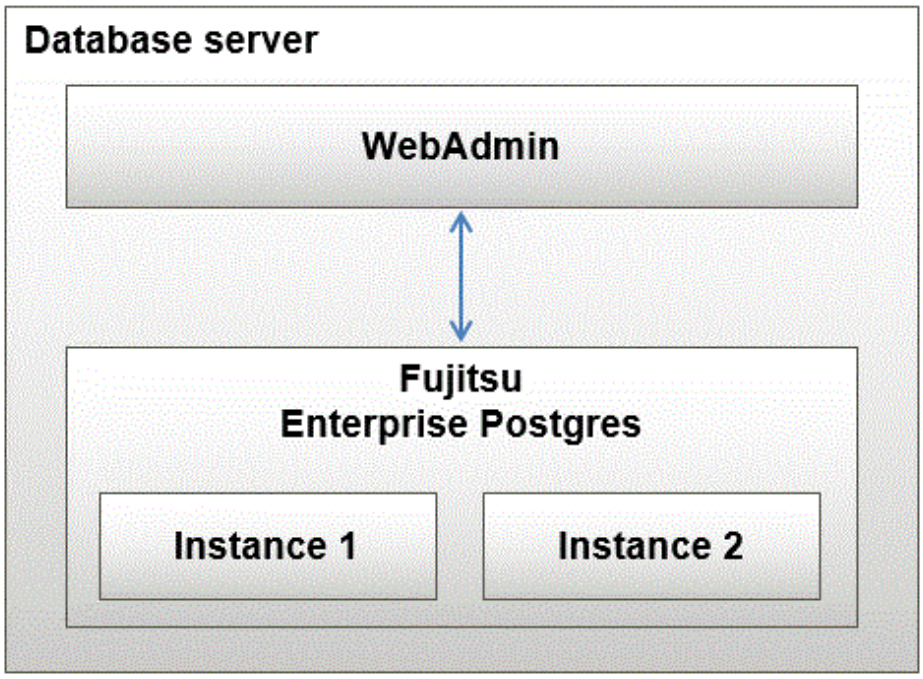
- Single-server
- Multiserver

WebAdmin supports the option to select http or secure https between browsers and servers and between servers. If you have a multi-server environment with a mix of older versions, select http (the default) during setup to continue using the HTTP protocol. This is because older versions do not support HTTPS and all HTTPS settings must be the same on the configuration server.

H.1.1 Single-Server Configuration

A single-server configuration enables you to create and operate instances on a single server. In this configuration, WebAdmin must be installed on the same database server as the Fujitsu Enterprise Postgres Server component.

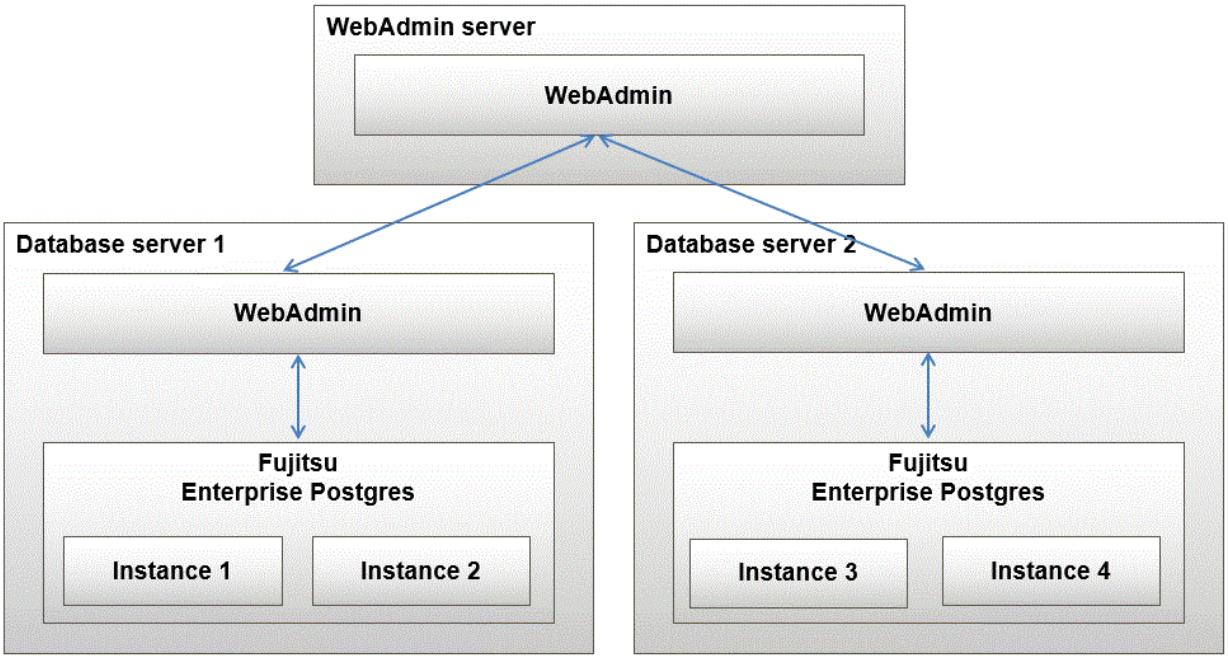
Single-server configuration



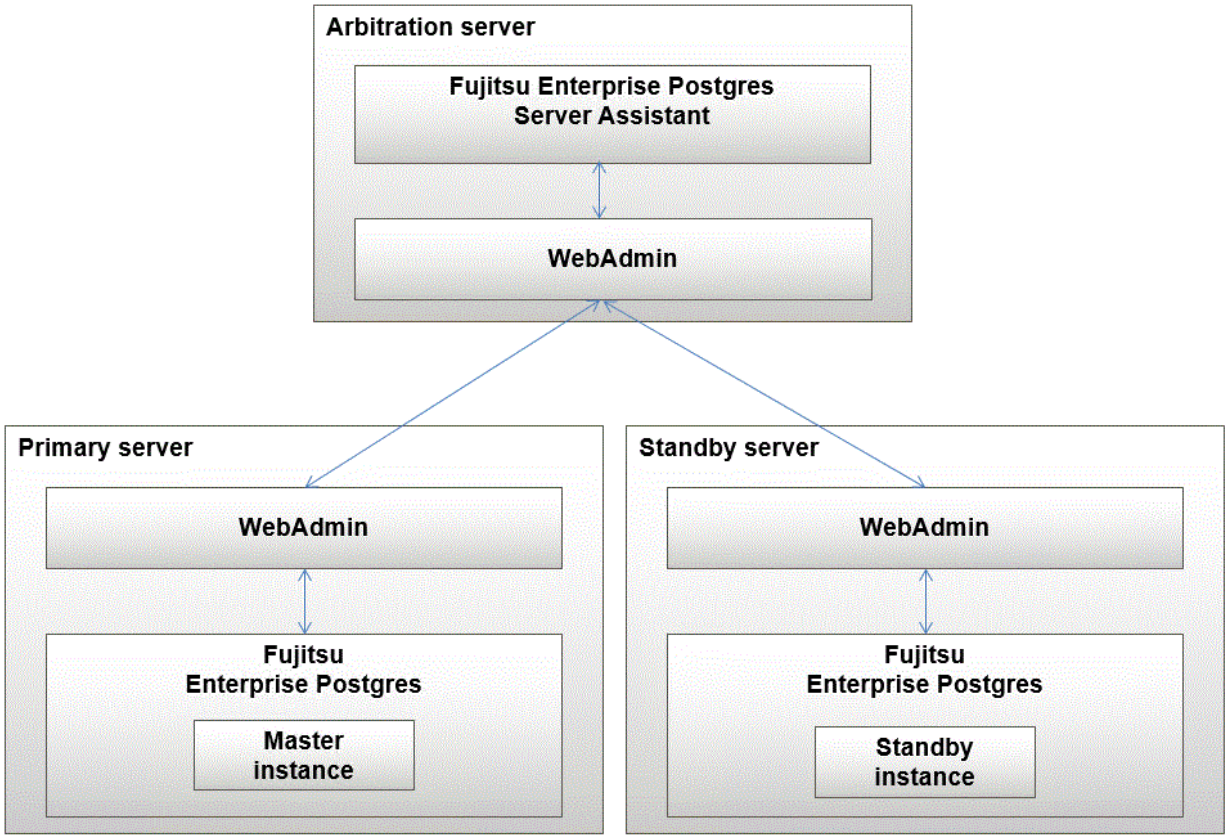
H.1.2 Multiserver Configuration

A multiserver configuration enables you to create and operate instances stored on multiple database servers. As shown in the figure below, WebAdmin can be installed on a dedicated WebAdmin server and used to collectively manage the instances stored on the database servers.

Multiserver configuration



Also, when setting up the arbitration server by WebAdmin during database multiplexing mode, install WebAdmin on the arbitration server.



H.2 Installing WebAdmin in a Single-Server Configuration

To install WebAdmin in a single-server configuration, the Fujitsu Enterprise Postgres Server component and WebAdmin must be installed on the same machine.

Select the following items when installing Fujitsu Enterprise Postgres in a single-server configuration:

- Fujitsu Enterprise Postgres Advanced Edition or Fujitsu Enterprise Postgres Standard Edition
- WebAdmin

H.3 Installing WebAdmin in a Multiserver Configuration

In a multiserver configuration, install WebAdmin on one server, and both WebAdmin and the Fujitsu Enterprise Postgres Server component on any number of database servers.

Select the following items when installing Fujitsu Enterprise Postgres in a multiserver configuration:

- WebAdmin server:
  - WebAdmin
- Database server:
  - Fujitsu Enterprise Postgres Advanced Edition or Fujitsu Enterprise Postgres Standard Edition
  - WebAdmin

Also, when setting up the arbitration server by WebAdmin during database multiplexing mode, select the following when installing Fujitsu Enterprise Postgres.

- Arbitration server
  - Fujitsu Enterprise Postgres Server Assistant
  - WebAdmin

See

Refer to the Installation and Setup Guide for Server Assistant for details on how to install the Server Assistant.

Appendix I Supported contrib Modules and Extensions Provided by External Projects

Fujitsu Enterprise Postgres supports PostgreSQL contrib modules, and extensions provided by external projects.

Refer to the following for details on the supported contrib modules:

- "Additional Supplied Modules" in the PostgreSQL Documentation
- "Additional Supplied Programs" in the PostgreSQL Documentation

Information

You can also check the list of available extensions using the pg_available_extensions view.

Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for information on supported extensions provided by external projects.

Appendix J Deploying Virtual Machines by Cloning

Learn how to install Fujitsu Enterprise Postgres on a virtual machine, clone the virtual machine, and deploy a new virtual machine.

J.1 If you are installing only

There are no guidelines for installing Fujitsu Enterprise Postgres on a virtual machine only and cloning a virtual machine.

J.2 If you are creating an instance

When creating an instance on a virtual machine and cloning the virtual machine, the following precautions must be taken:

- Clone the virtual machine while the instance and WebAdmin are stopped.
- Modify the IP address and host name settings in files such as postgresql.conf and pg_hba.conf if they are different for each replicated machine.
- Use transparent data encryption on the replicated machine. Instances that use transparent data encryption cannot be cloned for use.
- If you cloned the virtual machine that contains the WebAdmin server, reinstall WebAdmin and import the instance that WebAdmin created.

Appendix K Collecting Failure Investigation Data

If the cause of an error that occurs while building the environment or during operations is unclear, data must be collected for initial investigation.

This subsection describes how to collect information for the initial check of the database server.

Use FJQSS (Information Collection Tool) to collect data for initial investigation. However, if you are asked by a Fujitsu technical support representative to collect investigation information, use the pgx_fjqssinf.bat command to collect the information.

See

- Refer to the following manual for information on how to use FJQSS.
  - In the [Apps] menu, select [FJQSS (Information Collection Tool)], and then click [FJQSS User's Guide].
- Refer to "pgx_fjqssinf" in the Reference for informations about the pgx_fjqssinf.bat command.
- To collect information about the arbitration server in a database multiplexing, refer to "Collecting Failure Investigation Data" in the Installation and Setup Guide for Server Assistant.

Setting environment variables

When using FJQSS to collect data for initial investigation, a window will be displayed for you to set the following environment variables. When using the pgx_fjqssinf.bat command, set the following environment variables in advance:

- PGDATA

  Set the data storage destination.

- PGDATABASE

  Set the database name from which you want to collect data for initial investigation.

- PGPORT

  Set the instance port number. This does not need to be set if the default port number (27500) has not been changed.

- PGUSER

  Set the database superuser.
  Set the database superuser so that client authentication is possible.
  FJQSS establishes a TCP/IP connection with the template1 database and collects data from the database.

If you are using database multiplexing, you must set the following environment variables:

- MCCONTROLDIR

  Specify the Mirroring Controller management directory.
  For details about the Mirroring Controller management directory, refer to "Mirroring Controller Resources" in the Cluster Operation Guide (Database Multiplexing).

Deleting the Temporary Folder

After information collection by FJQSS, a temporary folder may remain in the installation directory. In such cases, please manually delete the temporary folder.

Example

Working directory: C:\Program Files\Fujitsu\fsepv<x>server64\tmp\pgx_fjqssinf_workdir

Note that "<x>" indicates the product version.

Fujitsu Enterprise Postgres
18SP1 for x86

Installation and Setup Guide for Client

Windows/Linux

J2UL-3078-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document describes how to install, uninstall and set up the "Fujitsu Enterprise Postgres client feature".

Intended readers

This document is intended for those who install and operate Fujitsu Enterprise Postgres.

Readers of this document are assumed to have general knowledge of:

W
- PostgreSQL
- SQL
- Windows

L
- PostgreSQL
- SQL
- Linux

Structure of this document

This document is structured as follows:

Chapter 1 Overview of Installation

Describes the features that can be installed, and provides an overview of installation methods

Chapter 2 Installation and Uninstallation of the Windows Client

Describes how to install the Fujitsu Enterprise Postgres client feature (Windows client)

Chapter 3 Installation and Uninstallation of the Linux Client

Describes how to install the Fujitsu Enterprise Postgres client feature (Linux client)

Chapter 4 Setup

Describes the setup procedures to be performed after installation completes

Appendix A Installation and Uninstallation of the Linux Client (Compatibility)

Describes how to install (interactive mode/silent mode) the Fujitsu Enterprise Postgres client feature (Linux client)

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Chapter 1 Overview of Installation

This chapter provides an overview of Fujitsu Enterprise Postgres installation.

1.1 Features that can be Installed

Fujitsu Enterprise Postgres provides features to enable access to the database from a variety of platforms and languages, as the connection environment for the client and the database server.

The following table shows the relationship between the platforms and the features provided.

Features Provided	Windows	Linux
JDBC	Y	Y
ODBC	Y	Y
.NET Data Provider	Y	Y
C language (libpq)	Y	Y
Embedded SQL (ECPG) in C language	Y	Y
Embedded SQL (ECOBPG) in COBOL	Y	Y
Python language (psycopg)	Y	Y
Go language		Y
Connection Manager	Y	Y
High-speed data load	Y	Y
pgAdmin	Y (*1)	
Pgpool-II		Y
ldap2pg		Y
pgBackRest		Y

Y: Supported

*1: Provides features for Windows clients (64bit).

Chapter 2 Installation and Uninstallation of the Windows Client

This chapter explains how to install and uninstall the Windows client.

2.1 Operating Environment

This section describes the operating environment required to use the Windows client.

2.1.1 Required Operating System

One of the following operating systems is required to use the Windows client:

Table 2.1 Operating systems

Operating system name
- Windows(R) 11 Home - Windows(R) 11 Education - Windows(R) 11 Pro - Windows(R) 11 Enterprise
- Microsoft(R) Windows Server(R) 2016 Datacenter - Microsoft(R) Windows Server(R) 2016 Standard - Microsoft(R) Windows Server(R) 2016 Essentials
- Microsoft(R) Windows Server(R) 2019 Datacenter - Microsoft(R) Windows Server(R) 2019 Standard - Microsoft(R) Windows Server(R) 2019 Essentials
- Microsoft(R) Windows Server(R) 2022 Datacenter - Microsoft(R) Windows Server(R) 2022 Standard - Microsoft(R) Windows Server(R) 2022 Essentials
- Microsoft(R) Windows Server(R) 2025 Datacenter - Microsoft(R) Windows Server(R) 2025 Standard - Microsoft(R) Windows Server(R) 2025 Essentials

The following components of Windows Server(R) 2016, Windows Server(R) 2019, Windows Server(R) 2022 and Windows Server(R) 2025 are not supported:

- Server Core
- Nano Server
- Windows Server Container

2.1.2 Related Software

The following table lists the software compatible (that can operate) with the Windows client.

Before using any of these, confirm that the OS supports the software.

Table 2.2 Related software

No.	Software name	Version
1	Visual Studio	2017 2019 2022 2026
2	.NET (*1)	8.0 9.0 10.0
3	.NET Framework (*1)	4.8
4	C compiler (*2)	-
5	JDK or JRE	JDK 8 JRE 8 JDK 11 JRE 11 JDK 17 JRE 17 JDK 21 JRE 21
6	NetCOBOL NetCOBOL for .NET	(*3) (*4)
7	Python (*5)	3.11 3.12 3.13

*1: Npgsql 8.0.x supports .NET 8.0 and .NET Framework.
Npgsql 10.0.x supports .NET 8.0, 9.0, and 10.0.

*2: Only operations using the C compiler provided with the operating system are guaranteed.

*3: NetCOBOL is available in the following editions:

- NetCOBOL Base Edition V11.0.1 or later
- NetCOBOL Standard Edition V11.0.1 or later
- NetCOBOL Professional Edition V11.0.1 or later
- NetCOBOL Enterprise Edition V11.0.1 or later

*4: NetCOBOL for .NET is available in the following editions:

- NetCOBOL Base Edition for .NET V7.0.0 or later
- NetCOBOL Standard Edition for .NET V7.0.0 or later
- NetCOBOL Enterprise Edition for .NET V7.0.0 or later

*5: Select Python 32-bit/64-bit depending on the Windows client you are using.

Information

The following JDKs or JREs are available:

- JDK or JRE shipped with the Interstage Application Server
- JDK shipped with the Enterprise Application Platform
- Oracle JDK or JRE
- An OpenJDK that has passed the Java TCK (Technology Compatibility Kit)

It is recommended that the JDK or JRE included with Interstage Application Server and Enterprise Application Platform is used.

You need the following Python packages:

Package name	Remarks
typing_extensions	Install 4.12.2.
tzdata	Install 2024.2.

Note

The following programs are installed during installation of Fujitsu Enterprise Postgres. Do not uninstall it because it is required for Fujitsu Enterprise Postgres to work.

- Microsoft Visual C++ 2015-2022 Redistributable version 14.44.35211.0

The following table lists servers that can be connected to the Windows client.

When connecting to a server product with a different version from this client function, only the range of functions provided by the server product version is available.

Table 2.3 Connectable servers

OS	Software name
Windows	- Fujitsu Enterprise Postgres Advanced Edition 10 or later , up to 18 SP1 - Fujitsu Enterprise Postgres Standard Edition 9.6 or later , up to 18 SP1
Linux	- Fujitsu Enterprise Postgres Advanced Edition 10 or later , up to 18 SP1 - Fujitsu Enterprise Postgres Standard Edition 9.6 or later , up to 18 SP1
Solaris	- FUJITSU Software Enterprise Postgres Standard Edition 9.6

2.1.3 Excluded Software

Fujitsu Enterprise Postgres

The Windows client cannot coexist with the Fujitsu Enterprise Postgres Community Edition (hereafter, "CE") client.

Other products

There are no exclusive products.

2.1.4 Required Patches

No patches are required.

2.1.5 Hardware Environment

The following hardware is required to use the Windows client.

Memory

At least 256 MB of memory is required.

Mandatory hardware

None.

2.1.6 Disk Space Required for Installation

The disk space shown below is required for new installation of the Windows client.

At the Windows (32-bit) client installation destination:

370 MB

At the Windows (64-bit) client installation destination:

2100 MB

Windows system drive:

310 MB

2.1.7 Supported System Environment

This section describes the supported system environment.

TCP/IP protocol

Fujitsu Enterprise Postgres supports version 4 and 6 (IPv4 and IPv6) of TCP/IP protocols.

Do not use link-local addresses if TCP/IP protocol version 6 addresses are used.

File system

You can install Fujitsu Enterprise Postgres only if the system folder is an NTFS volume.

2.1.8 Versions of Open-Source Software Used as the Base for Fujitsu Enterprise Postgres Drivers

For the version of open-source software that Fujitsu Enterprise Postgres each driver is based on, refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description.

2.2 Installation

This section explains how to install the Windows client.

Note

If you have antivirus software installed, the server may crash, fail to start, or stop responding, during installation or when starting up after installation. Set scan exception settings for the installation directory and resource allocation directory so that the files in these directories are not scanned for viruses.

2.2.1 Pre-installation Tasks

This section describes the operations to be performed before installing the Windows client.

Check the disk space

Ensure that there is sufficient disk space to install the Windows Server Assistant.

Refer to "2.1.6 Disk Space Required for Installation" for information on disk space requirements.

hosts file settings

Using an editor, add the IP address and server name of the connected server to the \System32\drivers\etc\hosts file in the folder where Windows is installed.

For Windows(R) 11, start an editor such as Notepad from [Run as administrator] and edit.

Check the installed product and determine the installation method

In [Start] menu, click [All apps], then [Fujitsu], and then [Uninstall (middleware)]. In the displayed window, check the installed products.

If the Windows client is already installed, determine the installation method to use:

- Reinstallation
- Multi-version installation

The shortcuts displayed on the [Start] menu might be arranged differently depending on the operating system.

Remove applied updates(For Reinstallation)

Use the following procedure to remove applied fixes.

If you install the product without removing the fix, you will apply the same version of the fix with the same fix number, resulting in an error that has already been applied. Remove the fix and then reinstall.

1. Display the applied updates

   Execute the following command to display the applied updates:

```
C:\Program Files (x86)\Fujitsu\UpdateAdvisor\UpdateAdvisorMW>uam showup
```

2. Remove the updates

   Execute the command below to remove the updates. If an update with the same update number was applied more than once, the updates are removed in order, starting from the highest version number.

```
C:\Program Files (x86)\Fujitsu\UpdateAdvisor\UpdateAdvisorMW>uam remove -i update-number
```

Confirm service

The Windows Installer service must be running.

Confirm Path system environment variable

Ensure that the Path system environment variable includes "%SystemRoot%\system32".

2.2.2 Pre-installation Considerations

This section describes points that the user must take into account prior to installation.

- The remote desktop service is installed in application server mode, it is necessary to switch to install mode by executing the command shown below before installation. Also, after the installation is completed, execute the command shown below to switch back to execute mode.

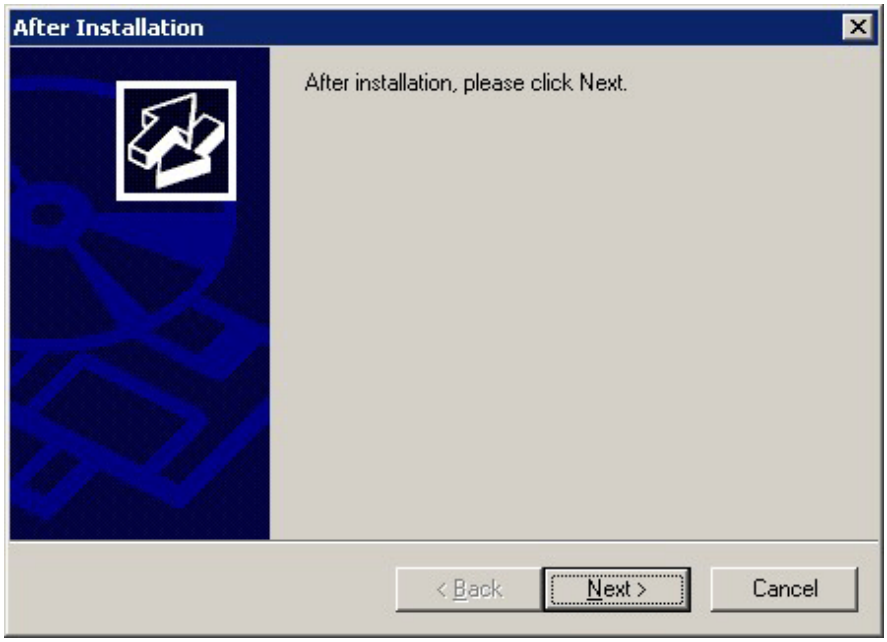
  Before installation:

```
CHANGE USER /INSTALL
```

  After installation:

```
CHANGE USER /EXECUTE
```

- The following window may be displayed when the installation program is executed.



If the above window is displayed, follow the procedure below:

1. Perform the steps in the installation procedure until the [InstallShield Wizard Complete] window is displayed.
2. Click [Next] in the [InstallShield Wizard Complete] window.
3. The following window is displayed. Click [Finish].

Information

- If the [User Account Control] dialog box is displayed when installation or uninstallation starts, click [Yes] to continue the operation.

  If [No] is clicked, the [Error] dialog box will be displayed because continuing is not permitted.
  Click [Retry] in the displayed [Error] dialog box to proceed with installation or uninstallation. To end operations, click [Cancel].

- If installation or uninstallation is suspended or processing terminates abnormally, the [Program Compatibility Assistant] dialog box may be displayed.
  If this happens, click [This program installed correctly] or [This program uninstalled correctly] and continue operation.

2.2.3 Installation in Interactive Mode

The installation procedure is described below.

Point

For installation in interactive mode, default values are set for the installation information. The following settings can be changed for a new installation or a multi-version installation:

- Installation folder

1. Stop applications and programs

Reinstallation requires stopping applications and programs.

Before starting the installation, stop the following:

- Applications that use the product
- Connection Manager
- pgAdmin

2. Insert the DVD

Insert the client program DVD into the DVD drive.

3. Run the installation

The installation menu is displayed. Click [Installation].

4. Select the product to install

Select the product to install, and then click [Next].
If a selected product can only be reinstalled, refer to "6. Check the settings".

Information

- When installing the Fujitsu Enterprise Postgres Client (32 bit), do not specify a destination folder under the environment ProgramFiles variable.
- If multi-version installation is possible, the [Select Installation Method] window is displayed for each selected product. Select "Multi-version installation" and click [Next].

5. Confirm the contents for installation

The [Confirm installation] window will be displayed.

Click [Next] to start the installation.

To modify the settings, select [Modify], and then click [Next]. Follow the on-screen instructions.

6. Check the settings

The [Confirm installation] window will be displayed for reinstallation, or if the installation information is modified.

Click [Install] to start the installation.

To modify the settings again, click [Back].

7. Completion of installation

The completion window is displayed. Click [Finish].

2.2.4 Installation in Silent Mode

Installation in silent mode can be performed only when the installation method is one of the following:

- New installation
- Multi-version installation

See

Refer to the Fujitsu Enterprise Postgres product website for information on installation in silent mode, such as the installation parameters and error messages.

The installation procedure is described below.

1. Insert the DVD

Insert the client program DVD into the DVD drive.

The [Install Menu] window is displayed. Click [Finish].

2. Create an installation parameters CSV file

Consider the server type or features that will be required for system operations, and then create an installation parameters CSV file that uses the following specification format.

```
sectionName, parameterName, value
sectionName, parameterName, value
        :
```

Information

- When installing the Fujitsu Enterprise Postgres Client (32 bit), do not specify a destination folder under the environment ProgramFiles variable.
- The template for the installation parameters CSV file is "*Z*:\sample\sample_windows.csv (*Z* is the drive into which the DVD is inserted.).

3. Start the command prompt

In Windows, right-click [Command Prompt] and then select [Run as administrator].

4. Run the installation

Execute the following command:

```
Z:\>silent.bat c:\temp\inspara.csv
```

Z: The drive into which the DVD is inserted.

c:\temp\inspara.csv: The installation parameter CSV file name.

If the silent installer ends in an error, a message is output to the log file and return values are returned.

2.3 Uninstallation

This section describes the procedure for uninstalling the Windows client.

2.3.1 Uninstallation in Interactive Mode

The uninstallation procedure is described below.

To uninstall, log in with an account with administrator privileges, or switch to an account with administrator privileges, and then uninstall.

If an error occurs while the product is being uninstalled, refer to "Uninstall (middleware) Messages" in the Fujitsu Enterprise Postgres product website, and take the required action.

1. Stop applications and programs

Before starting the uninstallation, stop the following:

- Applications that use the product
- Connection Manager
- pgAdmin

2. Start the Uninstall (middleware) tool

In [Start] menu, click [All apps], then [Fujitsu], and then [Uninstall (middleware)].

The shortcuts displayed on the [Start] menu might be arranged differently depending on the operating system.

3. Select the software

Select the product to be uninstalled from [Software Name], and then click [Remove].

4. Start the uninstallation

Click [Uninstall].

5. Finish the uninstallation

The uninstallation completion window is displayed. Click [Finish].

The installation folder may remain after uninstallation. If it is not required, delete it.

6. Stop the Uninstall (middleware) tool

The [Uninstall (middleware)] window is displayed. Click [Close].

2.3.2 Uninstallation in Silent Mode

The uninstallation procedure is described below.

To uninstall, log in with an account with administrator privileges, or switch to an account with administrator privileges, and then execute the command.

Refer to the Fujitsu Enterprise Postgres product website for information on uninstallation in silent mode, such as the error messages.

1. Stop applications and programs

Before starting the uninstallation, stop the following:

- Applications that use the product
- Connection Manager
- pgAdmin

2. Start the command prompt

In Windows, right-click [Command Prompt] and then select [Run as administrator].

3. Start the uninstaller

Execute the command below.

The installation folder may remain after uninstallation. If it is not required, delete it.

Example

```
X:> installFolder\suninst.bat
```

X: Drive on which the product is installed

Chapter 3 Installation and Uninstallation of the Linux Client

This chapter explains how to install and uninstall the Linux client.

3.1 Operating Environment

This section describes the operating environment required to use the Linux client.

3.1.1 Required Operating System

One of the following operating systems is required to use the Linux client:

- RHEL8.6 or later minor version
- RHEL9.2 or later minor version
- SLES 15 SP4 or later minor version

3.1.1.1 Packages Required for RHEL8

The following packages are required for operations on RHEL8.

Package name	Remarks
bzip2-libs	Required when using pgBackRest.
glibc	-
Go	Required when using Go language. Install 1.24 or later.
libnsl2	-
libcurl	Required when using using OAuth authentication.
libgcc	-
libmemcached	Required when using Pgpool-II.
libstdc++	-
libtool-ltdl	Required when using ODBC drivers
libzstd	-
lz4-libs	Required when using pgBackRest.
ncurses-libs	-
nss-softokn-freebl	-
rsync	Required when using Pgpool-II.
unixODBC	Required when using ODBC drivers Install 2.3 or later.
unzip	-
xz-libs	-
zlib	-

3.1.1.2 Packages Required for RHEL9

The following packages are required for operations on RHEL9.

Package name	Remarks
bzip2-libs	Required when using pgBackRest.
glibc	-
Go	Required when using Go language. Install 1.24 or later.
libcurl	Required when using using OAuth authentication.
libnsl2	-
libgcc	-
libmemcached-awesome	Required if Pgpool-II is used.
libstdc++	-
libtool-ltdl	Required if you are using an ODBC driver.
libzstd	-
lz4-libs	Required when using pgBackRest.
ncurses-libs	-
nss-softokn-freebl	-
rsync	Required if Pgpool-II is used.
unixODBC	Required if you are using an ODBC driver. Install 2.3 or later.
Unzip	-
xz-libs	-
zlib	-

3.1.1.3 Packages Required for SLES 15

The following packages are required for operations on SLES 15.

Package name	Remarks
glibc	-
glibc-32bit	-
Go	Required when using Go language. Install 1.24 or later.
libcurl4	Required when using using OAuth authentication.
libbz2-1	Required when using pgBackRest.
libfreebl3	-
libgcc	-
libltdl7	Required when using ODBC drivers.
liblz4-1	Required when using pgBackRest.
liblzma5	-
libmemcached	Required when using Pgpool-II.
libncurses5	-
libstdc++6	-
libz1	-
libzstd1	-

Package name	Remarks
rsync	Required when using Pgpool-II.
unixODBC	Required when using ODBC drivers. Install 2.3 or later.
unzip	-

3.1.2 Related Software

The following table lists the software required to use the Linux client.

Table 3.1 Related software

No.	Software name	Version
1	.NET (*1)	8.0 9.0 10.0
2	C compiler (*2)	-
3	JDK or JRE	JDK 8 JRE 8 JDK 11 JRE 11 JDK 17 JRE 17 JDK 21 JRE 21
4	NetCOBOL	(*3)
5	Python	3.11

*1: Npgsql 8.0.x supports .NET 8.0.
Npgsql 10.0.x supports .NET 8.0, 9.0, and 10.0.

*2: Only operations using the C compiler provided with the operating system are guaranteed.

*3: NetCOBOL is available in the following editions(Not supported because NetCOBOL does not work in a SLES environment):

- NetCOBOL Base Edition V12.2.0 or later
- NetCOBOL Standard Edition V12.2.0 or later
- NetCOBOL Enterprise Edition V12.2.0 or later

Information

The following JDKs or JREs are available:

- JDK or JRE shipped with the Interstage Application Server
- JDK shipped with the Enterprise Application Platform
- Oracle JDK or JRE
- An OpenJDK that has passed the Java TCK (Technology Compatibility Kit)

It is recommended that the JDK or JRE included with Interstage Application Server and Enterprise Application Platform is used.

You need the following Python packages:

Package name	Remarks
typing_extensions	Install 4.12.2.

When using the Go language, the following Go packages are required.

Package name	Remarks
github.com/jackc/pgpassfile	It will be obtained automatically.
github.com/jackc/pgservicefile	
github.com/jackc/puddle	
github.com/stretchr/testify	
golang.org/x/sync	
golang.org/x/text	
github.com/davecgh/go-spew	
github.com/kr/pretty	
github.com/pmezard/go-difflib	
gopkg.in/check.v1	
gopkg.in/yaml.v3	
github.com/stretchr/objx	
github.com/kr/text	
github.com/rogpeppe/go-internal	
github.com/creack/pty	
golang.org/x/mod	
github.com/kr/pty	
gopkg.in/errgo.v2	

The following table lists servers that can be connected to the Linux client.

When connecting to a server product with a different version from this client function, only the range of functions provided by the server product version is available.

Table 3.2 Connectable servers

OS	Software name
Windows	- Fujitsu Enterprise Postgres Advanced Edition 10 or later , up to 18 SP1 - Fujitsu Enterprise Postgres Standard Edition 9.6 or later , up to 18 SP1
Linux	- Fujitsu Enterprise Postgres Advanced Edition 10 or later , up to 18 SP1 - Fujitsu Enterprise Postgres Standard Edition 9.6 or later , up to 18 SP1
Solaris	- FUJITSU Software Enterprise Postgres Standard Edition 9.6

3.1.3 Excluded Software

Fujitsu Enterprise Postgres

The Linux client cannot coexist with the Fujitsu Enterprise Postgres Community Edition (hereafter, "CE") client.

Other products

There are no exclusive products.

3.1.4 Required Patches

There are no required patches.

3.1.5 Hardware Environment

The following hardware is required to use the Linux client.

Memory

At least 160 MB of memory is required.

Mandatory hardware

None.

3.1.6 Disk Space Required for Installation

The following table lists the disk space requirements of the corresponding directories for new installation of the Linux client. If necessary, increase the size of the file system.

Disk space required for installation

Table 3.3 RHEL

Directory	Required disk space Unit: MB
/etc	1
/var	1
Installation destination of the client (64-bit)	180
Installation destination of Pgpool-II	30
Installation destination of ldap2pg	20
Installation destination of pgBackRest	40

*1: Uninstall (middleware) must be installed.

Table 3.4 SLES

Directory	Required disk space Unit: MB
/etc	1
/var	1
Installation destination of the client (64-bit)	170
Installation destination of Pgpool-II	30
Installation destination of ldap2pg	20
Installation destination of pgBackRest	30

*1: Uninstall (middleware) must be installed.

3.1.7 Supported System Environment

This section describes the supported system environment.

TCP/IP protocol

Fujitsu Enterprise Postgres supports version 4 and 6 (IPv4 and IPv6) of TCP/IP protocols.

Do not use link-local addresses if TCP/IP protocol version 6 addresses are used.

3.1.8 Versions of Open-Source Software Used as the Base for Fujitsu Enterprise Postgres Drivers

For the version of open-source software that Fujitsu Enterprise Postgres each driver is based on, refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description.

3.2 Installation

This section explains how to install the Linux client.

If you have antivirus software installed, the server may crash, fail to start, or stop responding, during installation or when starting up after installation. Set scan exception settings for the installation directory and resource allocation directory so that the files in these directories are not scanned for viruses.

3.2.1 Pre-installation Tasks

Check the system environment for the following before the Linux client is installed.

Check the disk capacity

Check if sufficient free disk space is available for installing the Linux client.

Refer to 3.1.6 Disk Space Required for Installation" for information on disk space requirements.

If sufficient free disk space is unavailable, reconfigure disk partitions.

Executable Users

Installation and uninstallation is performed by superuser.

On the system, run the following command to become superuser.

```
$ su -
Password:******
```

3.2.2 Installation from RPM Package

The installation procedure is described below.

1. Stop applications and programs

Reinstallation requires stopping applications and programs.

Before starting the installation, stop the following:

- Applications that use the product
- Connection Manager
- pgBadger
- Pgpool-II
- ldap2pg

- pgBackRest

2. Mount the DVD drive

Insert the client program DVD into the DVD drive, and then execute the following command:

Example

```
# mount -t iso9660 -r -o loop /dev/dvd /media/dvd
```

Here /dev/dvd is the device name for the DVD drive (which may vary depending on your environment), and /media/dvd is the mount point (which may need to be created before calling the command).

3. Run the installation

The RPM packages required to install each product are stored under the mount point where you mounted the DVD.

The following shows a list of packages and the path of the storage directory.

Install all packages for the product you are installing.

Product name	Package storage directory	Package name
Client	CLIENT64/Linux/packages/<*os*>	FJSVfsep-client-*.rpm
Pgpool-II	PGPOOL2/Linux/packages/<os>	FJSVfsep-pgpool2-*.rpm
pgBackRest	PGBACKREST/Linux/packages/<*os*>	FJSVfsep-pgbackrest-*.rpm
ldap2pg	LDAP2PG/Linux/packages/<*os*>	FJSVfsep-ldap2pg-*.rpm

<os> is the OS of the operating environment. Depending on your system requirements, refer to RHEL8, RHEL9, or SLES15.

*is the detailed name of the package, version, OS, etc.

The default installation directory names are:

To specify a path different from the default installation directory, you can use the following characters:

`[a-zA-Z0-9], -,, and /`

Product name	Installation directory name (default)
Client	/opt/fsepv<*x*>client64
Pgpool-II	/opt/fsepv<*x*>pgpool-II
pgBackRest	/opt/fsepv<*x*>pgbackrest
ldap2pg	/opt/fsepv<*x*>ldap2pg

"<x>" is the product version.

Point

We recommend that you install the packages for each product in a batch.

You can use "*" to specify a package name, or you can install all packages in a batch by specifying all package names side by side.

Example

To install the client product in a RHEL8 environment, run the following command:

```
# cd /media/dvd/CLIENT64/Linux/packages/RHEL8
# rpm -ivh FJSVfsep-client-*.rpm
```

Use --prefix to specify a path different from the default installation directory.

4. Check the installed product

Check the installed products by following the procedure below.

Example

Displays the name of the installed package.

```
# rpm -qa | grep FJSVfsep
```

For detailed package information, run the following command:

```
# rpm -qi package name
```

Example

In the path, "<x>" and "<x0z>" refer to the x and z of x SPz, which is expressed as the product version. For products without SPz, <x0z> is <x00>.

```
# rpm -qi FJSVfsep-client-essential-<x>-<x0z>-0.el8.x86_64
Name        : FJSVfsep-client-essential-<x>
Version     : <x0z>
Release     : 0.el8
Architecture: x86_64
Install Date: ddd MMM DD hh:mm:ss YYYY
Group       : Applications/Databases
Size        : XXX
License     : Fujitsu Limited
Signature   : (none)
Source RPM  : FJSVfsep-client-essential-<x>-<x0z>-0.el8.src.rpm
Build Date  : ddd MMM DD hh:mm:ss YYYY
Build Host  : XXXXXXXXXX
Relocations : /opt/fsepv<x>client64
Packager    : Fujitsu Limited
Vendor      : Fujitsu Limited
URL         : https://www.fujitsu.com
Summary     : Fujitsu Enterprise Postgres Client(64bit) <x>
Description :
Fujitsu Enterprise Postgres Client Essential Package
```

3.3 Uninstallation

This section describes the procedure for uninstalling the Linux client.

Information

If you installed interactive mode/silent mode, uninstall interactive mode/silent mode. Refer to "A.3 Uninstallation" for more information.

3.3.1 Uninstallation RPM Packages

The uninstallation procedure is described below.

1. Stop applications and programs

Before starting the uninstallation, stop the following:

- Applications that use the product
- Connection Manager
- pgBadger
- Pgpool-II
- ldap2pg
- pgBackRest

2. Check the installed product

Check the installed products by following the procedure below.

Example

Displays the name of the installed package.

```
# rpm -qa | grep FJSVfsep
```

For detailed package information, run the following command:

```
# rpm -qi Package Name
```

3. Start the uninstaller

Uninstall all packages for the product to be uninstalled.

Refer to the table in "3.2.2 Installation from RPM Package" for the package set for each product.

The installation directory may remain after uninstallation. Delete them if they are not needed.

```
# rpm -e package name
```

Point

We recommend that you uninstall the packages of the products to be uninstalled in batches for each product.

Example

The following shows an example of uninstalling a client product.

```
# rpm -qa | grep FJSVfsep-client
FJSVfsep-client-essential-*
FJSVfsep-client-core-*
FJSVfsep-client-core-openssl-*
FJSVfsep-client-jdbc-*
FJSVfsep-client-odbc-*
FJSVfsep-client-dotnet-*
FJSVfsep-client-dotnet10-*
FJSVfsep-client-gopgx-*
FJSVfsep-client-conmgr-*
FJSVfsep-client-psycopg-*
# rpm -e FJSVfsep-client-psycopg-<x> FJSVfsep-client-conmgr-<x> FJSVfsep-client-gopgx-
<x> \
FJSVfsep-client-dotnet10-<x> FJSVfsep-client-dotnet-<x> FJSVfsep-client-odbc-<x> \
FJSVfsep-client-jdbc-<x> FJSVfsep-client-core-openssl-<x> FJSVfsep-client-core-<x> \
FJSVfsep-client-essential-<x>
```

*is the version, OS, and so on.

"<x>" indicates the version.

Chapter 4 Setup

This chapter describes the setup procedures to be performed after installation completes.

4.1 Configuring Environment Variables

Configure the following environment variables when using client commands.

4.1.1 Windows

PATH environment variable

Add "*installationFolder*\bin".

PGLOCALEDIR environment variable

Add "*installationFolder*\share\locale".

Examples of environment variable configurations are shown below.

Example

Note that "<*x*>" indicates the product version.

```
> SET PATH=%ProgramFiles%\Fujitsu\fsepv<x>client64\bin;%PATH%
> SET PGLOCALEDIR=%ProgramFiles%\Fujitsu\fsepv<x>client64\share\locale
```

4.1.2 Linux

PATH environment variable

Add "*installationDirectory*/bin".

MANPATH environment variable

Add "*installationDirectory*/share/man".

PGLOCALEDIR environment variable

Add "*installationDirectory*/share/locale".

Examples of environment variable configurations are shown below.

Example

Note that "<*x*>" indicates the product version.

```
$ PATH=/opt/fsepv<x>client64/bin:$PATH ; export PATH
$ MANPATH=/opt/fsepv<x>client64/share/man:$MANPATH ; export MANPATH
$ PGLOCALEDIR=/opt/fsepv<x>client64/share/locale ; export PGLOCALEDIR
```

4.2 Setting Up and Removing OSS

This section explains how to set up OSS supported by Fujitsu Enterprise Postgres.

If you want to use OSS supported by Fujitsu Enterprise Postgres, follow the setup procedure.

If you decide not to use the OSS supported by Fujitsu Enterprise Postgres, follow the removing procedure.

Information

In this section, the applicable database that enables the features of each OSS is described as "postgres".

Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for information on OSS other than those described below.

4.2.1 pgBackRest

This feature is not available for instances created with WebAdmin. It is available only for operation using server commands.

The pg_rman, pgx_dmpall, and pgx_rcvall commands cannot be used when using pgBackRest because of conflicting shell commands to set archive_command.

4.2.1.1 Setting Up pgBackRest

1. Install pgBackRest.

   To use the pgbackrest command on the same host as the Fujitsu Enterprise Postgres server, install pgBackRest using the server program DVD. If you want to use the pgbackrest command on a different host than the Fujitsu Enterprise Postgres server, install pgBackRest using the client program DVD.

2. Set the environment variable PATH for pgBackRest.

   The pgBackRest material is stored under /opt/fsepv<x>pgbackrest. Set the environment variable PATH to the storage location/bin of the pgBackRest material to be used.

   ```
   $ export PATH=/opt/fsepv<x>pgbackrest/bin:$PATH
   ```

3. Perform pgBackRest setup.

   Refer to "User Guides" in the pgBackRest website (https://pgbackrest.org/) for details.

4.2.1.2 Removing pgBackRest

1. Sets parameters in the postgresql.conf file.

   Reverses the information specified during setup

2. Restart Fujitsu Enterprise Postgres.

3. If it was set to perform periodic backups, unset it.

4.2.1.3 Servers to which pgBackRest can Connect

The following table lists server that pgBackRest can connected to.

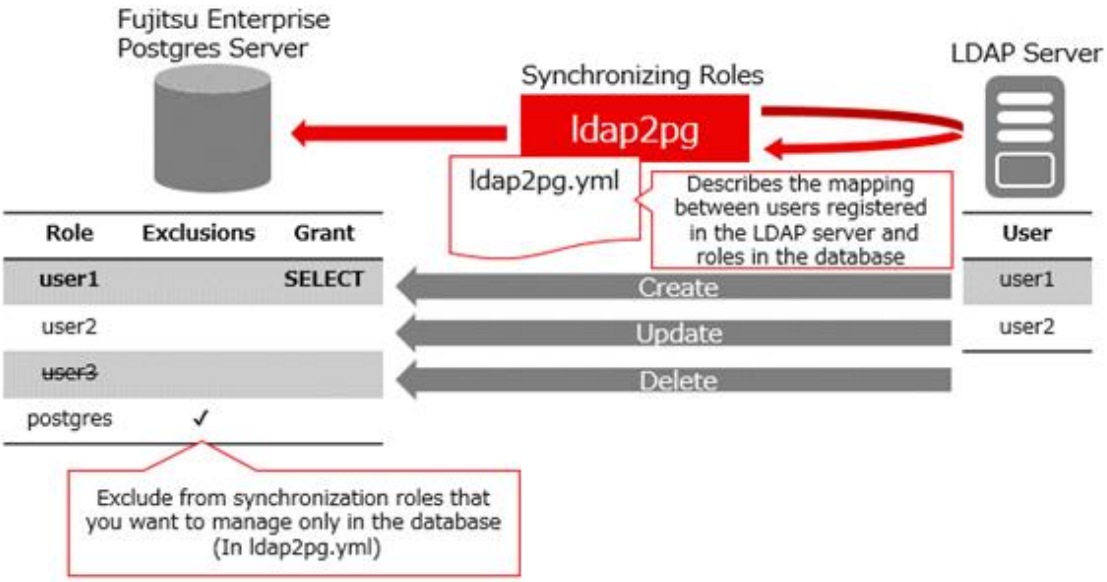
Table 4.1 Connectable server

OS	Product name
Linux	- Fujitsu Enterprise Postgres Advanced Edition 18, or 18 SP1 - Fujitsu Enterprise Postgres Standard Edition 18, or 18 SP1

4.2.2 ldap2pg

PostgreSQL supports LDAP authentication and can be used on both Linux and Windows. You can use an LDAP server to authenticate users, but you must first create a role for the database server.

ldap2pg allows users registered with the LDAP server to be synchronized with Fujitsu Enterprise Postgres roles, so that the above database server roles can be created automatically. This allows you to centrally manage roles on the LDAP server. Note that ldap2pg only supports Linux.



Users registered with the LDAP server and Fujitsu Enterprise Postgres roles are synchronized when the ldap2pg command is executed, based on the ldap2pg.yml that defines these mappings. If a role defined in ldap2pg.yml does not exist in Fujitsu Enterprise Postgres, it is created, and any roles not defined in ldap2pg.yml are removed. Roles that would be difficult to update or delete, such as database administrator roles that do not work with LDAP servers, can be excluded from synchronization by setting them to ldap2pg.yml.

The key points of operation are explained below.

Timing of Synchronization

Synchronize when the LDAP server user changes so that the database server is always up to date. Therefore, you must synchronize periodically to automatically propagate the LDAP server information, or manually propagate it as the LDAP server changes.

If you synchronize periodically, ensure that the synchronization interval is an acceptable time lag before LDAP server changes are propagated to the database server. This is because, even when fully synchronized, ldap2pg accesses the LDAP server and database to check for changes. For example, run the ldap2pg command periodically every 5 minutes or so.

If you use cron, for example, to run automatically on a regular basis, you should log the standard output and standard error output of ldap2pg using settings or redirects such as cron. You can check the log to see if ldap2pg was interrupted or if an unexpected role was removed.

If you want to synchronize immediately or if you want to control the synchronization timing yourself, synchronize manually.

Enhanced Security in Combination with Confidentiality Management

ldap2pg can also manage database privileges, but it cannot manage granular units such as tables and rowsets. Combined with the confidentiality management, which allows such configuration and allows auditing of privilege settings, it provides robust security measures.

For the settings for using ldap2pg in combination with the confidentiality management, refer to "4.2.2.4 Configuration with Confidentiality Management".

4.2.2.1 Setting Up ldap2pg

1. Install ldap2pg
   Install ldap2pg using the client program DVD.

2. Set the environment variable PATH for ldap2pg.

```
$ export PATH=/opt/fsepv<x>ldap2pg/bin:$PATH
```

3. Define a database role on the database server that has superuser privileges as the executor of ldap2pg. For more information about defining roles, refer to "CREATE ROLE" in "Reference" in the PostgreSQL Documentation for information on the CREATE ROLE.

4. Perform ldap2pg setup.
   Refer to "Configuration" or "Cookbook" in the ldap2pg document (https://ldap2pg.readthedocs.io/en/latest/) for details.

5. Set roles that are defined and used only by the database, such as database administrators not managed by an LDAP server, or roles that exclude synchronization, as defined by Fujitsu Enterprise Postgres.
   Add the settings to roles_blacklist_query in the ldap2pg.yml file.

   Fujitsu Enterprise Postgres-specific roles to add:

   - pgx_update_profile_status, and roles that inherit from pgx_update_profile_status (Role for streaming replication of the Policy-based Login Security)
   - pgx_cgroup_role_* (Confidentiality role for the confidentiality management)

When the Database Server is redundant

In a database redundancy environment, specify "primary" for the target_session_attrs parameter. You can also specify "read-write".

4.2.2.2 Removing ldap2pg

1. If you have set ldap2pg to run periodically, unset it.
2. Uninstall ldap2pg. Refer to "3.3 Uninstallation" for more information.
3. If you have defined a role on the database server specifically for running ldap2pg, remove that role.

4.2.2.3 Using ldap2pg to Synchronize Database Roles

Describes how to use ldap2pg to synchronize users of an LDAP server with a database server as database roles.

1. Edit the ldap2pg.yml file, for example if you want to grant access to a role that synchronizes with an LDAP user. For information on ldap2pg.yml, refer to the following document:
   https://ldap2pg.readthedocs.io/en/latest/config/
2. Use environment variables to specify information about the connection destination to the LDAP server or database.
   https://ldap2pg.readthedocs.io/en/latest/cli/#environment-variables
   The user who connects to the database server must be the user created during the setup procedure. Connections to LDAP servers support LDAP-initiated environment variables and ldaprc files, while database access supports PG-initiated environment variables available in libpq. These environment variables are used to configure the connection.
3. Run ldap2pg with the check option to verify that the role being modified matches the role being modified.
4. Run ldap2pg with the --real option to synchronize roles with the database server.
5. Configure LDAP server users and database roles to synchronize periodically after the initial synchronization.
   Prepare the script that sets the environment variables and the script that synchronizes the roles that you performed in steps 2 and 4, and register the script in the cron job so that the script that synchronizes the roles references the environment variables and synchronizes the roles.

[Configuration Examples for cron]

```
SHELL=/bin/bash
*/5 * * * * source /home/postgres/env.sh && . /home/postgres/sample.sh >> /home/postgres/
sample.log 2>&1
```

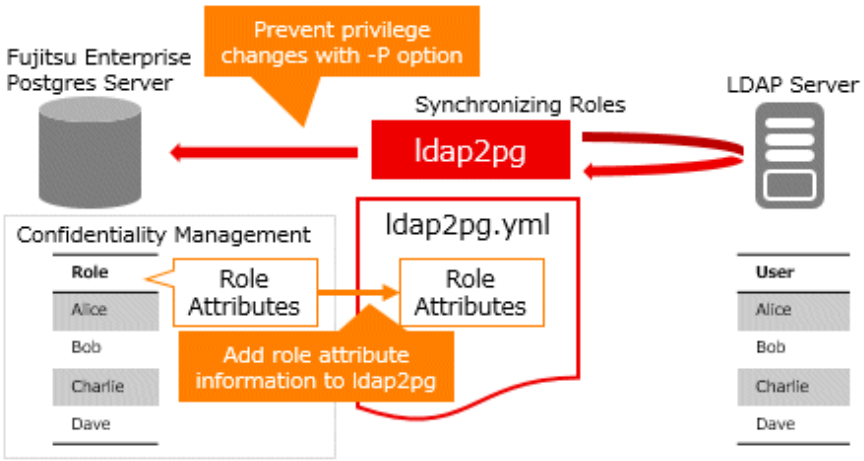
4.2.2.4 Configuration with Confidentiality Management

It combines ldap2pg with confidentiality management to provide detailed access control. There is overlap between the role management capabilities of ldap2pg and the confidentiality management. When used in combination, use ldap2pg and confidentiality management to separate role management:

Feature	Role Management Segregation
ldap2pg	Add, remove, and managing role membership
Confidentiality Management	Set role attributes, grant and revoke privileges, and audit them

To separate role management between ldap2pg and confidentiality management, do the following:

- Add attribute information for confidentiality management roles to the ldap2pg configuration file (ldap2pg.yml) so that the attributes of roles set for confidentiality management are not updated by running ldap2pg
- Run ldap2pg with the -P option to prevent deletion of confidentiality groups and role relationships in the confidentiality management when ldap2pg is run.



The configuration flow for ldap2pg combined with the confidentiality management is as follows.

Introduction

Configure the necessary settings to run ldap2pg as described in the following procedure.

1. Design user-role mappings on the LDAP server to create a list of roles that should be managed by the confidentiality management.
2. To create an yml file:
    a. Specify the settings for retrieving and synchronizing the listed objects from the LDAP server.
    b. Write a confidentiality management role starting with pgx_cgroup_role_ in roles_blacklist_query.
    c. Ensure that the grant and revoke privileges settings are not listed in the yml file.
3. Stop synchronization if it is already running using ldap2pg.
4. Create a role as described in "4.2.2.3 Using ldap2pg to Synchronize Database Roles".
5. Refer to "Confidentiality Management" in the "Security Operations Guide" and perform all necessary tasks.
   During this process, all the roles in the list of roles are registered in the confidentiality groups of the confidentiality management.

6. Modify the yml file so that ldap2pg does not update the attributes of the roles you have confidentiality management. Refer to "Settings When You Change the Attributes or Privileges of a role in a Confidentiality Groups" for a sample script that prints an yml file.
7. If you have already done regular synchronization using ldap2pg, try again.

Operation

Use the following procedure to manipulate roles according to your situation.

Adding an ldap2pg Role to a Confidentiality Groups

1. Creates a confidentiality management confidentiality groups.
2. Run ldap2pg with the -P option to create the LDAP server user as a database role.
3. Add the role you added above to the confidentiality groups.
4. Reflect the confidentiality management configuration in ldap2pg.yml, referring to the "Example of Applying Role Attributes".

Example of Applying Role Attributes

1. Use the following example to execute SQL and retrieve the settings for each role:
   For all roles, this example retrieves the LOGIN attribute, the role attributes of the confidentiality management, and the membership of the confidentiality management role. If you want to change the settings to suit your environment, rewrite the SQL, such as modifying the 'LOGIN' part of the SQL Execution Example, or modify the Example of Run Results directly.

   [SQL Execution Example]

```
SELECT '- name: ' ||pgxgr.name || chr(10) || '  options: ' || pgxgr.opt ||
chr(10) ||  '  parent: ' || chr(10) || '    - '  ||
string_agg(pgxgr.cgrorolename, chr(10) || '    - ')
FROM  (SELECT pgxg.cgrorolename,
        concat_ws(' ',
        'LOGIN',
        CASE pgxg.cgrosuperuser WHEN true THEN 'SUPERUSER' END,
        CASE pgxg.cgrocreatedb WHEN true THEN 'CREATEDB' END,
        CASE pgxg.cgrocreaterole WHEN true THEN 'CREATEROLE' END,
        CASE pgxg.cgroreplication WHEN true THEN 'REPLICATION' END,
        CASE pgxg.cgrobypassrls WHEN true THEN 'BYPASSRLS' END) AS opt,
        pgxroles.name
      FROM pgx_confidential_group pgxg,
     (SELECT pgxr.crolmatid as matid, pgxr.crolgroid as groid,  pgxr.crolname
AS name FROM pgx_confidential_role pgxr ) as pgxroles
      WHERE pgxg.cgromatid = pgxroles.matid and pgxg.cgroid = pgxroles.groid)
pgxgr
GROUP BY pgxgr.name, pgxgr.opt;
```

   [Example of Run Results]

```
- name: alice
    options: LOGIN CREATEDB
   parent:
    - pgx_cgroup_role_000000000000000001
- name: bob
   options: LOGIN CREATEDB
   parent:
    - pgx_cgroup_role_000000000000000001
- name: charlie
   options: LOGIN CREATEDB CREATEROLE
   parent:
    - pgx_cgroup_role_000000000000000002
- name: dave
```

```
  options: LOGIN CREATEDB CREATEROLE
  parent:
   - pgx_cgroup_role_000000000000000002
```

2. Put the setting of roles at the top of the rules in ldap2pg.yml based on the information in the above settings. If it is not at the top, the configuration information that synchronizes with the LDAP server takes effect, and the confidentiality management configuration does not take effect.

Settings When You Change the Attributes or Privileges of a role in a Confidentiality Groups

1. Confidentiality management modifies role attributes and privileges information.
2. Create a script to retrieve the confidentiality management configuration information and register it in a cron job so that the changed information is automatically reflected in the yml file.
   The following is an example shell script:.
   Please change the settings to suit your environment.
   The shell script shown here consists of two configuration files, ldap2pg_pre.yml and ldap2pg_after.yml, and the confidentiality management configuration information (In the sample, it is output to confidential_roles.yml) that is reflected in yml. Combine these three files to create the ldap2pg.yml file.
   ldap2pg_pre.yml is the information to be placed before the confidentiality management configuration information in ldap2pg.yml, and contains the postgres section and up to "roles:" in the rules section. ldap2pg_after.yml is information to be placed after tthe confidentiality management configuration information in ldap2pg.yml, and contains information about roles not managed by the confidentiality management.

   [Example of Shell Script]

   ldap2pg_pre.yml : Provides information about the postgres section

```
version: 6

#
#       1.   P O S T G R E S   I N S P E C T I O N
#
#  See https://ldap2pg.readthedocs.io/en/latest/postgres/
#
postgres:
# Exclude roles starting with postgres, pg that PostgreSQL uses internally
  roles_blacklist_query: [postgres, pg_*, pgx_update_profile_status,
pgx_cgroup_role* ]
  databases_query: [postgres]
(Omitted)
rules:
- description: "Setup static roles and grants."
  roles:
```

   ldap2pg_after.yml : Provides information about roles that are not part of the confidentiality groups

```
  - names:
    - readers
    options: NOLOGIN
  - name: writers
    # Grant reading to writers
    parent: [readers]
    options: NOLOGIN
(Omitted)
```

   sample.sh : A script that outputs information about confidentiality groups to confidential_roles.yml and combines them into a single yml file

```
#!/bin/bash
```

```
psql -h localhost -p 27500 -d postgres -U postgres -A -t <<EOF > /home/postgres/
confidential_roles.yml
SELECT '  - name: ' ||pgxgr.name || chr(10) || '    options: ' || pgxgr.opt ||
chr(10) ||  '    parent: ' || chr(10) || '    - '  || string_agg(pgxgr.cgrorolename,
chr(10) || '    - ')
FROM  (SELECT pgxg.cgrorolename,
        concat_ws(' ',
        'LOGIN',
        CASE pgxg.cgrosuperuser WHEN true THEN 'SUPERUSER' END,
        CASE pgxg.cgrocreatedb WHEN true THEN 'CREATEDB' END,
        CASE pgxg.cgrocreaterole WHEN true THEN 'CREATEROLE' END,
        CASE pgxg.cgroreplication WHEN true THEN 'REPLICATION' END,
        CASE pgxg.cgrobypassrls WHEN true THEN 'BYPASSRLS' END) AS opt,
        pgxroles.name
      FROM pgx_confidential_group pgxg,
      (SELECT pgxr.crolmatid as matid, pgxr.crolgroid as groid,  pgxr.crolname AS
name FROM
pgx_confidential_role pgxr ) as pgxroles
      WHERE pgxg.cgromatid = pgxroles.matid and pgxg.cgroid = pgxroles.groid) pgxgr
GROUP BY pgxgr.name, pgxgr.opt;
EOF
cat /home/postgres/ldap2pg_pre.yml /home/postgres/confidential_roles.yml /home/
postgres/ldap2pg_after.yml > /home/postgres/ldap2pg.yml

#Run  ldap2pg -P -c ldap2pg.yml to update retrieved role information
```

Information

If you want to manually apply the attribute or privilege information of a role that has been changed in confidentiality management to ldap2pg.yml, obtain the change information and apply it to ldap2pg.yml, referring to "Example of Applying Role Attributes".

Adding Roles Created with ldap2pg to a Confidentiality Groups

1. Create a role to add to the confidentiality groups in ldap2pg.
2. Add the database role you created in step 1 to the existing confidentiality groups.
3. Reflect the newly added role's confidentiality management settings in ldap2pg.yml, as shown in "Example of Applying Role Attributes".

Information

If cron automatically reflects changes to the confidentiality groups in ldap2pg.yml, stop cron and add the newly added database role to the confidentiality groups.

Removing Roles Added in ldap2pg from a Confidentiality Groups

1. Remove the role you want to remove from the confidentiality groups.
2. Reflect changes to confidentiality management in ldap2pg.yml, referring to "Example of Applying Role Attributes".
3. Execute ldap2pg with the -P option to reflect.

Point

If you deleted the confidentiality matrix and the confidentiality groups, perform steps 2 and 3 above.

See

- If you accidentally delete a role managed by confidentiality management using the ldap2pg, refer to "How to Check Confidentiality Objects and Roles" in the Security Operation Guide to recover the role managed by confidentiality management.
- If you accidentally delete the confidentiality role in ldap2pg, refer to "Creating a Confidentiality Management Role" in the Security Operations Guide to recover.

4.2.2.5 Servers to which ldap2pg can Connect

The following table lists server that ldap2pg can connected to.

Table 4.2 Connectable server

OS	Product name
Linux	- Fujitsu Enterprise Postgres Advanced Edition 18, or 18 SP1 - Fujitsu Enterprise Postgres Standard Edition 18, or 18 SP1

Appendix A Installation and Uninstallation of the Linux Client (Compatibility)

This chapter explains how to install and uninstall (interactive mode/silent mode) the Linux client.

A.1 Operating Environment

This section describes the operating environment required to use the Linux client.

A.1.1 Packages Required for RHEL8

In addition to the "3.1.1.1 Packages Required for RHEL8", you need:

Package name	Remarks
glibc.i686	Required by installer.
redhat-lsb	Required by installer.
sudo	Required by installer.

A.1.2 Packages Required for RHEL9

In addition to the "3.1.1.2 Packages Required for RHEL9", you need:

Package name	Remarks
glibc.i686	Required by installer.
sudo	Required by installer.

A.1.3 Packages Required for SLES 15

In addition to the "3.1.1.3 Packages Required for SLES 15", you need:

Package name	Remarks
JRE 8	Required by installer. The following JREs are available: - Oracle JRE Use the 64-bit version. - OpenJDK Past the Java TCK (Technology Compatibility Kit)
libstdc++6-32bit	Required for silent installation.
sudo	Required by installer.

A.1.4 Disk Space Required for Installation

The following table lists the disk space requirements of the corresponding directories for new installation of the Linux client. If necessary, increase the size of the file system.

Disk space required for installation

Table A.1 RHEL

Directory	Required disk space Unit: MB
/etc	1 + 1 (*1)

Directory	Required disk space Unit: MB
/var	1 + 2 (*1)
/opt	300 (*1)
Installation destination of the client (64-bit)	220
Installation destination of Pgpool-II	40
Installation destination of ldap2pg	30
Installation destination of pgBackRest	40

*1: Uninstall (middleware) must be installed.

Table A.2 SLES

Directory	Required disk space Unit: MB
/etc	1 + 1 (*1)
/var	1 + 2 (*1)
/opt	10 (*1)
Installation destination of the client (64-bit)	210
Installation destination of Pgpool-II	40
Installation destination of ldap2pg	30
Installation destination of pgBackRest	40

*1: Uninstall (middleware) must be installed.

A.2 Installation

This section explains how to install the Linux client.

If you have antivirus software installed, the server may crash, fail to start, or stop responding, during installation or when starting up after installation. Set scan exception settings for the installation directory and resource allocation directory so that the files in these directories are not scanned for viruses.

A.2.1 Pre-installation Tasks

Check the system environment for the following before the Linux client is installed.

Check the disk capacity

Check if sufficient free disk space is available for installing the Linux client.

Refer to "A.1.4 Disk Space Required for Installation" for information on disk space requirements.

If sufficient free disk space is unavailable, reconfigure disk partitions.

Set JAVA_HOME (SLES only)

Ensure that JRE 8 is installed, and export the JAVA_HOME environment variable.

```
#export JAVA_HOME="Jre8InstallDir"
```

Executable Users

Installation and uninstallation is performed by superuser.

On the system, run the following command to become superuser.

```
$ su -
Password:******
```

Check the installed product and determine the installation method

Using the operation shown below, start Uninstall (middleware), and check the installed products.

Example

```
# /opt/FJSVcir/cimanager.sh -c
Loading Uninstaller...

Currently installed products
1. productName
2. productName

Type [number] to select the software you want to uninstall.
[number,q]
=>q

Exiting Uninstaller.
```

If the Linux client is already installed, determine the installation method to use:

- Reinstallation
- Multi-version installation

Remove applied updates(For Reinstallation)

Use the following procedure to remove applied fixes.

If you install the product without removing the fix, you will apply the same version of the fix with the same fix number, resulting in an error that has already been applied. Remove the fix and then reinstall.

1. Checking the environment variable LD_LIBRARY_PATH

   If the installation directory/lib is set in the environment variable LD_LIBRARY_PATH for the running user, remove the installation directory/lib from LD_LIBRARY_PATH.

2. Display the applied updates

   Execute the following command to display the applied updates:

   ```
   # /opt/FJSVfupde/bin/uam showup
   ```

3. Remove the updates

   Execute the command below to remove the updates. If an update with the same update number was applied more than once, the updates are removed in order, starting from the highest version number.

   ```
   # /opt/FJSVfupde/bin/uam remove -i update-number
   ```

A.2.2 Installation in Interactive Mode

The installation procedure is described below.

Point

- The following characters can be used as input values:

  Alphanumeric characters, hyphens, commas and forward slashes

- For installation in interactive mode, default values are set for the installation information. The following settings can be changed for a new installation or a multi-version installation:

  - Installation directory

1. Stop applications and programs

Reinstallation requires stopping applications and programs.

Before starting the installation, stop the following:

- Applications that use the product
- Connection Manager
- pgBadger
- Pgpool-II
- ldap2pg
- pgBackRest

2. Mount the DVD drive

Insert the client program DVD into the DVD drive, and then execute the following command:

Example

```
# mount -t iso9660 -r -o loop /dev/dvd /media/dvd
```

Here /dev/dvd is the device name for the DVD drive (which may vary depending on your environment), and /media/dvd is the mount point (which may need to be created before calling the command).

If the DVD was mounted automatically using the automatic mount daemon (autofs), "noexec" is set as the mount option, so the installer may fail to start. In this case, use the mount command to remount the DVD correctly, and then run the installation. Note that the mount options of a mounted DVD can be checked by executing the mount command without any arguments.

3. Run the installation

Execute the following command:

Example

```
# cd /media/dvd
# ./install.sh
```

In the example above, /media/dvd is the DVD mount point.

4. Select the product to install

The list of installation target products is displayed.
Type the number for the product to be installed, or "all", and press Enter.

Information

If the selected product has already been installed, a window for selecting reinstallation or multi-version installation is displayed for each product. Follow the on-screen instructions to select the installation method.

5. Check the settings

The window for checking the installation information is displayed as shown below.
Type "y" and press Enter to start the installation.
To change the settings, type "c" and press Enter, and follow the on-screen instructions. This option is not displayed if there is no information that can be modified.

6. Check the changed settings

If the installation information has been modified, the new installation information is displayed.
Type "y" and press Enter to start the installation.
To change the settings again, type "c" and press Enter.

7. Finish the installation

When the installation is complete, a message is displayed showing the status.
If installation was successful, the following message is displayed:

```
Installed successfully.
```

If an error occurs during the installation, read the error message and remove the cause of the error, and then reexecute the install.sh command.

A.2.3 Installation in Silent Mode

Installation in silent mode can be performed only when the installation method is one of the following:

- New installation
- Multi-version installation

See

Refer to the Fujitsu Enterprise Postgres product website for information on installation in silent mode, such as the installation parameters and error messages.

The installation procedure is described below.

1. Mount the DVD drive

Insert the client program DVD into the DVD drive, and then execute the following command:

Example

```
# mount -t iso9660 -r -o loop /dev/dvd /media/dvd
```

Here /dev/dvd is the device name for the DVD drive (which may vary depending on your environment), and /media/dvd is the mount point (which may need to be created before calling the command).

If the DVD was mounted automatically using the automatic mount daemon (autofs), "noexec" is set as the mount option, so the installer may fail to start. In this case, use the mount command to remount the DVD correctly, and then run the installation. Note that the mount options of a mounted DVD can be checked by executing the mount command without any arguments.

2. Create an installation parameters CSV file

Consider the features that will be required for system operations, and then create an installation parameters CSV file that uses the following specification format.

```
sectionName, parameterName, value
sectionName, parameterName, value
    :
```

Information

The templates for the installation parameters CSV file is "*mountPoint*/sample/sample_linux.csv"

3. Run the installation

Execute the following command:

Example

```
# cd /media/dvd
# ./silent.sh /home/work/inspara.csv
```

In the example above, /media/dvd is the DVD mount point, and /home/work/inspara.csv is the installation parameter CSV.

If the silent installer ends in an error, a message is output to the log file and return values are returned.

A.3 Uninstallation

This section describes the procedure for uninstalling the Linux client.

Point

On SLES, before uninstallation, ensure that JRE 8 is installed, and export the JAVA_HOME environment variable.

```
#export JAVA_HOME="Jre8InstallDir"
```

A.3.1 Uninstallation in Interactive Mode

The uninstallation procedure is described below.

If an error occurs while the product is being uninstalled, refer to "Uninstall (middleware) Messages" in the Fujitsu Enterprise Postgres product website, and take the required action.

1. Stop applications and programs

Before starting the uninstallation, stop the following:

- Applications that use the product
- Connection Manager
- pgBadger
- Pgpool-II
- ldap2pg
- pgBackRest

2. Start the Uninstall (middleware)

Execute the following command:

```
# /opt/FJSVcir/cimanager.sh -c
```

3. Select the product

Enter the number for the product to be uninstalled, and press Enter.

4. Start the uninstallation

To start the uninstallation, type "y" and press Enter.

To display the list of products again, type "b" and press Enter.

5. Finish the uninstallation

If uninstallation is successful, the message below is displayed.

The installation directory may remain after uninstallation. If it is not required, delete it.

```
Uninstalling...

productName is being uninstalled now.
    100% ##############################

The following products have been uninstalled successfully:
    productName

Uninstallation of "productName" has completed successfully.

Exiting Uninstaller.
```

A.3.2 Uninstallation in Silent Mode

The uninstallation procedure is described below.

Refer to the Fujitsu Enterprise Postgres product website for information on uninstallation in silent mode, such as the error messages.

1. Stop applications and programs

Before starting the uninstallation, stop the following:

- Applications that use the product
- Connection Manager
- pgBadger
- Pgpool-II
- ldap2pg
- pgBackRest

2. Run the uninstallation

Execute the following command:

The installation directory may remain after uninstallation. If it is not required, delete it.

Example

```
# /opt/fsepv<x>client64/setup/suninst.sh
```

In the example above, /opt/fsepv<*x*>client64 is the installation directory, and "<*x*>" indicates the product version.

```
# /opt/fsepv<x>pgpool-II/setup/suninst.sh
```

In the example above, /opt/fsepv<*x*>pgpool-II/setup is the name of the installation directory in which the Pgpool-II is installed.

```
# /opt/fsepv<x>ldap2pg/setup/suninst.sh
```

In the example above, /opt/fsepv<*x*>ldap2pg/setup is the name of the installation directory in which the ldap2pg is installed.

```
# /opt/fsepv<x>pgbackrest/setup/suninst.sh
```

In the example above, /opt/fsepv<x>pgbackrest/setup is the name of the installation directory in which the pgBackRest is installed.

Installation and Setup Guide for Server Assistant

Windows/Linux

J2UL-3079-02ENZ0(00)

March-2026

Preface

Purpose of this document

This document describes how to install and uninstall the Fujitsu Enterprise Postgres Server Assistant.

Intended readers

This document is intended for those who install and operate Fujitsu Enterprise Postgres.

Readers of this document are assumed to have general knowledge of:

L
- PostgreSQL
- SQL
- Linux

W
- PostgreSQL
- SQL
- Windows

Structure of this document

This document is structured as follows:

Chapter 1 Overview of Installation

Describes the features that can be installed, and provides an overview of installation methods

Chapter 2 Installation and Uninstallation of the Linux Server Assistant

Describes how to install and uninstall the Linux Server Assistant

Chapter 3 Installation and Uninstallation of the Windows Server Assistant

Describes how to install and uninstall the Windows Server Assistant

Chapter 4 Setup of the Server Assistant

Describes the setup to be performed after installation

Appendix A Estimating Memory Requirements

Describes the formulas for estimating memory requirements

Appendix B Collecting Failure Investigation Data

Explains how to collect data for initial investigation.

Appendix C Installation and Uninstallation of the Linux Server Assistant (Compatibility)

Describes how to install (interactive mode/silent mode) the Fujitsu Enterprise Postgres server assistant feature.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Index 29

Chapter 1 Overview of Installation

This chapter provides an overview of Fujitsu Enterprise Postgres Server Assistant installation and uninstallation.

1.1 Features that can be Installed

The Server Assistant is installed on a different server (referred to as the arbitration server) to that of the database server.

The following table shows the relationship between the platforms and the features provided.

Platform	Server Assistant
Linux	Y
Windows	Y

Y: Can be installed

Chapter 2 Installation and Uninstallation of the Linux Server Assistant

This chapter explains how to install and uninstall the Linux Server Assistant.

2.1 Operating Environment

This section describes the operating environment required in order to use the Linux Server Assistant.

2.1.1 Required Operating System

One of the following operating systems is required in order to use the Linux Server Assistant:

- RHEL8.6 or later minor version
- RHEL9.2 or later minor version
- SLES 15 SP4 or later minor version

2.1.1.1 Packages Required for RHEL8

The following packages are required for operations on RHEL8.

Package name	Remarks
glibc	-
iputils	Required for Mirroring Controller.
libgcc	-
libstdc++	-
ncurses-libs	-
nss-softokn-freebl	-
rsync	Required when using Pgpool-II.
unzip	-
xz-libs	-
zlib	-

2.1.1.2 Packages Required for RHEL9

The following packages are required for operations on RHEL9.

Package name	Remarks
glibc	-
iputils	Required when using Mirroring Controller.
libgcc	-
libstdc++	-
ncurses-libs	-
nss-softokn-freebl	-
rsync	Required to use Pgpool-II.
unzip	-
xz-libs	-

Package name	Remarks
zlib	-

2.1.1.3 Packages Required for SLES 15

The following packages are required for operations on SLES 15.

Package name	Remarks
gdb	-
glibc	-
glibc-32bit	-
iputils	Required for Mirroring Controller.
JRE 8	The following JREs are available: - Oracle JRE Use the 64-bit version. - OpenJDK Past the Java TCK (Technology Compatibility Kit)
libfreebl3	-
libgcc	-
libltdl7	-
liblzma5	-
libncurses5	-
libstdc++6	-
libz1	-
rsync	Required when using Pgpool-II.
sysstat	Set up the sar command after installation.
unzip	-

2.1.2 Related Software

No other software is required in order to use Fujitsu Enterprise Postgres.

The following table lists servers that can be connected to the Linux Server Assistant.

Table 2.1 Connectable servers

OS	Software name
Linux	Fujitsu Enterprise Postgres Advanced Edition 18, or 18 SP1
Windows	Fujitsu Enterprise Postgres Advanced Edition 18, or 18 SP1

2.1.3 Excluded Software

There is no excluded software.

2.1.4 Required Patches

There are no required patches.

2.1.5 Hardware Environment

The following hardware is required in order to use the Linux Server Assistant:

Memory

At least 150 MB of memory is required.

Mandatory hardware

None.

2.1.6 Disk Space Required for Installation

The following table lists the disk space requirements of the corresponding directories for new installation of the Linux Server Assistant. If necessary, increase the size of the file system.

Disk space required for installation

Table 2.2 RHEL

Directory	Required disk space Unit: MB
/etc	1
/var	1
serverAssistantInstallDir	390

Table 2.3 SLES

Directory	Required disk space Unit: MB
/etc	1
/var	1
serverAssistantInstallDir	110

2.1.7 Supported System Environment

This section describes the supported system environment.

TCP/IP Protocol

Fujitsu Enterprise Postgres supports version 4 and 6 (IPv4 and IPv6) of TCP/IP protocols.

Do not use link-local addresses if TCP/IP protocol version 6 addresses are used.

2.2 Installation

This section describes how to install the Linux Server Assistant.

Note

If you have antivirus software installed, the server may crash, fail to start, or stop responding, during installation or when starting up after installation. Set scan exception settings for the installation directory and resource allocation directory so that the files in these directories are not scanned for viruses.

2.2.1 Pre-installation Tasks

Check the following system environment before installing the Linux Server Assistant.

Check the disk space

Ensure that there is sufficient disk space to install the Linux Server Assistant.

Refer to "2.1.6 Disk Space Required for Installation" for information on disk space requirements.

If sufficient free disk space is unavailable, reconfigure disk partitions.

Executable Users

Installation and uninstallation is performed by superuser.

On the system, run the following command to become superuser.

```
$ su -
Password:******
```

2.2.2 Installation from RPM Package

The installation procedure is described below.

1. Stop the program

Reinstallation requires stopping applications and programs.

Before starting the installation, stop the following:

- Mirroring Controller arbitration process

  Execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

  Example

  ```
  $ mc_arb stop -M /mcarb_dir/arbiter1
  ```

2. Mount the DVD drive

Insert the Server Assistant program DVD into the DVD drive, and then execute the following command:

Example

```
# mount -t iso9660 -r -o loop /dev/dvd /media/dvd
```

Here /dev/dvd is the device name for the DVD drive (which may vary depending on your environment), and /media/dvd is the mount point (which may need to be created before calling the command).

3. Run the installation

The RPM packages required to install each product are stored under the mount point where you mounted the DVD.

The following shows a list of packages and the path of the storage directory.

Install all packages for the product you are installing.

Product name	Package storage directory	Package name
Server Assistant	ASSISTANT/Linux/packages/<*os*>	FJSVfsep-assistant-*.rpm

<os> is the OS of the operating environment. Depending on your system requirements, refer to RHEL8, RHEL9, or SLES15.

*is the detailed name of the package, version, OS, etc.

The default installation directory names are:

To specify a path different from the default installation directory, you can use the following characters:

[a-zA-Z0-9], -,, and /

Product name	Installation directory name (default)
Server Assistant	/opt/fsepv<*x*>assistant

"<x>" is the product version.

Point

We recommend that you install the packages for each product in a batch.

You can use "*" to specify a package name, or you can install all packages in a batch by specifying all package names side by side.

Example

To install the server assistant product in a RHEL8 environment, run the following command:

```
# cd /media/dvd/ASSISTANT/Linux/packages/RHEL8
# rpm -ivh FJSVfsep-assistant-*.rpm
```

Use --prefix to specify a path different from the default installation directory.

4. Check the installed product

Check the installed products by following the procedure below.

Example

Displays the name of the installed package.

```
# rpm -qa | grep FJSVfsep
```

For detailed package information, run the following command:

```
# rpm -qi package name
```

Example

In the path, "<x>" and "<x0z>" refer to the x and z of x SPz, which is expressed as the product version. For products without SPz, <x0z> is <x00>.

```
# rpm -qi FJSVfsep-assistant-essential-<x>-<x0z>-0.el8.x86_64
Name        : FJSVfsep-assistant-essential-<x>
Version     : <x0z>
Release     : 0.el8
Architecture: x86_64
Install Date: ddd MMM DD hh:mm:ss YYYY
Group       : Applications/Databases
Size        : XXX
License     : Fujitsu Limited
Signature   : (none)
Source RPM  : FJSVfsep-assistant-essential-<x>-<x0z>-0.el8.src.rpm
Build Date  : ddd MMM DD hh:mm:ss YYYY
Build Host  : XXXXXXXXXX
Relocations : /opt/fsepv<x>assistant
Packager    : Fujitsu Limited
Vendor      : Fujitsu Limited
URL         : https://www.fujitsu.com
Summary     : Fujitsu Enterprise Postgres Server Assistant <x>
```

```
Description :
Fujitsu Enterprise Postgres Server Assistant Essential Package
```

2.3 Uninstallation

This section describes how to uninstall the Linux Server Assistant.

Information

If you installed interactive mode/silent mode, uninstall interactive mode/silent mode. Refer to "C.3 Uninstallation" for more information.

2.3.1 Uninstallation RPM Packages

The uninstallation procedure is described below.

1. Stop the program

Before starting the uninstallation, stop the following:

- Mirroring Controller arbitration process

  Execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

  Example

```
$ mc_arb stop -M /mcarb_dir/arbiter1
```

2. Check the installed product

Check the installed products by following the procedure below.

Example

Displays the name of the installed package.

```
# rpm -qa | grep FJSVfsep
```

For detailed package information, run the following command:

```
# rpm -qi Package Name
```

3. Start the uninstaller

Uninstall all packages for the product to be uninstalled.

Refer to the table in "2.2.2 Installation from RPM Package" for the package set for each product.

The installation directory may remain after uninstallation. Delete them if they are not needed.

```
# rpm -e package name
```

Point

We recommend that you uninstall the packages of the products to be uninstalled in batches for each product.

Example

The following shows an example of uninstalling a server assistant product.

```
# rpm -qa | grep FJSVfsep-assistant
FJSVfsep-assistant-essential-*
FJSVfsep-assistant-core-*
FJSVfsep-assistant-openjdk-*
# rpm -e FJSVfsep-assistant-openjdk-<x> FJSVfsep-assistant-core-<x> FJSVfsep-assistant-
essential-<x>
```

*is the version, OS, and so on.

"<x>" indicates the version.

Chapter 3 Installation and Uninstallation of the Windows Server Assistant

This chapter explains how to install and uninstall the Windows Server Assistant.

3.1 Operating Environment

This section describes the operating environment required in order to use the Windows Server Assistant.

3.1.1 Required Operating System

One of the following operating systems is required in order to use the Windows Server Assistant:

Table 3.1 Operating systems

Operating system name
- Microsoft(R) Windows Server(R) 2016 Datacenter - Microsoft(R) Windows Server(R) 2016 Standard - Microsoft(R) Windows Server(R) 2016 Essentials
- Microsoft(R) Windows Server(R) 2019 Datacenter - Microsoft(R) Windows Server(R) 2019 Standard - Microsoft(R) Windows Server(R) 2019 Essentials
- Microsoft(R) Windows Server(R) 2022 Datacenter - Microsoft(R) Windows Server(R) 2022 Standard - Microsoft(R) Windows Server(R) 2022 Essentials
- Microsoft(R) Windows Server(R) 2025 Datacenter - Microsoft(R) Windows Server(R) 2025 Standard - Microsoft(R) Windows Server(R) 2025 Essentials

The following features of Windows Server(R) 2016, Windows Server(R) 2019, Windows Server(R) 2022 and Windows Server(R) 2025 are not supported:

- Server Core
- Nano Server
- Windows Server Container

3.1.2 Related Software

There is no software related to Fujitsu Enterprise Postgres.

The following programs are installed during installation of Fujitsu Enterprise Postgres. Do not uninstall it because it is required for Fujitsu Enterprise Postgres to work.

- Microsoft Visual C++ 2015-2022 Redistributable version 14.44.35211.0

The following table lists servers that can be connected to the Windows Server Assistant.

Table 3.2 Connectable servers

OS	Software name
Linux	Fujitsu Enterprise Postgres Advanced Edition 18, or 18 SP1
Windows	Fujitsu Enterprise Postgres Advanced Edition 18, or 18 SP1

3.1.3 Excluded Software

There is no excluded software.

3.1.4 Required Patches

There are no required patches.

3.1.5 Hardware Environment

The following hardware is required in order to use the Windows Server Assistant:

Memory

At least 256 MB of memory is required.

Mandatory hardware

None.

3.1.6 Disk Space Required for Installation

The disk space shown below is required for new installation of the Windows Server Assistant.

Windows Server Assistant installation destination:

440 MB

Windows system drive:

350 MB

3.1.7 Supported System Environment

This section describes the supported system environment.

TCP/IP protocol

Fujitsu Enterprise Postgres supports version 4 and 6 (IPv4 and IPv6) of TCP/IP protocols.

Do not use link-local addresses if TCP/IP protocol version 6 addresses are used.

File system

You can install Fujitsu Enterprise Postgres only if the system folder is an NTFS volume.

3.2 Installation

This section describes how to install the Windows Server Assistant.

Note

If antivirus software is installed, the system may crash, fail to start, or stop responding during installation or when starting after installation. Set the scan exclusions so that the installation directory and the resource allocation directory are not scanned for viruses.

3.2.1 Pre-installation Tasks

This section describes the tasks to be performed before installing the Windows Server Assistant.

Check the disk space

Ensure that there is sufficient disk space to install the Windows Server Assistant.

Refer to "3.1.6 Disk Space Required for Installation" for information on disk space requirements.

hosts file settings

Using an editor, add the IP address and name of the server to be connected to the \System32\drivers\etc\hosts file in the folder where Windows is installed.

Check the installed product and determine the installation method

In [Start] menu, click [All apps], then [Fujitsu], and then [Uninstall (middleware)]. In the displayed window, check the installed products.

If the Windows Server Assistant is already installed, determine the installation method to use:

- Reinstallation
- Multi-version installation

The shortcuts displayed on the [Start] menu might be arranged differently depending on the operating system.

Remove applied updates(For Reinstallation)

Use the following procedure to remove applied fixes.

If you install the product without removing the fix, you will apply the same version of the fix with the same fix number, resulting in an error that has already been applied. Remove the fix and then reinstall.

1. Display the applied updates

   Execute the following command to display the applied updates:

```
C:\>uam showup
```

2. Remove the updates

   Execute the command below to remove the updates. If an update with the same update number was applied more than once, the updates are removed in order, starting from the highest version number.

```
C:\>uam remove -i update-number
```

Confirm service

The Windows Installer service must be running.

3.2.2 Pre-installation Considerations

- The remote desktop service is installed in application server mode, it is necessary to switch to install mode by executing the command shown below before installation. Also, after the installation is completed, execute the command shown below to switch back to execute mode.

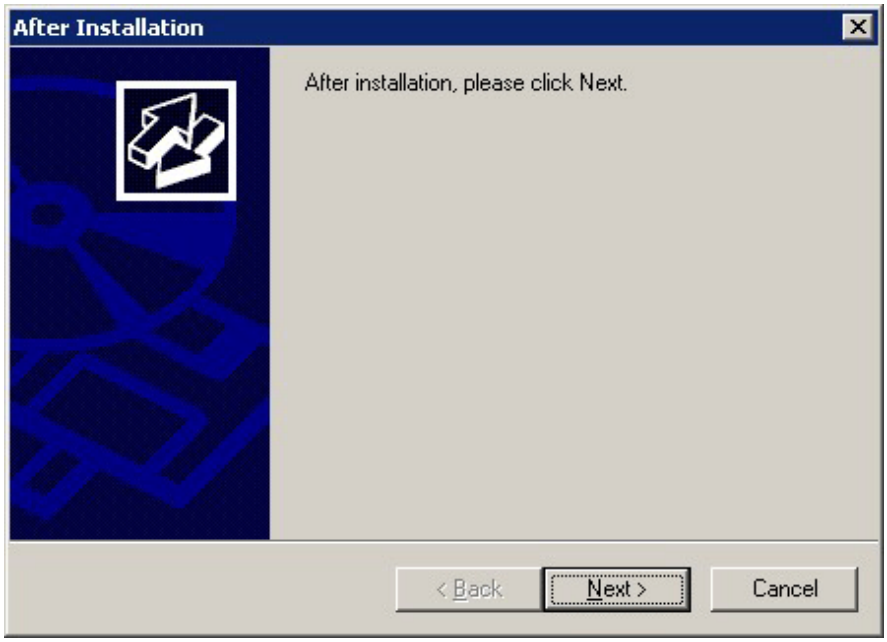
  [Before the installation]

```
CHANGE USER /INSTALL
```

  [After the installation]

```
CHANGE USER /EXECUTE
```

- The following window may be displayed when executing the installation program:



If this window is displayed, perform the following operations:

1. Perform the installation steps until the [InstallShield Wizard Complete] window is displayed.
2. At the window shown above, click [Next].
3. The window shown below is displayed. Click [Finish].

Information

- If a [User Account Control] dialog box is displayed at the start of the installation, click [Yes] to continue processing:

  If [No] is clicked, permission to continue is denied and an [Error] dialog box will be displayed.
  To continue the installation, click [Retry] at the [Error] dialog box. To end the installation, click [Cancel].

- If installation is suspended or processing terminates abnormally, the [Program Compatibility Assistant] dialog box may be displayed. Click [This program installed correctly] and continue operation.

3.2.3 Installation in Interactive Mode

The installation procedure is described below.

The installation must be performed by a user with administrator privileges (a user ID that belongs to the Administrators group).

Point

In interactive mode installation, the default values of the installation information are set. The following setting can be changed for a new installation or a multi-version installation.

- Installation folder

1. Stop the program

Reinstallation requires stopping applications and programs.

Before starting the installation, stop the following:

- Mirroring Controller arbitration process

  Execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

  Example

```
> mc_arb stop -M D:\mcarb_dir\arbiter1
```

2. Insert the DVD

Insert the Server Assistant program DVD into the DVD drive.

3. Run the installation

The installation menu is displayed. Click [Installation].

4. Select the product to install

The [Installation product] window is displayed.
Select the product to install, and then click [Next].
If a selected product can only be reinstalled, refer to "6. Check the settings".

5. Confirm the contents for installation

The [Confirm installation] window will be displayed.

Click [Next] to start the installation.

To modify the settings, select [Modify], and then click [Next]. Follow the on-screen instructions.

6. Check the settings

The [Confirm installation] window will be displayed. Click [Install] to start the installation.

To modify the settings again, click [Back].

7. Completion of installation

The completion window is displayed. Click [Finish].

3.2.4 Installation in Silent Mode

Installation in silent mode can be performed only when the installation method is one of the following:

- New installation
- Multi-version installation

See

Refer to the Fujitsu Enterprise Postgres product website for information on installation in silent mode, such as the installation parameters and error messages.

The installation procedure is described below.

The installation must be performed by a user with administrator privileges (a user ID that belongs to the Administrators group).

1. Insert the DVD

Insert the Server Assistant program DVD into the DVD drive.

The [Install Menu] window is displayed. Click [Finish].

2. Create an installation parameters CSV file

Create an installation parameters CSV file that uses the following specification format.

```
sectionName, parameterName, value
sectionName, parameterName, value
     :
```

Information

The template for the installation parameters CSV file is "Z:\sample\sample.csv (Z is the drive into which the DVD is inserted.).

3. Start the command prompt

In Windows, right-click [Command Prompt] and then select [Run as administrator].

4. Run the installation

Execute the following command:

```
Z:\>silent.bat c:\temp\inspara.csv
```

Z: The drive into which the DVD is inserted.

c:\temp\inspara.csv: The installation parameter CSV file name.

If the silent installer ends in an error, a message is output to the log file and return values are returned.

3.3 Uninstallation

This section describes how to uninstall the Windows Server Assistant.

Information

- If a [User Account Control] dialog box such as the following is displayed at the start of the uninstallation, click [Yes] to continue processing:

  If [No] is clicked, permission to continue is denied and an [Error] dialog box will be displayed.
  To continue the uninstallation, click [Retry] in the [Error] dialog box. To end the operation, click [Cancel].

- If uninstallation is suspended or processing terminates abnormally, a dialog box of the Program Compatibility Assistant similar to the one shown below may be displayed. Click [This program uninstalled correctly] and continue operation.

3.3.1 Uninstallation in Interactive Mode

The uninstallation procedure is described below.

Log in using an account that has administrator privileges and then execute the command, or switch to an account that has administrator privileges and then uninstall the product.

If an error occurs while the product is being uninstalled, refer to "Uninstall (middleware) Messages" in the Fujitsu Enterprise Postgres product website, and take the required action.

1. Stop the program

Before starting the uninstallation, stop the following:

Mirroring Controller arbitration process

1. Execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

   Example

   ```
   > mc_arb stop -M D:\mcarb_dir\arbiter1
   ```

2. Unregister the Mirroring Controller arbitration process from the Windows service.

   Execute the mc_arb command in unregister mode to unregister the Mirroring Controller arbitration process from the Windows service.

   Example

   ```
   > mc_arb unregister -M D:\mcarb_dir\arbiter1
   ```

3. Delete registrations related to the event log.

   If messages are output to the event log, DLLs are registered in accordance with "Preparatory Tasks for the Output of Error Logs to the Event Log (Windows)" in the Cluster Operation Guide (Database Multiplexing). Delete these registrations so that no unnecessary issues occur.

   Ensure that you delete the DLLs before the uninstallation. If you perform the uninstallation without doing so, you may not be able to delete the DLLs at a later time.

   - Delete registration for the default event source name

     Example)
     The example below deletes a DLL of a 64-bit product registered under the default event source name. "<*x*>" indicates the product version.

     ```
     > regsvr32 /u "c:\Program Files\Fujitsu\fsepv<x>assistant64\lib\mcarbevent.dll"
     ```

   - Delete registration for other event source names

     DLL registration is performed so that messages output to the event log are output to any event source named by the user.

     Accordingly, it is necessary to delete the DLL registration. Do this for any event source name.

Example)
The example below deletes a DLL of a 64-bit product registered under the event source name "Mirroring Controller arbiter1". "<*x*>" indicates the product version.

```
> regsvr32 /u /i:"Mirroring Controller arbiter1" "c:\Program Files\Fujitsu
\fsepv<x>assistant64\lib\mcarbevent.dll"
```

- If installing multiple versions

  If error logs are set to be output to the event log, use the DLL path name that you took note of previously as explained in "Preparatory Tasks for the Output of Error Logs to the Event Log (Windows)" in the Cluster Operation Guide (Database Multiplexing) to reregister the default event source name.

2. Start Uninstall (middleware)

In [Start] menu, click [All apps], then [Fujitsu], and then [Uninstall (middleware)].

The shortcuts displayed on the [Start] menu might be arranged differently depending on the operating system.

3. Select the software

Select the product to be uninstalled from [Software Name], and then click [Remove].

4. Start the uninstallation

Click [Uninstall].

5. Finish the uninstallation

The uninstallation completion window will be displayed. Click [Finish].

The installation folder may remain after uninstallation. If it is not required, delete it.

6. Stop Uninstall (middleware)

Click [Close].

3.3.2 Uninstallation in Silent Mode

The uninstallation procedure is described below.

Log in using an account that has administrator privileges and then execute the command, or switch to an account that has administrator privileges and then uninstall the product.

Refer to the Fujitsu Enterprise Postgres product website for information on uninstallation in silent mode, such as the error messages.

1. Stop the program

Before starting the uninstallation, stop the following:

Mirroring Controller arbitration process

1. Execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

   Example

   ```
   > mc_arb stop -M D:\mcarb_dir\arbiter1
   ```

2. Unregister the Mirroring Controller arbitration process from the Windows service.

   Execute the mc_arb command in unregister mode to unregister the Mirroring Controller arbitration process from the Windows service.

   Example

   ```
   > mc_arb unregister -M D:\mcarb_dir\arbiter1
   ```

3. Delete registrations related to the event log.

   If messages are output to the event log, DLLs are registered in accordance with "Preparatory Tasks for the Output of Error Logs to the Event Log (Windows)" in the Cluster Operation Guide (Database Multiplexing). Delete these registrations so that no unnecessary issues occur.

   Ensure that you delete the DLLs before the uninstallation. If you perform the uninstallation without doing so, you may not be able to delete the DLLs at a later time.

   - Delete registration for the default event source name

     Example)
     The example below deletes a DLL of a 64-bit product registered under the default event source name. "<*x*>" indicates the product version.

     ```
     > regsvr32 /u "c:\Program Files\Fujitsu\fsepv<x>assistant64\lib\mcarbevent.dll"
     ```

   - Delete registration for other event source names

     DLL registration is performed so that messages output to the event log are output to any event source named by the user.

     Accordingly, it is necessary to delete the DLL registration. Do this for any event source name.

     Example)
     The example below deletes a DLL of a 64-bit product registered under the event source name "Mirroring Controller arbiter1". "<*x*>" indicates the product version.

     ```
     > regsvr32 /u /i:"Mirroring Controller arbiter1" "c:\Program Files\Fujitsu
     \fsepv<x>assistant64\lib\mcarbevent.dll"
     ```

   - If installing multiple versions

     If error logs are set to be output to the event log, use the DLL path name that you took note of previously as explained in "Preparatory Tasks for the Output of Error Logs to the Event Log (Windows)" in the Cluster Operation Guide (Database Multiplexing) to reregister the default event source name.

2. Start the command prompt

In Windows, right-click [Command Prompt] and then select [Run as administrator].

3. Run the uninstallation

Execute the following command:

The installation folder may remain after uninstallation. If it is not required, delete it.

Example

```
X:> installFolder\suninst.bat
```

X: Drive on which the product is installed

Chapter 4 Setup of the Server Assistant

The Server Assistant is a feature that is installed and used on the arbitration server, so its setup is performed as the arbitration server setup.

See

Refer to "Setting Up Database Multiplexing Mode" in the Cluster Operation Guide (Database Multiplexing) for information on setting up and operating the Mirroring Controller arbitration server.

L

4.1 Setting Up and Removing OSS

This section explains how to set up OSS supported by Fujitsu Enterprise Postgres.

If you want to use OSS supported by Fujitsu Enterprise Postgres, follow the setup procedure.

If you decide not to use the OSS supported by Fujitsu Enterprise Postgres, follow the removing procedure.

Refer to "OSS Supported by Fujitsu Enterprise Postgres" in the General Description for information on OSS other than those described below.

4.1.1 etcd

When using etcd commands on a different host from the Fujitsu Enterprise Postgres server, perform the following steps.

4.1.1.1 Setting Up etcd

1. As superuser, run the following command:

```
$ su -
Password:******
# cp -r /opt/fsepv<x>assistant/OSS/etcd/* /opt/fsepv<x>assistant
```

4.1.1.2 Removing etcd

1. As superuser, run the following command:

```
$ su -
Password:******
# rm -rf /opt/fsepv<x>assistant/filesCopiedDuringSetup
```

Information

The files copied during setup can be checked below.

```
# find /opt/fsepv<x>assistant/OSS/etcd
```

Appendix A Estimating Memory Requirements

This appendix explains how to estimate the memory.

A.1 Server Assistant Memory Requirements

This section describes the formula for estimating memory requirements for the Server Assistant.

Use the following formula to obtain a rough estimate of memory requirements:

```
Memory usage of the Server Assistant
                                = Peak memory usage of the Mirroring Controller arbitration
processes
                                  + Peak memory usage of the Mirroring Controller commands

Peak memory usage of the Mirroring Controller arbitration processes=100 MB

Peak memory usage of the Mirroring Controller commands=50 MB * Number of commands executed
simultaneously
```

Appendix B Collecting Failure Investigation Data

If the cause of an error that occurs while building the environment or during operations is unclear, data must be collected for initial investigation.

This subsection describes how to collect information for the initial investigation on the arbitration server for multiplexed database operation.

- Linux

  Use the pgx_fjqssinf command to collect data for initial investigation.

- Windows

  Use FJQSS (Information Collection Tool) to collect data for initial investigation. However, if you are asked by a Fujitsu technical support representative to collect investigation information, use the pgx_fjqssinf.bat command to collect the information.

See

- Linux
  - Refer to "pgx_fjqssinf" in the Reference for informations about the pgx_fjqssinf command.
- Windows
  - Refer to the following manual for information on how to use FJQSS.
    - In the [Apps] menu, select [FJQSS (Information Collection Tool)], and then click [FJQSS User's Guide].
  - Refer to "pgx_fjqssinf" in the Reference for informations about the pgx_fjqssinf.bat command.
- For details about how to collect database server information, refer to "Collecting Failure Investigation Data" in the Installation and Setup Guide for Server.

Setting environment variables

- Windows

  When using FJQSS to collect data for initial investigation, a window will be displayed for you to set the following environment variables. When using the pgx_fjqssinf.bat command, set the following environment variables in advance:

  - ARBCONTROLDIR

    Set the Mirroring Controller arbitration process management directory.
    For details about the Mirroring Controller arbitration server management directory, refer to "Mirroring Controller Resources" in the Cluster Operation Guide (Database Multiplexing).

Deleting the Temporary Folder

After information collection by FJQSS, a temporary folder may remain in the installation directory. In such cases, please manually delete the temporary folder.

Example

Working directory: C:\Program Files\Fujitsu\fsep<x>assistant64\tmp\pgx_fjqssinf_workdir

Note that "<x>" indicates the product version.

Appendix C Installation and Uninstallation of the Linux Server Assistant (Compatibility)

This chapter explains how to install and uninstall (interactive mode/silent mode) the Linux Server Assistant.

C.1 Operating Environment

This section describes the operating environment required in order to use the Linux Server Assistant.

C.1.1 Packages Required for RHEL8

In addition to the "2.1.1.1 Packages Required for RHEL8", you need:

Package name	Remarks
gdb	Required to run FJQSS.
glibc.i686	Required by installer.
redhat-lsb	Required by installer.
sudo	Required by installer.
sysstat	Required when using FJQSS. Set up the sar command after installation.

C.1.2 Packages Required for RHEL9

In addition to the "2.1.1.2 Packages Required for RHEL9", you need:

Package name	Remarks
gdb	Required to run FJQSS.
glibc.i686	Required by installer.
sudo	Required by installer.
sysstat	Required if using FJQSS. Set up the sar command after installation.

C.1.3 Packages Required for SLES 15

In addition to the "2.1.1.3 Packages Required for SLES 15", you need:

Package name	Remarks
libstdc++6-32bit	Required for silent installation.
sudo	Required by installer.

C.1.4 Disk Space Required for Installation

The following table lists the disk space requirements of the corresponding directories for new installation of the Linux Server Assistant. If necessary, increase the size of the file system.

Disk space required for installation

Table C.1 RHEL

Directory	Required disk space Unit: MB
/etc	1 + 1 (*1)
/var	1 + 2 (*1) +1 (*2)
/opt	300 (*1) +1 (*2)
serverAssistantInstallDir	560

*1: Uninstall (middleware) must be installed.

*2: Required for the installation of FJQSS.

Table C.2 SLES

Directory	Required disk space Unit: MB
/etc	1 + 1 (*1)
/var	1 + 2 (*1)
/opt	10 (*1)
serverAssistantInstallDir	150

*1: Uninstall (middleware) must be installed.

C.2 Installation

This section describes how to install the Linux Server Assistant.

Note

If you have antivirus software installed, the server may crash, fail to start, or stop responding, during installation or when starting up after installation. Set scan exception settings for the installation directory and resource allocation directory so that the files in these directories are not scanned for viruses.

C.2.1 Pre-installation Tasks

Check the following system environment before installing the Linux Server Assistant.

Check the disk space

Ensure that there is sufficient disk space to install the Linux Server Assistant.

Refer to "C.1.4 Disk Space Required for Installation" for information on disk space requirements.

If sufficient free disk space is unavailable, reconfigure disk partitions.

Set JAVA_HOME (SLES only)

Ensure that JRE 8 is installed, and export the JAVA_HOME environment variable.

```
#export JAVA_HOME="Jre8InstallDir"
```

Executable Users

Installation and uninstallation is performed by superuser.

On the system, run the following command to become superuser.

```
$ su -
Password:******
```

Check the installed product and determine the installation method

Using the operation shown below, start Uninstall (middleware), and check the installed products.

Example

```
# /opt/FJSVcir/cimanager.sh -c
Loading Uninstaller...

Currently installed products
1. productName

Type [number] to select the software you want to uninstall.
[number,q]
=>q

Exiting Uninstaller.
```

If the Linux Server Assistant is already installed, determine the installation method to use:

- Reinstallation
- Multi-version installation

Remove applied updates(For Reinstallation)

Use the following procedure to remove applied fixes.

If you install the product without removing the fix, you will apply the same version of the fix with the same fix number, resulting in an error that has already been applied. Remove the fix and then reinstall.

1. Checking the environment variable LD_LIBRARY_PATH

   If the installation directory/lib is set in the environment variable LD_LIBRARY_PATH for the running user, remove the installation directory/lib from LD_LIBRARY_PATH.

2. Display the applied updates

   Execute the following command to display the applied updates:

   ```
   # /opt/FJSVfupde/bin/uam showup
   ```

3. Remove the updates

   Execute the command below to remove the updates. If an update with the same update number was applied more than once, the updates are removed in order, starting from the highest version number.

   ```
   # /opt/FJSVfupde/bin/uam remove -i update-number
   ```

C.2.2 Installation in Interactive Mode

The installation procedure is described below.

Point

- The following characters can be used as input values:

  Alphanumeric characters, hyphens and forward slashes

- In interactive mode installation, the default values of the installation information are set. The following setting can be changed for a new installation or a multi-version installation.
  - Installation directory

1. Stop the program

- Reinstallation requires stopping applications and programs

Before starting the installation, stop the following:

- Mirroring Controller arbitration process

  Execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

  Example

```
$ mc_arb stop -M /mcarb_dir/arbiter1
```

2. Mount the DVD drive

Insert the Server Assistant program DVD into the DVD drive, and then execute the following command:

Example

```
# mount -t iso9660 -r -o loop /dev/dvd /media/dvd
```

Here /dev/dvd is the device name for the DVD drive (which may vary depending on your environment), and /media/dvd is the mount point (which may need to be created before calling the command).

If the DVD was mounted automatically using the automatic mount daemon (autofs), "noexec" is set as the mount option, so the installer may fail to start. In this case, use the mount command to remount the DVD correctly, and then run the installation. Note that the mount options of a mounted DVD can be checked by executing the mount command without any arguments.

3. Run the installation

Execute the following command:

Example

```
# cd /media/dvd
# ./install.sh
```

In the example above, /media/dvd is the DVD mount point.

4. Select the product to install

The list of installation target products is displayed.
Type the number for the product to be installed, or "all", and press Enter.

Information

If the selected product has been installed, a window for selecting reinstallation or multi-version installation is displayed for each product. Follow the on-screen instructions to select the installation method.

5. Check the settings

The window for checking the installation information is displayed.
Type "y" and press Enter to start the installation.
To change the settings, type "c", press Enter, and follow the on-screen instructions. This option is not displayed if there is no information that can be modified.

6. Check the changed settings

If the settings have been changed, the new installation information is displayed.
Type "y" and press Enter to start the installation.
To change the settings again, type "c" and press Enter.

7. Finish the installation

When the installation is complete, a message is displayed showing the status.
If installation was successful, the following message is displayed:

```
Installed successfully.
```

If an error occurs during the installation, read the error message and remove the cause of the error, and then reexecute the install.sh command.

C.2.3 Installation in Silent Mode

Installation in silent mode can be performed only when the installation method is one of the following:

- New installation
- Multi-version installation

See

Refer to the Fujitsu Enterprise Postgres product website for information on installation in silent mode, such as the installation parameters and error messages.

The installation procedure is described below.

1. Mount the DVD drive

Insert the Server Assistant program DVD into the DVD drive, and then execute the following command:

Example

```
# mount -t iso9660 -r -o loop /dev/dvd /media/dvd
```

Here /dev/dvd is the device name for the DVD drive (which may vary depending on your environment), and /media/dvd is the mount point (which may need to be created before calling the command).

If the DVD was mounted automatically using the automatic mount daemon (autofs), "noexec" is set as the mount option, so the installer may fail to start. In this case, use the mount command to remount the DVD correctly, and then run the installation. Note that the mount options of a mounted DVD can be checked by executing the mount command without any arguments.

2. Create an installation parameters CSV file

Create an installation parameters CSV file that uses the following specification format.

```
sectionName, parameterName, value
sectionName, parameterName, value
    :
```

Information

The templates for the installation parameters CSV file is "*mountPoint*/sample/sample.csv"

3. Run the installation

Execute the following command:

Example

```
# cd /media/dvd
# ./silent.sh /home/work/inspara.csv
```

In the example above, /media/dvd is the DVD mount point, and /home/work/inspara.csv is the installation parameter CSV.

If the silent installer ends in an error, a message is output to the log file and return values are returned.

C.3 Uninstallation

This section describes how to uninstall the Linux Server Assistant.

C.3.1 Uninstallation in Interactive Mode

The uninstallation procedure is described below.

If an error occurs while the product is being uninstalled, refer to "Uninstall (middleware) Messages" in the Fujitsu Enterprise Postgres product website, and take the required action.

1. Stop the program

Before starting the uninstallation, stop the following:

- Mirroring Controller arbitration process

  Execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

  Example

  ```
  $ mc_arb stop -M /mcarb_dir/arbiter1
  ```

2. Start Uninstall (middleware)

Execute the following command:

```
# /opt/FJSVcir/cimanager.sh -c
```

3. Select the product

Enter the number for the product to be uninstalled, and press Enter.

4. Start the uninstallation

To start the uninstallation, type "y" and press Enter.

To display the list of products again, type "b" and press Enter.

5. Finish the uninstallation

If uninstallation is successful, the message below is displayed.

The installation directory may remain after uninstallation. If it is not required, delete it.

```
Uninstalling...

productName is being uninstalled now.
    100% ##############################

The following products have been uninstalled successfully:
```

```
    productName

Uninstallation of "productName" has completed successfully.

Exiting Uninstaller.
```

C.3.2 Uninstallation in Silent Mode

The uninstallation procedure is described below.

Refer to the Fujitsu Enterprise Postgres product website for information on uninstallation in silent mode, such as the error messages.

1. Stop the program

Before starting the uninstallation, stop the following:

- Mirroring Controller arbitration process

  Execute the mc_arb command in stop mode to stop the Mirroring Controller arbitration process.

  Example

  ```
  $ mc_arb stop -M /mcarb_dir/arbiter1
  ```

2. Run the uninstallation

Execute the following command:

The installation directory may remain after uninstallation. If it is not required, delete it.

Example

```
# /opt/fsepv<x>assistant/setup/suninst.sh
```

In the example above, /opt/fsepv<*x*>assistant is the installation directory, and "<*x*>" indicates the product version.

C.4 Collecting Failure Investigation Data

If the cause of an error that occurs while building the environment or during operations is unclear, data must be collected for initial investigation.

This subsection describes how to collect information for the initial investigation on the arbitration server for multiplexed database operation.

- RHEL8 and RHEL9

  Use FJQSS (Information Collection Tool) to collect data for initial investigation. However, if you are asked by a Fujitsu technical support representative to collect investigation information, use the pgx_fjqssinf command to collect the information.

- SLES 15

  Use the pgx_fjqssinf command to collect data for initial investigation.

See

- Refer to the FJQSS manual for information on how to use FJQSS.
- Refer to "pgx_fjqssinf" in the Reference for informations about the pgx_fjqssinf command.
- For details about how to collect database server information, refer to "Collecting Failure Investigation Data" in the Installation and Setup Guide for Server.

Setting environment variables

When using FJQSS to collect data for initial investigation, you must set the following environment variables:

- FSEP_SA_HOME

  Set the Server Assistant installation directory.

Additionally, if you are operating a database multiplexing, please also set the following environment variables.

- ARBCONTROLDIR

  Set the Mirroring Controller arbitration process management directory.
  For details about the Mirroring Controller arbitration server management directory, refer to "Mirroring Controller Resources" in the Cluster Operation Guide (Database Multiplexing).

- ARBUSER

  Specify the operating system user who started the Mirroring Controller arbitration process.

Application Development Guide

Windows/Linux

J2UL-3064-02ENZ0(00)

March-2026

Preface

Purpose of this document

This is a guide for the developers of Fujitsu Enterprise Postgres applications.

Intended readers

This document is intended for developers of applications that use Fujitsu Enterprise Postgres. Of the interfaces provided by Fujitsu Enterprise Postgres, this guide describes the PostgreSQL extended interface.

Readers of this document are also assumed to have general knowledge of:

L
- PostgreSQL
- SQL
- Linux

W
- PostgreSQL
- SQL
- Windows

Structure of this document

This document is structured as follows:

Chapter 1 Overview of the Application Development Function

Provides an overview of Fujitsu Enterprise Postgres application development.

Chapter 2 JDBC Driver

Explains how to use JDBC drivers.

Chapter 3 ODBC Driver

Explains how to use ODBC drivers.

Chapter 4 .NET Data Provider

Explains how to use .NET Data Provider.

Chapter 5 C Library (libpq)

Explains how to use C applications.

Chapter 6 Embedded SQL in C

Explains how to use embedded SQL in C.

Chapter 7 Embedded SQL in COBOL

Explains how to use embedded SQL in COBOL.

Chapter 8 Python Language Package (psycopg)

Explains how to use Python language package (psycopg).

L
Chapter 9 Go Language

Explains how to use Go language.

Chapter 10 SQL References

Explains the SQL statements which were extended in Fujitsu Enterprise Postgres development.

Chapter 11 Compatibility with Oracle Databases

Explains features that are compatible with Oracle databases.

Chapter 12 Application Connection Switch Feature

Explains the application connection switch feature.

Chapter 13 Scan Using a Vertical Clustered Index (VCI)

Explains how to perform scan using a Vertical Clustered Index (VCI).

Chapter 14 Performance Tuning

Explains the performance tuning.

Appendix A Precautions when Developing Applications

Provides some points to note about application development.

Appendix B Conversion Procedures Required due to Differences from Oracle Database

Explains how to convert from an Oracle database to Fujitsu Enterprise Postgres, within the scope noted in "Compatibility with Oracle Databases" from the following perspectives.

Appendix C Tables Used by the Features Compatible with Oracle Databases

Explains the tables used by the features compatible with Oracle databases.

Appendix D ECOBPG - Embedded SQL in COBOL

Explains application development using embedded SQL in COBOL.

Appendix E Quantitative Limits

This appendix explains limitations.

Appendix F Reference

Provides a reference for each interface.

Appendix G DBMS_SQL Package

Explains the DBMS_SQL package.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Index 224

Chapter 1 Overview of the Application Development Function

The interface for application development provided by Fujitsu Enterprise Postgres is perfectly compatible with PostgreSQL.

Along with the PostgreSQL interface, Fujitsu Enterprise Postgres also provides the following extended interfaces:

- Support for National Characters

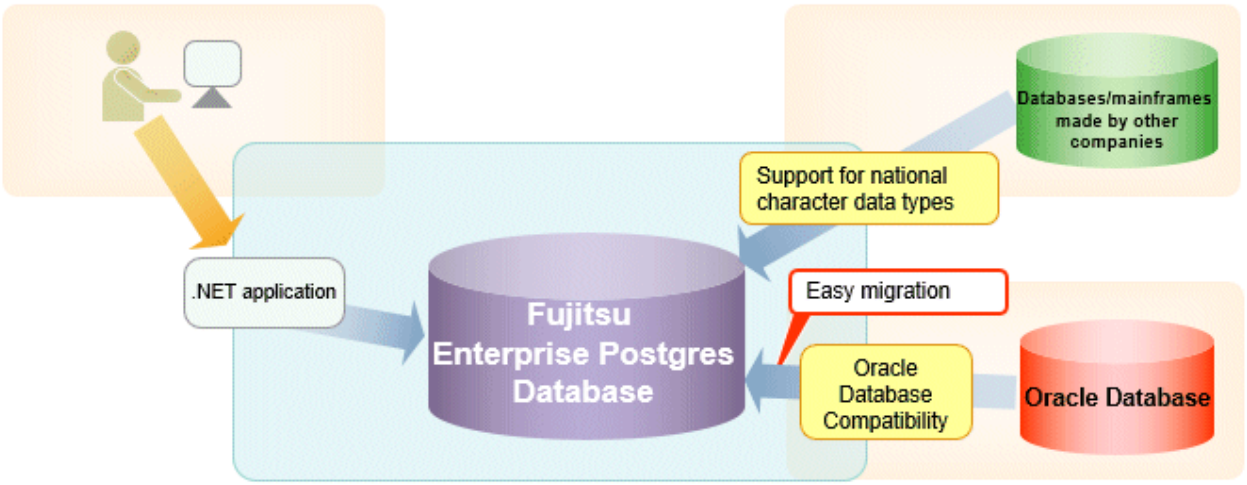
  In order to secure portability from mainframes and databases of other companies, Fujitsu Enterprise Postgres provides data types that support national characters. The national characters are usable from the client application languages.

  Refer to "1.1 Support for National Characters" for details.

- Compatibility with Oracle Databases

  Compatibility with Oracle databases is offered. Use of the compatible features means that the revisions to existing applications can be isolated, and migration to open interfaces is made simpler.

  Refer to "1.2 Compatibility with Oracle Database" for details.



- Application connection switch feature

  The application connection switch feature is provided to enable automatic connection to the target server when there are multiple servers with redundant configurations.

  Refer to "1.3 Application Connection Switch Feature" for details.

- Scanning using a Vertical Clustered Index (VCI)

  Scans becomes faster during aggregation of many rows by providing the features below:

  - Vertical clustered index (VCI)
  - In-memory data

  This feature can only be used in Advanced Edition.

  Refer to "Chapter 13 Scan Using a Vertical Clustered Index (VCI)" for details.

1.1 Support for National Characters

NCHAR type is provided as the data type to deal with national characters.

The NCHAR type can be used with Fujitsu Enterprise Postgres pgAdmin.

Point

- NCHAR can only be used when the character set of the database is UTF-8.
- NCHAR can be used in the places where CHAR can be used (function arguments, etc.).
- For applications handling NCHAR type data in the database, the data format is the same as CHAR type. Therefore, applications handling data in NCHAR type columns can also be used to handle data stored in CHAR type columns.

Note

Note the following in order to cast NCHAR type data as CHAR type.

- When comparing NCHAR type data where the length differs, ASCII spaces are used to fill in the length of the shorter NCHAR type data so that it can be processed as CHAR type data.
- Depending on the character set, the data size may increase by between 1.5 and 2 times.
- Use the AS clause to specify "varchar" as the column alias.

1.1.1 Literal

Syntax

```
{ N | n }'[national character [ ...]]'
```

General rules

National character string literals consist of an 'N' or 'n', and the national character is enclosed in single quotation marks ('). Example: N'ABCDEF'

The data type is national character string type.

1.1.2 Data Type

Syntax

```
{ NATIONAL CHARACTER | NATIONAL CHAR | NCHAR } [ VARYING ][(length) ]
```

The data type of the NCHAR type column is as follows:

Data type specification format	Explanation
NATIONAL CHARACTER(*n*) NATIONAL CHAR(*n*) NCHAR(*n*)	National character string with a fixed length of *n* characters This will be the same as (1) if (*n*) is omitted. *n* is a whole number larger than 0.
NATIONAL CHARACTER VARYING(*n*) NATIONAL CHAR VARYING(*n*) NCHAR VARYING(*n*)	National character string with a variable length with a maximum of *n* characters Any length of national character string can be accepted when this is omitted.

Data type specification format	Explanation
	n is a whole number larger than 0.

General rules

NCHAR is the national character string type data type. The length is the number of characters.

The length of the national character string type is as follows:

- When VARYING is not specified, the length of national character strings is fixed and will be the specified length.
- When VARYING is specified, the length of national character strings will be variable.
  In this case, the lower limit will be 0 and the upper limit will be the value specified for length.
- NATIONAL CHARACTER, NATIONAL CHAR, and NCHAR each have the same meaning.

When the national character string to be stored is shorter than the declared upper limit, the NCHAR value is filled with spaces, whereas NCHAR VARYING is stored as is.

The upper limit for character storage is approximately 1GB.

1.1.3 Functions and Operator

Comparison operator

When a NCHAR type or NCHAR VARYING type is specified in a comparison operator, comparison is only possible between NCHAR types or NCHAR VARYING types.

String functions and operators

All of the string functions and operators that can be specified by a CHAR type can also be specified by a NCHAR type. The behavior of these string functions and operators is also the same as with CHAR type.

Pattern matching (LIKE, SIMILAR TO regular expression, POSIX regular expression)

The patterns specified when pattern matching with NCHAR types and NCHAR VARYING types specify the percent sign (%) and the underline (_).

The underline (_) means a match with one national character. The percent sign (%) means a match with any number of national characters 0 or over.

1.2 Compatibility with Oracle Database

The following features have been extended in order to enhance compatibility with Oracle databases:

- Query (external join operator (+), DUAL table)
- Function (DECODE, SUBSTR, NVL)
- Built-in package (DBMS_OUTPUT, UTL_FILE, DBMS_SQL)

Refer to "Chapter 11 Compatibility with Oracle Databases" for information on the features compatible with Oracle databases.

1.3 Application Connection Switch Feature

The application connection switch feature enables automatic connection to the target server when there are multiple servers with redundant configurations.

Refer to " Chapter 12 Application Connection Switch Feature " for information on the application connection switch feature.

1.3.1 Integration with Database Multiplexing

The application connection switch feature is provided to enable automatic connection to the appropriate server when there are multiple servers with redundant configurations.

See

Refer to the Cluster Operation Guide (Database Multiplexing) for information on database multiplexing.

1.4 Notes on Application Compatibility

Fujitsu Enterprise Postgres upgrades contain feature improvements and enhancements that may affect the applications.

Accordingly, note the points below when developing applications, to ensure compatibility after upgrade.

- Checking execution results
- Referencing system catalogs
- Using functions

1.4.1 Checking Execution Results

Refer to SQLSTATE output in messages to check the SQL statements used in applications and the execution results of commands used during development.

See

Refer to Messages for information on the message content and number.

Refer to "PostgreSQL Error Codes" under "Appendixes" in the PostgreSQL Documentation for information on SQLSTATE.

1.4.2 Referencing System Catalogs

System catalogs can be used to obtain information about the Fujitsu Enterprise Postgres system and database objects.

However, system catalogs may change when the Fujitsu Enterprise Postgres version is upgraded. Also, there are many system catalogs that return information that is inherent to Fujitsu Enterprise Postgres.

Accordingly, reference the information schema defined in standard SQL (information_schema) wherever possible. Note also that queries specifying "*" in the selection list must be avoided to prevent columns being added.

See

Refer to "The Information Schema" under "Client Interfaces" in the PostgreSQL Documentation for details.

The system catalog must be referenced to obtain information not found in the information schema. Instead of directly referencing the system catalog in the application, define a view for that purpose. Note, however, that when defining the view, the column name must be clearly specified after the view name.

An example of defining and using a view is shown below.

Example

```
CREATE VIEW my_tablespace_view(spcname) AS SELECT spcname FROM pg_tablespace;
SELECT * FROM my_tablespace_view V1, pg_tables T1 WHERE V1.spcname = T1.tablespace;
```

If changes are made to a system catalog, the user will be able to take action by simply making changes to the view, without the need to make changes to the application.

The following shows an example of taking action by redefining a view as if no changes were made.

The pg_tablespace system catalog is redefined in response to the column name being changed from spcname to spacename.

Example

```
DROP VIEW my_tablespace_view;
CREATE VIEW my_tablespace_view(spcname) AS SELECT spacename FROM pg_tablespace;
```

1.4.3 Using Functions

The default functions provided with Fujitsu Enterprise Postgres enable a variety of operations and manipulations to be performed, and information to be obtained, using SQL statements.

However, it is possible that internal Fujitsu Enterprise Postgres functions, such as those relating to statistical information or for obtaining system-related information, may change as Fujitsu Enterprise Postgres versions are upgraded.

Accordingly, when using these functions, define them as new functions and then use the newly-defined functions in the applications.

An example of defining and using a function is shown below.

Example

```
CREATE FUNCTION my_func(relid regclass) RETURNS bigint LANGUAGE SQL AS 'SELECT
pg_relation_size(relid)';
SELECT my_func(2619);
```

If changes are made to a function, the user will be able to take action by simply redefining the function, without the need to make changes to the application.

The following shows an example of taking action by redefining a function as if no changes were made.

The pg_relation_size function is redefined after arguments are added.

Example

```
DROP FUNCTION my_func(regclass);
CREATE FUNCTION my_func(relid regclass) RETURNS bigint LANGUAGE SQL AS 'SELECT
pg_relation_size(relid,$$main$$)';
```

Chapter 2 JDBC Driver

This section describes how to use JDBC drivers.

2.1 Development Environment

This section describes application development using JDBC drivers and the runtime environment.

2.1.1 Combining with JDK or JRE

Refer to Installation and Setup Guide for Client for information on combining with JDK or JRE where JDBC drivers can operate.

2.2 Setup

This section describes the environment settings required to use JDBC drivers and how to encrypt communication data.

2.2.1 Environment Settings

Configuration of the CLASSPATH environment variable is required as part of the runtime environment for JDBC drivers.

The name of the JDBC driver file is as follows:

```
postgresql-jdbc42.jar
```

Same name whether you use JDK 8, JRE 8, JDK 11, JRE 11, JDK 17, JRE 17, JDK 21 or JRE 21 environment.

The examples below show how to set the CLASSPATH environment variable.

Note that "<*x*>" indicates the product version.

L

- Linux
  - Setting example (TC shell)

```
setenv CLASSPATH /opt/fsepv<x>client64/jdbc/lib/postgresql-jdbc42.jar:${CLASSPATH}
```

  - Setting example (bash)

```
CLASSPATH=/opt/fsepv<x>client64/jdbc/lib/postgresql-jdbc42.jar:$CLASSPATH;export
CLASSPATH
```

W

- Windows (32-bit)
  - Setting example

```
set CLASSPATH=C:\Program Files\Fujitsu\fsepv<x>client32\JDBC\lib\postgresql-
jdbc42.jar;%CLASSPATH%
```

- Windows (64-bit)
  - Setting example (when Fujitsu Enterprise Postgres Client 32-bit is installed)

```
set CLASSPATH=C:\Program Files (x86)\Fujitsu\fsepv<x>client32\JDBC\lib\postgresql-
jdbc42.jar;%CLASSPATH%
```

  - Setting example (when Fujitsu Enterprise Postgres Client 64-bit is installed)

```
set CLASSPATH=C:\Program Files\Fujitsu\fsepv<x>client64\JDBC\lib\postgresql-
jdbc42.jar;%CLASSPATH%
```

2.2.2 Message Language and Encoding System Used by Applications Settings

If the JDBC driver is used, it will automatically set the encoding system on the client to UTF-8, so there is no need to configure this.

See

Refer to "Automatic Character Set Conversion Between Server and Client" in "Server Administration" in the PostgreSQL Documentation for information on encoding systems.

Language settings

You must match the language settings for the application runtime environment with the message locale settings of the database server.

Set language in the "user.language" system property.

Example

Example of running a Java command with system property specified

```
java -Duser.language=en TestClass1
```

2.2.3 Settings for Encrypting Communication Data

When using the communication data encryption feature to connect to the database server, set as follows:

Settings for encrypting communication data for connection to the server

This section describes how to create applications for encrypting communication data.

Set the property of the SSL parameter to "true" to encrypt. The default for the SSL parameter is "false".

If ssl is set to "true", sslmode is internally treated as "verify-full".

Example

- Setting example 1

```
String url = "jdbc:postgresql://sv1/test";
Properties props = new Properties();
props.setProperty("user","fsepuser");
props.setProperty("password","secret");
props.setProperty("ssl","true");
props.setProperty("sslfactory","org.postgresql.ssl.DefaultJavaSSLFactory");
Connection conn = DriverManager.getConnection(url, props);
```

- Setting example 2

```
String url = "jdbc:postgresql://sv1/test?
user=fsepuser&password=secret&ssl=true&sslfactory=org.postgresql.ssl.DefaultJavaSSLF
actory";
Connection conn = DriverManager.getConnection(url);
```

To prevent spoofing of the database server, you need to use the keytool command included with Java to import the CA certificate to the Java keystore. In addition, specify "org.postgresql.ssl.DefaultJavaSSLFactory" for the sslfactory parameter.

Refer to JDK documentation and the Oracle website for details.

Note

There is no need to set the ssl parameter if the connection string of the DriverManager class is specified, or if the sslmode parameter is specified in the data source, such as when the application connection switch feature is used. If the ssl parameter is set, the value in the sslmode parameter will be enabled.

See

Refer to "Secure TCP/IP Connections with SSL" in "Server Administration" in the PostgreSQL Documentation for information on encrypting communication data.

2.3 Connecting to the Database

This section explains how to connect to a database.

- Using the DriverManager Class
- Using the PGConnectionPoolDataSource Class
- Using the PGXADataSource Class

Note

Do not specify "V2" for the "*protocolVersion*" of the connection string.

2.3.1 Using the DriverManager Class

To connect to the database using the DriverManager class, first load the JDBC driver, then specify the connection string as a URI in the API of the DriverManager class.

Load the JDBC driver

Specify org.postgresql.Driver.

Connection string

URI connection is performed as follows:

```
jdbc:postgresql://host:port/database?
user=user&password=password1&loginTimeout=loginTimeout&socketTimeout=socketTimeout
```

Argument	Description
host	Specify the host name for the connection destination. The default is "localhost".
port	Specify the port number for the database server. The default is "27500".
database	Specify the database name.
user	Specify the username that will connect with the database. If this is omitted, the username logged into the operating system that is executing the application will be used.
password	Specify a password when authentication is required.
loginTimeout	Specify the timeout for connections (in units of seconds).

Argument	Description
	Specify a value between 0 and 2147483647. There is no limit set if you set 0 or an invalid value. An error occurs when a connection cannot be established within the specified time.
socketTimeout	Specify the timeout for communication with the server (in units of seconds). Specify a value between 0 and 2147483647. There is no limit set if you set 0 or an invalid value. An error occurs when data is not received from the server within the specified time.

Example

Code examples for applications

```
import java.sql.*;
...
Class.forName("org.postgresql.Driver");
String url = "jdbc:postgresql://sv1:27500/mydb?
user=myuser&password=myuser01&loginTimeout=20&socketTimeout=20";
Connection con = DriverManager.getConnection(url);
```

2.3.2 Using the PGConnectionPoolDataSource Class

To connect to databases using data sources, specify the connection information in the properties of the data source.

Method description

Argument	Description
setServerName	Specify the host name for the connection destination. The default is "localhost".
setPortNumber	Specify the port number for the database server. The default is "27500".
setDatabaseName	Specify the database name.
setUser	Specify the username of the database. By default, the name used will be that of the user on the operating system that is executing the application.
setPassword	Specify a password for server authentication.
setLoginTimeout	Specify the timeout for connections (in units of seconds). Specify a value between 0 and 2147483647. There is no limit set if you set 0 or an invalid value. An error occurs when a connection cannot be established within the specified time.
setSocketTimeout	Specify the timeout for communication with the server (in units of seconds). Specify a value between 0 and 2147483647. There is no limit set if you set 0 or an invalid value. An error occurs when data is not received from the server within the specified time.

Example

Code examples for applications

```
import java.sql.*;
import org.postgresql.ds.PGConnectionPoolDataSource;
...
PGConnectionPoolDataSource source = new PGConnectionPoolDataSource();
source.setServerName("sv1");
source.setPortNumber(27500);
source.setDatabaseName("mydb");
source.setUser("myuser");
source.setPassword("myuser01");
source.setLoginTimeout(20);
source.setSocketTimeout(20);
...
Connection con = source.getConnection();
```

2.3.3 Using the PGXADataSource Class

To connect to databases using data sources, specify the connection information in the properties of the data source.

Method description

Argument	Description
setServerName	Specify the host name for the connection destination. The default is "localhost".
setPortNumber	Specify the port number for the database server. The default is "27500".
setDatabaseName	Specify the database name.
setUser	Specify the username that will connect with the database. If this is omitted, the name used will be that of the user on the operating system that is executing the application.
setPassword	Specify a password when authentication by a password is required.
setLoginTimeout	Specify the timeout for connections. The units are seconds. Specify a value between 0 and 2147483647. There is no limit set if you set 0 or an invalid value. An error occurs when a connection cannot be established within the specified time.
setSocketTimeout	Specify the timeout for communication with the server. The units are seconds. Specify a value between 0 and 2147483647. There is no limit set if you set 0 or an invalid value. An error occurs when data is not received from the server within the specified time.

Example

Code examples for applications

```
import java.sql.*;
import org.postgresql.xa.PGXADataSource;
...
PGXADataSource source = new PGXADataSource();
source.setServerName("sv1");
source.setPortNumber(27500);
source.setDatabaseName("mydb");
source.setUser("myuser");
source.setPassword("myuser01");
source.setLoginTimeout(20);
```

```
source.setSocketTimeout(20);...
Connection con = source.getConnection();
```

2.4 Application Development

This section describes the data types required when developing applications that will be connected with Fujitsu Enterprise Postgres.

2.4.1 Relationship between the Application Data Types and Database Data Types

The following table shows the correspondence between data types in applications and data types in databases.

Data type on the server	Java data type	Data types prescribed by java.sql.Types
character	String	java.sql.Types.CHAR
national character	String	java.sql.Types.NCHAR
character varying	String	java.sql.Types.VARCHAR
national character varying	String	java.sql.Types.NVARCHAR
text	String	java.sql.Types.VARCHAR
bytea	byte[]	java.sql.Types.BINARY
smallint	short	java.sql.Types.SMALLINT
integer	int	java.sql.Types.INTEGER
bigint	long	java.sql.Types.BIGINT
smallserial	short	java.sql.Types.SMALLINT
serial	int	java.sql.Types.INTEGER
bigserial	long	java.sql.Types.BIGINT
real	float	java.sql.Types.REAL
double precision	double	java.sql.Types.DOUBLE
numeric	java.math.BigDecimal	java.sql.Types.NUMERIC
decimal	java.math.BigDecimal	java.sql.Types.DECIMAL
money	String	java.sql.Types.OTHER
date	java.sql.Date	java.sql.Types.DATE
time with time zone	java.sql.Time	java.sql.Types.TIME
time without time zone	java.sql.Time	java.sql.Types.TIME
timestamp without time zone	java.sql.Timestamp	java.sql.Types.TIMESTAMP
timestamp with time zone	java.sql.Timestamp	java.sql.Types.TIMESTAMP
interval	org.postgresql.util.PGInterval	java.sql.Types.OTHER
boolean	boolean	java.sql.Types.BIT
bit	boolean	java.sql.Types.BIT
bit varying	org.postgresql.util.Pgobject	java.sql.Types.OTHER
oid	long	java.sql.Types.BIGINT
xml	java.sql.SQLXML	java.sql.Types.SQLXML

Data type on the server	Java data type	Data types prescribed by java.sql.Types
array	java.sql.Array	java.sql.Types.ARRAY
uuid	java.util.UUID	java.sql.Types.OTHER
point	org.postgresql.geometric.Pgpoint	java.sql.Types.OTHER
box	org.postgresql.geometric.Pgbox	java.sql.Types.OTHER
lseg	org.postgresql.geometric.Pglseg	java.sql.Types.OTHER
path	org.postgresql.geometric.Pgpath	java.sql.Types.OTHER
polygon	org.postgresql.geometric.PGpolygon	java.sql.Types.OTHER
circle	org.postgresql.geometric.PGcircle	java.sql.Types.OTHER
json	org.postgresql.util.PGobject	java.sql.Types.OTHER
Network address type (inet,cidr,macaddr, macaddr8)	org.postgresql.util.PGobject	java.sql.Types.OTHER
Types related to text searches (svector, tsquery)	org.postgresql.util.PGobject	java.sql.Types.OTHER
Enumerated type	org.postgresql.util.PGobject	java.sql.Types.OTHER
Composite type	org.postgresql.util.PGobject	java.sql.Types.OTHER
Range type	org.postgresql.util.PGobject	java.sql.Types.OTHER

Although the getString() method of the ResultSet object can be used for all server data types, it is not guaranteed that it will always return a string in the same format for the same data type.

Strings in a format compatible with the JDBC specifications can be obtained using the Java toString() method of the appropriate data type (for example, getInt(), getTimestamp()) to conform to the data type on the server.

2.4.2 Creating Applications while in Database Multiplexing Mode and Multi-master Replication

This section explains points to consider when creating applications while in database multiplexing mode and multi-master replication.

See

- Refer to the Cluster Operation Guide (Database Multiplexing) for information on database multiplexing mode.
- Refer to the Cluster Operation Guide (Multi-master Replication) for information on multi-master replication and points to consider when creating applications.
- Refer to "Application Development" in the Cluster Operation Guide (PRIMECLUSTER) for points to consider when creating applications using the failover feature integrated with the cluster software.

2.4.2.1 Errors when an Application Connection Switch Occurs and Corresponding Actions

If an application connection switch occurs while in database multiplexing mode and multi-master replication, explicitly close the connection and then reestablish the connection or reexecute the application.

The table below shows errors that may occur during a switch, and the corresponding action to take.

State		Error information (*1)	Action
Server failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	57P01 57P02 08006 08007	After the switch is complete, reestablish the connection, or reexecute the application.
	Accessed during system failure	08001	
Switch to the standby server	Switched during access	57P01 57P02 08006 08007	
	Accessed during switch	08001	

*1: Return value of the getSQLState() method of SQLException.

Chapter 3 ODBC Driver

This section describes application development using ODBC drivers.

3.1 Development Environment

Applications using ODBC drivers can be developed using ODBC interface compatible applications, such as Access, Excel, and Visual Basic.

Refer to the manuals for the programming languages corresponding to the ODBC interface for information about the environment for development.

Fujitsu Enterprise Postgres supports ODBC 3.5.

3.2 Setup

You need to set up PsqlODBC, which is an ODBC driver, in order to use applications that use ODBC drivers with Fujitsu Enterprise Postgres. PsqlODBC is included in the Fujitsu Enterprise Postgres client package.

The following describes how to register the ODBC drivers and the ODBC data source.

3.2.1 Registering ODBC Drivers

When using the ODBC driver on Linux platforms, register the ODBC driver using the following procedure:

1. Install the ODBC driver manager (unixODBC).
2. Register the ODBC drivers.

   Edit the ODBC driver manager (unixODBC) odbcinst.ini file.

   Information

   [location of the odbcinst.ini file]

   ```
   unixOdbcInstallDir/etc/odbcinst.ini
   ```

   Set the following content:

Definition name	Description	Setting value
[Driver name]	ODBC driver name	Set the name of the ODBC driver. Select the two strings below that correspond to the application type. Concatenate the strings with no spaces, enclose in "[ ]", and then specify this as the driver name. **Note** The placeholders shown below are enclosed in angle brackets '<>' to avoid confusion with literal text. Do not include the angle brackets in the string. - Application architecture "FujitsuEnterprisePostgres<*fujitsuEnterprisePostgresClientVers*>x64"

Definition name	Description	Setting value

		- Encoding system used by the application
		  - In Unicode (only UTF-8 can be used)
		  "unicode"
		  - Other than Unicode
		  "ansi"
		Example: The encoding system used by the application is Unicode:
		"[FujitsuEnterprisePostgres<*fujitsuEnterprisePostgresClientVers*>x64unicode]"

Description	Description of the ODBC driver	Specify a supplementary description for the current data source. Any description may be set.

Driver64	Path of the ODBC driver (64-bit)	Set the path of the ODBC driver (64-bit).
		- If the encoding system is Unicode:
		`*fujitsuEnterprisePostgresClientInstallDir*/odbc/lib/psqlodbcw.so`
		- If the encoding system is other than Unicode:
		`*fujitsuEnterprisePostgresClientInstallDir*/odbc/lib/psqlodbca.so`

FileUsage	Use of the data source file	Specify 1.
Threading	Level of atomicity secured for connection pooling	Specify 2.

Example

Note that "<*x*>" indicates the product version.

```
[Fujitsu Enterprise Postgres<x>x64unicode]
Description = Fujitsu Enterprise Postgres <x> x64 unicode driver
Driver64    = /opt/fsepv<x>client64/odbc/lib/psqlodbcw.so
FileUsage   = 1
Threading   = 2
```

3.2.2 Registering ODBC Data Sources(for Windows(R))

This section describes how to register ODBC data sources.

There are the following two ways to register ODBC data sources on Windows(R).

3.2.2.1 Registering Using GUI

This section describes how to start the [ODBC Data Source Administrator] and register ODBC data sources.

Use the following procedure to register ODBC data sources:

1. Start the [ODBC Data Source Administrator].

   Select [Start] >> [Control Panel] >> [Administrative Tools] >> [ODBC Data Source Administrator].

   Note

   To register data sources for 32-bit applications in Windows(R) for 64-bit, execute the ODBC administrator (odbcad32.exe) for 32-bit, as shown below.

   ```
   %SYSTEMDRIVE%\WINDOWS\SysWOW64\odbcad32.exe
   ```

2. When only the current user is to use the ODBC data source, select [User DSN]. When all users using the same computer are to use the ODBC data source, select [System DSN].

3. Click [Add].

4. Select one of the following drivers from the list of available ODBC drivers displayed in [Create New Data Source], and then click [Finish]. The notation "*x*" indicates the version of the Fujitsu Enterprise Postgres client feature.

   - Fujitsu Enterprise Postgres Unicode *x*
     Select this driver if using Unicode as the application encoding system.
   - Fujitsu Enterprise Postgres ANSI *x*
     Select this driver if using other than Unicode as the application encoding system.

5. The [PostgreSQL Unicode ODBC Driver (psqlODBC) Setup] window is displayed. Enter or select the required items, then click [Save].

   Set the following content:

Definition name	Setting value
Data Source	Specify the data source name to be registered in the ODBC driver manager. The application will select the name specified here and connect with the Fujitsu Enterprise Postgres database. This parameter cannot be omitted. Specify the following characters up to 32 bytes. - National characters - Alphanumerics - "_", "<", ">", "+", "`", "|", "~", "'" " "&" , """, "#" , "$" , "%" , "-" , "^" , ":" , "/" , "."
Description	Specify a supplementary description for the current data source. Specify characters up to 255 bytes. - National characters - Alphanumerics
Database	Specify the database name to be connected.
SSLMode	Specify to encrypt communications. The default is "disable". The setting values for SSLMode are as follows: - disable: Connect without SSL - allow: Connect without SSL, and if it fails, connect using SSL - prefer: Connect using SSL, and if it fails, connect without SSL - require: Connect always using SSL - verify-ca: Connect using SSL, and use a certificate issued by a trusted CA (*1) - verify-full: Connect using SSL, and use a certificate issued by a trusted CA to verify if the server host name matches the certificate (*1)
Server	Specify the host name of the database server to connect to, using up to 63 bytes. This parameter cannot be omitted.
Port	Specify the port number to be used for remote access. The default value is "27500".
Username(*2)	Specify the user that will access the database.
Password(*2)	Specify the password for the user that will access the database.

*1: If specifying either "verify-ca" or "verify-full", use the system environment variable PGSSLROOTCERT of your operating system to specify the CA certificate file as shown below.

Example:

```
Variable name: PGSSLROOTCERT
Variable value: cACertificateFile
```

*2: In consideration of security, specify the Username and the Password by the application.

3.2.2.2 Registering Using Commands

This section describes how to use commands to register ODBC data sources.

Use the following tools from Microsoft to register ODBC data sources.

- ODBCConf.exe
- Add-OdbcDsn

Refer to the Microsoft Developer Network (MSDN) Library for information on how to use these tools.

When using ODBCConf.exe

ODBCConf.exe is a tool supported on all Windows(R) platforms.

Specification format

```
ODBCConf.exe /A { dataSourceType "odbcDriverName" "optionName=value[|
optionName=value...]"} [/Lv fileName]
```

Refer to the Microsoft MSDN library for information on the format and parameters.

Description

Set the following content:

Definition name	Setting value
Data source type	Specify the data source type. - "CONFIGSYSDSN": A system data source is created. This requires user admin rights. The data source can be used by all users of the same computer. - "CONFIGDSN": A user data source is created. The data source can be used by the current user only. **Note** When CONFIGSYSDSN is specified as the data source type, it is necessary to execute the command in the command prompt in administrator mode.
ODBC driver name	Specify an ODBC driver name that has already been registered on the system. Specify one of the following. **Note** The placeholders shown below are enclosed in angle brackets '<>' to avoid confusion with literal text. Do not include the angle brackets in the string. - "Fujitsu Enterprise Postgres Unicode *<fujitsuEnterprisePostgresClientVers>*" Specify this driver name if using Unicode as the application encoding system. - "Fujitsu Enterprise Postgres ANSI *<fujitsuEnterprisePostgresClientVers>*" Specify this driver name if using other than Unicode as the application encoding system.
Option name	The following items must be set: - "DSN": Specify the data source name. - "Servername": Specify the host name for the database server. - "Port": Specify the port number for connection to the database - "Database": Specify the database name. Specify the following values as required: - "UID": User ID - "Password": Password

Definition name	Setting value
	- "SSLMode": Specify to encrypt communications. The default is "disable". Refer to the SSLMode explanation in the table under step 5 of "3.2.2.1 Registering Using GUI" for information on how to configure SSLMode.
File Name	You can output process information to a file when creating a data source. This operand can be omitted.

Example

Note that "<*x*>" indicates the product version.

```
ODBCConf.exe /A {CONFIGSYSDSN "Fujitsu Enterprise Postgres Unicode <x>" "DSN=odbcconf1|
Servername=sv1|Port=27500|Database=db01|SSLMode=verify-ca"} /Lv log.txt
```

Note

In consideration of security, specify the UID and the Password by the application.

When using Add-OdbcDsn

Add-OdbcDsn is used in the PowerShell command interface.

Specification format

```
Add-OdbcDsn dataSourceName -DriverName "odbcDriverName" -DsnType dataSourceType -
Platform oSArchitecture -SetPropertyValue @("optionName=value" [,"optionName=value"...])
```

Refer to the Microsoft MSDN library for information on the format and parameters.

Description

Set the following content:

Definition name	Setting value
Data source name	Specify any name for the data source name.
ODBC driver name	Specify an ODBC driver name that has already been registered on the system. Specify one of the following. **Note** The placeholders shown below are enclosed in angle brackets '<>' to avoid confusion with literal text. Do not include the angle brackets in the string. - "Fujitsu Enterprise Postgres Unicode *<fujitsuEnterprisePostgresClientVers>*" Specify this driver name if using Unicode as the application encoding system. - "Fujitsu Enterprise Postgres ANSI *<fujitsuEnterprisePostgresClientVers>*" Specify this driver name if using other than Unicode as the application encoding system.
Data source type	Specify the data source type.

Definition name	Setting value
	- "System": A system data source is created. Requires user admin rights. The data source can be used by all users of the same computer. - "User": A user data source is created. The data source can be used by the current user only. **Note** When System is specified as the data source type, it is necessary to execute the command in the administrator mode of the command prompt.
OS architecture	Specify the OS architecture of the system. - "32-bit": 32-bit system - "64-bit": 64-bit system
Option name	The following items must be set: - "Servername": Specify the host name for the database server. - "Port": Specify the port number for connection to the database - "Database": Specify the database name. Specify the following values as required: - "SSLMode": Specify to encrypt communications. The default is "disable". Refer to the SSLMode explanation in the table under step 5 of "3.2.2.1 Registering Using GUI" for information on how to configure SSLMode. **Note** When using Add-OdbcDsn, the strings "UID" and "Password" cannot be set as option names. These can only be used when using ODBCConf.exe.

Example

Note that "<*x*>" indicates the product version.

```
Add-OdbcDsn odbcps1 -DriverName "Fujitsu Enterprise Postgres Unicode <x>" -DsnType System -
Platform 32-bit -SetPropertyValue @("Servername=sv1", "Port=27500", "Database=db01",
"SSLMode=verify-ca")
```

L

3.2.3 Registering ODBC Data Sources(for Linux)

This section describes how to register ODBC data sources on Linux.

1. Register the data sources

   Edit the odbc.ini definition file for the data source.

   Information

   Edit the file in the installation directory for the ODBC driver manager (unixODBC)

   ```
   unixOdbcInstallDir/etc/odbc.ini
   ```

Or

Create a new file in the HOME directory

```
~/.odbc.ini
```

Point

If *unixOdbcInstallDir* is edited, these will be used as the shared settings for all users that log into the system. If created in the HOME directory (~/), the settings are used only by the single user.

Set the following content:

Definition name	Setting value
[Data source name]	Set the name for the ODBC data source.
Description	Set a description for the ODBC data source. Any description may be set.
Driver	Set the following as the name of the ODBC driver. Do not change this value. Select the two strings below that correspond to the application type. Concatenate the strings with no spaces and then specify this as the driver name. **Note** The placeholders shown below are enclosed in angle brackets '<>' to avoid confusion with literal text. Do not include the angle brackets in the string. - Application architecture "Fujitsu Enterprise Postgres <*fujitsuEnterprisePostgresClientVers*>x64" - Encoding system used by the application - In Unicode (only UTF-8 can be used) "unicode" - Other than Unicode "ansi" Example: The encoding system used by the application is Unicode: "Fujitsu Enterprise Postgres <*fujitsuEnterprisePostgresClientVers*>x64unicode"
Database	Specify the database name to be connected.
Servername	Specify the host name for the database server.
Username	Specify the user ID that will connect with the database.
Password	Specify the password for the user that will connect to the database.
Port	Specify the port number for the database server. The default is "27500".
SSLMode	Specify the communication encryption method. The setting values for SSLMode are as follows: - disable: Connect without SSL - allow: Connect without SSL, and if it fails, connect using SSL

Definition name	Setting value
	- prefer: Connect using SSL, and if it fails, connect without SSL - require: Connect always using SSL - verify-ca: Connect using SSL, and use a certificate issued by a trusted CA (*1) - verify-full: Connect using SSL, and use a certificate issued by a trusted CA to verify if the server host name matches the certificate (*1)
ReadOnly	Specify whether to set the database as read-only. - 1: Set read-only - 0: Do not set read-only

*1: If specifying either "verify-ca" or "verify-full", use the environment variable PGSSLROOTCERT to specify the CA certificate file as shown below.

Example

```
export PGSSLROOTCERT=cACertificateFileStorageDir/root.crt
```

Example

Note that "<*x*>" indicates the product version.

```
[MyDataSource]
Description     = Fujitsu Enterprise Postgres
Driver          = Fujitsu Enterprise Postgres<x>x64unicode
Database        = db01
Servername      = sv1
Port            = 27500
ReadOnly        = 0
```

Note

In consideration of security, specify the UserName and the Password by the application.

2. Configure the environment variable settings

   To execute applications that use ODBC drivers, all of the following settings must be configured in the LD_LIBRARY_PATH environment variable:

   - *unixOdbcInstallDir(*1)*/lib
   - *libtoolInstallDir(*1)*/lib

   *1: If the installation directory is not specified when unixODBC and libtool are installed, they will be installed in /usr/local.

3.2.4 Message Language and Encoding System Used by Applications Settings

This section explains the language settings for the application runtime environment and the encoding settings for the application.

Language settings

You must match the language settings for the application runtime environment with the message locale settings of the database server.

Messages output by an application may include text from messages sent from the database server. In the resulting text, the text of the application message will use the message locale of the application, and the text of the message sent by the database server will use the message locale of the database server. If the message locales do not match, more than one language or encoding system will be used. Moreover, if the encoding systems do not match, characters in the resulting text can be garbled.

L - Linux

Set the locale for messages (LC_MESSAGES category) to match the message locale of the database server. This can be done in a few different ways, such as using environment variables. Refer to the relevant manual of the operating system for information on the setlocale function.

Example

Example of specifying "en_US.UTF-8" with the setlocale function

```
setlocale(LC_ALL,"en_US.UTF-8");
```

Specifying the locale of the LC_ALL category propagates the setting to LC_MESSAGE.

W - Windows(R)

Align the locale of the operating system with the message locale of the database server.

Encoding System Settings

Ensure that the encoding system that is embedded in the application and passed to the database, and the encoding system setting of the runtime environment, are the same. The encoding system cannot be converted correctly on the database server.

Use one of the following methods to set the encoding system for the application:

- Set the PGCLIENTENCODING environment variable in the runtime environment.
- Set the client_encoding keyword in the connection string.
- Use the PQsetClientEncoding function.

See

Refer to "Supported Character Sets" in "Server Administration" in the PostgreSQL Documentation for information on the strings that represent the encoding system that can be set.

For example, when using "Unicode" and "8 bit", set the string "UTF8".

Example

Setting the "PGCLIENTENCODING" environment variable

L An example of setting when the encoding of the client is "UTF8" (Bash)

```
> PGCLIENTENCODING=UTF8; export PGCLIENTENCODING
```

W An example of setting when the encoding of the client is "UTF8"

```
> set PGCLIENTENCODING=UTF8
```

Note

Text may be garbled when outputting results to the command prompt. Review the font settings for the command prompt if this occurs.

3.3 Connecting to the Database

Refer to the manual for the programming language corresponding to the ODBC interface, i.e. Access, Excel, or Visual Basic, for example.

3.4 Application Development

This section describes how to develop applications using ODBC drivers.

3.4.1 Compiling Applications (for Windows (R))

Refer to the manual for the programming language corresponding to the ODBC interface, i.e. Access, Excel, or Visual Basic, for example.

Note

The cl command expects input to be a program that uses one of the following code pages, so convert the program to these code pages and then compile and link it (refer to the Microsoft documentation for details).

- ANSI console code pages (example: UTF8)
- UTF-16 little-endian with or without BOM (Byte Order Mark)
- UTF-16 big-endian with or without BOM
- UTF-8 with BOM

The cl command converts strings in a program to an ANSI console code page before generating a module, so the data sent to and received from the database server becomes an ANSI console code page. Therefore, set the coding system corresponding to the ANSI console code page as the coding system of the client.

Refer to "Character Set Support" in "Server Administration" in the PostgreSQL Documentation for information on how to set the client encoding system.

3.4.2 Compiling Applications (for Linux)

Specify the following options when compiling applications.

Table 3.1 Include file and library path

Option	How to specify the option
Path of the include file	-I *unixOdbc64bitIncludeFileDir*
Path of the library	-L *unixOdbc64bitLibraryDir*

Table 3.2 ODBC library

Type of library	Library name
Dynamic library	libodbc.so

Note

Specify -m64 when creating a 64-bit application.

Example

The following are examples of compiling ODBC applications:

```
gcc -m64 -I/usr/local/include(*1) -L/usr/local/lib(*1) -lodbc testproc.c -o testproc
```

*1: This is an example of building and installing from the source without specifying an installation directory for unixODBC. If you wish to specify a location, set the installation directory.

3.4.3 Creating Applications While in Database Multiplexing Mode and Multi-master Replication

This section explains points to consider when creating applications while in database multiplexing mode and multi-master replication.

See

- Refer to the Cluster Operation Guide (Database Multiplexing) for information on database multiplexing mode.
- Refer to the Cluster Operation Guide (Multi-master Replication) for information on multi-master replication and points to consider when creating applications.
- Refer to "Application Development" in the Cluster Operation Guide (PRIMECLUSTER) for points to consider when creating applications using the failover feature integrated with the cluster software.

3.4.3.1 Errors when an Application Connection Switch Occurs and Corresponding Actions

If an application connection switch occurs while in database multiplexing mode and multi-master replication, explicitly close the connection and then reestablish the connection or reexecute the application.

The table below shows errors that may occur during a switch, and the corresponding action to take.

State		Error information (*1)	Action
Server failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	57P01 08S01	After the switch is complete, reestablish the connection, or reexecute the application.
	Accessed during system failure	08001	
Switch to the standby server	Switched during access	57P01 08S01	
	Accessed during switch	08001	

*1: Return value of SQLSTATE.

Chapter 4 .NET Data Provider

This chapter describes how to configure for the purpose of creating .NET applications.

.NET Data Provider offers Npgsql 8.x and Npgsql 10.x packages. NuGet packages for each version are stored in separate folders within the installation directory of Fujitsu Enterprise Postgres client feature.

4.1 Development Environment

.NET Data Provider can operate in the following environments.

We recommend using the latest version of the .NET Data Provider package. Only use Npgsql 8.x if your .NET application needs to be developed and run on .NET Framework.

For Npgsql 10.x

Environment required for development and operation of .NET applications	.NET 8.0 .NET 9.0 .NET 10.0 (*1)
Integrated development environment for applications running in a .NET environment	Visual Studio 2022 Visual Studio 2026
Available development languages	C# Visual Basic .NET

*1: If you are using .NET 10.0, use Visual Studio 2026.

For Npgsql 8.x

Environment required for development and operation of .NET applications	.NET 8.0 .NET Framework 4.8 (Windows(R) only)
Integrated development environment for applications running in a .NET environment	Visual Studio 2017 Visual Studio 2019 Visual Studio 2022 Visual Studio 2026
Available development languages	C# Visual Basic .NET

4.2 Setup

This section explains how to set up .NET Data Provider and Entity Framework Core.

When using Npgsql 10.x, read the NuGet package storage location described in this section as follows:

L - Linux

```
fujitsuEnterprisePostgresClientInstallDir/dotnet10/...
```

W - Windows(R)

```
fujitsuEnterprisePostgresClientInstallDir\dotnet10\...
```

4.2.1 Setting Up .NET Data Provider

The .NET Data Provider of Fujitsu Enterprise Postgres can be installed as a local NuGet package. Follow the steps below to install.

Location of NuGet package

The NuGet package are stored in the following location. "<*x*>" indicates the product version.

- Linux

```
fujitsuEnterprisePostgresClientInstallDir/dotnet/Npgsql.<x>.0.0.nupkg
```

- Windows(R)

```
fujitsuEnterprisePostgresClientInstallDir\dotnet\Npgsql.<x>.0.0.nupkg
```

Add a local package source

Add a NuGet local package source if one does not exist.

- Linux

  Add the above Nuget package location as a local package source.

```
dotnet nuget add source fujitsuEnterprisePostgresClientInstallDir/dotnet -n
sourceName
```

- Windows(R)

  1. Start Visual Studio, click [Tools] >> [Options] >> [NuGet Package Manager], and then select [Package Sources].
  2. Click [+] in the upper-right corner, and then set [Name] to "Local Package Source".
  3. Click [···] and navigate to the folder above. Select this folder, and then click [OK].

Install the NuGet package

Install the NuGet package from the local package source.

- Linux

  Add a package reference to the project file.

```
dotnet add projectFilePath package Npgsql
```

- Windows(R)

  1. Start Visual Studio, click [Tools] >> [NuGet Package Manager] >> [Manage NuGet Packages for Solution].
  2. In the upper-right corner, select "Local Package Source" from [Package Source].
  3. Once the local package source is set, all available NuGet packages in this local location will be displayed. Select "Npgsql", and then select the projects for which this package is to be installed.
  4. Click [Install].

4.2.2 Setting Up .NET Data Provider Type Plugins

Fujitsu Enterprise Postgres .NET Data Provider now comes packaged with 4 Type Plugins that provide additional support for more data type mappings (eg date time support via the Npgsql.NodaTime). The plugins modify how Npgsql maps the PostgreSQL values to CLR types.

The type plugins are available for installation as a local NuGet packages. There are 4 pacakages available for installation. "<*x*>" indicates the product version.

- Npgsql.NodaTime.<*x*>.0.0.nupkg
- Npgsql.Json.NET.<*x*>.0.0.nupkg
- Npgsql.NetTopologySuite.<*x*>.0.0.nupkg: Spatial type(*1)
- Npgsql.GeoJSON.<*x*>.0.0.nupkg: Spatial type(*1)

*1: Please note that the Spatial Type plugins require the PostGIS extension installed on the server.

Also, Refre to "Type Plugins" and "Additional Notes on each Type Plugin" on the each type plugins.

To install any of the plugins please follow the procedure below:

Location of NuGet package

The Plugin NuGet package are stored in the following location. "<*x*>" indicates the product version.

- Linux

```
fujitsuEnterprisePostgresClientInstallDir/dotnet/Npgsql.*.<x>.0.0.nupkg
```

- Windows(R)

```
fujitsuEnterprisePostgresClientInstallDir\dotnet\Npgsql.*.<x>.0.0.nupkg
```

Add a local package source

Add a NuGet local package source if one does not exist.

- Linux

Add the above Nuget package location as a local package source.

```
dotnet nuget add source fujitsuEnterprisePostgresClientInstallDir/dotnet -n
sourceName
```

- Windows(R)

1. Start Visual Studio, click [Tools] >> [Options] >> [NuGet Package Manager], and then select [Package Sources].
2. Click [+] in the upper-right corner, and then set [Name] to "Local Package Source".
3. Click [···] and navigate to the folder above. Select this folder, and then click [OK].

Install the NuGet package

Install the NuGet package from the local package source.

- Linux

Add a package reference to the project file (Example: Npgsql.NodaTime).

```
dotnet add projectFilePath package Npgsql.NodaTime
```

- Windows(R)

1. Start Visual Studio, click [Tools] >> [NuGet Package Manager] >> [Manage NuGet Packages for Solution].
2. In the upper-right corner, select "Local Package Source" from [Package Source].
3. Once the local package source is set, all available NuGet packages in this local location will be displayed. Select the plugin to be installed (eg "Npgsql.NodaTime", and then select the projects for which this package is to be installed.
4. Click [Install].

4.2.3 Setting Up Entity Framework Core

Entity Framework Core is supplied as a NuGet package file. To install it locally, follow the procedure below.

Location of NuGet package

The EntityFramework Core NuGet package is stored in the following location. "<*y*>" indicates the version of Entity Framework Core.

- Linux

```
fujitsuEnterprisePostgresClientInstallDir/dotnet/
Npgsql.EntityFrameworkCore.PostgreSQL.<y>.nupkg
```

- Windows(R)

```
fujitsuEnterprisePostgresClientInstallDir\dotnet
\Npgsql.EntityFrameworkCore.PostgreSQL.<y>.nupkg
```

Add a local package source

Add a NuGet local package source if one does not exist.

- Linux

Add the above Nuget package location as a local package source.

```
dotnet nuget add source fujitsuEnterprisePostgresClientInstallDir/dotnet -n
sourceName
```

- Windows(R)

1. Start Visual Studio, click [Tools] >> [Options] >> [NuGet Package Manager], and then select [Package Sources].
2. Click [+] in the upper-right corner, and then set [Name] to "Local Package Source".
3. Click [···] and navigate to the folder above. Select this folder, and then click [OK].

Install the NuGet package

Install the NuGet package from the local package source.

- Linux

Add a package reference to the project file.

```
dotnet add projectFilePath package Npgsql.EntityFrameworkCore.PostgreSQL
```

- Windows(R)

1. Start Visual Studio, click [Tools] >> [NuGet Package Manager] >> [Manage NuGet Packages for Solution].
2. In the upper-right corner, select "Local Package Source" from [Package Source].
3. Once the local package source is set, all available NuGet packages in this local location will be displayed. Select "Npgsql.EntityFrameworkCore.PostgreSQL", and then select the projects for which this package is to be installed.
4. Click [Install].

4.2.4 Setting Up Npgsql.OpenTelemetry

Fujitsu Enterprise Postgres .NET Data Provider comes with a plug-in that supports tracing by the observability framework OpenTelemetry. This will allow Npgsql to emit trace data.

OpenTelemetry plugin is supplied as a local NuGet package. To install it locally, follow the procedure below.

Location of NuGet package

The NuGet packages for OpenTelemetry are stored in the following location. "<*x*>" indicates the product version.

L - Linux

```
fujitsuEnterprisePostgresClientInstallDir/dotnet/Npgsql.OpenTelemetry.<x>.0.0.nupkg
```

W - Windows(R)

```
fujitsuEnterprisePostgresClientInstallDir\dotnet\Npgsql.OpenTelemetry.<x>.0.0.nupkg
```

Add a local package source

Add a NuGet local package source if one does not exist.

L - Linux

Add the above Nuget package location as a local package source.

```
dotnet nuget add source fujitsuEnterprisePostgresClientInstallDir/dotnet -n
sourceName
```

W - Windows(R)

1. Start Visual Studio, click [Tools] >> [Options] >> [NuGet Package Manager], and then select [Package Sources].
2. Click [+] in the upper-right corner, and then set [Name] to "Local Package Source".
3. Click [···] and navigate to the folder above. Select this folder, and then click [OK].

Install the NuGet package

Install the NuGet package from the local package source.

L - Linux

Add a package reference to the project file.

```
dotnet add projectFilePath package Npgsql.OpenTelemetry
```

W - Windows(R)

1. Start Visual Studio, click [Tools] >> [NuGet Package Manager] >> [Manage NuGet Packages for Solution].
2. In the upper-right corner, select "Local Package Source" from [Package Source].
3. Once the local package source is set, all available NuGet packages in this local location will be displayed. Select "Npgsql.OpenTelemetry", and then select the projects for which this package is to be installed.
4. Click [Install].

4.3 Connecting to the Database

This section explains how to connect to a database.

- Using NpgsqlConnection
- Using NpgsqlConnectionStringBuilder

4.3.1 Using NpgsqlConnection

Connect to the database by specifying the connection string.

Example

Code examples for applications

```
using Npgsql;

NpgsqlConnection conn = new NpgsqlConnection("Server=sv1;Port=27500;Database=mydb;
Username=myuser;Password=myuser01; Timeout=20;CommandTimeout=20;");
```

Refer to "4.3.3 Connection String" for information on database connection strings.

4.3.2 Using NpgsqlConnectionStringBuilder

Generate connection strings by specifying the connection information in the properties of the NpgsqlConnectionStringBuilder object.

Example

Code examples for applications

```
using Npgsql;

NpgsqlConnectionStringBuilder sb = new NpgsqlConnectionStringBuilder();
sb.Host = "sv1";
sb.Port = 27500;
sb.Database = "mydb";
sb.Username = "myuser";
sb.Password = "myuser01";
sb.Timeout = 20;
sb.CommandTimeout = 20;
NpgsqlConnection conn = new NpgsqlConnection(sb.ConnectionString);
```

Refer to "4.3.3 Connection String" for information on database connection strings.

4.3.3 Connection String

Specify the following connection information to connect to the database.

```
Server=127.0.0.1;Port=27500;Database=mydb;Username=myuser;Password=myuser01;...;
      (1)           (2)           (3)          (4)            (5)      (6)
```

(1) Specify the host name or IP address of the server to be connected. This must be specified.

(2) Specify the port number for the database server. The default is "27500".

(3) Specify the database name to be connected.

(4) Specify the username that will connect with the database.

(5) Specify the password for the user that will connect to the database.

(6) Refer to the following for information on how to specify other connection information.

The table below shows keywords that are available to specify in the connection string in .NET Data Provider (Npgsql):

Note that some settings require care if using an Oracle database-compatible feature (refer to "11.2.3 Notes when Integrating with the Interface for Application Development" for details).

Basic connection

Keyword	Description	Default
Host	Specify the host name of the server to be connected. Multiple hosts may be specified. A host name must be specified.	
Port	Specify the TCP port number of the server.	27500
Database	Specify the database name to connect to.	Same as Username
Username	Specify the username for the username that will connect to the database. Not required if using Integrated Security.	PGUSER
Password	Specify the password for the username that will connect to the database. Not required if using Integrated Security.	PGPASSWORD
Passfile	Specify the path of the password file (PGPASSFILE) to obtain the password.	PGPASSFILE

Security and encryption

Keyword	Description	Default
SSL Mode	Specify one of the following values to indicate whether or not to use SSL, depending on your server's support. Disable: No SSL connection is made. Allow: SSL connection will be made only if the server requires it. Prefer: Make an SSL connection if possible. Require: Perform SSL connection. It does not verify the authenticity of Connection Server at this time. VerifyCA: Make an SSL connection. At this time, verify the authenticity of the connection server. VerifyFull: Make an SSL connection. This time it verifies the authenticity of the Connection Server and verifies that it is the server you specified.	Prefer
SSL Certificate	Specify the location of the client certificate sent to the server.	PGSSLCERT
SSL Key	Specify the location of the client key for the client certificate sent to the server.	PGSSLKEY
SSL Password	Specify the password for the client certificate key.	
Root Certificate	Specify the location of the CA certificate used to validate server certificates.	PGSSLROOTCERT
Check Certificate Revocation	Specify whether to check the certificate revocation list during authentication.	false
Integrated Security	Specify whether to log in using integrated security (GSS/SSPI).	false
Persist Security Info	Gets or sets a Boolean value that indicates whether security-sensitive information, such as passwords, should not be returned as part of a connection if it is connected or has ever been connected.	false
Kerberos Service Name	Specify the Kerberos service name used for authentication.	postgres
Include Realm	Specify the Kerberos realm used for authentication.	

Keyword	Description	Default
Include Error Detail	When enabled, database error and notification details are included in PostgresException.Detail and PostgresNotice.Detail. These can contain confidential information.	false
Log Parameters	When enabled, parameter values are logged when the command is executed.	false

Pooling

Keyword	Description	Default
Pooling	Specify whether to use connection pooling.	true
Minimum Pool Size	Minimum connection pool size.	0
Maximum Pool Size	Maximum size of the connection pool.	100
Connection Idle Lifetime	Specify the time (in seconds) to wait before disconnecting idle connections in the pool when the number of all connections exceeds the Minimum Pool Size.	300
Connection Pruning Interval	Specify the number of seconds the pool waits before attempting to prune an idle connection that has exceeded its lifetime. See Connection Idle Lifetime.	10
ConnectionLifetime	Specify the total maximum lifetime of the connection in seconds. Connections beyond this value are discarded rather than returned from the pool. This is useful in cluster configurations that force load balancing between running servers and servers that have just come online.	0 (disabled)

Timeouts and keepalive

Keyword	Description	Default
Timeout	Specify the amount of time (in seconds) to wait before terminating the attempt and generating an error during connection establishment.	15
Command Timeout	Specify how long to wait (in seconds) while executing a command before terminating the attempt and generating an error. Set to 0 for infinity.	30
Internal Command Timeout	Specify how long to wait (in seconds) before terminating the attempt and generating an error when attempting to execute an internal command. -1 uses CommandTimeout, 0 means no timeout.	-1
Cancellation Timeout	Specify the number of milliseconds to wait while trying to read a response to a cancel request for a timed-out or canceled query before terminating the attempt and generating an error. -1 skips the wait, 0 means infinite wait.	2000
Keepalive	Npgsql will send his keep-alive queries if the connection has been inactive for more than the number of seconds specified here.	0 (disabled)
Tcp Keepalive	Specify whether TCP keepalives are used by the system default if no override is specified.	false
Tcp Keepalive Time	A TCP keep-alive query is sent when the connection inactivity exceeds the number of milliseconds specified here. Use of this option is not recommended. We recommend using Keepalive. This is supported on Windows only.	0 (disabled)

Keyword	Description	Default
Tcp Keepalive Interval	Specify the interval (in milliseconds) between successive keepalive packets sent if no acknowledgment is received. Tcp KeepAlive Time must also be non-zero. This is supported on Windows only.	TCP Keepalive Time value

Performance

Keyword	Description	Default
Max Auto Prepare	Maximum number of SQL statements that can be automatically prepared at any given time. When this number is exceeded, the last used statement is reused. A value of 0 disables autoprepare.	0
Auto Prepare Min Usages	A SQL statement is automatically prepared when its usage count exceeds the value specified here.	5
Read Buffer Size	The size of the internal buffer Npgsql uses when reading. Increasing this value may improve performance when transferring large amounts of data from the database.	8192
Write Buffer Size	Determines the size of the internal buffer Npgsql uses when writing. Increasing this value may improve performance when transferring large amounts of data to the database.	8192
Socket Receive Buffer Size	The size of the socket receive buffer.	System dependent
Socket Send Buffer Size	The size of the socket send buffer.	System dependent
No Reset On Close	When true, do not reset the connection state when the connection is returned to the pool. In some cases, this improves performance at the cost of leak conditions. Use it only if your benchmark shows performance improvements.	false

Failover and load balancing

Keyword	Description	Default
Target Session Attributes	Specifies the server type to preferentially connect to. any: Allows any successful connection. primary: Connect to the primary server. standby: Connect to the standby server. prefer-primary: Attempt to connect to the primary server first, but retry in any mode if none of the listed hosts has a primary server. prefer-standby: Attempt to connect to the standby server first, but retry in any mode if there is no standby server on the listed host. read-write: Connect to a server whose default transaction mode is read/write. read-only: Connect to a server whose default transaction mode is read-only.	PGTARGETSESSIONATTRS, Any
Load Balance Hosts	Specify whether to perform load balancing among multiple hosts using the round-robin method.	false
Host Recheck Seconds	Controls how long a host's cached state is considered valid.	10

Keyword	Description	Default
Enable Fdw Acs	Specifies whether to switch the connection destination type of the data node with on or off when using the connection routing function. This cannot be set to on when "Target Session Attributes=prefer-primary" is specified.	off

Others

Keyword	Description	Default
Options	Specify valid database connection options. (Example: Options=-c synchronous_commit=local)	PGOPTIONS
Application Name	Specify the application name sent to the backend when opening a connection.	
Enlist	Specify whether the connection should participate in transactions declared in the transaction scope.	true
Search Path	Sets the schema search path.	None
Client Encoding	Gets or sets the client_encoding parameter.	PGCLIENTENCODING
Encoding	Gets or sets the .NET encoding used to encode/decode string data in the database.	UTF8
Timezone	Gets or sets the session timezone.	PGTZ
EF Template Database	A database template that is specified when creating a database with Entity Framework.	template1
EF Admin Database	The managed database that you specify when creating and deleting databases in Entity Framework.	template1
Load Table Composites	Specify whether to load complex type definitions for tables in addition to independent complex types.	false
Array Nullability Mode	Sets how to return an array of value types when requested as an object instance. Possible values are: Never: Always return as a non-nullable array. Always: Always return as a nullable array. PerInstance: The returned array is determined at runtime.	Never

4.4 Application Development

4.4.1 Data Types

A variety of data types can be used with Fujitsu Enterprise Postgres.

List of supported data types

Data Type
boolean
smallint
integer
bigint
real

Data Type
double precision
numeric
money
text
character varying
character
national character varying
national character
citext
json
jsonb
xml
uuid
bytea
timestamp without time zone
timestamp with time zone
date
time without time zone(*1)
time with time zone(*1)
interval(*2)
cidr
inet
macaddr
tsquery
tsvector
bit(1)
bit(n)
bit varying
point
lseg
path
polygon
line
circle
box
hstore
oid
xid
cid

Data Type
oidvector
name
(internal) char
geometry (PostGIS)
record
composite types
range types
multirange types (PG14)
enum types
array types

*1: As shown below, "time with time zone" and "time without time zone" values display the date portion as additional information. However, the actual data comprises the time data only, so with the exception of this displayed format, there are no other resulting issues.

Example:

Composition of table (t1)

col1 (time with time zone)	col2 (time without time zone)
1/01/0001 10:21:30 +08:00	10:21:30
1/01/0001 23:34:03 +08:00	23:34:03
1/01/0001 17:23:54 +08:00	17:23:54

"time with time zone" values display a fixed value of “2/01/0001” in the date portion, while "time without time zone" values display just the time data.

```
SELECT *
  FROM t1;
 col1                        |    col2
-----------------------------+---------------------
 1/01/0001 10:21:30 +08:00 | 10:21:30
 1/01/0001 23:34:03 +08:00 | 23:34:03
 1/01/0001 17:23:54 +08:00 | 17:23:54
```

*2: The format is d.hh:mm:ss, where d is an integer and hh:mm:ss is a maximum of 23.59.59 (23 hours, 59 minutes, and 59 seconds).

4.4.2 Relationship between Application Data Types and Database Data Types

The data types available for SQL data types are as follows:

Read mappings

PostgreSQL Type	Default.NET Type	Non-default Type
boolean	bool	
smallint	short	byte, sbyte, int, long, float, double, decimal
integer	int	byte, short, long, float, double, decimal
bigint	long	long, byte, short, int, float, double, decimal

PostgreSQL Type	Default.NET Type	Non-default Type
real	float	double
double precision	double	
numeric	decimal	byte, short, int, long, float, double, BigInteger
money	decimal	
text	string	char[]
character varying	string	char[]
character	string	char[]
national character varying	string	char[]
national character	string	char[]
citext	string	char[]
json	string	char[]
jsonb	string	char[]
xml	string	char[]
uuid	Guid	
bytea	byte[]	
timestamp without time zone	DateTime (Unspecified)	
timestamp with time zone	DateTime (Utc)(*1)	DateTimeOffset (Offset=0)(*2)
date	DateTime	DateOnly
time without time zone	TimeSpan	TimeOnly
time with time zone	DateTimeOffset	
interval	TimeSpan(*3)	NpgsqlInterval
cidr	NpgsqlCidr	
inet	IPAddress	NpgsqlInet
macaddr	PhysicalAddress	
tsquery	NpgsqlTsQuery	
tsvector	NpgsqlTsVector	
bit(1)	bool	BitArray
bit(n)	BitArray	
bit varying	BitArray	
point	NpgsqlPoint	
lseg	NpgsqlLSeg	
path	NpgsqlPath	
polygon	NpgsqlPolygon	
line	NpgsqlLine	
circle	NpgsqlCircle	
box	NpgsqlBox	

PostgreSQL Type	Default.NET Type	Non-default Type
hstore	Dictionary<string, string>	
oid	uint	
xid	uint	
cid	uint	
oidvector	uint[]	
name	string	char[]
(internal) char	char	byte, short, int, long
geometry (PostGIS)	PostgisGeometry	
record	object[]	
composite types	T	
range types	NpgsqlRange<TElement>	
multirange types (PG14)	NpgsqlRange<TElement>[]	
enum types	TEnum	
array types	Array (of element type)	

*1: When Npgsql.EnableLegacyTimestampBehavior is enabled, reading a timestamp with time zone returns a Local DateTime instead of Utc.

*2: When Npgsql.EnableLegacyTimestampBehavior is enabled, reading a timestamp with time zone as a DateTimeOffset returns a local offset based on the timezone of the server where Npgsql is running.

*3: PostgreSQL intervals with month or year components cannot be read as TimeSpan. Consider using NodaTime's Period type, or NpgsqlInterval.

Write mappings

PostgreSQL Type	Default.NET Type	Non-default.NET Type	NpgsqlDbType	DbType
boolean	bool		Boolean	Boolean
smallint	short, byte, sbyte		Smallint	Int16
integer	int		Integer	Int32
bigint	long		Bigint	Int64
real	float		Real	Single
double precision	double		Double	Double
numeric	decimal, BigInteger		Numeric	Decimal, VarNumeric
money		decimal	Money	Currency
text	string, char[], char		Text	String, StringFixedLength, AnsiString, AnsiStringFixedLength
character varying		string, char[], char	Varchar	
character		string, char[], char	Char	
citext		string, char[], char	Citext	

PostgreSQL Type	Default.NET Type	Non-default.NET Type	NpgsqlDbType	DbType
json		string, char[], char	Json	
jsonb		string, char[], char	Jsonb	
xml		string, char[], char	Xml	
uuid	Guid		Uuid	
bytea	byte[]	ArraySegment<byte>	Bytea	Binary
timestamp with time zone	DateTime (Utc) (*1), DateTimeOffset		TimestampTz	DateTime(*2), DateTimeOffset
timestamp without time zone	DateTime (Local/ Unspecified) (*1)		Timestamp	DateTime2
date	DateOnly	DateTime	Date	Date
time without time zone	TimeOnly	TimeSpan	Time	Time
time with time zone		DateTimeOffset	TimeTz	
interval	TimeSpan	NpgsqlInterval	Interval	
cidr		ValueTuple<IPAddress, int>, IPAddress	Cidr	
inet	IPAddress	ValueTuple<IPAddress, int>	Inet	
macaddr	PhysicalAddress		MacAddr	
tsquery	NpgsqlTsQuery		TsQuery	
tsvector	NpgsqlTsVector		TsVector	
bit		bool, BitArray, string	Bit	
bit varying	BitArray	bool, BitArray, string	Varbit	
point	NpgsqlPoint		Point	
lseg	NpgsqlLSeg		LSeg	
path	NpgsqlPath		Path	
polygon	NpgsqlPolygon		Polygon	
line	NpgsqlLine		Line	
circle	NpgsqlCircle		Circle	
box	NpgsqlBox		Box	
hstore	IDictionary<string, string>		Hstore	
oid		uint	Oid	
xid		uint	Xid	
cid		uint	Cid	
oidvector		uint[]	Oidvector	

PostgreSQL Type	Default.NET Type	Non-default.NET Type	NpgsqlDbType	DbType
name		string, char[], char	Name	
(internal) char		byte	InternalChar	
composite types	Pre-mapped type		Composite	
range types	NpgsqlRange<T Subtype>		Range | NpgsqlDbType	
enum types	Pre-mapped type		Enum	
array types	T[], List<T>		Array | NpgsqlDbType	

*1: UTC DateTime is written as timestamp with time zone, Local/Unspecified DateTimes are written as timestamp without time zone. When Npgsql.EnableLegacyTimestampBehavior is enabled, DateTime is always written as timestamp without time zone.

*2: When Npgsql.EnableLegacyTimestampBehavior is enabled, DbType.DateTime is mapped to timestamp without time zone.

4.4.3 Creating Applications while in Database Multiplexing Mode and Multi-master Replication

This section explains points to consider when creating applications while in database multiplexing mode and multi-master replication.

See

- Refer to the Cluster Operation Guide (Database Multiplexing) for information on database multiplexing mode.
- Refer to the Cluster Operation Guide (Multi-master Replication) for information on multi-master replication and points to consider when creating applications.
- Refer to "Application Development" in the Cluster Operation Guide (PRIMECLUSTER) for points to consider when creating applications using the failover feature integrated with the cluster software.

4.4.3.1 Errors when an Application Connection Switch Occurs and Corresponding Actions

If an application connection switch occurs while in database multiplexing mode and multi-master replication, explicitly close the connection and then reestablish the connection or reexecute the application.

The table below shows errors that may occur during a switch, and the corresponding action to take.

State		Error information	Action
Server failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	57P01 (*1) 57P02 (*1) Empty string (*1)	After the switch is complete, reestablish the connection, or reexecute the application.
	Accessed during system failure	Empty string (*1)	
Switch to the standby server	Switched during access	57P01 (*1) 57P02 (*1) Empty string (*1)	
	Accessed during switch	Empty string (*1)	

*1: This is the return value of the PostgresException attribute SqlState.

4.4.4 Notes

Type Plugins

- These type libraries include:
  - NodaTime - the recommended way to interact with PostgrSQL date/time types
  - Json.NET - allows Npgsql to use the NewtonSoft Json.NET library when reading and writing JSON data (both json and jsonb)
  - NetTopologySuite - allows Npgsql to map PostGIS spatial types directly to the NetTopology suite types (the leading spatial library in .NET)
  - GeoJSON - allows Npgsql to read and write PostGIS spatial types as GeoJSON types via the GeoJSON.NET library
- Setup the plugin in your application simply by adding a dependency on the plugin (this should have been done automatically when installed to the project) and set it up. See the following code snippet for an example of setting up the Npgsql.NodaTime plugin:

```
    using Npgsql;
    // Place this at the beginning of your program to use NodaTime everywhere
(recommended)
    NpgsqlConnection.GlobalTypeMapper.UseNodaTime();
    // Or to temporarily use NodaTime on a single connection only:
    conn.TypeMapper.UseNodaTime();
```

Once the plugin is setup, you can read and write NodaTime objects as per the code snippet below:

```
    // Write NodaTime Instant to PostgreSQL "timestamp without time zone"
    using (var cmd = new NpgsqlCommand(@"INSERT INTO mytable (my_timestamp) VALUES
(@p)", conn))
    {
        cmd.Parameters.Add(new NpgsqlParameter("p", Instant.FromUtc(2011, 1, 1, 10,
30)));
        cmd.ExecuteNonQuery();
    }

    // Read timestamp back from the database as an Instant
    using (var cmd = new NpgsqlCommand(@"SELECT my_timestamp FROM mytable", conn))
    using (var reader = cmd.ExecuteReader())
    {
        reader.Read();
        var instant = reader.GetFieldValue<Instant>(0);
    }
```

- To apply the type plugin updates, do one of the following:
  - After uninstalling the type plugin (Refer to "4.5.2 Uninstalling .NET Data Provider Type Plugins"), setup the type plugin (Refer to "4.2.2 Setting Up .NET Data Provider Type Plugins**").**
  - Remove the type plugin directory from the packages directory of the solution, and then restore it using the nuget restore command.
- When you deploy an application with a type plugin, the type plugin is included in the distribution. Therefore, after applying the type plugin updates, you must rebuild the application and deploy the updated application.

Additional Notes on each Type Plugin

Describe notes about each type plugin.

NodaTime

Describes the mapping of PostgreSQL data types to NodaTime data types.

Mapping Table

PostgreSQL Type	Default NodaTime Type	Additional NodaTime Type	Note
timestamp with time zone	Instant	ZonedDateTime(*1), OffsetDateTime(*1)	UTC timestamp in database. Only UTC ZonedDateTime and OffsetDateTime are supported.
timestamp without time zone	LocalDateTime(*2)		A timestamp in an unknown or implied timezone.
date	LocalDate		A simple date with no timezone or offset information.
time without time zone	LocalTime		A simple time with no timezone or offset information.
time with time zone	OffsetTime		A type that stores a time and an offset. Generally not recommended for use.
interval	Period	Duration	A time interval from fractional seconds to years. NodaTime Duration is supported for days and smaller intervals, but not for years or months (because they have no absolute duration). Duration can be used in any interval unit.
tszrange	Interval	NpgsqlRange<Instant> ,etc	The time interval between two time instances (start and end).
strange	NpgsqlRange<LocalDateTime>		The time interval between two timestamps in unknown or implied timezones.
daterange	DateInterval	NpgsqlRange<LocalDate> ,etc	The interval between two dates.

*1: When Npgsql.EnableLegacyTimestampBehavior is enabled, writing or reading ZonedDateTime or OffsetDateTime is automatically converted to UTC.

*2: When Npgsql.EnableLegacyTimestampBehavior is enabled, timestamp without time zone is mapped to Instant instead of LocalDateTime by default.

Json.NET

Once the JSON plugin has been setup, users can transparently read and write CLR objects as JSON values and the plugin will automatically serialize/deserialize them

See the code snippet below:

```
// Write arbitrary CLR types as JSON
using (var cmd = new NpgsqlCommand(@"INSERT INTO mytable (my_json_column) VALUES (@p)",
conn))
{
    cmd.Parameters.Add(new NpgsqlParameter("p", NpgsqlDbType.Jsonb) { Value =
MyClrType });
    cmd.ExecuteNonQuery();
}

// Read arbitrary CLR types as JSON
using (var cmd = new NpgsqlCommand(@"SELECT my_json_column FROM mytable", conn))
using (var reader = cmd.ExecuteReader())
{
    reader.Read();
    var someValue = reader.GetFieldValue<MyClrType>(0);
}
```

NetTopologySuite (spatial)

By default the plugin handles only ordinates provided by the DefaultCoordinateSequenceFactory of GeometryServiceProvider.Instance. If GeometryServiceProvider is initialized automatically the X and Y ordinates are handled. To change the behavior specify the handleOrdinates parameter like in the following example:

```
conn.TypeMapper.UseNetTopologySuite(handleOrdinates: Ordinates.XYZ);
```

To process the M ordinate, you must initialize GeometryServiceProvider.Instance to a new NtsGeometryServices instance with coordinateSequenceFactory set to a DotSpatialAffineCoordinateSequenceFactory. Or you can specify the factory when calling UseNetTopologySuite.

```
// Place this at the beginning of your program to use the specified settings everywhere
(recommended)
GeometryServiceProvider.Instance = new NtsGeometryServices(
    new DotSpatialAffineCoordinateSequenceFactory(Ordinates.XYM),
    new PrecisionModel(PrecisionModels.Floating),
    -1);

// Or specify settings for Npgsql only
conn.TypeMapper.UseNetTopologySuite(
    new DotSpatialAffineCoordinateSequenceFactory(Ordinates.XYM));
```

Reading and Writing Geometry Values

When reading PostGIS values from the database, Npgsql will automatically return the appropriate NetTopologySuite types: Point, LineString, and so on. Npgsql will also automatically recognize NetTopologySuite's types in parameters, and will automatically send the corresponding PostGIS type to the database. The following code demonstrates a roundtrip of a NetTopologySuite Point to the database:

```
var point = new Point(new Coordinate(1d, 1d));
conn.ExecuteNonQuery("CREATE TEMP TABLE data (geom GEOMETRY)");
using (var cmd = new NpgsqlCommand("INSERT INTO data (geom) VALUES (@p)", conn))
{
    cmd.Parameters.AddWithValue("@p", point);
    cmd.ExecuteNonQuery();
}
```

```
using (var cmd = new NpgsqlCommand("SELECT geom FROM data", conn))
using (var reader = cmd.ExecuteReader())
{
    reader.Read();
    Assert.That(reader[0], Is.EqualTo(point));
}
```

You may also explicitly specify a parameter's type by setting NpgsqlDbType.Geometry.

Geography (geodetic) Support

PostGIS has two types:geometry (for Cartesian coordinates) and geography (for geodetic or spherical coordinates). You can read about the geometry/geography distinction in the PostGIS docs. In a nutshell, geography is much more accurate when doing calculations over long distances, but is more expensive computationally and supports only a small subset of the spatial operations supported by geometry.

Npgsql uses the same NetTopologySuite types to represent both geometry and geography - the Point type represents a point in either Cartesian or geodetic space. You usually don't need to worry about this distinction because PostgreSQL will usually cast types back and forth as needed. However, it's worth noting that Npgsql sends Cartesian geometry by default, because that's the usual requirement. You have the option of telling Npgsql to send geography instead by specifying NpgsqlDbType.Geography:

```
using (var cmd = new NpgsqlCommand("INSERT INTO data (geog) VALUES (@p)", conn))
{
    cmd.Parameters.AddWithValue("@p", NpgsqlDbType.Geography, point);
    cmd.ExecuteNonQuery();
}
```

If you prefer to use geography everywhere by default, you can also specify that when setting up the plugin:

```
NpgsqlConnection.GlobalTypeMapper.UseNetTopologySuite(geographyAsDefault: true);
```

GeoJSON (spatial)

Using the GeoJSON plugin is the same as the NetTopologuSuite.

Notes on the Query Builder

- Prefix named parameters with "@".
- Uppercase object names cannot be used, even when enclosed in double quotation marks.
  To use uppercase object names enclosed in double quotation marks, include them in SQL statements and enter these in the [Generate the SQL statements] window rather than in the Query Builder.
- SQL statements cannot be correctly generated if the SQL statement specified in Filter matches any of the conditions below:
  - It uses PostgreSQL intrinsic operators such as << or ::.
  - It uses functions with keywords such as AS, FROM, IN, OVER.

    Example: extract(field from timestamp), RANK( ) OVER
  - It uses functions with the same names as those prescribed in SQL conventions, but that require different arguments.

Notes on metadata

- The CommandBehavior.KeyInfo argument must be specified if executing ExecuteReader before obtaining metadata using GetSchemaTable.

Example

```
NpgsqlDataReader  ndr=cmd.ExecuteReader(CommandBehavior.KeyInfo);
DataTable dt = dr.GetSchemaTable();
```

Notes on automatically generating update-type SQL statements

- If the SQL statement includes a query (which cannot be updated) that matches any of the conditions below, an update-type SQL statement will be generated (note that it may not be possible to execute this SQL statement in some cases):
  - It includes derived tables
  - It includes the same column name as the select list

  Update-type SQL statements will be automatically generated in the following cases:
  - If update statements are obtained using NpgsqlCommandBuilder
  - If data is updated using NpgsqlDataAdapter

Notes on distributed transactions

- Applications using transaction scope can use distributed transactions by linking with Microsoft Distributed Transaction Coordinator (MSDTC). In this case, note the following:
  - Ensure that the value of max_prepared_transactions is greater than max_connection, so that "PREPARE TRANSACTION" can be issued for each transaction that simultaneously connects to the database server.
  - If each transaction in the transaction scope accesses the same resource using different connections, the database server will perceive it as requests from different applications, and a deadlock may occur. By configuring a timeout value for the transaction scope beforehand, the deadlock can be broken.

4.5 Uninstallation

This section explains how to uninstall .NET Data Provider and Entity Framework Core.

4.5.1 Uninstalling Npgsql

Npgsql is installed per project. To uninstall it, follow the procedure below:

L

- Linux

  Remove a package reference to the project file.

```
dotnet remove projectFilePath package Npgsql
```

W

- Windows(R)
  1. In Visual Studio, open a project for which Npgsql is installed.
  2. Click [Tools] >> [NuGet Package Manager] >> [Manage NuGet Packages for Solution].
  3. Select all the projects that have Npgsql installed, and then click [Uninstall].
     Alternatively, if the plugin packages have been removed and is no longer installed, in the solution explorer open the Dependencies/NuGet node and delete the plugins that require uninstallation.

4.5.2 Uninstalling .NET Data Provider Type Plugins

The **.NET Data Provider** type plugins are installed per project. To uninstall it, follow the procedure below:

- Linux

Remove a package reference to the project file (Example: Npgsql.NodaTime).

```
dotnet remove projectFilePath package Npgsql.NodaTime
```

- Windows(R)

1. In Visual Studio, open a project for which Npgsql the Plugin to be removed is installed.
2. Click [Tools] >> [NuGet Package Manager] >> [Manage NuGet Packages for Solution].
3. Select all the projects that have Npgsql Plugin(s) installed, and then click [Uninstall].
   Alternatively, if the plugin packages have been removed and are no longer installed, in the solution explorer open the Dependencies/NuGet node and delete the plugins that require uninstallation.

4.5.3 Uninstalling Entity Framework Core

Entity Framework Core is installed per project. To uninstall it, follow the procedure below:

- Linux

Remove a package reference to the project file.

```
dotnet remove projectFilePath package Npgsql.EntityFrameworkCore.PostgreSQL
```

- Windows(R)

1. In Visual Studio, open a project for which Entity Framework Core is installed.
2. Click [Tools] >> [NuGet Package Manager] >> [Manage NuGet Packages for Solution].
3. Select all the projects that have Entity Framework Core installed, and then click [Uninstall].
   Alternatively, if the Entity Framework package has been removed and is no longer installed, in the solution explorer open the Dependencies/NuGet node and delete the packages that require uninstallation.

4.5.4 Uninstalling Npgsql.OpenTelemetry

Npgsql.OpenTelemetry is installed per project. To uninstall it, follow the procedure below:

- Linux

Remove a package reference to the project file.

```
dotnet remove projectFilePath package Npgsql.OpenTelemetry
```

- Windows(R)

1. In Visual Studio, open a project for which Npgsql.OpenTelemetry is installed.
2. Click [Tools] >> [NuGet Package Manager] >> [Manage NuGet Packages for Solution].
3. Select all the projects that have Npgsql.OpenTelemetry installed, and then click [Uninstall].
   Alternatively, if the Npgsql.OpenTelemetry package has been removed and is no longer installed, in the solution explorer open the Dependencies/NuGet node and delete the packages that require uninstallation.

Chapter 5 C Library (libpq)

This chapter describes how to use C libraries.

5.1 Development Environment

Install Fujitsu Enterprise Postgres Client Package for the architecture to be developed and executed.

See

Refer to Installation and Setup Guide for Client for information on the C compiler required for C application development.

5.2 Setup

This section describes the environment settings required to use C libraries and how to encrypt data for communication.

5.2.1 Environment Settings

To execute an application that uses libpq, set the environment variable as shown below.

L

Linux

- Required for execution of the application
  - PGLOCALEDIR
    fujitsuEnterprisePostgresClientInstallDir/share/locale

Example

"<*x*>" indicates the product version.

```
> PGLOCALEDIR=/opt/fsepv<x>client64/share/locale;export PGLOCALEDIR
```

W

Windows (R)

- Required for compile/link
  - LIB
    fujitsuEnterprisePostgresClientInstallDir\lib
  - INCLUDE
    fujitsuEnterprisePostgresClientInstallDir\include
- Required for execution of the application
  - PATH
    fujitsuEnterprisePostgresClientInstallDir\lib
  - PGLOCALEDIR
    fujitsuEnterprisePostgresClientInstallDir\share\locale

Example

When the 32-bit version client package is installed on a 64-bit operating system. "<*x*>" indicates the product version.

```
> SET PATH=%ProgramFiles(x86)%\Fujitsu\fsepv<x>client32\lib;%PATH%
> SET LIB=%ProgramFiles(x86)%\Fujitsu\fsepv<x>client32\lib;%LIB%
```

```
> SET INCLUDE=%ProgramFiles(x86)%\Fujitsu\fsepv<x>client32\include;%INCLUDE%
> SET PGLOCALEDIR=%ProgramFiles(x86)%\Fujitsu\fsepv<x>client32\share\locale
```

5.2.2 Message Language and Encoding System Used by Applications Settings

This section explains the language settings for the application runtime environment and the encoding settings for the application.

Language settings

You must match the language settings for the application runtime environment with the message locale settings of the database server.

Messages output by an application may include text from messages sent from the database server. In the resulting text, the text of the application message will use the message locale of the application, and the text of the message sent by the database server will use the message locale of the database server. If the message locales do not match, more than one language or encoding system will be used. Moreover, if the encoding systems do not match, characters in the resulting text can be garbled.

L

- Linux

Set the locale for messages (LC_MESSAGES category) to match the message locale of the database server. This can be done in a few different ways, such as using environment variables. Refer to the relevant manual of the operating system for information on the setlocale function.

Example

Example of specifying "en_US.UTF-8" with the setlocale function

```
setlocale(LC_ALL,"en_US.UTF-8");
```

Specifying the locale of the LC_ALL category propagates the setting to LC_MESSAGE.

W

- Windows(R)

Align the locale of the operating system with the message locale of the database server.

Encoding System Settings

Ensure that the encoding system that is embedded in the application and passed to the database, and the encoding system setting of the runtime environment, are the same. The encoding system cannot be converted correctly on the database server.

Use one of the following methods to set the encoding system for the application:

- Set the PGCLIENTENCODING environment variable in the runtime environment.
- Set the client_encoding keyword in the connection string.
- Use the PQsetClientEncoding function.

See

Refer to "Supported Character Sets" in "Server Administration" in the PostgreSQL Documentation for information on the strings that represent the encoding system that can be set.

For example, when using "Unicode" and "8 bit", set the string "UTF8".

Note

Text may be garbled when outputting results to the command prompt. Review the font settings for the command prompt if this occurs.

5.2.3 Settings for Encrypting Communication Data

Set in one of the following ways when performing remote access using communication data encryption:

When setting from outside with environment variables

Specify "require", "verify-ca", or "verify-full" in the PGSSLMODE environment variable.

In addition, the parameters for the PGSSLROOTCERT and PGSSLCRL environment variables need to be set to prevent spoofing of the database server.

See

Refer to "Environment Variables" in "Client Interfaces" in the PostgreSQL Documentation for information on environment variables.

When specifying in the connection URI

Specify "require", "verify-ca", or "verify-full" in the "sslmode" parameter of the connection URI.

In addition, the parameters for the sslcert, sslkey, sslrootcert, and sslcrl need to be set to prevent spoofing of the database server.

See

Refer to "Secure TCP/IP Connections with SSL" in "Server Administration" in the PostgreSQL Documentation for information on encrypting communication data.

5.3 Connecting with the Database

Point

Use the connection service file to specify the connection destination. In the connection service file, a name (service name) is defined as a set, comprising information such as connection destination information and various types of tuning information set for connections. By using the service name defined in the connection service file when connecting to databases, it is no longer necessary to modify applications when the connection information changes.

Refer to "Client Interfaces", "The Connection Service File" in the PostgreSQL Documentation for details.

See

Refer to "Database Connection Control Functions" in "Client Interfaces" in the PostgreSQL Documentation.

In addition, refer to "6.3 Connecting with the Database" in "Embedded SQL in C " for information on connection string.

5.4 Application Development

See

Refer to "libpq - C Library" in "Client Interfaces" in the PostgreSQL Documentation for information on developing applications.

However, if you are using the C library, there are the following differences to the PostgreSQL C library (libpq).

5.4.1 Compiling Applications

Specify the following paths when compiling applications.

Refer to your compiler documentation for information on how to specify the path.

Also, when using a shared library, refer to "A.6 How to Build and Run an Application that Uses Shared Libraries".

L - Linux

L Table 5.1 Include file and library path

Type of path	Path name
Path of the include file	*fujitsuEnterprisePostgresClientInstallDir*/include
Path of the library	*fujitsuEnterprisePostgresClientInstallDir*/lib

L Table 5.2 C Library (libpq library)

Type of library	Library name
Dynamic library	libpq.so
Static library	libpq.a

W - Windows(R)

If the include file and the library path have been set in the environment variable, there is no need to specify the paths shown below for the compile.

W Table 5.3 Include file and library path

Type of path	Path name
Path of the include file	*fujitsuEnterprisePostgresClientInstallDir*\include
Path of the library	*fujitsuEnterprisePostgresClientInstallDir*\lib

W Table 5.4 C Library (libpq library)

Type of library	Library name
Library for links	libpq.lib
Dynamic library	libpq.dll

5.4.2 Creating Applications while in Database Multiplexing Mode and Multi-master Replication

This section explains points to consider when creating applications while in database multiplexing mode and multi-master replication.

See

- Refer to the Cluster Operation Guide (Database Multiplexing) for information on database multiplexing mode.

- Refer to the Cluster Operation Guide (Multi-master Replication) for information on multi-master replication and points to consider when creating applications.
- Refer to "Application Development" in the Cluster Operation Guide (PRIMECLUSTER) for points to consider when creating applications using the failover feature integrated with the cluster software.

5.4.2.1 Errors when an Application Connection Switch Occurs and Corresponding Actions

If an application connection switch occurs while in database multiplexing mode and multi-master replication, explicitly close the connection and then reestablish the connection or reexecute the application.

The table below shows errors that may occur during a switch, and the corresponding action to take.

State		Error information	Action
Server failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	PGRES_FATAL_ERROR(*1) 57P01(*2) NULL(*2)	After the switch is complete, reestablish the connection, or reexecute the application.
	Accessed during system failure	CONNECTION_BAD(*3)	
Switch to the standby server	Switched during access	PGRES_FATAL_ERROR(*1) 57P01(*2) NULL(*2)	
	Accessed during switch	CONNECTION_BAD(*3)	

*1: Return value of PQresultStatus().

*2: Return value of PQresultErrorField() PG_DIAG_SQLSTATE.

*3: Return value of PQstatus().

Chapter 6 Embedded SQL in C

This chapter describes application development using embedded SQL in C.

6.1 Development Environment

Install Fujitsu Enterprise Postgres Client Package for the architecture to be developed and executed.

See

Refer to Installation and Setup Guide for Client for information on the C compiler required for C application development.

Note

C++ is not supported. Create a library by implementing embedded SQL in C, and call it from C++.

6.2 Setup

6.2.1 Environment Settings

When using embedded SQL in C, the same environment settings as when using the C library (libpq) are required.

Refer to "5.2.1 Environment Settings" in "C Library (libpq)" for information on the environment settings for the library for C.

Additionally, set the following path for the precompiler ecpg in the PATH environment variable:

L Linux

```
fujitsuEnterprisePostgresClientInstallDir/bin
```

W Windows(R)

```
fujitsuEnterprisePostgresClientInstallDir\bin
```

6.2.2 Message Language and Encoding System Used by Applications Settings

The message language and the encoding System Settings Used by Applications settings are the same as when using the library for C.

However, in embedded SQL, the PQsetClientEncoding function cannot be used in the encoding system settings. In embedded SQL, use the SET command to specify the encoding system in client_encoding.

Refer to "5.2.2 Message Language and Encoding System Used by Applications Settings" in "C Library (libpq)" for information on the settings for the library for C.

6.2.3 Settings for Encrypting Communication Data

When encrypting the communication data, the same environment settings as when using the C library (libpq) are required.

Refer to "5.2.3 Settings for Encrypting Communication Data" in "C Library (libpq)" for information on the environment settings for the C library.

6.3 Connecting with the Database

Point

- It is recommended to use a connection service file to specify connection destinations. In the connection service file, a name (service name) is defined as a set, comprising information such as connection destination information and various types of tuning information set for connections. By using the service name defined in the connection service file when connecting to databases, it is no longer necessary to modify applications when the connection information changes. Refer to "The Connection Service File" in "Client Interfaces" in the PostgreSQL Documentation for information.
- If using a connection service file, perform either of the procedures below:
  - Set the service name as a string literal or host variable, as follows:

    tcp:postgresql://?service=my_service
  - Set the service name in the environment variable PGSERVICE, and use CONNECT TO DEFAULT

Use the CONNECT statement shown below to create a connection to the database server.

Format

```
EXEC SQL CONNECT TO target [AS connection-name] [USER user-name];
```

target

Write in one of the following formats:

- dbname@host:port
- tcp:postgresql://host:port/dbname[?options]
- unix:postgresql://host[:port][/dbname][?options]
  (Definition method when using the UNIX domain socket)
- SQL string literal containing one of the above formats
- Reference to a character variable containing one of the above formats
- DEFAULT

user-name

Write in one of the following formats:

- username
- username/password
- username IDENTIFIED BY password
- username USING password

Description of the arguments

Argument	Description
dbname	Specify the database name.
host	Specify the host name for the connection destination.
port	Specify the port number for the database server. The default is "27500".
connection-name	Specify connection names to identify connections when multiple connections are to be processed within a single program.

Argument	Description
username	Specify the user that will connect with the database. If this is omitted, the name used will be that of the user on the operating system that is executing the application.
password	Specify a password when authentication is required.
options	Specify the following parameter when specifying a time for timeout. Connect parameters with & when specifying more than one. The following shows the values specified for each parameter. - connect_timeout Specify the timeout for connections. Specify a value between 0 and 2147483647 (in seconds). There is no limit set if you set 0 or an invalid value. If "1" is specified, the behavior will be the same as when "2" was specified. An error occurs when a connection cannot be established within the specified time. - keepalives This enables keepalive. Keepalive is disabled if 0 is specified. Keepalive is enabling when any other value is specified. The default is keepalive enabled. Keepalive causes an error to occur when it is determined that the connection with the database is disabled. - keepalives_idle Specify the time until the system starts sending keepalive messages when communication with the database is not being performed. - Linux Specify a value between 1 and 32767 (in seconds). The default value of the system is used if this is not specified. - Windows(R) Specify a value between 1 and 2147483647 (in seconds). 7200 will be set as default if a value outside this range is specified or if nothing is specified. - keepalives_interval Specify the interval between resends when there is no response to keepalive messages. - Linux Specify a value between 1 and 32767 (in seconds). The default value of the system is used if this is not specified. - Windows(R) Specify a value between 1 and 2147483647 (in seconds). 1 will be set as default if a value outside this range is specified or if nothing is specified. - keepalives_count Specify the number of resends for keepalive messages. - Linux Specify a value between 1 and 127. The default value of the system is used if this is not specified. - Windows(R) The system default value is used irrespective of what is specified for this parameter. - tcp_user_timeout

Argument	Description
	After establishing the connection, when sending from the client to the server, if the TCP resend process operates, specify the time until it is considered to be disconnected. - Linux Specify a value between 0 and 2147483647 (in millseconds). The default value of the system is used if 0. 0 will be set as default if nothing is specified. - Windows(R) Cannot be specified.

L

Note

If a value other than 0 is specified for the tcp_user_timeout parameter, the waiting time set by the tcp_keepalives_idle parameter and tcp_keepalives_interval parameter will be invalid and the waiting time specified by the tcp_user_timeout parameter will be used.

Code examples for applications

```
EXEC SQL CONNECT TO tcp:postgresql://sv1:27500/mydb?
connect_timeout=20&keepalives_idle=20&keepalives_interval=5&keepalives_count=2&keepalives=
1 USER myuser/myuser01;
```

6.4 Application Development

Refer to "ECPG - Embedded SQL in C" in "Client Interfaces" in the PostgreSQL Documentation for information on developing applications.

However, when using embedded SQL in C, there are the following differences to the embedded SQL (ECPG) in PostgreSQL C.

6.4.1 Support for National Character Data Types

This section describes how to use the national character data types using the SQL embedded C preprocessor.

The following explains the C language variable types corresponding to the NCHAR type:

Specify the number of characters specified for the NCHAR type multiple by 4, plus 1 for the length of the host variable.

Data Type	Host variable type
NATIONAL CHARACTER(*n*)	NCHAR variable name [nx4+1]
NATIONAL CHARACTER VARYING(*n*)	NVARCHAR variable name [nx4+1]

See

Refer to "Handling Character Strings" in "Client Interfaces" in the PostgreSQL documentation for information on using character string types.

6.4.2 Compiling Applications

Append the extension "pgc" to the name of the source file for the embedded SQL in C.

When the pgc file is precompiled using the ecpg command, C source files will be created, so use the C compiler for the compile.

Precompiling example

```
ecpg testproc.pgc
```

If an optimizer hint block comment is specified for the SQL statement, specify the following option in the ecpg command:

--enable-hint

Enables the optimizer hint block comment (hereafter, referred to as the "hint clause"). If this option is not specified, the hint clause will be removed as a result of the ecpg precompile and be disabled.

The SQL statements that can be specified in the hint clause are SELECT, INSERT, UPDATE, and DELETE.

The locations in which the hint clause can be specified are immediately after one of the SELECT, INSERT, UPDATE, DELETE, or WITH keywords. A syntax error will occur if any other location is specified.

Example of specifying the hint clause

```
EXEC SQL SELECT /*+ IndexScan(prod ix01) */ name_id INTO :name_id FROM prod WHERE id
= 1;
```

See

For basic usage of pg_hint_plan and pg_dbms_stats, see below.

- Control execution plans with pg_hint_plan

  https://www.postgresql.fastware.com/postgresql-insider-tun-hint-plan

Note

Take the following points into account when using embedded SQL source files:

- Multibyte codes expressed in SJIS or UTF-16 cannot be included in statements or host variable declarations specified in EXEC SQL.
- Do not use UTF-8 with a byte order mark (BOM), because an error may occur during compilation if the BOM character is incorrectly recognized as the source code.
- Multibyte characters cannot be used in host variable names.
- It is not possible to use a TYPE name that contains multibyte characters, even though it can be defined.

Specify the following paths when compiling a C application output with precompiling.

Refer to your compiler documentation for information on how to specify the path.

Also, when using a shared library, refer to "A.6 How to Build and Run an Application that Uses Shared Libraries".

Linux

Table 6.1 Include file and library path

Type of path	Path name
Path of the include file	*fujitsuEnterprisePostgresClientInstallDir*\include
Path of the library	*fujitsuEnterprisePostgresClientInstallDir*\lib

L

Table 6.2 C Library

Type of library	Library name	Note
Dynamic library	libecpg.so	
	libpgtypes.so	When using the pgtypes library
Static library	libecpg.a	
	libpgtypes.a	When using the pgtypes library

W

Windows(R)

If the include file and the library path have been set in the environment variable, there is no need to specify the paths shown below for the compile.

W

Table 6.3 Include file and library path

Type of path	Path name
Path of the include file	*fujitsuEnterprisePostgresClientInstallDir\include*
Path of the library	*fujitsuEnterprisePostgresClientInstallDir\lib*

W

Table 6.4 C Library

Type of library	Library name	Note
Library for links	libecpg.lib	
	libpgtypes.lib	When using the pgtypes library
Dynamic library	libecpg.dll	
	libpgtypes.dll	When using the pgtypes library

Note

- The libecpg library in Windows(R) is created by "release" and "multithreaded" options. When using the ECPGdebug function included in this library, compile using the "release" and "multithreaded" flags in all programs that use this library. When you do this, use the "dynamic" flag if you are using libecpg.dll, and use the "static" flag if you are using libecpg.lib.

  Refer to "Library Functions" in "Client Interfaces" in the PostgreSQL Documentation for information on the ECPGdebug function.

- The cl command expects input to be a program that uses one of the following code pages, so convert the program to these code pages and then compile and link it (refer to the Microsoft documentation for details).

  - ANSI console code pages (example: Shift-JIS for Japanese)
  - UTF-16 little-endian with or without BOM (Byte Order Mark)
  - UTF-16 big-endian with or without BOM
  - UTF-8 with BOM

  The cl command converts strings in a program to an ANSI console code page before generating a module, so the data sent to and received from the database server becomes an ANSI console code page. Therefore, set the coding system corresponding to the ANSI console code page as the coding system of the client.

  Refer to "Character Set Support" in "Server Administration" in the PostgreSQL Documentation for information on how to set the client encoding system.
  (Example: To use environment variables in Japanese, set SJIS in PGCLIENTENCODING.)

6.4.3 Bulk INSERT

This section describes the bulk INSERT.

Synopsis

```
EXEC SQL [ AT conn ] [ FOR { numOfRows | ARRAY_SIZE } ]
    INSERT INTO tableName [ ( colName [, ...] ) ]
    { VALUES ( { expr | DEFAULT } [, ...] ) [, ...] | query }
    [ RETURNING * | outputExpr [ [ AS ] outputName ] [, ...]
    INTO outputHostVar [ [ INDICATOR ] indicatorVar  ]  [, ...] ];
```

Description

Bulk INSERT is a feature that inserts multiple rows of data in bulk.

By specifying the array host variable that stored the data in the VALUES clause of the INSERT statement, the data for each element in the array can be inserted in bulk. This feature is used by specifying the insertion count in the FOR clause immediately before the INSERT statement.

FOR Clause

Specify the insertion count using numOfRows or ARRAY_SIZE in the FOR clause. The FOR clause can be specified only in the INSERT statement, not in other update statements.

numOfRows and ARRAY_SIZE

Insertion processing will be executed only for the specified count. However, if the count is 1, it will be assumed that the FOR clause was omitted when the application is executed. In this case, proceed according to the INSERT specification in the PostgreSQL Documentation.

Specify the FOR clause with a short, int, or long long host variable or with a literal.

Specify ARRAY_SIZE to insert all elements of the array in the table. When specifying ARRAY_SIZE, specify at least one array in *expr*.

If two or more arrays were specified in expr, it will be assumed that ARRAY_SIZE is the minimum number of elements in the array.

numOfRows or ARRAY_SIZE must exceed the minimum number of elements in all arrays specified in *expr*, *outputHostVar*, and *indicatorVal*.

The following example shows how to specify the FOR clause.

```
int  number_of_rows = 10;
int id[25];
char name[25][10];

EXEC SQL FOR :number_of_rows    /* will process 10 rows */
INSERT INTO prod (name, id) VALUES (:name, :id);

EXEC SQL FOR ARRAY_SIZE           /* will process 25 rows */
INSERT INTO prod (name, id) VALUES (:name, :id);
```

expr

Specify the value to be inserted in the table. Array host variables, host variable literals, strings, and pointer variables can be specified. Structure type arrays and pointer variable arrays cannot be specified.

Do not use pointer variables and ARRAY_SIZE at the same time. The reason for this is that the number of elements in the area represented by the pointer variable cannot be determined.

query

A query (SELECT statement) that supplies the rows to be inserted. The number of rows returned by *query* must be 1. If two or more rows are returned, an error will occur. This cannot be used at the same time as ARRAY_SIZE.

outputHostVar, indicatorVal

These must be array host variables or pointer variables.

Error Messages

Given below are the error messages that are output when bulk INSERT functionality is not used correctly.

Message

invalid statement name "FOR value should be positive integer"

Cause

The value given for *numOfRows* is less than or equal to 0.

Solution

Specify a value that is more than or equal to 1 for *numOfRows*.

Message

invalid statement name "Host array variable is needed when using FOR ARRAY_SIZE"

Cause

A host array is not specified in the values clause when using the ARRAY_SIZE keyword.

Solution

At least one host array variable should be included in the values clause

Message

SELECT...INTO returns too many rows

Cause

The number of rows returned by the 'SELECT ... INTO' query in the INSERT statement is more than one.

Solution

When the value of *numOfRows* is more than one, the maximum number of rows that can be returned by the 'SELECT ... INTO' query in the INSERT statement is one.

Limitations

The limitations when using bulk INSERT are given below.

- Array of structures should not be used as an input in the 'VALUES' clause. Attempted use will result in junk data being inserted into the table.
- Array of pointers should not be used as an input in the 'VALUES' clause. Attempted use will result in junk data being inserted into the table.
- ECPG supports the use of 'WITH' clause in single INSERT statements. 'WITH' clause cannot be used in bulk INSERT statements.
- ECPG does not calculate the size of the pointer variable. So when a pointer variable is used that includes multiple elements, *numOfRows* should be less than or equal to the number of elements in the pointer. Otherwise, junk data will be inserted into the table.
- If an error occurs, all bulk INSERT actions will be rolled back, therefore, no rows are inserted. However, if the RETURNING clause was used, and the error occurred while obtaining the rows after the insertion was successful, the insertion processing will not be rolled back.

Samples

Given below are some sample usages of the bulk INSERT functionality.

Basic Bulk INSERT

```
int in_f1[4] = {1,2,3,4};
...
EXEC SQL FOR 3 INSERT INTO target (f1) VALUES (:in_f1);
```

The number of rows to insert indicated by the FOR clause is 3, so the data in the first 3 elements of the host array variable are inserted into the table. The contents of the target table will be:

```
 f1
----
  1
  2
  3
(3 rows)
```

Also a host integer variable can be used to indicate the number of rows that will be inserted in FOR clause, which will produce the same result as above:

```
int num = 3;
int in_f1[4] = {1,2,3,4};
...
EXEC SQL FOR :num INSERT INTO target (f1) VALUES (:in_f1);
```

Inserting constant values

Constant values can also be bulk INSERTed into the table as follows:

```
EXEC SQL FOR 3 INSERT INTO target (f1,f2) VALUES (DEFAULT,'hello');
```

Assuming the 'DEFAULT' value for the 'f1' column is '0', the contents of the target table will be:

```
f1 |  f2
---+-------
 0 | hello
 0 | hello
 0 | hello
(3 rows)
```

Using ARRAY_SIZE

'FOR ARRAY_SIZE' can be used to insert the entire contents of a host array variable, without explicitly specifying the size, into the table.

```
    int in_f1[4] = {1,2,3,4};
...
EXEC SQL FOR ARRAY_SIZE INSERT INTO target (f1) VALUES (:in_f1);
```

In the above example, four rows are inserted into the table.

Note

If there are multiple host array variables specified as input values, then the number of rows inserted is same as the smallest array size. The example given below demonstrates this usage.

```
int in_f1[4] = {1,2,3,4};
char in_f3[3][10] = {"one", "two", "three"};
```

```
...
EXEC SQL FOR ARRAY_SIZE INSERT INTO target (f1,f3) VALUES (:in_f1,:in_f3);
```

In the above example, the array sizes are 3 and 4. Given that the smallest array size is 3, only three rows are inserted into the table. The table contents are given below.

```
 f1 |  f3
----+-------
  1 | one
  2 | two
  3 | three
(3 rows)
```

Using Pointers as Input

Pointers that contain multiple elements can be used in bulk INSERT.

```
int *in_pf1 = NULL;
in_pf1 = (int*)malloc(4*sizeof(int));
in_pf1[0]=1;
in_pf1[1]=2;
in_pf1[2]=3;
in_pf1[3]=4;
...
EXEC SQL FOR 4 INSERT INTO target (f1) values (:in_pf1);
```

The above example will insert four rows into the target table.

Using SELECT query

When using bulk INSERT, the input values can be got from the results of a SELECT statement. For example,

```
EXEC SQL FOR 4 INSERT INTO target(f1) SELECT age FROM source WHERE name LIKE 'foo';
```

Assuming that the 'SELECT' query returns one row, the same row will be inserted into the target table four times.

If the 'SELECT' query returns more than one row, the INSERT statement will throw an error.

```
EXEC SQL FOR 1 INSERT INTO target(f1) SELECT age FROM source;
```

In the above example, all the rows returned by the 'SELECT' statement will be inserted into the table. In this context '1' has the meaning of 'returned row equivalent'.

Using RETURNING clause

Bulk INSERT supports the same RETURNING clause syntax as normal INSERT. An example is given below.

```
int out_f1[4];
int in_f1[4] = {1,2,3,4};
...
EXEC SQL FOR 3 INSERT INTO target (f1) VALUES (:in_f1) RETURNING f1 INTO :out_f1;
```

After the execution of the above INSERT statement, the 'out_f1' array will have 3 elements with the values of '1','2' and '3'.

6.4.4 Creating Applications while in Database Multiplexing Mode and Multi-master Replication

This section explains points to consider when creating applications while in database multiplexing mode and multi-master replication.

See

- Refer to the Cluster Operation Guide (Database Multiplexing) for information on database multiplexing mode.
- Refer to the Cluster Operation Guide (Multi-master Replication) for information on multi-master replication and points to consider when creating applications.
- Refer to "Application Development" in the Cluster Operation Guide (PRIMECLUSTER) for points to consider when creating applications using the failover feature integrated with the cluster software.

6.4.4.1 Errors when an Application Connection Switch Occurs and Corresponding Actions

If an application connection switch occurs while in database multiplexing mode and multi-master replication, explicitly close the connection and then reestablish the connection or reexecute the application.

The table below shows errors that may occur during a switch, and the corresponding action to take.

State		Error information (*1)	Action
Server failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	57P01 57P02 YE000 26000 40001	After the switch is complete, reestablish the connection, or reexecute the application.
	Accessed during node/system failure	08001	
Switch to the standby server	Switched during access	57P01 57P02 YE000 26000 40001	
	Accessed during switch	08001	

*1: Return value of SQLSTATE.

6.4.5 Notes

Notes on creating multithreaded applications

In embedded SQL in C, DISCONNECT ALL disconnects all connections within a process, and therefore it is not thread-safe in all operations that use connections. Do not use it in multithreaded applications.

Chapter 7 Embedded SQL in COBOL

This chapter describes application development using embedded SQL in COBOL.

7.1 Development Environment

Install Fujitsu Enterprise Postgres Client Package for the architecture to be developed and executed.

See

Refer to the Installation and Setup Guide for Client for information on the COBOL compiler required for COBOL application development.

7.2 Setup

7.2.1 Environment Settings

When using embedded SQL in COBOL, the same environment settings as when using the C library (libpq) are required. Refer to "5.2.1 Environment Settings" in "C Library (libpq)" for information on the environment settings for the library for C.

Additionally, set the following path for the precompiler ecobpg in the PATH environment variable:

L

Linux

```
fujitsuEnterprisePostgresClientInstallDir/bin
```

W

Windows(R)

```
fujitsuEnterprisePostgresClientInstallDir\bin
```

7.2.2 Message Language and Encoding System Used by Applications

The settings for the message language and the encoding system used by applications should be the same as those required when using the library for C.

However, in embedded SQL, the PQsetClientEncoding function cannot be used in the encoding system settings. In embedded SQL, use the SET command to specify the encoding system in client_encoding.

Refer to "5.2.2 Message Language and Encoding System Used by Applications Settings" in "C Library (libpq)" for information on the settings for the library for C.

7.2.3 Settings for Encrypting Communication Data

When encrypting the communication data, the same environment settings as when using the C library (libpq) are required.

Refer to "5.2.3 Settings for Encrypting Communication Data" in "C Library (libpq)" for information on the environment settings for the C library.

7.3 Connecting with the Database

Use the CONNECT statement shown below to create a connection to the database server.

Format

```
EXEC SQL CONNECT TO target [AS connection-name] [USER user-name]END-EXEC.
```

target

Write in one of the following formats:

- dbname@host:port
- tcp:postgresql://host:port/dbname[?options]
- unix:postgresql://host[:port][/dbname][?options]
  (Definition method when using the UNIX domain socket)
- SQL string literal containing one of the above formats
- Reference to a character variable containing one of the above formats
- DEFAULT

Note

If target is DEFAULT, the AS clause and USER clause cannot be specified.

user-name

Write in one of the following formats:

- username
- username/password
- username IDENTIFIED BY password
- username USING password

Description of the arguments

Argument	Description
dbname	Specify the database name.
host	Specify the host name for the connection destination.
port	Specify the port number for the database server. The default is "27500".
connection-name	Specify connection names to identify connections when multiple connections are to be processed within a single program.
username	Specify the user that will connect with the database. If this is omitted, the name used will be that of the user on the operating system that is executing the application.
password	Specify a password when authentication is required.
options	Specify the following parameter when specifying a time for timeout. Connect parameters with & when specifying more than one. The following shows the values specified for each parameter. - connect_timeout Specify the timeout for connections. Specify a value between 0 and 2147483647 (in seconds). There is no limit set if you set 0 or an invalid value. If "1" is specified, the behavior will be the same as when "2" was specified. An error occurs when a connection cannot be established within the specified time. - keepalives This enables keepalive.

Argument	Description
	Keepalive is disabled if 0 is specified. Keepalive is enabled when any other value is specified. The default is keepalive enabled. Keepalive causes an error to occur when it is determined that the connection with the database is disabled. - keepalives_idle Specify the time until the system starts sending keepalive messages when communication with the database is not being performed. - Linux Specify a value between 1 and 32767 (in seconds). The default value of the system is used if this is not specified. - Windows(R) Specify a value between 1 and 2147483647 (in seconds). 7200 will be set as default if a value outside this range is specified or if nothing is specified. - keepalives_interval Specify the interval between resends when there is no response to keepalive messages. - Linux Specify a value between 1 and 32767 (in seconds). The default value of the system is used if this is not specified. - Windows(R) Specify a value between 1 and 2147483647 (in seconds). 1 will be set as default if a value outside this range is specified or if nothing is specified. - keepalives_count Specify the number of resends for keepalive messages. - Linux Specify a value between 1 and 127. The default value of the system is used if this is not specified. - Windows(R) The system default value is used irrespective of what is specified for this parameter.

Code examples for applications

```
EXEC SQL CONNECT TO tcp:postgresql://sv1:27500/mydb?
connect_timeout=20&keepalives_idle=20&keepalives_interval=5&keepalives_count=2&keepalives=
1 USER myuser/myuser01 END-EXEC.
```

7.4 Application Development

Refer to "Appendix D ECOBPG - Embedded SQL in COBOL" for information on developing applications.

7.4.1 Support for National Character Data Types

This section describes how to use the national character data types using the SQL embedded COBOL preprocessor.

The table below lists the COBOL variable types supporting the national character data types. The number of characters specified for the national character data type must be specified for the length of the host variable.

National character data type	COBOL variable type
CHARACTER(*n*)	*varName* PIC N(*n*)

National character data type	COBOL variable type
NATIONAL CHARACTER(*n*)	
CHARACTER VARYING(*n*) NATIONAL CHARACTER VARYING(*n*)	*varName* PIC N(*n*) VARYING

To use COBOL variable types that support national character data types, it is necessary to specify the ECOBPG_NCHAR environment variable.

ECOBPG_NCHAR={ UTF16LE | UTF16BE | UTF32LE | UTF32BE | SJIS }

In SQL embedded COBOL, specify the encoding of the COBOL variable types that support national character data types.

- UTF16LE: UTF-16 little-endian
- UTF16BE: UTF-16 big-endian
- UTF32LE: UTF-32 little-endian
- UTF32BE: UTF-32 big-endian
- SJIS: Shift JIS

If this environment variable is omitted, the encoding will be determined according to the encoding system of the client.

- If UTF8 is used: UTF16 (endians will be encoded in accordance with endians of the client system)
- If SJIS is used: SJIS

If encoding is specified for the translation option when compiling with NetCOBOL, the encoding specified for the national character data types should be used for the environment variable ECOBPG_NCHAR.

The list below shows NetCOBOL translation options and their corresponding environment variable ECOBPG_NCHAR values.

NetCOBOL translation options	Environment variable ECOBPG_NCHAR
ENCODE (UTF-8,UTF16,LE) RCS (UTF-16,LE)	UTF-16LE
ENCODE (UTF-8,UTF-16,BE) RCS (UTF-16,BE)	UTF-16BE
ENCODE (UTF-8,UTF-32,LE)	UTF-32LE
ENCODE (UTF-8,UTF-32,BE)	UTF-32BE
ENCODE (SJIS,SJIS)	SJIS
Not specified	No need to specify

Also, if the post-compiling encoding for an application differs from the locale of the execution environment, then the client encoding must be used for the application.

The list below shows the values supported for the combinations of application encoding, locale of the execution environment, and client encodings.

Application encoding	Locale used when executing an application	Client encoding
UTF-8	UTF-8	UTF-8
	SJIS	UTF-8
SJIS	UTF-8	SJIS

Application encoding	Locale used when executing an application	Client encoding
	SJIS	SJIS

Refer to "7.2.2 Message Language and Encoding System Used by Applications" for information on how to set client encoding systems.

The following example shows host variable declaration of a national character data type.

```
01 DATA1 PIC N(10).
01 DATA2 PIC N(10) VARYING.
```

Note

- Halfwidth characters should not be used for the national character data type COBOL variable.
- The national character data type column attribute obtained by applications should be the CHAR type.
- Encoding cannot be specified using the ENCODING clause, which is a feature of NetCOBOL.

7.4.2 Compiling Applications

Append the extension "pco" to the name of the source file for the embedded SQL in COBOL.

When the pco file is precompiled using the ecobpg command, COBOL source files will be created, so use the COBOL compiler for the compile.

Precompiling example

```
ecobpg testproc.pco
```

For COBOL code notation, "fixed" or "variable" format can be specified as an ecobpg command option. If not specified, "fixed" format is used.

Refer to "D.1 Precautions when Using Functions and Operators" and "D.12.1 ecobpg" for information on COBOL code notation and how to specify options for ecobpg.

If an optimizer hint block comment is specified for the SQL statement, specify the following option in the ecobpg command:

--enable-hint

Enables the optimizer hint block comment (hereafter, referred to as the "hint clause"). If this option is not specified, the hint clause will be removed as a result of the ecobpg precompile and be disabled.

The SQL statements that can be specified in the hint clause are SELECT, INSERT, UPDATE, and DELETE.

The locations in which the hint clause can be specified are immediately after one of the SELECT, INSERT, UPDATE, DELETE, or WITH keywords. A syntax error will occur if it is specified in any other location.

Example of specifying the hint clause

```
EXEC SQL SELECT /*+ IndexScan(prod ix01) */ name_id
INTO :name_id FROM prod WHERE id = 1 END-EXEC.
```

See

For basic usage of pg_hint_plan and pg_dbms_stats, see below.

- Control execution plans with pg_hint_plan

  https://www.postgresql.fastware.com/postgresql-insider-tun-hint-plan

If the encoding used for embedded SQL source files differs from that of the locale when precompiling was executed, set the encoding for the embedded SQL source files by specifying the following option for ecobpg.

-E-encode

Specify "UTF8", "SJIS", or "EUC_JP".

If this option is omitted, the encoding is processed based on the locale.

Path of the library file

The ecobpg command defines a group item "sqlca_t" to handle errors, which is defined in the library file stored in the following path:

Linux

Library file name	The storage destination of library file
SQLCA-COBOL.cob	*fujitsuEnterprisePostgresClientInstallDir*/include

Windows(R)

Library file name	The storage destination of library file
SQLCA-COBOL.cob	*fujitsuEnterprisePostgresClientInstallDir*\include

When the ecobpg command generates a COBOL file, it inserts a COPY statement with no options to copy the library file. Therefore, specify the path of the storage destination of library file when compiling. How to specify the path must conform to your compiler's specifications.

There is also a library file with the same contents without the extension"cob".

Information

Refer "D.7.2 sqlca"for information on the sqlca_t.

Libraries to use

The applications generated by ecobpg connect to PostgreSQL through the ECPG library. The ECPG library internally loads the libpq library.

Path of library

Refer to "6.4.2 Compiling Applications" for information on the location and name of the ECPG library. And Refer to " Chapter 5 C Library (libpq)" for information on the location and name of the libpq library.

Also, when using a shared library, refer to "A.6 How to Build and Run an Application that Uses Shared Libraries".

The COBOL compiler provides the how to link various libraries, so be sure to specify the path and libraries according to the specifications of your compiler.

Entry information of subprogram

If you use the ECPG library with a dynamic program structure, copy the entry information stored below. For details, follow the specifications of your compiler.

Linux

```
fujitsuEnterprisePostgresClientInstallDir/share/cobol_entry.info
```

Windows(R)

```
fujitsuEnterprisePostgresClientInstallDir\share\cobol_entry.info
```

Temporary work file

The ecobpg command generates the following temporary work files during precompilation at the output destination of the COBOL language source file.

- "*Output file name*" + "*.4-digit number*" + ".IPB" + ".ecw"
- "*Output file name*" + "*.4-digit number*" + ".COB" + ".ecw"

Do not delete these work files while the ecobpg command is running. Also, these work files will be deleted when the ecobpg command finishes, but if they remain after the command execution, delete them.

Example

The examples of compiling the applications that dynamically links the COBOL language library.
Note that "<*x*>" indicates the product version.

L Linux

- Linux 64-bit application:

```
cobol -M  -o testproc -I/opt/fsepv<x>client64/include -L/opt/fsepv<x>client64/lib -
lecpg -lpq testproc.cob
```

- Linux 64-bit application(When to set DT_RUNPATH):

```
cobol -c -M -o testproc.o -I/opt/fsepv<x>client64/include testproc.cob
ld -dynamic-linker /lib64/ld-linux-x86-64.so.2 -rpath /opt/fsepv<x>client64/lib --
enable-new-dtags -o testproc /usr/lib64/crti.o /usr/lib64/crt1.o /usr/lib64/crtn.o
testproc.o  -L/opt/fsepv<x>client64/lib -lecpg -lpq -Bdynamic -L/opt/FJSVcbl64/lib -
lrcobol -ldl -lc
```

W Windows(R)

The examples of compiling on a 64-bit operating system.

- 64-bit application

```
> SET LIB=%ProgramFiles%\Fujitsu\fsepv<x>client64\lib;%LIB%
> cobol -I "%ProgramFiles%\Fujitsu\fsepv<x>client64\include" -M testproc.cob
> link testproc.obj F4AGCIMP.LIB LIBCMT.LIB LIBECPG.LIB LIBPQ.LIB /OUT:testproc.exe
```

- 32-bit application

[NetCOBOL V10.5 or earlier]

```
> SET LIB=%ProgramFiles(x86)%\Fujitsu\fsepv<x>client32\lib;%LIB%
> cobol32 -I "%ProgramFiles(x86)%\Fujitsu\fsepv<x>client32\include" -M testproc.cob
> link testproc.obj LIBC.LIB F3BICIMP.LIB LIBECPG.LIB LIBPQ.LIB /OUT:testproc.exe
```

[NetCOBOL V11.0 or later]

```
> SET LIB=%ProgramFiles(x86)%\Fujitsu\fsepv<x>client32\lib;%LIB%
> cobol32 -I "%ProgramFiles(x86)%\Fujitsu\fsepv<x>client32\include" -M testproc.cob
> link testproc.obj MSVCRT.LIB F3BICIMP.LIB LIBECPG.LIB LIBPQ.LIB /OUT:testproc.exe
```

7.4.3 Bulk INSERT

This section describes the bulk INSERT.

Synopsis

```
EXEC SQL [ AT conn ] [ FOR { numOfRows | ARRAY_SIZE } ]
    INSERT INTO tableName [ ( colName [, ...] ) ]
    { VALUES ( { expr | DEFAULT } [, ...] ) [, ...] | query }
    [ RETURNING * | outputExpr [ [ AS ] outputName ] [, ...]
    INTO outputHostVar [ [ INDICATOR ] indicatorVar ] [, ...] ] END-EXEC
```

Description

Bulk INSERT is a feature that inserts multiple rows of data in bulk.

By specifying the array host variable that stored the data in the VALUES clause of the INSERT statement, the data for each element in the array can be inserted in bulk. This feature is used by specifying the insertion count in the FOR clause immediately before the INSERT statement.

FOR Clause

Specify the insertion count using *numOfRows* or ARRAY_SIZE in the FOR clause. The FOR clause can be specified only in the INSERT statement, not in other update statements.

numOfRows and ARRAY_SIZE

Insertion processing will be executed only for the specified count. However, if the count is 1, it will be assumed that the FOR clause was omitted when the application is executed. In this case, proceed according to the INSERT specification in the PostgreSQL Documentation.

Specify the FOR clause with a host variable defined as an integer item or with a literal.

Specify ARRAY_SIZE to insert all elements of the array in the table. When specifying ARRAY_SIZE, specify at least one array in *expr*.

If two or more arrays were specified in *expr*, it will be assumed that ARRAY_SIZE is the minimum number of elements in the array.

numOfRows or ARRAY_SIZE must exceed the minimum number of elements in all arrays specified in *expr*, *outputHostVar*, and *indicatorVal*.

The following example shows how to specify the FOR clause.

```
01 NUMBER-OF-ROWS PIC S9(9) COMP VALUE 10.
01 GROUP-ITEM.
05 ID1 PIC S9(9) OCCURS 25.
05 NAME PIC X(10) OCCURS 25.
* will process 10 rows
EXEC SQL FOR :NUMBER-OF-ROWS
INSERT INTO prod (name, id) VALUES (:NAME, :ID1) END-EXEC
* will process 25 rows
EXEC SQL FOR ARRAY_SIZE
INSERT INTO prod (name, id) VALUES (:NAME, :ID1) END-EXEC
```

expr

Specify the value to be inserted in the table. Array host variables, host variable literals, strings, and pointer variables can be specified. Structure type arrays and pointer variable arrays cannot be specified.

Do not use pointer variables and ARRAY_SIZE at the same time. The reason for this is that the number of elements in the area represented by the pointer variable cannot be determined.

query

A query (SELECT statement) that supplies the rows to be inserted. The number of rows returned by *query* must be 1. If two or more rows are returned, an error will occur. This cannot be used at the same time as ARRAY_SIZE.

outputHostVar and indicatorVal

These must be array host variables or pointer variables.

Error Messages

The messages below are output if an error occurs when the bulk INSERT is used.

Message

The value for the FOR clause must be a positive integer.

Cause

The value given for *numOfRows* is less than or equal to 0.

Solution

Specify a value that is more than or equal to 1 for *numOfRows*.

Message

Array host variable is needed when using FOR ARRAY_SIZE.

Cause

An array host variable is not specified in the VALUES clause.

Solution

Specify more than one array host variable in the VALUES clause.

Message

The SELECT..INTO query returned too many rows in row number %d.

Cause

The "SELECT ... INTO" query in the INSERT statement returned more than one row.

Solution

If *numOfRows* is more than one, the maximum number of rows that can be returned in the "SELECT ... INTO" query in the INSERT statement is one.

Limitations

The limitations when using bulk INSERT are given below.

- Array of structures should not be used as an input in the 'VALUES' clause.
- Array of pointers should not be used as an input in the 'VALUES' clause.
- ECOBPG supports the use of 'WITH' clause in single INSERT statements. 'WITH' clause cannot be used in bulk INSERT statements.
- If an error occurs, all bulk INSERT actions will be rolled back, therefore, no rows are inserted. However, if the RETURNING clause was used, and the error occurred while obtaining the rows after the insertion was successful, the insertion processing will not be rolled back.

Samples

Given below are some sample usages of the bulk INSERT functionality.

Basic Bulk INSERT

```
01 GROUP-ITEM.
05 IN-F1 PIC S9(9) OCCURS 4.
MOVE 1 TO IN-F1(1)
```

```
MOVE 2 TO IN-F1(2)
MOVE 3 TO IN-F1(3)
MOVE 4 TO IN-F1(4)
...
EXEC SQL FOR 3 INSERT INTO target (f1) VALUES (:IN-F1) END-EXEC
```

The number of rows to insert indicated by the FOR clause is 3, so the data in the first 3 elements of the host array variable are inserted into the table. The contents of the target table will be:

```
f1
----
1
2
3
(3 rows)
```

Also a host integer variable can be used to indicate the number of rows that will be inserted in FOR clause, which will produce the same result as above:

```
01 NUM PIC S9(9) COMP VALUE 3.
01 GROUP-ITEM.
05 IN-F1 PIC S9(9) OCCURS 4.
MOVE 1 TO IN-F1(1)
MOVE 2 TO IN-F1(2)
MOVE 3 TO IN-F1(3)
MOVE 4 TO IN-F1(4)
...
EXEC SQL FOR :NUM INSERT INTO target (f1) VALUES (:IN-F1) END-EXEC
```

Inserting constant values

Constant values can also be bulk INSERTed into the table as follows:

```
EXEC SQL FOR 3 INSERT INTO target (f1,f2) VALUES (DEFAULT,'hello') END-EXEC
```

Assuming the 'DEFAULT' value for the 'f1' column is '0', the contents of the target table will be:

```
f1 | f2
---+-------
0  | hello
0  | hello
0  | hello
(3 rows)
```

Using ARRAY_SIZE

'FOR ARRAY_SIZE' can be used to insert the entire contents of a host array variable, without explicitly specifying the size, into the table.

```
01 GROUP-ITEM.
05 IN-F1 PIC S9(9) OCCURS 4.
MOVE 1 TO IN-F1(1)
MOVE 2 TO IN-F1(2)
MOVE 3 TO IN-F1(3)
MOVE 4 TO IN-F1(4)
...
EXEC SQL FOR ARRAY_SIZE INSERT INTO target (f1) VALUES (:IN-F1) END-EXEC
```

Note

If there are multiple host array variables specified as input values, then the number of rows inserted is same as the smallest array size. The example given below demonstrates this usage.

```
01 GROUP-ITEM.
05 IN-F1 PIC S9(9) OCCURS 4.
05 IN-F3 PIC X(10) OCCURS 3.
MOVE 1 TO IN-F1(1)
MOVE 2 TO IN-F1(2)
MOVE 3 TO IN-F1(3)
MOVE 4 TO IN-F1(4)
MOVE "one" TO IN-F3(1)
MOVE "two" TO IN-F3(2)
MOVE "three" TO IN-F3(3)
...
EXEC SQL FOR ARRAY_SIZE INSERT INTO target (f1,f3) VALUES (:IN-F1,:IN-F3) END-EXEC
```

In the above example, the array sizes are 3 and 4. Given that the smallest array size is 3, only three rows are inserted into the table. The table contents are given below.

```
f1 | f3
---+-------
1  | one
2  | two
3  | three
(3 rows)
```

Using SELECT query

The result of a SELECT query can be used to insert values.

```
EXEC SQL FOR 4 INSERT INTO target(f1) SELECT age FROM source WHERE name LIKE 'foo' END-
EXEC
```

In the example above, assuming that the SELECT query returns one row, the same row will be inserted into the table four times.

Note

If "2" or more is specified for the FOR clause, the INSERT statement returns an error when two or more rows of query results are returned.

If "1" is specified for the FOR clause, all rows returned by the SELECT query will be inserted into the table.

```
EXEC SQL FOR 1 INSERT INTO target(f1) SELECT age FROM source END-EXEC
```

In the example above, "1" specified for the FOR clause indicates all returned rows.

Using RETURNING clause

Bulk INSERT supports the same RETURNING clause syntax as normal INSERT. An example is given below.

```
01 GROUP-ITEM.
05 IN-F1 PIC S9(9) OCCURS 4.
05 OUT-F1 PIC S9(9) OCCURS 4.
MOVE 1 TO IN-F1(1)
MOVE 2 TO IN-F1(2)
MOVE 3 TO IN-F1(3)
```

```
MOVE 4 TO IN-F1(4)
...
EXEC SQL FOR 3 INSERT INTO target (f1) VALUES (:IN-F1) RETURNING f1 INTO :OUT-F1 END-EXEC
```

After the execution of the above INSERT statement, the 'out_f1' array will have 3 elements with the values of '1', '2' and '3'.

7.4.4 DECLARE STATEMENT

Refer to "DECLARE STATEMENT" in the PostgreSQL Documentation.

7.4.5 Creating Applications while in Database Multiplexing Mode and Multi-master Replication

This section explains points to consider when creating applications while in database multiplexing mode and multi-master replication.

See

- Refer to the Cluster Operation Guide (Database Multiplexing) for information on database multiplexing mode.
- Refer to the Cluster Operation Guide (Multi-master Replication) for information on multi-master replication and points to consider when creating applications.
- Refer to "Application Development" in the Cluster Operation Guide (PRIMECLUSTER) for points to consider when creating applications using the failover feature integrated with the cluster software.

7.4.5.1 Errors when an Application Connection Switch Occurs and Corresponding Actions

If an application connection switch occurs while in database multiplexing mode and multi-master replication, explicitly close the connection and then reestablish the connection or reexecute the application.

The table below shows errors that may occur during a switch, and the corresponding action to take.

State		Error information (*1)	Action
Server failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	57P01 57P02 YE000 26000 40001	After the switch is complete, reestablish the connection, or reexecute the application.
	Accessed during system failure	08001	
Switch to the standby server	Switched during access	57P01 57P02 YE000 26000 40001	
	Accessed during switch	08001	

*1: Return value of SQLSTATE.

Chapter 8 Python Language Package (psycopg)

This chapter describes how to use Python language package (psycopg).

8.1 Development Environment

Install Fujitsu Enterprise Postgres Client Package for the architecture to be developed and executed.

See

Refer to Installation and Setup Guide for Client for information on the Python and Python packages required to develop Python language application.

8.2 Setup

This section describes the Python language package (psycopg), configure the environment, and encrypt communication data when using the package.

8.2.1 Environment Settings

To run an application that uses the Python language package (psycopg), set the environment variables as follows.

When using on a machine on which a package with the same name of OSS is installed, make sure that Python language packages (psycopg) group (under the directory added to PYTHONPATH) and packages with the same name of OSS are not mixed in the module search path (sys.path).

L Linux

- Required for execution of the application
  - PYTHONPATH
    fujitsuEnterprisePostgresClientInstallDir/psycopg/python*<PythonVersionToUse>*/site-packages

Example

Note that "*<x>*" indicates the product version, "*<y>*" is the version of Python you want to use.

```
PYTHONPATH=/opt/fsepv<x>client64/psycopg/python<y>/site-packages:$PYTHONPATH; export
PYTHONPATH
```

W Windows(R)

- Required for execution of the application
  - PATH
    fujitsuEnterprisePostgresClientInstallDir\lib
  - PYTHONPATH
    fujitsuEnterprisePostgresClientInstallDir \psycopg\python*<PythonVersionToUse>*\site-packages

Example

When the 32-bit version client package is installed on a 64-bit operating system. "*<x>*" indicates the product version, "*<y>*" is the version of Python you want to use.

```
SET PATH=%ProgramFiles(x86)%\Fujitsu\fsepv<x>client32\lib;%PATH%
SET PYTHONPATH=%ProgramFiles(x86)%\Fujitsu\fsepv<x>client32\psycopg\python<y>\site-
packages;%PYTHONPATH%
```

8.2.2 Message Language and Encoding System Used by Applications Settings

Setting the message language and encoding used by the application requires the same environment setup as using the C language library.

However, the Python language package (psycopg) cannot use the PQsetClientEncoding function to set the encoding. Use the SET command with the execute function to specify the encoding for client_encoding.

For information about settings in the C language library, refer to "5.2.2 Message Language and Encoding System Used by Applications Settings" in the "C Library (libpq)".

8.2.3 Settings for Encrypting Communication Data

Encrypting the communication data requires the same setup as using the C library (libpq).

For information about setting up the environment in the C library, refer to "5.2.3 Settings for Encrypting Communication Data" in the "C Library (libpq)".

8.3 Connecting with the Database

Use the connection service file to specify the connection destination. In the connection service file, a name (service name) is defined as a set, comprising information such as connection destination information and various types of tuning information set for connections. By using the service name defined in the connection service file when connecting to databases, it is no longer necessary to modify applications when the connection information changes.

Refer to "Client Interfaces", "The Connection Service File" in the PostgreSQL Documentation for details.

In addition, refer to "6.3 Connecting with the Database" in "Embedded SQL in C" for information on connection string.

See

Refer to the OSS Psycopg3 API documentation (https://www.psycopg.org/psycopg3/docs/api/index.html) for more information about other connection functions.

8.4 Application Development

PEP 249 - Enables development with an interface that conforms to the Python Database API Specification v2.0. Refer to the OSS Psycopg documentation (https://www.psycopg.org/psycopg3/docs/) for details.

Here is an example of an application using a package for the Python language (psycopg).

```
import psycopg

# Connect to an existing database
with psycopg.connect("host=localhost port=27500 dbname=test user=postgres") as conn:

    # Open a cursor to perform database operations
    with conn.cursor() as cur:

        # Execute a command: this creates a new table
        cur.execute("""
            CREATE TABLE IF NOT EXISTS test (
                id serial PRIMARY KEY,
                num integer,
```

```
            data text)
        """)

    # Pass data to fill a query placeholders and let Psycopg perform
    # the correct conversion (no SQL injections!)
    cur.execute(
        "INSERT INTO test (num, data) VALUES (%s, %s)",
        (100, "abc'def"))

    # Query the database and obtain data as Python objects.
    cur.execute("SELECT * FROM test")

    # You can use `cur.fetchmany()`, `cur.fetchall()` to return a list
    # of several records, or even iterate on the cursor
    for record in cur:
        print(record)

    # Make the changes to the database persistent
    conn.commit()
```

However, if you are using the Python language package (psycopg), there are the following differences to the OSS Psycopg.

8.4.1 Creating Applications while in Database Multiplexing Mode and Multi-master Replication

This section explains points to consider when creating applications while in database multiplexing mode and multi-master replication.

See

- Refer to the Cluster Operation Guide (Database Multiplexing) for information on database multiplexing mode.
- Refer to the Cluster Operation Guide (Multi-master Replication) for information on multi-master replication and points to consider when creating applications.
- Refer to "Application Development" in the Cluster Operation Guide (PRIMECLUSTER) for points to consider when creating applications using the failover feature integrated with the cluster software.

8.4.1.1 Errors when an Application Connection Switch Occurs and Corresponding Actions

If an application connection switch occurs while in database multiplexing mode and multi-master replication, explicitly close the connection and then reestablish the connection or reexecute the application.

The table below shows errors that may occur during a switch, and the corresponding action to take.

State		Error information	Action
Server failure or Fujitsu Enterprise Postgres system failure	Failure occurs during access	PGRES_FATAL_ERROR(*1) 57P01(*2) NULL(*2)	After the switch is complete, reestablish the connection, or reexecute the application.
	Accessed during system failure	CONNECTION_BAD(*3)	
Switch to the standby server	Switched during access	PGRES_FATAL_ERROR(*1) 57P01(*2)	

State		Error information	Action
		NULL(*2)	
	Accessed during switch	CONNECTION_BAD(*3)	

*1: Return value of psycopg.pq.ExecStatus().

*2: Return value of SQLSTATE from psycopg.pq.DiagnosticField().

*3: Return value of psycopg.pq.ConnStatus().

8.4.2 Data Types

The Python client (psycopg) of Fujitsu Enterprise Postgres supports database data types.

Chapter 9 Go Language

This chapter describes application development using Go language.

9.1 Development Environment

Install Fujitsu Enterprise Postgres Client Package for the architecture to be developed and executed.

Also, to obtain the necessary packages for developing applications using the Go language, an environment where you can connect to the internet is required.

9.2 Setup

This section describes the setup for developing applications using the Go language.

9.2.1 Environment Settings

Set the following environment variables to obtain and use the Go language package (fep-gopgx) required for developing applications using the Go language.

See

Refer to Installation and Setup Guide for Client for information on the packages required for application development using the Go language.

- GOPROXY

  Set the location to place the Go language package (fep-gopgx).

  Example

  Note that "<*x*>" indicates the product version.

```
GOPROXY ="file:///opt/fsepv<x>client64/gopgx/pkg,direct"; export GOPROXY
```

- GONOSUMDB

  Add "github.com/fujitsu/fep-gopgx" to GONOSUMDB to skip checksum verification for the Go language package (fep-gopgx) module provided by Fujitsu Enterprise Postgres.

  Example

```
GONOSUMDB="github.com/fujitsu/fep-gopgx"; export GONOSUMDB
```

9.2.2 Message Language and Encoding System Used by Applications Settings

Set the encoding method to UTF-8.

9.2.3 Settings for Encrypting Communication Data

Encrypting the communication data requires the same setup as using the C library (libpq).

For information about setting up the environment in the C library, refer to "5.2.3 Settings for Encrypting Communication Data" in the "C Library (libpq)".

9.3 Connecting with the Database

Connect to the database using the following:

- Connect
- ConnectConfig
- ConnectWithOptions

Example

Example of connection method using Connect

```
conn, err := pgx.Connect(context.Background(), "postgres://username:password@localhost:
27500/database_name"
)
```

Connect to the database by specifying a connection string. The connection string can be written in either the URL format or the keyword=value format, similar to the C library (libpq).

The connection string can specify parameters that can be specified by the following environment variables in the C library (libpq).

- PGHOST
- PGPORT
- PGDATABASE
- PGUSER
- PGPASSWORD
- PGPASSFILE
- PGSERVICE
- PGSERVICEFILE
- PGSSLMODE
- PGSSLCERT
- PGSSLKEY
- PGSSLROOTCERT
- PGSSLPASSWORD
- PGOPTIONS
- PGAPPNAME
- PGCONNECT_TIMEOUT
- PGTARGETSESSIONATTRS
- PGTZ

In Go language, you cannot set different passwords for each host using the .pgpass file.

When using ParseConfig, you can specify 'servicefile' as a keyword in addition to the PGSERVICEFILE environment variable.

9.4 Application Development

To use the Go language package (fep-gopgx), do the following:

- Declare the version of fep-gopgx to be used by one of the following methods:
  - Update the go.mod file using the go get command

    Example

    "<*y*>" indicates the major version of fep-gopgx, and @latest indicates that the latest version should be used.

    ```
    $ go get github.com/fujitsu/fep-gopgx/v<y>@latest
    ```

  - Add a require directive to the go.mod file

    Example

    "<*y*>" indicates the major version of fep-gopgx, and "<*z*>" indicates the version of fep-gopgx.

    ```
    require github.com/fujitsu/fep-gopgx/v<y> <z>
    ```

- Import fep-gopgx into the Go file that uses fep-gopgx.
  Add the following to the source code.

  Example

  "<*y*>" indicates the major version of fep-gopgx.

  ```
  import "github.com/fujitsu/fep-gopgx/v<y>"
  ```

9.4.1 Creating Applications while in Database Multiplexing Mode and Multi-master Replication

This section explains points to consider when creating applications while in database multiplexing mode and multi-master replication.

See

- Refer to the Cluster Operation Guide (Database Multiplexing) for information on database multiplexing mode.
- Refer to the Cluster Operation Guide (Multi-master Replication) for information on multi-master replication and points to consider when creating applications.
- Refer to "Application Development" in the Cluster Operation Guide (PRIMECLUSTER) for points to consider when creating applications using the failover feature integrated with the cluster software.

9.4.1.1 Errors when an Application Connection Switch Occurs and Corresponding Actions

If an application connection switch occurs while in database multiplexing mode and multi-master replication, explicitly close the connection and then reestablish the connection or reexecute the application.

The table below shows errors that may occur during a switch, and the corresponding action to take.

State	Error information	Action
When connection is executed	All	After the switch is complete, reestablish the connection, or reexecute the application.
When SQL is executed	57P01(*1) 08000(*1)	

State	Error information	Action
	unexpected EOF(*2)	

*1: The Code value of the error

*2: The Message value of the error

Chapter 10 SQL References

This chapter explains the SQL statement features expanded by Fujitsu Enterprise Postgres.

10.1 Expanded Trigger Definition Feature

This section explains the expanded trigger definition feature.

10.1.1 CREATE TRIGGER

In addition to features of PostgreSQL, triggers can be created with DO option.

Synopsis

```
CREATE [ OR REPLACE ] [ CONSTRAINT ] TRIGGER name { BEFORE | AFTER | INSTEAD OF } { event
[ OR ... ] }
    ON table_name
    [ FROM referenced_table_name ]
    [ NOT DEFERRABLE | [ DEFERRABLE ] [ INITIALLY IMMEDIATE | INITIALLY DEFERRED ] ]
    [ REFERENCING { { OLD | NEW } TABLE [ AS ] transition_relation_name } [ ... ] ]
    [ FOR [ EACH ] { ROW | STATEMENT } ]
    [ WHEN ( condition ) ]
    { EXECUTE { FUNCTION | PROCEDURE } function_name ( arguments )
        | DO [ LANGUAGE lang_name ] code }
```

Description

Refer to the PostgreSQL Documentation for information about CREATE TRIGGER. This section describes DO option.

A trigger which is created with DO option will be associated with the specified table or view and will execute the specified code by the specified procedural language of DO (unnamed code block) when certain events occur.

Parameters

lang_name

The name of the language that the function is implemented in.

plpgsql is supported in CREATE TRIGGER.

code

When the certain events occur, it executes the code in a specified procedural language. The unnamed code block does not require a prior definition like a function. Syntax is same as procedural language.

Note

- A trigger defined with DO option cannot be replaced by a trigger defined with EXECUTE PROCEDURE option.
- A trigger defined with EXECUTE PROCEDURE option cannot be replaced by a trigger defined with DO option.

Examples

It executes the code block that is specified by DO before the table is updated.
(Example that LANGUAGE is plpgsql)

```
CREATE TRIGGER check_update
    BEFORE UPDATE ON accounts
```

```
    FOR EACH ROW
    DO $$BEGIN RETURN NEW; END;$$ ;
```

Information

When a trigger created with DO option, a new function is created internally. The name of function is "schema name"."on table name"_"trigger name"_TRIGPROC(serial number).

10.1.2 How to Define Triggers in pgAdmin

The expanded features of the trigger definition can also be used in pgAdmin.

See

Refer to "pgAdmin Help" for information on how to define triggers using pgAdmin.

Chapter 11 Compatibility with Oracle Databases

This chapter describes the environment settings and functionality offered for features that are compatible with Oracle databases.

11.1 Overview

Features compatible with Oracle databases are provided. These features enable you to easily migrate to Fujitsu Enterprise Postgres and reduce the costs of reconfiguring applications.

The table below lists features compatible with Oracle databases.

Table 11.1 Features compatible with Oracle databases

Category		Feature	
		Item	Overview
SQL	Queries	Outer join operator (+)	Operator for outer joins
		DUAL table	Table provided by the system
	Functions	DECODE	Compares values, and if they match, returns a corresponding value
		SUBSTR	Extracts part of a string using characters to specify position and length
		NVL	Returns a substitute value when a value is NULL
Package		DBMS_ALERT	Sends alerts
		DBMS_ASSERT	Perform assertions on input values
		DBMS_OUTPUT	Sends messages to clients
		DBMS_PIPE	Execution of inter-session communication
		DBMS_RANDOM	Random number generation
		DBMS_UTILITY	Addition of various functions
		UTL_FILE	Enables text file operations
		DBMS_SQL (*1)	Enables dynamic SQL execution

*1: DBMS_SQL

Fujitsu Enterprise Postgres 17 includes enhancements to the DBMS_SQL package and changes to the function interface for better migration from Oracle databases. If you are using an application developed prior to Fujitsu Enterprise Postgres 16 SPz, simply upgrading the database will not take advantage of DBMS_SQL. Take one of the following actions. The "z" in SPz indicates the number at which the product is upgraded.

- If you want to use the conventional interface as it is

  Refer to "G.1 When using the DBMS_SQL package compatible with Fujitsu Enterprise Postgres 16 SPz or earlier" to change to a compatible DBMS_SQL package so that functions from the DBMS_SQL package prior to Fujitsu Enterprise Postgres 16 SPz are still available.

  If you use the old interface as is, you can use only the functional range of the compatible DBMS_SQL package (Functional range up to Fujitsu Enterprise Postgres 16 SPz).

- If you want to take advantage of the new enhanced interface

  Refer to "G.2 How to Migrate Applications that Use the DBMS_SQL Package" and modify the functions used by your application to support the new interface.

Note

The DBMS_SQL package for Fujitsu Enterprise Postgres 16 SPz and earlier is provided as a deprecated feature for compatibility reasons, and will not be supported in the future. Please check the support status in advance when upgrading your system in the future.

See

Refer to the file below for information on the features compatible with Oracle databases.

- Linux:
  fujitsuEnterprisePostgresInstallDir/share/doc/extension/README.asciidoc
- Windows(R):
  fujitsuEnterprisePostgresInstallDir\doc\extension\README.asciidoc

11.2 Precautions when Using the Features Compatible with Oracle Databases

This section provides notes on using the features compatible with oracle databases.

11.2.1 Notes on search_path

Objects defined with the features compatible with oracle databases are defined in the oracle schema. Therefore, when using this function, it is necessary to add "oracle" to the "search_path" parameter in postgresql.conf.

```
search_path = '"$user", public, oracle'
```

Information

- The search_path parameter specifies the order in which schemas are searched.
- Refer to "Statement Behavior" in "Client Connection Defaults" in "Server Administration" in the PostgreSQL Documentation for information on search_path.

11.2.2 Notes on SUBSTR

SUBSTR is implemented in Fujitsu Enterprise Postgres and Oracle databases using different external specifications.

For this reason, when using SUBSTR, define which specification is to take precedence. In the default configuration of Fujitsu Enterprise Postgres, the specifications of Fujitsu Enterprise Postgres take precedence.

When using the SUBSTR function compatible with Oracle databases, set "oracle" and "pg_catalog" in the "search_path" parameter of postgresql.conf. You must specify "oracle" before "pg_catalog" when doing this.

```
search_path = '"$user", public, oracle, pg_catalog'
```

11.2.3 Notes when Integrating with the Interface for Application Development

The SQL noted in "Table 11.1 Features compatible with Oracle databases" can be used in the interface for application development.

Note that both "public" and the schema name in the SQL statement must be specified as the SearchPath parameter before "oracle" and "pg_catalog" when using the Oracle database-compatible feature SUBSTR.

11.3 Queries

The following queries are supported:

- Outer Join Operator (+)
- DUAL Table

11.3.1 Outer Join Operator (+)

In the WHERE clause conditional expression, by adding the plus sign (+), which is the outer join operator, to the column of the table you want to add as a table join, it is possible to achieve an outer join that is the same as a joined table (OUTER JOIN).

Syntax

SELECT statement

```
SELECT … [WHERE [NOT] joinCond ...] …
SELECT … [WHERE srchCond ]... ] …
```

Join condition

```
{ colSpec(+) = colSpec | colSpec = colSpec(+) }
```

Note

Here we are dealing only with the WHERE clause of the SELECT statement. Refer to "SQL Commands" in "Reference" in the PostgreSQL Documentation for information on the overall syntax of the SELECT statement.

General rules

WHERE clause

- The WHERE clause specifies search condition or join conditions for the tables that are derived.
- Search conditions are any expressions that return BOOLEAN types as the results of evaluation. Any rows that do not meet these conditions are excluded from the output. When the values of the actual rows are assigned to variables and if the expression returns TRUE, those rows are considered to have met the conditions.
- Join conditions are comparison conditions that specify outer join operators. Join conditions in a WHERE clause return a table that includes all the rows that meet the join conditions, including rows that do not meet all the join conditions.
- Join conditions take precedence over search conditions. For this reason, all rows returned by the join conditions are subject to the search conditions.
- The following rules and restrictions apply to queries that use outer join operators. It is therefore recommended to use FROM clause joined tables (OUTER JOIN) rather than outer join operators:
  - Outer join operators can only be specified in the WHERE clause.
  - Outer join operators can only be specified for base tables or views.
  - To perform outer joins using multiple join conditions, it is necessary to specify outer join operators for all join conditions.
  - When combining join conditions with constants, specify outer join operators in the corresponding column specification. When not specified, they will be treated as search conditions.
  - The results column of the outer join of table t1 is not returned if table t1 is joined with table t2 by specifying an outer join operator in the column of t1, then table t1 is joined with table t3 by using search conditions.
  - It is not possible to specify columns in the same table as the left/right column specification of a join condition.

- It is not possible to specify an expression other than a column specification for outer join operators, but they may be specified for the columns that compose the expression.

  There are the following limitations on the functionality of outer join operators when compared with joined tables (OUTER JOIN). To use functionality that is not available with outer join operators, use joined tables (OUTER JOIN).

Table 11.2 Range of functionality with outer join operators

Functionality available with joined tables (OUTER JOIN)	Outer join operator
Outer joins of two tables	Y
Outer joins of three or more tables	Y (*1)
Used together with joined tables within the same query	N
Use of the OR logical operator to a join condition	N
Use of an IN predicate to a join condition	N
Use of subqueries to a join condition	N

Y: Available
N: Not available

*1: The outer joins by outer join operators can return outer join results only for one other table. For this reason, to combine outer joins of table t1 and table t2 or table t2 and table t3, it is not possible to specify outer join operators simultaneously for table t2.

Example

Table configuration

t1

col1	col2	col3
1001	AAAAA	1000
1002	BBBBB	2000
1003	CCCCC	3000

t2

col1	col2
1001	aaaaa
1002	bbbbb
1004	ddddd

Example 1: Return all rows in table t2, including those that do not exist in table t1.

```
SELECT *
  FROM t1, t2
  WHERE t1.col1(+) = t2.col1;
 col1 |    col2    | col3 | col1 |    col2
------+------------+------+------+------------
 1001 | AAAAA      | 1000 | 1001 | aaaaa
 1002 | BBBBB      | 2000 | 1002 | bbbbb
```

```
      |            |      | 1004 | ddddd
(3 rows)
```

This is the same syntax as the joined table (OUTER JOIN) of the FROM clause shown next.

```
SELECT *
  FROM t1 RIGHT OUTER JOIN t2
       ON t1.col1 = t2.col1;
```

Example 2: In the following example, the results are filtered to records above 2000 in t1.col3 by search conditions, and the records are those in table t2 that include ones that do not exist in table t1. After filtering with the join conditions, there is further filtering with the search conditions, so there will only be one record returned.

```
SELECT *
  FROM t1, t2
  WHERE t1.col1(+) = t2.col1
    AND t1.col3 >= 2000;
 col1 |    col2    | col3 | col1 |    col2
------+------------+------+------+------------
 1002 | BBBBB      | 2000 | 1002 | bbbbb
(1 row)
```

This is the same syntax as the joined table (OUTER JOIN) of the FROM clause shown next.

```
SELECT *
  FROM t1 RIGHT OUTER JOIN t2
       ON t1.col1 = t2.col1
  WHERE t1.col3 >= 2000;
```

11.3.2 DUAL Table

DUAL table is a virtual table provided by the system. Use when executing SQL where access to a base table is not required, such as when performing tests to get result expressions such as functions and operators.

Example

In the following example, the current system date is returned.

```
SELECT  CURRENT_DATE  "date" FROM DUAL;
    date
------------
 2013-05-14
(1 row)
```

11.4 SQL Function Reference

The following SQL functions are supported:

- DECODE
- SUBSTR
- NVL

11.4.1 DECODE

Description

Compares values and if they match, returns a corresponding value.

Syntax

```
DECODE(expr, srch, result [, srch, result ]... [, default ])
```

General rules

- DECODE compares values of the value expression to be converted and the search values one by one. If the values match, a corresponding result value is returned. If no values match, the default value is returned if it has been specified. A NULL value is returned if a default value has not been specified.
- If the same search value is specified more than once, then the result value returned is the one listed for the first occurrence of the search value.
- The following data types can be used in result values and in the default value:
  - CHAR
  - VARCHAR
  - NCHAR
  - NCHAR VARYING
  - TEXT
  - INTEGER
  - BIGINT
  - NUMERIC
  - DATE
  - TIME WITHOUT TIME ZONE
  - TIMESTAMP WITHOUT TIME ZONE
  - TIMESTAMP WITH TIME ZONE
- The same data type must be specified for the values to be converted and the search values. However, note that different data types may also be specified if a literal is specified in the search value, and the value expression to be converted contains data types that can be converted. When specifying literals, refer to "Table A.1 Data type combinations that contain literals and can be converted implicitly" in "A.3 Implicit Data Type Conversions" for information on the data types that can be specified.
- If the result values and default value are all literals, the data types for these values will be as shown below:
  - If all values are string literals, all will become character types.
  - If there is one or more numeric literal, all will become numeric types.
  - If there is one or more literal cast to the datetime/time types, all will become datetime/time types.
- If the result values and default value contain a mixture of literals and non-literals, the literals will be converted to the data types of the non-literals. When specifying literals, refer to "Table A.1 Data type combinations that contain literals and can be converted implicitly" in "A.3 Implicit Data Type Conversions" for information on the data types that can be converted.
- The same data type must be specified for all result values and for the default value. However, different data types can be specified if the data type of any of the result values or default value can be converted - these data types are listed below:

Table 11.3 Data type combinations that can be converted by DECODE (summary)

		Other result values or default value		
		Numeric type	Character type	Date/time type
Result value (any)	Numeric type	Y	N	N
	Character type	N	Y	N

		Other result values or default value		
		Numeric type	Character type	Date/time type
	Date/time type	N	N	S (*1)

Y: Can be converted
S: Some data types can be converted
N: Cannot be converted

*1: The data types that can be converted for date/time types are listed below:

Table 11.4 Result value and default value date/time data types that can be converted by DECODE

		Other result values or default value			
		DATE	TIME WITHOUT TIME ZONE	TIMESTAMP WITHOUT TIME ZONE	TIMESTAMP WITH TIME ZONE
Result value (any)	DATE	Y	N	Y	Y
	TIME WITHOUT TIME ZONE	N	Y	N	N
	TIMESTAMP WITHOUT TIME ZONE	Y	N	Y	Y
	TIMESTAMP WITH TIME ZONE	Y	N	Y	Y

Y: Can be converted
N: Cannot be converted

- The data type of the return value will be the data type within the result or default value that is longest and has the highest precision.

Example

In the following example, the value of col3 in table t1 is compared and converted to a different value. If the col3 value matches search value 1, the result value returned is "one". If the col3 value does not match any of search values 1, 2, or 3, the default value "other number" is returned.

```
SELECT col1, DECODE(col3, 1000, 'one',
                          2000, 'two',
                          3000, 'three',
                          'other number') "num-word"
       FROM t1;
col1  | num-word
------+----------
 1001 | one
 1002 | two
 1003 | three
(3 rows)
```

11.4.2 SUBSTR

Description

Extracts part of a string using characters to specify position and length.

Syntax

```
SUBSTR(str, startPos [, len ])
```

General rules

- SUBSTR extracts and returns a substring of string *str*, beginning at position *startPos*, for number of characters *len*.
- When *startPos* is positive, it will be the number of characters from the beginning of the string.
- When *startPos* is 0, it will be treated as 1.
- When *startPos* is negative, it will be the number of characters from the end of the string.
- When *len* is not specified, all characters to the end of the string are returned. NULL is returned when *len* is less than 1.
- For *startPos* and *len*, specify a SMALLINT or INTEGER type. When specifying literals, refer to "Table A.1 Data type combinations that contain literals and can be converted implicitly" in "A.3 Implicit Data Type Conversions" for information on the data types that can be specified.
- The data type of the return value is TEXT.

Note

- There are two types of SUBSTR. One that behaves as described above, and one that behaves the same as SUBSTRING. The search_path parameter must be modified for it to behave the same as the specification described above.
- It is recommended to set search_path in postgresql.conf. In this case, it will be effective for each instance. Refer to "11.2.2 Notes on SUBSTR" for information on how to configure postgresql.conf.
- The configuration of search_path can be done at the user level or at the database level. Setting examples are shown below.
  - Example of setting at the user level

    This can be set by executing an SQL command. In this example, user1 is used as the username.

    ```
    ALTER USER user1 SET search_path = "$user",public,oracle,pg_catalog;
    ```

  - Example of setting at the database level

    This can be set by executing an SQL command. In this example, db1 will be used as the database name.

    ```
    ALTER DATABASE db1 SET search_path = "$user",public,oracle,pg_catalog;
    ```

    You must specify "oracle" before "pg_catalog".
- If the change has not been implemented, SUBSTR is the same as SUBSTRING.

See

Refer to "SQL Commands" in "Reference" in the PostgreSQL Documentation for information on ALTER USER and ALTER DATABASE.

Information

The general rules for SUBSTRING are as follows:

- The start position will be from the beginning of the string, whether positive, 0, or negative.
- When *len* is not specified, all characters to the end of the string are returned.
- An empty string is returned if no string is extracted or *len* is less than 1.

See

Refer to "String Functions and Operators" under "The SQL Language" in the PostgreSQL Documentation for information on SUBSTRING.

Example

In the following example, part of the string "ABCDEFG" is extracted:

```
SELECT SUBSTR('ABCDEFG',3,4) "Substring" FROM DUAL;

 Substring
-----------
 CDEF
(1 row)

SELECT SUBSTR('ABCDEFG',-5,4) "Substring" FROM DUAL;

 Substring
-----------
(1 row)
```

11.4.3 NVL

Description

Returns a substitute value when a value is NULL.

Syntax

```
NVL(expr1, expr2)
```

General rules

- NVL returns a substitute value when the specified value is NULL. When *expr1* is NULL, *expr2* is returned. When *expr1* is not NULL, *expr1* is returned.
- Specify the same data types for *expr1* and *expr2*. However, if a constant is specified in *expr2*, and the data type can also be converted by *expr1*, different data types can be specified. When this happens, the conversion by *expr2* is done to suit the data type in *expr1*, so the value of *expr2* returned when *expr1* is a NULL value will be the value converted in the data type of *expr1*.
- When specifying literals, refer to "Table A.1 Data type combinations that contain literals and can be converted implicitly" in "A.3 Implicit Data Type Conversions" for information on the data types that can be converted.

Example

In the following example, "IS NULL" is returned if the value of col1 in table t1 is a NULL value.

```
SELECT col2, NVL(col1,'IS NULL') "nvl" FROM t1;
 col2 |   nvl
------+---------
 aaa  | IS NULL
(1 row)
```

11.5 Package Reference

A "package" is a group of features, brought together by schemas, that have a single functionality, and are used by calling from PL/pgSQL.

The following packages are supported:

- DBMS_ALERT
- DBMS_ASSERTION
- DBMS_OUTPUT
- DBMS_PIPE
- DBMS_RANDOM
- DBMS_UTILITUY
- UTL_FILE
- DBMS_SQL

To call each feature from PL/pgSQL, use the PERFORM or SELECT statement and qualify the feature name with the package name. For more information on the calling format, refer to the feature-specific description for each package.

See

For packages, refer to the following file.

- Linux:
  fujitsuEnterprisePostgresInstallDir/share/doc/extension/README.asciidoc

- Windows(R):
  fujitsuEnterprisePostgresInstallDir\doc\extension\README.asciidoc

Chapter 12 Application Connection Switch Feature

The application connection switch feature enables automatic connection to the target server when there are multiple servers with redundant configurations.

When using this feature, specify the primary server and secondary server as the connected servers in the application connection information. A standby server can optionally be prioritized over the primary server as the target server.

If an application connection switch occurs, explicitly close the connection and then reestablish the connection or reexecute the application. Refer to "Errors when an Application Connection Switch Occurs and Corresponding Actions" of the relevant client interface for information on how to confirm the switch.

12.1 Connection Information for the Application Connection Switch Feature

To use the application connection switch feature, set the information shown below when connecting the database.

IP address or host name

Specify the IP address or host name that will be used to configure the database multiplexing system.

Port number

A port number used by each database server to listen for connections from applications.
In each client interface, multiple port numbers can be specified, however in the format shown below, for example:

host1,host2:port2

JDBC and .NET

If only one port number is specified, it will be assumed that host1: 27500 (the default value) and host2:port2 were specified.
Omit all port numbers, or specify only one per server.

Others

If only one port number is specified, it will be assumed that the same port is used for all the hosts.

Target server

From the specified connection destination server information, specify the selection sequence of the servers to which the application will connect. The values specified for the target server have the meanings shown below. If a value is omitted, "any" will be assumed.

Primary server

The primary server is selected as the connection target from the specified "IP addresses or host names". Specify this to perform tasks that can be performed only on the primary server, such as applications in line with updates, or management tasks such as REINDEX and VACUUM.

Standby server

The standby server is selected as the connection target from the specified "IP addresses or host names". On standby server, the update will always fail. If the target server is not standby, the JDBC driver will throw an error stating that it is unable to find a server with the specified targetServerType.

Priority given to a primary server

The primary server is selected preferentially as the connection target from the specified "IP addresses or host names". If there is no primary server, the application will connect to the standby server.

Priority given to a standby server

The standby server is selected preferentially as the connection target from the specified "IP addresses or host names". If there is no standby server, the application will connect to the primary server.

Any

This method is not recommended in database multiplexing systems. This is because, although the connection destination server is selected in the specified sequence from the specified "IP addresses or host names", if the server that was successfully connected to first is the standby server, the write operations will always fail.

The table below shows the server selection order values to set for each driver:

Server selection order	JDBC drivers	.NET Data Provider	Other drivers
Primary server	"primary"(*1)	"read-write"(*1) "primary"(*2)	"read-write"(*1) "primary"(*2)
Standby server	"secondary"(*2)	"standby" "read-only"(*2)	"standby" "read-only"(*2)
Priority given to a primary server	"preferPrimary"(*3)	"prefer-primary"	-
Priority given to a standby server	"preferSecondary"(*2)	"prefer-standby"	"prefer-standby"(*4)
Any	"any"	"any"	"any"

*1: The primary server whose default transaction mode is read-only is not selected.

*2: The primary server whose default transaction mode is read-only is also selected.

*3: Prefer primary servers whose default transaction mode is read-write.

*4: While it is possible to specify "prefer-read" instead of "prefer-standby" for compatibility with Fujitsu Enterprise Postgres 13 and earlier, this is not recommended.

SSL server certificate Common Name (CN)

To perform SSL authentication by creating the same server certificate for each server in a multiplexing system, specify the SSL server certificate Common Name (CN) in this parameter. Accordingly, SSL authentication using the CN can be performed without having to consider the names of the multiple servers contained in the multiplexing system.

12.2 Using the Application Connection Switch Feature

This section explains how to set the connection destination server using the application connection switch feature.

Of the parameters used as connection information for each client interface, only the parameters specific to the application connection switch feature are explained here. Refer to "Setup" and "Connecting to the Database" for information on the other parameters of each client interface.

12.2.1 Using the JDBC Driver

Set the following information in the connection string of the DriverManager class, or in the data source.

Table 12.1 Information to be set

Argument	Explanation
host1 host2	Specify the IP address or host name. The IP address or host name can be omitted. If omitted, the default is localhost.
port1 port2	Specify the port number for the connection. The port number can be omitted. If omitted, the default is 27500.
database_name	Specify the database name.
targetServerType	Specify the selection sequence of the servers to which the application will connect. Refer to "Target server" for details.

Argument	Explanation
sslmode	Specify this to encrypt communications. By default, this is disabled. The setting values for sslmode are as follows: disable: Connect without SSL require: Connect always with SSL verify-ca: Connect with SSL, using a certificate issued by a trusted CA (*1) verify-full: Connect with SSL, using a certificate issued by a trusted CA to verify if the server host name matches the certificate (*1)
sslservercertcn	This parameter is enabled only to perform SSL authentication (sslmode=verify-full). Specify the server certificate CN. If this is omitted, the value will be null, and the server certificate CN will be authenticated using the host name specified in host.

*1: If specifying either "verify-ca" or "verify-full", the CA certificate file can be specified using connection string sslrootcert.

When using Driver Manager

Specify the following URL in the API of the DriverManager class:

```
jdbc:postgresql://[host1][:port1],[host2][:port2]/dbName[?targetServerType={primary |
secondary| preferPrimary | preferSecondary | any}][&sslmode=verify-
full&sslrootcert=cACertificateFile&sslservercertcn=targetServerCertificateCN]
```

- If the target server is omitted, the default value "any" is used.
- When using IPV6, specify the host in the "[*host*]" (with square brackets) format.

  [Example]

```
jdbc:postgresql://[2001:Db8::1234]:27500,192.168.1.1:27500/dbName
```

When using the data source

Specify the properties of the data source in the following format:

```
source.setServerName("[host1][:port1],[host2][:port2]");
source.setTargetServerType("primary");
source.setSslmode("verify-full");
source.setSslrootcert("cACertificateFile");
source.setSslservercertcn("targetServerCertificateCN");
```

- If the IP address or host name are omitted, localhost will be used.
- If the port number is omitted, the value specified in the portNumber property will be used. Also, if the portNumber property is omitted, the default is 27500.
- If the target server is omitted, the value will be "any".
- When using IPV6, specify the host in the "[*host*]" (with square brackets) format.

  [Example]

```
source.setServerName("[2001:Db8::1234]:27500,192.168.1.1:27500");
```

Note

If using the connection parameter loginTimeout, the value will be applied for the time taken attempting to connect to all of the specified hosts.

12.2.2 Using the ODBC Driver

Set the following information in the connection string or data source.

Table 12.2 Information to be set

Parameter	Explanation
Servername	Specify IP address 1 and IP address 2, or the host name, using a comma as the delimiter. Based on ODBC rules, it is recommended to enclose the whole string containing comma delimiters with {}. Format: {host1,host2}
Port	Specify the connection destination port numbers, using a comma as the delimiter. Based on ODBC rules, it is recommended to enclose the whole string containing comma delimiters with {}. Format: {port1,port2} Specify the port number corresponding to the IP address or host specified for the nth Servername as the nth Port. The port number can be omitted. If omitted, the default is 27500. If *n* server names are specified, and m ports are specified then there will be error reported. The only exceptions are where m=n or m=1. In case only one port is specified, then the same is applied for all the hosts.
target_session_attrs	Specify the selection sequence of the servers to which the application will connect. Refer to "Target server" for details.
SSLMode	Specify this to encrypt communications. By default, this is disabled. The setting values for SSLMode are as follows: disable: Connect without SSL allow: Connect without SSL, and if it fails, connect with SSL prefer: Connect with SSL, and if it fails, connect without SSL require: Connect always with SSL verify-ca: Connect with SSL, using a certificate issued by a trusted CA (*1) verify-full: Connect with SSL, using a certificate issued by a trusted CA to verify if the server host name matches the certificate (*1)
SSLServerCertCN	This parameter is enabled only to perform SSL authentication (SSLMode=verify-full). Specify the server certificate CN. If this is omitted, the value will be null, and the server certificate CN will be authenticated using the host name specified in Servername.

*1: If specifying either "verify-ca" or "verify-full", use the system environment variable PGSSLROOTCERT of your operating system to specify the CA certificate file as shown below.

Example)
Variable name: PGSSLROOTCERT
Variable value: *cACertificateFile*

When specifying a connection string

Specify the following connection string:

```
...;Servername={host1,host2};Port={port1,port2};[target_session_attrs={any | read-
write | read-only | primary | standby | prefer-standby}];[ SSLMode=verify-
full;SSLServerCertCN=targetServerCertificateCN]...
```

- When using IPV6, specify the host in the "*host*" format.

  [Example]

```
Servername={2001:Db8::1234,192.168.1.1};Port={27500,27500};
```

When using the data source

Specify the properties of the data source in the following format:

```
Servername={host1,host2}
Port={port1,port2}
target_session_attrs={any | read-write | read-only | primary | standby | prefer-standby}
SSLMode=verify-full
SSLServerCertCN=targetServerCertificateCN
```

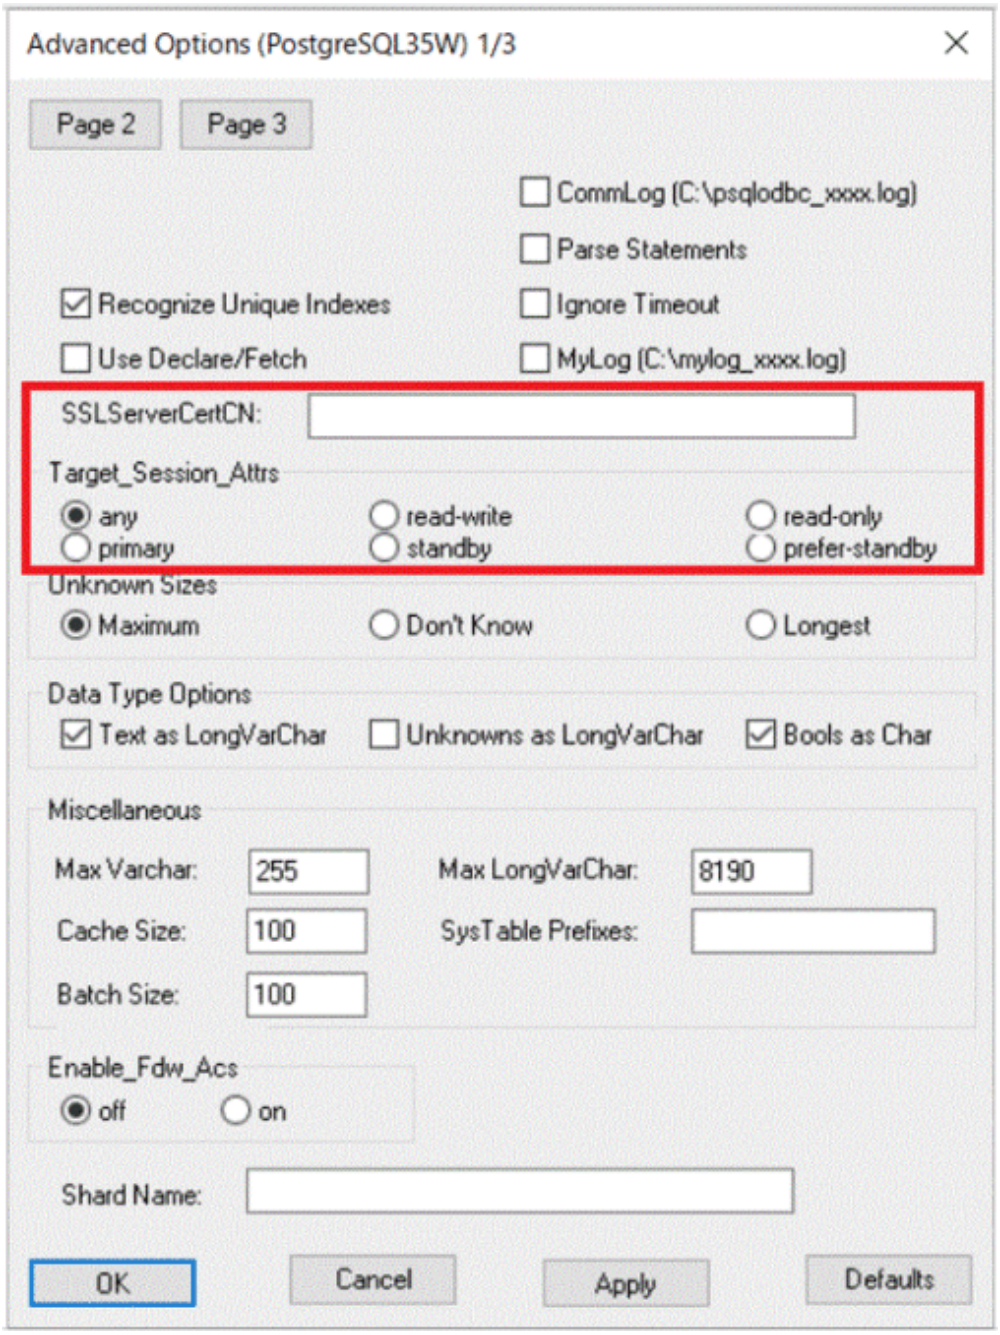
- When using IPV6, specify the host in the "*host*" format.

  [Example]

```
Servername={2001:Db8::1234,192.168.1.1}
```

Registering the data source using the ODBC Data Source Administrator

Using the ODBC Data Source Administrator, specify the items within the red border below:



Note

If using the connection parameter login_timeout, this value is applied for connections to each of the specified hosts. If both multiplexed database servers have failed, the connection will time out when a time equal to double the login_timeout value elapses.

12.2.3 Using a .NET Data Provider

Set the following information in the connection string of NpgsqlConnection, or in the data source.

Table 12.3 Information to be set

Argument	Explanation
host1 host2	Specify the IP address or host name.
port1 port2	Specify the port number for the connection.
TargetSessionAttributes	Specify the selection sequence of the servers to which the application will connect. Refer to "Target server" for details.

When specifying a connection string

Specify the following connection string:

```
host1[:port1],host2[:port2];[Target Session Attributes={any | primary | standby |
prefer-primary | prefer-standby | read-write | read-only}];
```

- If the port number is omitted from the host string, the value specified for the Port keyword of the connection string will be used. Refer to "4.3.3 Connection String" for information on the Port keyword.
- When using IPV6, specify the host in the "[*host*]" (with square brackets) format.
- If the target server type is omitted, the value will be any.

  [Example]

```
host=[2001:Db8::1234]:27500,192.168.1.1:27500;
```

When specifying the NpgsqlConnectionStringBuilder property

Specify the Host property of the data source in the following format:

```
host1[:port1],host2[:port2]
```

- If the port number is omitted from the host string, the value specified in the Port property will be used. Also, if the Port property is omitted, the default is 27500.

Specify the TargetSessionAttributes property of the data source in the following format:

```
any | primary | standby | prefer-primary | prefer-standby | read-write | read-only
```

- If the target server type is omitted, the value will be any.

Note

If using the connection parameter Timeout, this value is applied for connections to each of the specified hosts. If both multiplexed database servers have failed, the connection will time out when a time equal to double the Timeout value elapses.

12.2.4 Using a Connection Service File

Set the connection parameters as follows.

Table 12.4 Information to be set

Parameter	Explanation
host	Specify the host names, using a comma as the delimiter.
hostaddr	Specify IP address 1 and IP address 2, using a comma as the delimiter.

Parameter	Explanation
port	Specify the connection destination port numbers, using a comma as the delimiter. Specify the port number for the server specified for the nth host or hostaddr as the nth port. The port number can be omitted. If omitted, the default is 27500. If *n* server names are specified, and m ports are specified then there will be error reported. The only exceptions are where m=n or m=1. In case only one port is specified, then the same is applied for all the hosts.
target_session_attrs	Specify the selection sequence of the servers to which the application will connect. Refer to "Target server" for details.
sslmode	Specify this to encrypt communications. By default, this is disabled. The setting values for sslmode are as follows: disable: Connect without SSL allow: Connect without SSL, and if it fails, connect with SSL prefer: Connect with SSL, and if it fails, connect without SSL require: Connect always with SSL verify-ca: Connect with SSL, using a certificate issued by a trusted CA (*1) verify-full: Connect with SSL, using a certificate issued by a trusted CA to verify if the server host name matches the certificate (*1)
sslservercertcn	This parameter is enabled only to perform SSL authentication (sslmode=verify-full). Specify the server certificate CN. If this is omitted, the value will be null, and the server certificate CN will be authenticated using the host name specified in host.

*1: If specifying either "verify-ca" or "verify-full", use the system environment variable PGSSLROOTCERT (connection parameter sslrootcert) of your operating system to specify the CA certificate file as shown below.

Example)
Variable name: PGSSLROOTCERT
Variable value: *cACertificateFile*

Note

If using the connection parameter connect_timeout, this value is applied for connections to each of the specified hosts. If both multiplexed database servers have failed, the connection will time out when a time equal to double the connect_timeout value elapses.

Point

If using the C Library, embedded SQL or psql commands (including other client commands that specify connection destinations), it is recommended to use a connection service file to specify connection destinations.

In the connection service file, a name (service name) is defined as a set, comprising information such as connection destination information and various types of tuning information set for connections. By using the service name defined in the connection service file when connecting to databases, it is no longer necessary to modify applications when the connection information changes.

12.2.5 Using the C Library (libpq)

It is recommended that you use a connection service file. Refer to "12.2.4 Using a Connection Service File" for details.

If a connection service file will not be used, set the following information for the database connection control functions (PQconnectdbParams, PQconnectdb, and so on) or environment variables.

Table 12.5 Information to be set

Parameter (environment variable name)	Explanation
host(PGHOST)	Specify the host names, using a comma as the delimiter.
hostaddr(PGHOSTADDR)	Specify IP address 1 and IP address 2, using a comma as the delimiter.
port(PGPORT)	Specify the connection destination port numbers, using a comma as the delimiter. Specify the port number for the server specified for the nth host or hostaddr as the nth port. The port number can be omitted. If omitted, the default is 27500. If *n* server names are specified, and m ports are specified then there will be error reported. The only exceptions are where m=n or m=1. In case only one port is specified, then the same is applied for all the hosts.
target_session_attrs(PGTARGETSESSIONATTRS)	Specify the selection sequence of the servers to which the application will connect. Refer to "Target server" for details.
sslmode(PGSSLMODE)	Specify this to encrypt communications. By default, this is disabled. The setting values for sslmode are as follows: disable: Connect without SSL allow: Connect without SSL, and if it fails, connect with SSL prefer: Connect with SSL, and if it fails, connect without SSL require: Connect always with SSL verify-ca: Connect with SSL, using a certificate issued by a trusted CA (*1) verify-full: Connect with SSL, using a certificate issued by a trusted CA to verify if the server host name matches the certificate (*1)
sslservercertcn(PGXSSLSERVERCERTCN)	This parameter is enabled only to perform SSL authentication (sslmode=verify-full). Specify the server certificate CN. If this is omitted, the value will be null, and the server certificate CN will be authenticated using the host name specified in host.

*1: If specifying either "verify-ca" or "verify-full", use the system environment variable PGSSLROOTCERT (connection parameter sslrootcert) of your operating system to specify the CA certificate file as shown below.

Example)
Variable name: PGSSLROOTCERT
Variable value: *cACertificateFile*

When using URI

```
postgresql://host1[:port1],host2[:port2][,...]/database_name
[?target_session_attrs={read-write | read-only | primary | standby | prefer-standby |
any }]
```

- When using IPV6, specify the host in the "[*host*]" (with square brackets) format.

  [Example]

```
postgresql://postgres@[2001:Db8::1234]:27500,192.168.1.1:27500/database_name
```

When using key-value

```
host=host1[,host2] port=port1[,port2] user=user1 password=pwd1 dbname=mydb
[target_session_attrs={read-write | read-only | primary | standby | prefer-standby |
any }]
```

- When using IPV6, specify the host in the "*host*" format.

  [Example]

```
host=2001:Db8::1234,192.168.1.1 port=27500,27500
```

Note

If using the connection parameter connect_timeout, this value is applied for connections to each of the specified hosts. If both multiplexed database servers have failed, the connection will time out when a time equal to double the connect_timeout value elapses.

Information

If using a password file (.pgpass), describe the entries matching each server.

- Example 1:

```
host1:port1:dbname:user:password
host2:port2:dbname:user:password
```

- Example 2:

```
*:port:dbname:user:password
```

12.2.6 Using Embedded SQL

It is recommended that you use a connection service file. Refer to "12.2.4 Using a Connection Service File" for details.

Point

If using a connection service file, either of the following methods is available:

- Set the service name as a string literal or host variable, as follows:

  tcp:postgresql://?service=my_service

- Set the service name in the environment variable PGSERVICE, and use CONNECT TO DEFAULT

If a connection service file will not be used, use a literal or variable to specify the connection destination server information for target in the SQL statement below:

```
EXEC SQL CONNECT TO target [AS connection-name] [USER user-name];
```

Method used

```
dbname@host1,host2[:[port1][,port2]]
tcp:postgresql://host1,host2[:[port1][,port2]] [/dbname] [?target_session_attrs={read-
write | read-only | primary | standby | prefer-standby | any}][&sslmode=verify-
full&sslservercertcn=targetServerCertificateCN]
```

- The above format cannot be specified directly without using a literal or variable.

Table 12.6 Information to be set

Argument	Explanation
host1 host2	Specify the IP address or host name. IPv6 format addresses cannot be specified.
port1 port2	Specify the connection destination port numbers, using a comma as the delimiter. The port number can be omitted. If omitted, the default is 27500.
dbname	Specify the database name.
target_session_attrs	Specify the selection sequence of the servers to which the application will connect. Refer to "Target server" for details.
sslmode	Specify this to encrypt communications. By default, this is disabled. The setting values for sslmode are as follows: disable: Connect without SSL allow: Connect without SSL, and if it fails, connect with SSL prefer: Connect with SSL, and if it fails, connect without SSL require: Connect always with SSL verify-ca: Connect with SSL, using a certificate issued by a trusted CA (*1) verify-full: Connect with SSL, using a certificate issued by a trusted CA to verify if the server host name matches the certificate (*1)
sslservercertcn	This parameter is enabled only to perform SSL authentication (sslmode=verify-full). Specify the server certificate CN. If this is omitted, the value will be null, and the server certificate CN will be authenticated using the host name specified in host.

*1: If specifying either "verify-ca" or "verify-full", use the system environment variable PGSSLROOTCERT (connection parameter sslrootcert) of your operating system to specify the CA certificate file as shown below.

Example)
Variable name: PGSSLROOTCERT
Variable value: *cACertificateFile*

Point

Environment variables can also be used. Refer to "12.2.5 Using the C Library (libpq)" for information on environment variables.

Note

If using the connection parameter connect_timeout, this value is applied for connections to each of the specified hosts. If both multiplexed database servers have failed, the connection will time out when a time equal to double the connect_timeout value elapses.

12.2.7 Using the psql Command

It is recommended that you use a connection service file. Refer to "12.2.4 Using a Connection Service File" for details.

If a connection service file will not be used, specify the following information in the psql command option/environment variable.

Table 12.7 Information to be set

Option (environment variable)	Explanation
-h/--host(PGHOST/ PGHOSTADDR)	Specify IP address 1 and IP address 2, or the host name, using a comma as the delimiter. This can also be specified for the environment variable PGHOST or PGHOSTADDR.
-p/--port(PGPORT)	Specify the connection destination port numbers, using a comma as the delimiter. This can also be specified for the environment variable PGPORT. Specify the port number corresponding to the IP address specified for the nth -h option as the nth -p option. The port number can be omitted. If omitted, the default is 27500. If *n* -h options are specified, and m -p options are specified then there will be error reported. The only exception is where m=n or m=1. In case only one port is specified, then the same is applied for all the hosts.
(PGTARGETSESSIONATTRS)	Specify the selection sequence of the servers to which the application will connect. Refer to "Target server" for details.
(PGSSLMODE)	Specify this to encrypt communications. By default, this is disabled. The setting values for PGSSLMODE are as follows: disable: Connect without SSL allow: Connect without SSL, and if it fails, connect with SSL prefer: Connect with SSL, and if it fails, connect without SSL require: Connect always with SSL verify-ca: Connect with SSL, using a certificate issued by a trusted CA (*1) verify-full: Connect with SSL, using a certificate issued by a trusted CA to verify if the server host name matches the certificate (*1)
(PGXSSLSERVERCERTCN)	This environment variable is enabled only to perform SSL authentication (PGSSLMODE=verify-full). Specify the server certificate CN. If this is omitted, the value will be null, and the server certificate CN will be authenticated using the host name specified in host.

*1: If specifying either "verify-ca" or "verify-full", use the system environment variable PGSSLROOTCERT (connection parameter sslrootcert) of your operating system to specify the CA certificate file as shown below.

Example)
Variable name: PGSSLROOTCERT
Variable value: *cACertificateFile*

Note

If using the connection parameter connect_timeout, this value is applied for connections to each of the specified hosts. If both multiplexed database servers have failed, the connection will time out when a time equal to double the connect_timeout value elapses.

Information

Use the same method as for psql commands to specify connection destination server information for other client commands used to specify connection destinations.

12.2.8 Using the Python Language Package (psycopg)

It is recommended that you use a connection service file. Refer to "12.2.4 Using a Connection Service File" for details.

If a connection service file will not be used, set the the necessary information in the connection information (conninfo of the connect function) or in the environment variable for database connection. Refer to "12.2.5 Using the C Library (libpq)" for more information about parameters or environment variables.

L

12.2.9 Using the Go Language

Set the necessary information in the connection string, a key=value format string, or environment variables to be passed to the database connection function. Refer to "12.2.5 Using the C Library (libpq)" for more information about parameters or environment variables. However, the following settings are different from those in the C library (libpq).

Parameter (environment variable name)	Explanation
port(PGPORT)	Specify the connection destination port numbers, using a comma as the delimiter. Specify the port number of the nth server specified in host as the nth port. The port number can be omitted. If everything is omitted, the default is 27500. Either omit all or specify the same number as designated for the host.
sslservercertcn(PGXSSLSERVERCERTCN)	This parameter is enabled only to perform SSL authentication (sslmode=verify-full). If the server certificate has a SAN (Subject Alternative Name), specify the value to be matched with that entry. If there is no SAN and the certificate only has a CN (Common Name), specify the value to be matched with that CN. If omitted, it will be null, and the server certificate's SAN or CN will be authenticated using the hostname specified in host.

Chapter 13 Scan Using a Vertical Clustered Index (VCI)

This chapter describes scanning using a VCI.

This feature can only be used in Advanced Edition.

13.1 Operating Conditions

Faster aggregation can be achieved by using a VCI defined for all columns to be referenced.

This section describes the conditions under which a scan can use a VCI.

Whether to use VCI is determined based on cost estimation in the same way as normal indexes. Therefore, another execution plan will be selected if it is cheaper than a VCI even if a VCI is available.

SQL statements that can use VCIs

In addition to general SELECT statements, VCIs can be used for the SQL statements below (as long as they do not specify any of the elements listed in "SQL statements that cannot use VCIs" below):

- SELECT INTO
- CREATE TABLE AS SELECT
- CREATE MATERIALIZED VIEW ... AS SELECT
- CREATE VIEW ... AS SELECT
- COPY (SELECT ...) TO

SQL statements that cannot use VCIs

VCIs cannot be used for SQL statements that specify any of the following:

- Subquery to reference the column in which the parent query is referencing is specified
- Lock clause (such as FOR UPDATE)
- Cursor declared with WITH HOLD or scrollable
- SERIALIZABLE transaction isolation level
- Function or operator listed in "Functions and operators that do not use a VCI"
- User-defined function

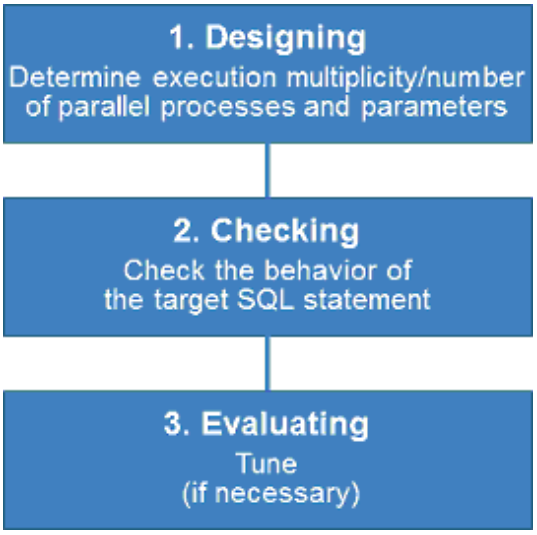
Table 13.1 Functions and operators that cannot use VCIs

Classification		Function/operator
Mathematical functions and operators	Random functions	random and setseed
String functions and operators	String functions	format (if the *format* argument is specified), regexp_matches, regexp_split_to_array and regexp_split_to_table
Date/time functions and operators	Date/time functions	age(timestamp), current_date, current_time, current_timestamp, localtime, localtimestamp, statement_timestamp and transaction_timestamp
	Delaying execution functions	pg_sleep, pg_sleep_for, and pg_sleep_until
Enum support functions		All functions and operators
Geometric functions and operators		All functions and operators

Classification		Function/operator
Network address functions and operators		All functions and operators
Text search functions and operators		All functions and operators
XML functions		All functions
JSON functions and operators		All functions and operators
Sequence manipulation functions		All functions
Array functions and operators		All functions and operators
Range functions and operators		All functions and operators
Aggregate functions	General-purpose aggregate functions	array_agg, json_agg, json_object_agg, string_agg and xmlagg
	Aggregate functions for statistics	corr, covar_pop, covar_samp, regr_avgx, regr_avgy, regr_count, regr_intercept, regr_r2, regr_slope, regr_sxx, regr_sxy and regr_syy
	Ordered-set aggregate functions	All functions
	Hypothetical-set aggregate functions	All functions
Window functions		All functions
Subquery expressions		Subquery expressions with its row constructor specified on the left side
Row and array comparisons		Row constructor and composite type comparisons
Set returning functions		All functions
System information functions		All functions
System administration functions		All functions
Trigger functions		All functions
Session information functions		current_role and current_user

13.2 Usage

This section describes how to use a VCI in line with the following steps:



13.2.1 Designing

Design as follows before using a VCI.

- Execution multiplicity and number of parallel processes
- Parameters

Execution multiplicity and number of parallel processes

Determine the maximum number of SQL statements that can be executed simultaneously and the number of parallel processes based on the number of CPU cores that can be allocated for scans that use VCI to perform aggregate processing. Design in advance the multiplicity of SQL statements for executing scans that use VCI and the number of parallel processes for scans that use VCI.

For example, if the number of CPUs that can be allocated is 32 cores, then the maximum number of SQL statements that can be executed simultaneously is 8 and the number of parallel processes is 4.

Note

L

A temporary file is created in /dev/shm or in a directory specified for the vci.smc_directory parameter as the dynamic shared memory for each SQL statement during a scan using a VCI.

W

A temporary file is created in a directory under the data storage directory or in a directory specified for the vci.smc_directory parameter as the dynamic shared memory for each SQL statement during a scan using a VCI.

Ensure that this directory has sufficient space to meet the memory requirements estimated for the execution multiplicity and number of parallel processes of SQL statements (refer to "Memory used per scanning" in "VCI Memory Requirements" in the Installation and Setup Guide for Server for details). If it does not have sufficient space when a scan is performed, SQL statements will return errors due to the insufficient memory.

Parameters

The VCI parallel scan feature cannot be used for setting parameters immediately after creating an instance.

Therefore, set the parameters below based on the values determined in "Execution multiplicity and number of parallel processes of SQL statements" above.

Parameter name	Description	Default	Value index
vci.max_parallel_degree	Maximum number of VCI parallel processes (background processes) to be used per SQL statement.	0	Specify the number of parallel processes.
vci.smc_directory	Directory name in which a temporary file is created as the dynamic shared memory during a scan using a VCI.	L /dev/shm W A directory (*dataStorageDir*\\base\\pgsql_tmp) under the data storage directory	Specify a directory that has enough free space for the memory used for each query during the scan.
max_worker_processes	Maximum number of background processes that	8	Add the value of the maximum number of SQL statements that can be executed simultaneously for scans that use VCI

Parameter name	Description	Default	Value index
	the system supports.		multiplied by vci.max_parallel_degree.

See

Refer to "Parameters" in the Operation Guide for information on the details of and how to set the parameters.

13.2.2 Checking

Execute the SQL statement with "EXPLAIN ANALYZE" to check the following:

- If a VCI was used
  "Custom Scan (VCI...)" is displayed in the plan if a VCI was used.
- Number of parallel processes
  The number of parallel processes when the SQL statement is executed is displayed in "Allocated Workers". Check that it is running the designed number of parallel processes.
- Response
  Check if the execution time displayed in "Execution time" is as estimated.

The following shows an example of the output result of EXPLAIN ANALYZE:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM test WHERE x > 10000;
                                                    QUERY
PLAN
-------------------------------------------------------------------------------------------------
------------------------
Custom Scan (VCI Aggregate)  (cost=19403.15..19403.16 rows=1 width=0) (actual
time=58.505..58.506 rows=1 loops=1)
       Allocated Workers: 4
   ->  Custom Scan (VCI Scan) using test_x_idx on test (cost=0.00..16925.00 rows=991261
width=0) (never executed)
         Filter: (x > 10000)
Planning time: 0.151 ms
Execution time: 86.910 ms
(6 rows)
```

Note

A cost output by the execution plan that uses a VCI may be inaccurate. A VCI works if all or part of the best execution plan when the SQL statement was executed is replaced with an execution plan that uses a VCI. If the cost of the execution plan to be replaced is lower than a certain value (vci.cost_threshold parameter), it will not be replaced or recalculated. Therefore, the cost of the original execution plan is output as is.

13.2.3 Evaluating

If the results in "13.2.2 Checking" is any of the following, tune accordingly:

If a VCI is not used

- Check if the "13.1 Operating Conditions" are met.
- Check if vci.enable is set to "on".
- A VCI may not be appropriately used when statistics are outdated, such as immediately after inserting a large amount of data. In such cases, execute the VACUUM ANALYZE statement or the ANALYZE statement.

- A VCI is not used if there is insufficient memory for VCI scan. This may occur during time-consuming transactions involving tables for which VCIs were defined. Set vci.log_query to "on", and check if either "could not use VCI: local ROS size (%zu) exceeds limit (%zu)" or "out of memory during local ROS generation" is output. If it is, then increase the value of the vci.max_local_ros.

Response is not as expected

Tuning may improve response. Check the following:

- If vci.max_parallel_degree is not set or is set to 0, set an appropriate value according to "13.2.1 Designing".
- If there is a margin in the CPU usage, increase the value of vci.max_parallel_degree and check again. In addition, if the value that of max_worker_processes is lower than the maximum number of SQL statements that can be executed simultaneously for parallel scan multiplied by vci.max_parallel_degree, increase it and check again.

13.3 Usage Notes

This section provides notes on using VCI.

- Regardless of whether VCI is used, the content of the result does not change. However, records may be returned in a different order if the ORDER BY clause is not specified.
- To reduce resource consumption, edit postgresql.conf or use the SET statement to enable/disable vci.enable when you use this feature only for specific times or jobs (SQL applications).
- The optimizer hint (pg_hint_plan) cannot be specified for a VCI. The hint clause is ignored if it is specified.
- If a plan other than VCI is specified for the optimizer hint (pg_hint_plan), a VCI may be used. Therefore, if you specify a query plan with the hint clause, use the SET statement to set vci.enable to "off".
- The message below may be output when a scan that uses VCI is performed on the streaming replication standby server:

```
"LOG: recovery has paused"
"HINT: Execute pg_wal_replay_resume() to continue."
```

  This message is output because application of the WAL to the VCI temporarily pauses due to the scan being performed.

- Even if a scan is performed using a VCI, information in the idx_scan, idx_tup_read, and idx_tup_fetch columns of the collected statistics views, pg_stat_all_indexes and pg_stat_user_indexes, will not be updated.
- Currently, it is not possible to replace the query plan for parallel aggregation with the query plan using VCI. Therefore, if you create a VCI on a column of a partition table and aggregate (sum () etc.) on that column, one of the following plans will be selected. Use different setting parameters according to the situation of the target table.
  - Plan of the parallel aggregations using scan methods other than VCI scan

    It is selected when max_parallel_workers_per_gather is 1 or more.

```
explain select sum(value) from test;
                                        QUERY PLAN
-------------------------------------------------------------------------------------
 Finalize Aggregate  (cost=99906.30..99906.31 rows=1 width=8)
   ->  Gather  (cost=99906.08..99906.29 rows=2 width=8)
         Workers Planned: 2
         ->  Partial Aggregate  (cost=98906.08..98906.09 rows=1 width=8)
               ->  Parallel Append  (cost=0.00..94739.83 rows=1666500 width=4)
                   ->  Parallel Seq Scan on test_1  (cost=0.00..43203.67 rows=833250
width=4)
                   ->  Parallel Seq Scan on test_2  (cost=0.00..43203.67 rows=833250
width=4)
```

    This plan is fast when the number of records to be aggregated (number of records that hit the search conditions) is very large. This is because the benefit of parallelizing aggregation is important, not the performance of scanning. For example, each parallel worker will perform a sequential scan and aggregate most of the scanned records.

- Plan that aggregates VCI scan results by a single aggregator node

  It is selected by setting max_parallel_workers_per_gather to 0 and not creating a query plan of parallel aggregate.

```
explain select sum(value) from test;
                                          QUERY PLAN
-----------------------------------------------------------------------------------------
 Aggregate  (cost=145571.00..145571.01 rows=1 width=8)
   ->  Append  (cost=0.00..135572.00 rows=3999600 width=4)
         ->  Custom Scan (VCI Scan) using test_1_id_value_idx on test_1
(cost=0.00..57787.00 rows=1999800 width=4)
               Allocated Workers: 2
         ->  Custom Scan (VCI Scan) using test_2_id_value_idx on test_2
(cost=0.00..57787.00 rows=1999800 width=4)
               Allocated Workers: 2
```

  This plan is fast when the number of aggregated items is not large or when the size of the aggregated column is smaller than the record size. This is because the scan performance is more important, so it is faster to aggregate the results of VCI scans of each partition.

- Originally, if there is only one partition to be accessed, the following VCI aggregation plan can be used. Below is an example of scanning only one partition with partition pruning.

```
explain select sum(value) from test where id < 1000001;
                                       QUERY PLAN
-----------------------------------------------------------------------------------------
 Custom Scan (VCI Aggregate)  (cost=62786.50..62786.51 rows=1 width=8)
   Allocated Workers: 2
   ->  Custom Scan (VCI Scan) using test_1_id_value_idx on test_1  (cost=0.00..57787.00
rows=1999800 width=4)
         Filter: (id < 1000001)
```

  However, the current planner does not try to choose VCI aggregation because it creates a plan for parallel aggregation if the table is partitioned. So in this case, set max_parallel_workers_per_gather to 0 to force the planner to choose VCI aggregation.

Chapter 14 Performance Tuning

14.1 SQL Statement Tuning

14.1.1 Tuning for FETCH Statement

When executing a FETCH statement to retrieve multiple rows of data, you can specify the number of rows to be retrieved as a parameter and obtain them all at once. This reduces overhead compared to retrieving data one row at a time, and performance improvement can be expected. At this time, the cursor moves to the last row of the retrieved data, so if you want to retrieve data other than the last row, use other search conditions instead of the cursor position.

Example

Definition of cursor

```
EXEC SQL DECLARE CUR01 CURSOR FOR SELECT * FROM tbl01 END-EXEC.
```

In the case of one FETCH

Store a value in the variable (VAR01).

```
EXEC SQL FETCH CUR01 INTO :VAR01 END-EXEC.
```

In the case of multiple FETCH

Store values in the array (ARRAY01).

```
EXEC SQL FETCH 100 INTO :ARRAY01 END-EXEC.
```

14.1.2 Tuning for Static SQL

When the same static SQL statement (INSERT statement, UPDATE statement, DELETE statement) is executed repeatedly many times, the parsing process can become an overhead and affect the application's processing performance. To reduce the parsing process, prepare the statement to be executed with the PREPARE statement and execute it with the EXECUTE statement.

Example

Examples of PREPARE statement and EXECUTE statement

```
PREPARE fooplan (int, text, bool, numeric) AS INSERT INTO foo VALUES($1, $2, $3, $4);
    EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

In the precompiler for embedded SQL in C language and COBOL language, there is a feature that automatically prepares statements for execution without rewriting SQL statements. By specifying the "-r prepare" option in the precompile command, SQL statements are prepared before execution, which can improve performance.

Example

In the case of embedded SQL using COBOL language

```
ecobpg -r prepare testproc.pco
```

Appendix A Precautions when Developing Applications

This appendix describes precautions when developing applications with Fujitsu Enterprise Postgres.

A.1 Precautions when Using Functions and Operators

This section describes notes for using functions and operators.

A.1.1 General rules of Functions and Operators

This section describes general rules for using functions and operators. Ensure the general rules are followed when using functions and operators to develop applications.

General rules

- Specify the stated numbers for arguments when specifying numbers for arguments in functions.
- Specify the stated data types when specifying data types for functions. If you use a data type other than the stated data types, use CAST to explicitly convert the data type.
- Specify data types that can be compared when specifying data types for operators. If you use a data type that cannot be compared, use CAST to explicitly convert the data type.

See

Refer to "Functions and Operators" under "The SQL Language" in the PostgreSQL Documentation for information on the functions and operators available with Fujitsu Enterprise Postgres.

A.1.2 Errors when Developing Applications that Use Functions and/or Operators

This section provides examples of problems that may occur when developing applications that use functions and/or operators, and describes how to deal with them.

The error "Function ***** does not exist" occurs when executing SQL

The following error will occur when executing an SQL statement that does not abide by the general rules for functions:

```
ERROR:  Function ****** does not exist
```

Note: "*****" denotes the function for which the error occurred, and the data type of its arguments.

The cause of the error will be one of the following:

- The specified function does not exist.
- The wrong number of arguments or wrong argument data type was specified

Corrective action

Check the following points and correct any errors:

- Check if there are any errors in the specified function name, number of arguments, or argument data type, and revise accordingly.
- Check the argument data type of the function displayed in the message. If an unintended data type is displayed, use a function such as CAST to convert it.

The error "Operator does not exist" occurs when executing SQL

The following error will occur when executing an SQL statement that specifies a data type in the operator that cannot be compared:

```
ERROR:  Operator does not exist: *****
```

Note: "*****" denotes the operator for which the error occurred, and the data type of the specified value.

Corrective action

Ensure the data type of the expressions specified on the left and right sides of the operator can be compared. If required, revise to ensure these data types can be compared by using a function such as CAST to explicitly convert them.

A.2 Notes when Using Temporary Tables

In standard SQL, a temporary table can be defined in advance to enable an empty temporary table to be created automatically when the application connects to the database. However, in Fujitsu Enterprise Postgres, a temporary table must be created when the application connects to the database by explicitly using the CREATE TABLE statement.

If the same temporary table is repeatedly created and deleted during the same session, the system table might expand, and memory usage might increase. To prevent this, specify the CREATE TABLE statement to ensure the temporary table is reused.

For example, in cases where a temporary table would be created and deleted for repeatedly executed transactions, specify the CREATE TABLE statement as shown below:

- Specify "IF NOT EXISTS" to create a temporary table only if none exists when the transaction starts.
- Specify "ON COMMIT DELETE ROWS" to ensure all rows are deleted when the transaction ends.

See

Refer to "SQL Commands" under "Reference" in the PostgreSQL Documentation for information on the CREATE TABLE statement.

Examples of SQL using a temporary table are shown below:

Example of bad use (creating and deleting a temporary table)

```
BEGIN;
CREATE TEMPORARY TABLE mytable(col1 CHAR(4), col2 INTEGER) ON COMMIT DROP;
     (mytable processes)

COMMIT;
```

Example of good use (reusing a temporary table)

```
BEGIN;
CREATE TEMPORARY TABLE IF NOT EXISTS mytable(col1 CHAR(4), col2 INTEGER) ON COMMIT
DELETE ROWS;
     (mytable processes)

COMMIT;
```

A.3 Implicit Data Type Conversions

An implicit data type conversion refers to a data type conversion performed automatically by Fujitsu Enterprise Postgres, without the need to explicitly specify the data type to convert to.

The combination of possible data type conversions differs, depending on whether the expression in the conversion source is a literal.

For non-literals, data types can only be converted to other types within the same range.

For literals, character string literal types can be converted to the target data type. Numeric literals are implicitly converted to specific numeric types. These implicitly converted numeric literals can then have their types converted to match the conversion target data type within the numeric type range. For bit character string literals, only the bit column data type can be specified. The following shows the range of type conversions for literals.

Table A.1 Data type combinations that contain literals and can be converted implicitly

Conversion target		Conversion source		
		Character literal (*1)	Numeric literal(*2)	Bit character string literal
Numeric type	SMALLINT	Y	N	N
	INTEGER	Y	Y (*3)	N
	BIGINT	Y	Y (*4)	N
	DECIMAL	Y	Y (*5)	N
	NUMERIC	Y	Y (*5)	N
	REAL	Y	N	N
	DOUBLE PRECISION	Y	N	N
	SMALLSERIAL	Y	N	N
	SERIAL	Y	Y (*3)	N
	BIGSERIAL	Y	Y (*4)	N
Currency type	MONEY	Y	N	N
Character type	CHAR	Y	N	N
	VARCHAR	Y	N	N
	NCHAR	Y	N	N
	NCHAR VARYING	Y	N	N
	TEXT	Y	N	N
Binary data type	BYTEA	Y	N	N
Date/time type	TIMESTAMP WITHOUT TIME ZONE	Y	N	N
	TIMESTAMP WITH TIME ZONE	Y	N	N
	DATE	Y	N	N
	TIME WITHOUT TIME ZONE	Y	N	N
	TIME WITH TIME ZONE	Y	N	N
	INTERVAL	Y	N	N
Boolean type	BOOLEAN	Y	N	N
Geometric type	POINT	Y	N	N
	LSEG	Y	N	N
	BOX	Y	N	N

Conversion target		Conversion source		
		Character literal (*1)	Numeric literal(*2)	Bit character string literal
	PATH	Y	N	N
	POLYGON	Y	N	N
	CIRCLE	Y	N	N
Network address type	CIDR	Y	N	N
	INET	Y	N	N
	MACADDR	Y	N	N
	MACADDR8	Y	N	N
Bit string type	BIT	Y	N	Y
	BIT VARYING	Y	N	Y
Text search type	TSVECTOR	Y	N	N
	TSQUERY	Y	N	N
UUID type	UUID	Y	N	N
XML type	XML	Y	N	N
JSON type	JSON	Y	N	N

Y: Can be converted
N: Cannot be converted

*1: Only strings that can be converted to the data type of the conversion target can be specified (such as "1" if the conversion target is a numeric type)

*2: "Y" indicates specific numeric types that are converted first.

*3: Integers that can be expressed as INTEGER types can be specified

*4: Integers that cannot be expressed as INTEGER types, but can be expressed as BIGINT types, can be specified

*5: Integers that cannot be expressed as INTEGER or BIGINT types, but that can be expressed as NUMERIC types, or numeric literals that contain a decimal point or the exponent symbol (e), can be specified

Implicit data type conversions can be used when comparing or storing data.

The conversion rules differ, depending on the reason for converting. Purpose-specific explanations are provided below.

A.3.1 Function Argument

Value expressions specified in a function argument will be converted to the data type of that function argument.

See

Refer to "Functions and Operators" under "The SQL Language" in the PostgreSQL Documentation for information on data types that can be specified in function arguments.

A.3.2 Operators

Comparison operators, BETWEEN, IN

Combinations of data types that can be compared using comparison operators, BETWEEN, or IN are shown below.

Table A.2 Combinations of comparable data type

Left side	Right side		
	Numeric type	Character string type	Date/time type
Numeric type	Y	N	N
Character type	N	Y	N
Date/time type	N	N	Y

Y: Can be compared
N: Cannot be compared

When strings with different lengths are compared, the shorter one is padded with spaces to make the lengths match.

When numeric values with different precisions are compared, data will be converted to the type with the higher precision.

Set operation and CASE also follow the same rules.

Other operators

Value expressions specified in operators will be converted to data types that are valid for that operator.

See

Refer to "Functions and Operators" under "The SQL Language" in the PostgreSQL Documentation for information on data types that can be specified in operators.

A.3.3 Storing Values

Value expressions specified in the VALUES clause of the INSERT statement or the SET clause of the UPDATE statement will be converted to the data type of the column in which they will be stored.

A.4 Notes on Using Index

This section explains the notes on using the following indexes:

- SP-GiST index

A.4.1 SP-GiST Index

If more than 2 concurrent updates are performed on a table in which the SP-GiST index is defined, applications may stop responding. When this occur, all system processes including the Check Pointer process will also be in the state of no response. For these reasons, use of the SP-GiST index is not recommended.

A.5 Notes on Using Multibyte Characters in Definition Names

Do not use multibyte characters in database names or user names if using a Windows database server.

Multibyte characters must not be used in database names or user names on non-Windows database servers, because certain conditions may apply or it may not be possible to connect to some clients.

Related notes and constraints are described below.

1) Configuring the client encoding system

The client encoding system must be configured when the names are created.

See

Refer to "Character Set Support" in "Server Administration" in the PostgreSQL Documentation for information on how to configure the client encoding system.

2) Encoding system of names used for connection

Ensure that the encoding system of names used for connection is the same as that of the database that was connected when these names were created.

The reasons for this are as follows:

- Storage system for names in Fujitsu Enterprise Postgres

  The system catalog saves encoded names by using the encoding system of the database at the time the names were created.

- Encoding conversion policy when connected

  When connected, names sent from the client are matched with names in the system catalog without performing encoding conversion.

Accordingly, if the database that was connected when the names were defined uses the EUC_JP encoding system, but the database name is specified using UTF-8 encoding, then the database will be considered to be non-existent.

3) Connection constraints

The table below shows the connection constraints for each client type, based on the following assumptions:

- The conditions described in 1) and 2) above are satisfied.
- The database name and user names use the same encoding system.

Client type	Client operating system	
	Windows(R)	Linux
JDBC driver	Cannot be connected	Cannot be connected
ODBC driver	Cannot be connected	No connection constraints
.NET Data Provider	Can only connect when the encoding system used for definitions is UTF-8	-
SQLEmbedded SQL in C	Can only connect when the connection service file (pg_service.conf) is used	No connection constraints
psql command	Can only connect when the connection service file (pg_service.conf) is used	No connection constraints

A.6 How to Build and Run an Application that Uses Shared Libraries

This section describes the following supplementary items regarding the use of shared libraries when developing applications with Fujitsu Enterprise Postgres.

- Setting DT_RUNPATH for the application
- Direct linking of indirectly used libraries to applications

A.6.1 Setting DT_RUNPATH for Applications

Searching for libraries used by applications

If your application uses Fujitsu Enterprise Postgres shared libraries such as libpq and ecpg, you need to load those libraries when you run your application.

When loading a library, it searches the machine for the library.

Library Search allows you to specify the path to search.

To specify the path, you can use the DT_RUNPATH attribute recorded in the application or library, or the environment variable LD_LIBRARY_PATH.

In general, use of the DT_RUNPATH attribute is recommended. This is because the environment variable LD_LIBRARY_PATH may affect the execution of applications other than the corresponding application.

The following explains when to use DT_RUNPATH.

Build so that the path in the operating environment that stores the library to be used is set in the DT_RUNPATH attribute of the application.

For example, when using libpq or ecpg, set "<*Fujitsu Enterprise Postgres client feature installation directory in operating environment*>/lib". (Note 1)

For how to set the DT_RUNPATH attribute, refer to the documentation of your compiler or linker.

There are the following three types of paths to be set and how to operate them. Please select the one suitable for each operation, and set and operate.

(1) Specify an absolute path

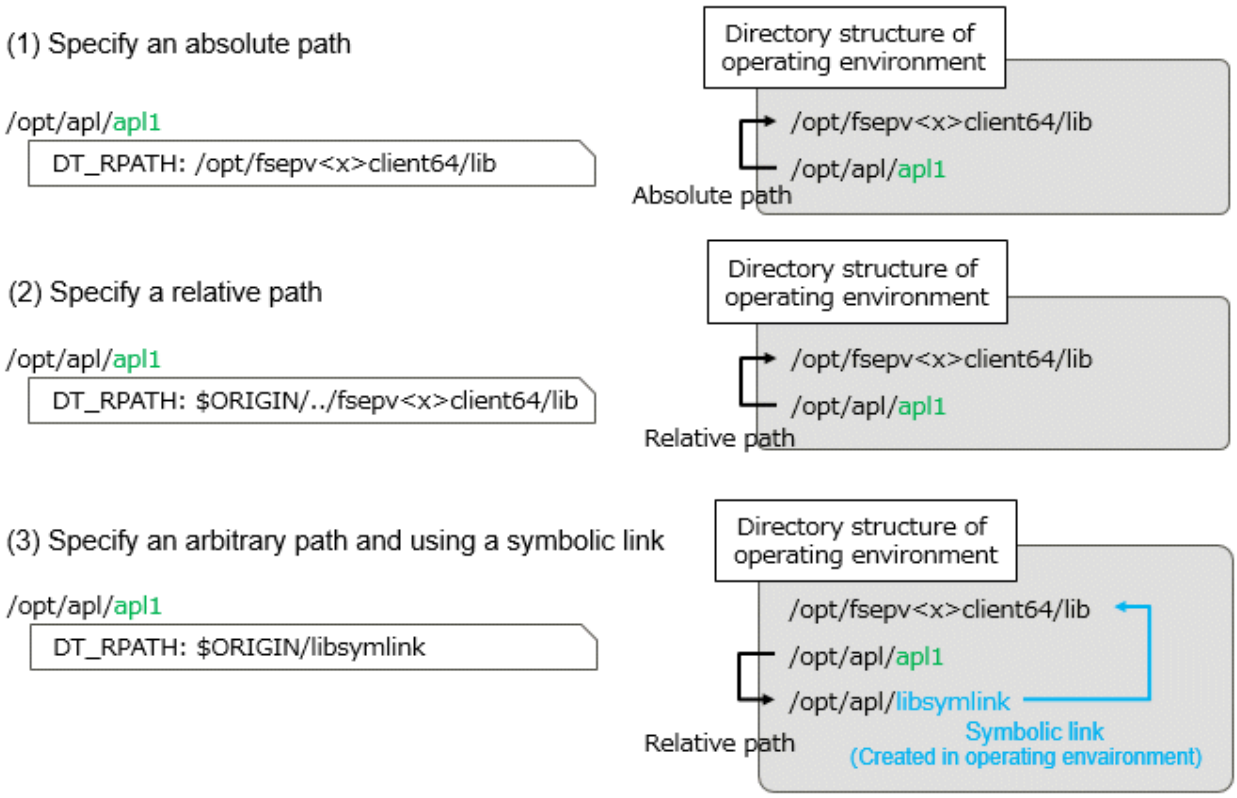
Set "<absolute path of the directory where the library is stored>/lib".

(2) Specify a relative path (Note 1)

Set "<relative path from the application of the directory that stores the library>/lib".

(3) Specify an arbitrary path and using a symbolic link

Set "(any path)". Also, create a symbolic link to the directory that stores the library at any path location.



Note 1:

For example, if you are building an application with gcc, add "-Wl,-rpath,<*Fujitsu Enterprise Postgres installation directory in the operating environment*/lib>,--enable-new-dtags" as gcc options, DT_RUNPATH can be set.

See

For setting DT_RUNPATH, refer to the linker ld's rpath and enable-new-dtags options, for example.

Also, refer to $ORIGIN in ld.so for specifying the relative position from the application.

When DT_RUNPATH cannot be set

If none of the above settings work, you can find the shared libraries your application needs by setting the environment variable LD_LIBRARY_PATH to the path to the directory that stores the libraries when you run your application.

However, if you set LD_LIBRARY_PATH and execute commands or programs other than the applicable application, please be aware that they may result in run-time errors or unexpected behavior.

See

Check the ld.so man page for more information on searching for shared libraries.

A.6.2 Direct Linking of Indirectly Used Libraries to Applications

Note

This content is complicated, and the possibility that it corresponds to this content in many applications is considered to be low.

Use this as a reference only when the application cannot be executed unexpectedly during a test, etc., when creating the application (as explained below, libF3 fails to load, or a runtime error occurs due to conflicts with other libraries).

For applications that use the libraries bundled with Fujitsu Enterprise Postgres, for example, if libF1, libF2, and libF3 have the following dependencies with other applications and libraries as shown below, libF3 can be directly Please specify in the build option to link.

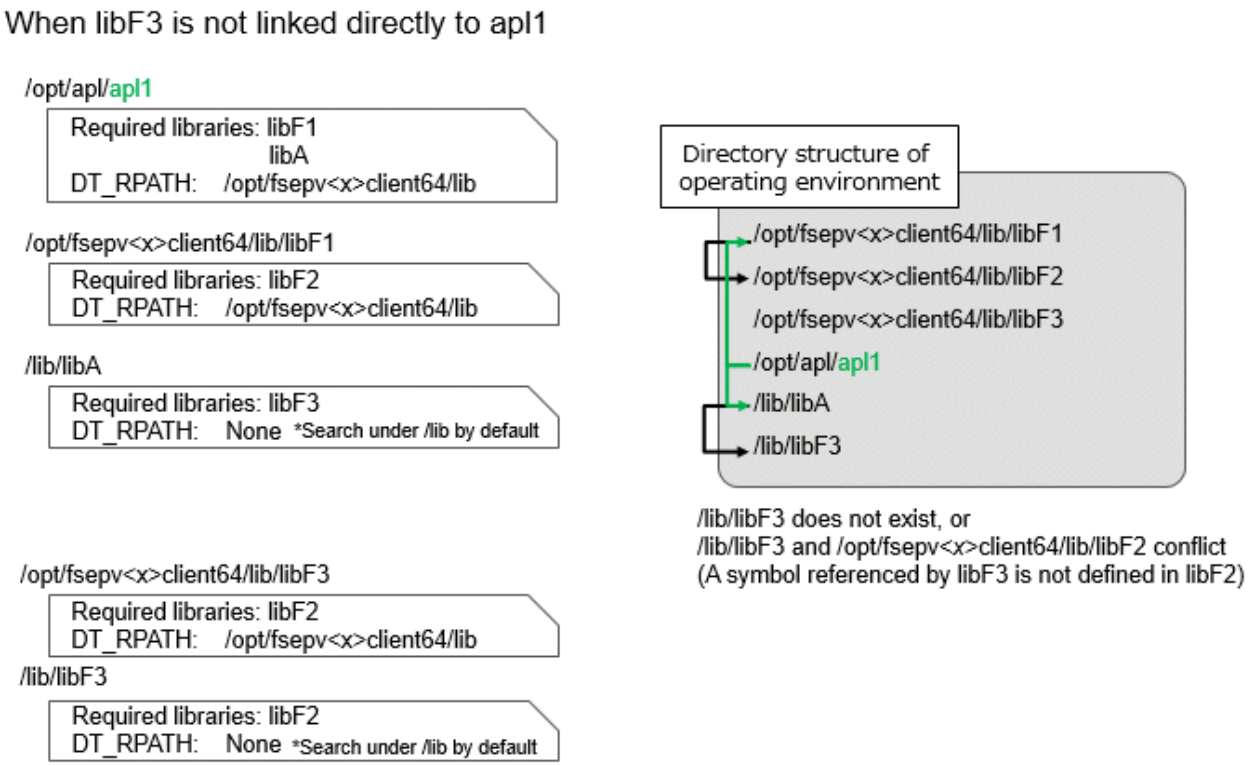
If you do not link directly, specify the path where libF3 is stored in LD_LIBRARY_PATH when running the application.

Otherwise, an error may occur during application execution.

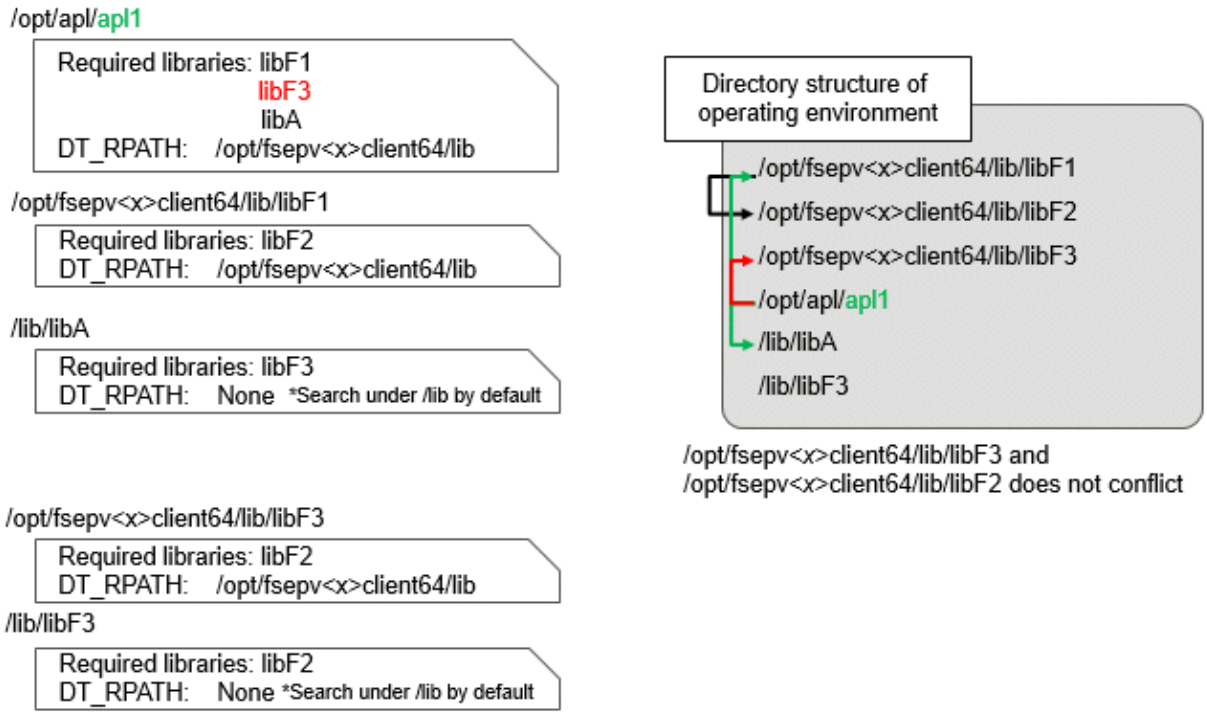
Example

The assumptions for this example are:

- There are the following dependencies between the application and the library.
  - apl1->libF1->libF2 (apl1 requires libF1 and libF1 requires libF2)
  - apl1->libA->libF3->libF2 (apl1 requires libA, libA requires libF3, libF3 requires libF2)
- libF1, libF2, and libF3 are libraries bundled with Fujitsu Enterprise Postgres.



When libF3 is directly linked to apl1



Generally, when loading libraries, if some libA requires libB and libB requires libC, only the DT_RUNPATH value set in libA is used to search libB, and only the DT_RUNPATH value set in libB is used to search libC.

In the figure above "When libF3 is not linked directly to apl1", the search for libF1 uses the DT_RUNPATH value set in apl1. The search for libF2 uses the DT_RUNPATH value set for libF1. Since "*Fujitsu Enterprise Postgres installation directory*/lib" is set in each DT_RUNPATH, libF1 and libF2 bundled with Fujitsu Enterprise Postgres can be found and loaded when searching for libF1 and libF2. .

However, searching for libF3 fails to load libF3 shipped with Fujitsu Enterprise Postgres. This is because the search for libF3 uses the DT_RUNPATH value set for libA, but libA does not have a DT_RUNPATH value.

Therefore, either libF3 cannot be found and loading of libF3 fails, or even if an unexpected libF3 is found in the machine and loaded, there is a conflict between libF2 bundled with Fujitsu Enterprise Postgres conflicts and can result in run-time errors. (The conflict here is that a symbol referenced in libF3 is not defined in libF2.)

By directly linking libF3 to the application, as shown in the figure above "When libF3 is directly linked to apl1", it is possible to use the DT_RUNPATH of the application and load the libF3 bundled with Fujitsu Enterprise Postgres. can. Alternatively, you can load libF3 shipped with Fujitsu Enterprise Postgres by setting LD_LIBRARY_PATH.

Appendix B Conversion Procedures Required due to Differences from Oracle Database

This appendix explains how to convert from an Oracle database to Fujitsu Enterprise Postgres, within the scope noted in "Chapter 11 Compatibility with Oracle Databases" from the following perspectives:

- Feature differences
- Specification differences

This document assumes that the version of the Oracle database to be converted is 7-10.2g.

B.1 Outer Join Operator (Perform Outer Join)

Features

In the WHERE clause conditional expression, by adding the plus sign (+), which is the outer join operator, to the column of the table you want to add as a table join, it is possible to achieve an outer join that is the same as a joined table (OUTER JOIN).

B.1.1 Comparing with the ^= Comparison Operator

Oracle database

```
SELECT *
  FROM t1, t2
  WHERE t1.col1(+) ^= t2.col1;
```

Note: col1 is assumed to be CHAR(4) type

Fujitsu Enterprise Postgres

```
SELECT *
  FROM t1, t2
  WHERE t1.col1(+) != t2.col1;
```

Note: col1 is assumed to be CHAR(4) type

Feature differences

Oracle database

The ^= comparison operator can be specified.

Fujitsu Enterprise Postgres

The ^= comparison operator cannot be specified.

Conversion procedure

Convert using the following procedure:

1. Locate the places where the keyword "^=" is used.
2. Ensure that the keyword, "(+)", is either on the right or left-hand side.
3. Change "^=" to " !=".

B.2 DECODE (Compare Values and Return Corresponding Results)

Features

DECODE compares values of the conversion target value expression and the search values one by one, and if the values of the conversion target value expression and the search values match, a corresponding result value is returned.

B.2.1 Comparing Numeric Data of Character String Types and Numeric Characters

Oracle database

```
SELECT DECODE( col1,
               1000, 'ITEM-A',
               2000, 'ITEM-B',
               'ITEM-C')
  FROM t1;
```

Note: col1 is assumed to be CHAR(4) type

Fujitsu Enterprise Postgres

```
SELECT DECODE( CAST(col1 AS INTEGER),
               1000, 'ITEM-A',
               2000, 'ITEM-B',
               'ITEM-C')
  FROM t1;
```

Note: col1 is assumed to be CHAR(4) type

Feature differences

Oracle database

When the value expression is a string and the search value is a numeric, the string value will be converted to the data type of the comparison target numeric, so that they can be compared.

Fujitsu Enterprise Postgres

If the conversion target value expression is a string value, then no search value can be specified with numbers.

Conversion procedure

Since the data type that can be specified for the conversion target value expression is unknown, use CAST to explicitly convert the conversion target value expression (col1 in the example) to a numeric (INTEGER type in the example).

B.2.2 Obtaining Comparison Result from more than 50 Conditional Expressions

Oracle database

```
SELECT DECODE(col1,
               1,'A',
               2,'B',
               ...
               78,'BZ',
               NULL,'UNKNOWN',
               'OTHER')
   FROM t1;
```

Note: col1 is assumed to be INTEGER type

Fujitsu Enterprise Postgres

```
SELECT CASE
           WHEN col1 = 1 THEN 'A'
           WHEN col1 = 2 THEN 'B'
           ...
           WHEN col1 = 78 THEN 'BZ'
           WHEN col1 IS NULL THEN 'UNKNOWN'
           ELSE 'OTHER'
       END
    FROM t1;
```

Note: col1 is assumed to be INTEGER type

Feature differences

Oracle database

Search value with a maximum of 127 items (up to 255 arguments in total) can be specified.

Fujitsu Enterprise Postgres

Search value with a maximum of 49 items (up to 100 arguments in total) only can be specified.

Conversion procedure

Convert to the CASE expression using the following procedure:

1. Specify the DECODE conversion target value expression (col1 in the first argument, in the example) and the search value (1 in the second argument, in the example) for the CASE expression search condition. Specify the DECODE result value ('A' in the third argument, in the example) for the CASE expression THEN (WHEN col1 = 1 THEN 'A', in the example). Note that if the search value is NULL, specify "IS NULL" for the search condition for the CASE expression.
2. If the DECODE default value ('OTHER' in the last argument, in the example) is specified, specify the default value for the CASE expression ELSE (ELSE 'OTHER', in the example).

B.2.3 Obtaining Comparison Result from Values with Different Data Types

Oracle database

```
SELECT DECODE( col1,
               '1000', 'A',
               '2000', 1,
               'OTHER')
FROM t1;
```

Note: col1 is assumed to be CHAR(4) type

Fujitsu Enterprise Postgres

```
SELECT DECODE( col1,
              '1000', 'A',
              '2000', '1',
              'OTHER')
FROM t1;
```

Note: col1 is assumed to be CHAR(4) type

Feature differences

Oracle database

The data types of all result values are converted to the data type of the first result value.

Fujitsu Enterprise Postgres

Results in an error.

Conversion procedure

Convert using the following procedure:

1. Check the literal data type for the first result value specified.
2. Change the literals specified for each result value to the literal data type checked in the step 1.

B.3 SUBSTR (Extract a String of the Specified Length from Another String)

Features

SUBSTR returns the number of characters specified in the third argument (starting from the position specified in the second argument) from the string specified in the first argument.

Refer to "11.2.2 Notes on SUBSTR" for details on precautions when using SUBSTR.

B.3.1 Specifying a Value Expression with a Data Type Different from the One that can be Specified for Function Arguments

Oracle database

```
SELECT SUBSTR( col1,
               1,
               col2)
  FROM DUAL;
```

Note: col1 and col2 are assumed to be CHAR type

Fujitsu Enterprise Postgres

```
CREATE CAST (CHAR AS INTEGER) WITH INOUT AS IMPLICIT;

SELECT SUBSTR( col1,
               1,
               col2)
  FROM DUAL;
# No changes to SELECT statement;
```

Note: col1 and col2 are assumed to be CHAR type

Feature differences

Oracle database

If the type can be converted to a data type that can be specified for function arguments, conversion is performed implicitly.

Fujitsu Enterprise Postgres

If the data types are different from each other, or if loss of significance occurs, implicit conversion is not performed.

Conversion procedure

Since the data type of the string length is clear, first execute the following CREATE CAST only once so that the CHAR type value (col2 in the example) specified for the string length is implicitly converted to INTEGER type.

```
CREATE CAST (CHAR AS INTEGER) WITH INOUT AS IMPLICIT;
```

B.3.2 Extracting a String with the Specified Format from a Datetime Type Value

Oracle database

```
SELECT SUBSTR( CURRENT_TIMESTAMP,
               1,
               8)
  FROM DUAL;
```

Fujitsu Enterprise Postgres

```
SELECT SUBSTR( TO_CHAR(CURRENT_TIMESTAMP,
               'DD-MON-YY HH.MI.SS.US PM')
                1,
                8)
  FROM DUAL;
```

Feature differences

Oracle database

A datetime value such as CURRENT_TIMESTAMP can be specified for character value expressions.

Fujitsu Enterprise Postgres

A datetime value such as CURRENT_TIMESTAMP cannot be specified for character value expressions.

Conversion procedure

First, specify TO_CHAR for the SUBSTR character value expression.
Specify datetime type (CURRENT_TIMESTAMP, in the example) in firstArg of TO_CHAR, and specify the format template pattern ('DD-MON-YY HH.MI.SS.US PM', in the example) for secondArg to match with the result of SUBSTR before conversion.

TO_CHAR specification format: TO_CHAR(*firstArg, secondArg*)

Information

Refer to "Data Type Formatting Functions" in the PostgreSQL Documentation for information on format template patterns that can be specified for TO_CHAR in Fujitsu Enterprise Postgres.

B.3.3 Concatenating a String Value with a NULL value

Oracle database

```
SELECT SUBSTR( col1 || col2,
               2,
               5)
  FROM t1;
```

Note: col1 and col2 are assumed to be character string type, and col2 may contain NULL

Fujitsu Enterprise Postgres

```
SELECT SUBSTR( col1 || NVL(col2, '')
               2,
               5)
  FROM t1;
```

Note: col1 and col2 are assumed to be character string type, and col2 may contain NULL

Feature differences

Oracle database

NULL is handled as an empty string, and strings are joined.

Fujitsu Enterprise Postgres

NULL is not handled as an empty string, and the result of joining the strings becomes NULL.

Conversion procedure

Convert using the following procedure:

1. Locate the places where the keyword "||" is used.
2. Check if any of the value expressions can contain NULL - if they can, then execute step 3.
3. Modify to NVL(*valExpr,*'').

B.4 NVL (Replace NULL)

Features

NVL converts NULL values.

B.4.1 Obtaining Result from Arguments with Different Data Types

Oracle database

```
SELECT NVL( col1,
            col2)
  FROM t1;
```

Note: col1 is assumed to be VARCHAR(100) type, and col2 is assumed to be CHAR(100) type

Fujitsu Enterprise Postgres

```
SELECT NVL( col1,
            CAST(col2 AS VARCHAR(100)))
  FROM t1;
```

Note: col1 is assumed to be VARCHAR(100) type, and col2 is assumed to be CHAR(100) type

Feature differences

Oracle database

Value expressions with different data types can be specified. If the first argument is a string value, then VARCHAR2 is returned, and if it is a numeric, then a numeric type with greater range is returned.

Fujitsu Enterprise Postgres

Value expressions with different data types cannot be specified.

Conversion procedure

Since the data types that can be specified for the expressions in the two arguments are unknown, use the following steps to convert:

1. Check the data types specified for each of the two expressions.
2. Using the data type that is to be received as a result, explicitly convert the other argument with CAST.

B.4.2 Operating on Datetime/Numeric, Including Adding Number of Days to a Particular Day

Oracle database

```
SELECT NVL( col1 + 10, CURRENT_DATE)
  FROM t1;
```

Note: col1 is assumed to be TIMESTAMP WITHOUT TIME ZONE type or TIMESTAMP WITH TIME ZONE type

Fujitsu Enterprise Postgres

```
SELECT NVL( CAST(col1 AS DATE) + 10, CURRENT_DATE)
  FROM t1;
```

Note: col1 is assumed to be TIMESTAMP WITHOUT TIME ZONE type or TIMESTAMP WITH TIME ZONE type

Feature differences

Oracle database

Numbers can be operated (added to or subtracted from) with either TIMESTAMP WITHOUT TIME ZONE type or TIMESTAMP WITH TIME ZONE type. Operation result will be DATE type.

Fujitsu Enterprise Postgres

Numbers cannot be operated (added to or subtracted from) with neither TIMESTAMP WITHOUT TIME ZONE type nor TIMESTAMP WITH TIME ZONE type. However, numbers can be operated (added to or subtracted from) with DATE type.

Conversion procedure

Convert using the following procedure:

1. Search locations where the keyword "+" or "-" is used in addition or subtraction, and check if these operations are between numbers and TIMESTAMP WITHOUT TIME ZONE type or TIMESTAMP WITH TIME ZONE type.
2. If they are, use CAST to explicitly convert TIMESTAMP WITHOUT TIME ZONE type or TIMESTAMP WITH TIME ZONE type to DATE type.

B.4.3 Calculating INTERVAL Values, Including Adding Periods to a Date

Oracle database

```
SELECT NVL( CURRENT_DATE + (col1 * 1.5), col2)
  FROM t1;
```

Note: col1 and col2 are assumed to be INTERVAL YEAR TO MONTH types

Fujitsu Enterprise Postgres

```
SELECT NVL( CURRENT_DATE +
        CAST(col1 * 1.5 AS
```

```
          INTERVAL YEAR TO MONTH), col2)
  FROM t1;
```

Note: col1 and col2 are assumed to be INTERVAL YEAR TO MONTH types

Feature differences

Oracle database

INTERVAL YEAR TO MONTH type multiplication and division result in INTERVAL YEAR TO MONTH type and any fraction (number of days) will be truncated.

Fujitsu Enterprise Postgres

INTERVAL YEAR TO MONTH type multiplication and division result in INTERVAL type and fractions (number of days) will not be truncated.

Conversion procedure

Convert using the following procedure:

1. Search locations where the keywords "*" or "/" are used in multiplication or division, and check if the specified value is INTERVAL YEAR TO MONTH type.
2. If the value is INTERVAL YEAR TO MONTH type, use CAST to explicitly convert the operation result to INTERVAL YEAR TO MONTH type.

B.5 DBMS_OUTPUT (Output Messages)

Features

DBMS_OUTPUT sends messages to clients such as psql from PL/pgSQL.

B.5.1 Outputting Messages Such As Process Progress Status

Oracle database

```
set serveroutput on;...(1)

DECLARE
  v_col1        CHAR(20);
  v_col2        INTEGER;
  CURSOR c1 IS
    SELECT col1, col2 FROM t1;
BEGIN
  DBMS_OUTPUT.PUT_LINE('-- BATCH_001 Start --');
  OPEN c1;
  DBMS_OUTPUT.PUT_LINE('-- LOOP Start --');
  LOOP
    FETCH c1 INTO v_col1, v_col2;
    EXIT WHEN c1%NOTFOUND;
    DBMS_OUTPUT.PUT('.');
  END LOOP;
  DBMS_OUTPUT.NEW_LINE; ...(2)
  DBMS_OUTPUT.PUT_LINE('-- LOOP End --');
  CLOSE c1;

  DBMS_OUTPUT.PUT_LINE('-- BATCH_001 End --');

EXCEPTION
  WHEN OTHERS THEN
     DBMS_OUTPUT.PUT_LINE('-- SQL Error --');
     DBMS_OUTPUT.PUT_LINE('ERROR : ' || SQLERRM );
```

```
END;
/
```

Fujitsu Enterprise Postgres

```
DO $$
DECLARE
    v_col1      CHAR(20);
    v_col2      INTEGER;
    c1 CURSOR FOR
        SELECT col1, col2 FROM t1;
BEGIN
    PERFORM DBMS_OUTPUT.SERVEROUTPUT(TRUE); ...(1)
    PERFORM DBMS_OUTPUT.ENABLE(NULL); ...(1)

    PERFORM DBMS_OUTPUT.PUT_LINE('-- BATCH_001 Start --');

    OPEN c1;
    PERFORM DBMS_OUTPUT.PUT_LINE('-- LOOP Start --');
    LOOP
        FETCH c1 INTO v_col1, v_col2;
        EXIT WHEN FOUND = false;
        PERFORM DBMS_OUTPUT.PUT('.');
    END LOOP;
    PERFORM DBMS_OUTPUT.NEW_LINE(); ...(2)

    PERFORM DBMS_OUTPUT.PUT_LINE('-- LOOP End --');
    CLOSE c1;

    PERFORM DBMS_OUTPUT.PUT_LINE('-- BATCH_001 End --');

EXCEPTION
    WHEN OTHERS THEN
        PERFORM DBMS_OUTPUT.PUT_LINE('-- SQL Error --');
        PERFORM DBMS_OUTPUT.PUT_LINE('ERROR : ' || SQLERRM );
END;
$$
;
```

(1) SERVEROUTPUT/ENABLE

Specification differences

Oracle database

Use SET statement and specify SERVEROUTPUT ON.

Fujitsu Enterprise Postgres

Specify DBMS_OUTPUT.SERVEROUTPUT(TRUE).

Conversion procedure

Convert using the following procedure:

1. Check if a SET SERVEROUTPUT statement is specified before the PL/SQL block of a stored procedure.
2. If a SET SERVEROUTPUT statement is specified, specify DBMS_OUTPUT.SERVEROUTPUT straight after BEGIN of PL/pgSQL. If ON is specified to have messages output to a window, then specify TRUE. If OFF is specified, then specify FALSE.
3. Specify DBMS_OUTPUT.ENABLE only if SET SERVEROUTPUT is ON. The values to be specified for the argument are as follows:
   - If SIZE is specified for the SET SERVEROUTPUT statement, specify this size for the argument.

- If SIZE is not specified for the SET SERVEROUTPUT statement, then specify 2000 for Oracle10.1g or earlier, NULL for Oracle10.2g or later.

If DBMS_OUTPUT.ENABLE is specified for the PL/SQL block of the stored procedure, specify the same value as that argument.

(2) NEW_LINE

Specification differences

Oracle database

If there is no argument for *packageName.featureName*, parenthesis can be omitted.

Fujitsu Enterprise Postgres

Even if there is no argument for *packageName.featureName*, parenthesis cannot be omitted.

Conversion procedure

Convert using the following procedure:

1. Locate the places where the keyword "DBMS_OUTPUT.NEW_LINE" is used in the stored procedure.
2. If there is no parenthesis after *packageName.featureName*, add the parenthesis.

B.5.2 Receiving a Return Value from a Procedure (PL/SQL) Block (For GET_LINES)

Oracle database

```
set serveroutput off;

DECLARE
    v_num        INTEGER;
BEGIN

    DBMS_OUTPUT.DISABLE; ...(3)
    DBMS_OUTPUT.ENABLE(20000); ...(4)
    DBMS_OUTPUT.PUT_LINE('-- ITEM CHECK --');

    SELECT count(*) INTO v_num FROM t1;

    IF v_num = 0 THEN
        DBMS_OUTPUT.PUT_LINE('-- NO ITEM --');

    ELSE
        DBMS_OUTPUT.PUT_LINE('-- IN ITEM(' || v_num || ') --');
    END IF;
END;
/

set serveroutput on;

DECLARE
    v_buffs      DBMSOUTPUT_LINESARRAY; ...(5)
    v_num        INTEGER := 10;
BEGIN

    DBMS_OUTPUT.GET_LINES(v_buffs, v_num); ...(5)

    FOR i IN 1..v_num LOOP
        DBMS_OUTPUT.PUT_LINE('LOG : ' || v_buffs(i)); ...(5)
```

```
    END LOOP;
END;
/
```

Fujitsu Enterprise Postgres

```
DO $$
DECLARE
    v_num        INTEGER;
BEGIN
    PERFORM DBMS_OUTPUT.SERVEROUTPUT(FALSE);
    PERFORM DBMS_OUTPUT.DISABLE(); ...(3)
    PERFORM DBMS_OUTPUT.ENABLE(20000); ...(4)
PERFORM DBMS_OUTPUT.PUT_LINE('-- ITEM CHECK --');

    SELECT count(*) INTO v_num FROM t1;

    IF v_num = 0 THEN
        PERFORM DBMS_OUTPUT.PUT_LINE('-- NO ITEM --');
    ELSE
        PERFORM DBMS_OUTPUT.PUT_LINE('-- IN ITEM(' || v_num || ') --');
    END IF;
END;
$$
;

DO $$
DECLARE
    v_buffs      VARCHAR[]; ...(5)
    v_num        INTEGER := 10;
BEGIN
    PERFORM DBMS_OUTPUT.SERVEROUTPUT(TRUE);
    SELECT lines, numlines INTO v_buffs, v_num FROM DBMS_OUTPUT.GET_LINES(v_num); ...(5)

    FOR i IN 1..v_num LOOP
        PERFORM DBMS_OUTPUT.PUT_LINE('LOG : ' || v_buffs[i]); ...(5)
    END LOOP;
END;
$$
;
```

(3) DISABLE

Same as the NEW_LINE in the DBMS_OUTPUT package. Refer to NEW_LINE for information on specification differences and conversion procedures associated with specification differences.

(4) ENABLE

Same as NEW_LINE in the DBMS_OUTPUT package. Refer to NEW_LINE for information on specification differences and conversion procedures associated with specification differences.

(5) GET_LINES

Specification format for Oracle database

DBMS_OUTPUT.GET_LINES(*firstArg, secondArg*)

Specification differences

Oracle database

Obtained values are received with variables specified for arguments.

Fujitsu Enterprise Postgres

Since obtained values are the search results for DBMS_OUTPUT.GET_LINES, they are received with variables specified for the INTO clause of the SELECT statement.

Conversion procedure

Convert using the following procedure:

1. Locate the places where the keyword "DBMS_OUTPUT.GET_LINES" is used in the stored procedure.
2. Change the data type (DBMSOUTPUT_LINESARRAY in the example) of the variable (v_buffs in the example) specified as *firstArg* of DBMS_OUTPUT.GET_LINES into a VARCHAR type array (VARCHAR[] in the example).
3. Replace the DBMS_OUTPUT.GET_LINES location called with a SELECT INTO statement.
   - Use the literal "lines, numlines" in the select list.
   - Specify *firstArg* (v_buffs in the example) and *secondArg* (v_num in the example) configured in DBMS_OUTPUT.GET_LINES, in the INTO clause.
   - Use DBMS_OUTPUT.GET_LINES in the FROM clause. Specify only *secondArg* (v_num in the example) before modification.
4. Identify the location that references *firstArg* (v_buffs in the example), and change it to the PL/pgSQL array reference format (v_buffs[i] in the example).

B.5.3 Receiving a Return Value from a Procedure (PL/SQL) Block (For GET_LINE)

Oracle database

```
set serveroutput on;

DECLARE
    v_buff1       VARCHAR2(100);
    v_buff2       VARCHAR2(1000);
    v_num        INTEGER;
BEGIN

    v_buff2 := '';
    LOOP
        DBMS_OUTPUT.GET_LINE(v_buff1, v_num); ...(6)
        EXIT WHEN v_num = 1;
        v_buff2 := v_buff2 || v_buff1;
    END LOOP;

    DBMS_OUTPUT.PUT_LINE(v_buff2);
END;
/
```

Note: Only the process to obtain a value is stated

Fujitsu Enterprise Postgres

```
DO $$
DECLARE
    v_buff1       VARCHAR(100);
    v_buff2       VARCHAR(1000);
    v_num        INTEGER;
BEGIN
    PERFORM DBMS_OUTPUT.SERVEROUTPUT(TRUE);
    v_buff2 := '';
    LOOP
```

```
        SELECT line, status INTO v_buff1, v_num FROM DBMS_OUTPUT.GET_LINE(); ...(6)
        EXIT WHEN v_num = 1;
        v_buff2 := v_buff2 || v_buff1;
    END LOOP;

    PERFORM DBMS_OUTPUT.PUT_LINE(v_buff2);
END;
$$
;
```

Note: Only the process to obtain a value is stated

(6) GET_LINE

Specification format for Oracle database

DBMS_OUTPUT.GET_LINE(*firstArg, secondArg*)

Specification differences

Oracle database

Obtained values are received with variables specified for arguments.

Fujitsu Enterprise Postgres

Since obtained values are the search results for DBMS_OUTPUT.GET_LINES, they are received with variables specified for the INTO clause of the SELECT statement.

Conversion procedure

Convert using the following procedure:

1. Locate the places where the keyword "DBMS_OUTPUT.GET_LINE" is used in the stored procedure.
2. Replace the DBMS_OUTPUT.GET_LINE location called with a SELECT INTO statement.
   - Use the literal "line, status" in the select list.
   - Specify *firstArg* (v_buff1 in the example) and *secondArg* (v_num in the example) configured in DBMS_OUTPUT.GET_LINE, in the INTO clause.
   - Use DBMS_OUTPUT.GET_LINE in the FROM clause. Although arguments are not specified, parenthesis must be specified.

B.6 UTL_FILE (Perform File Operation)

Features

UTL_FILE reads and writes text files from PL/pgSQL.

B.6.1 Registering a Directory to Load and Write Text Files

Oracle database

```
[Oracle9i or earlier]
Configure the following with initialization parameter
   UTL_FILE_DIR='/home/fsep' ...(1)

[Oracle9.2i or later]
   Configure the following with CREATE DIRECTORY statement
   CREATE DIRECTORY DIR AS '/home/fsep'; ...(1)
```

Fujitsu Enterprise Postgres

```
INSERT INTO UTL_FILE.UTL_FILE_DIR(dir)
       VALUES('/home/fsep'); ...(1)
```

(1) UTL_FILE_DIR/CREATE DIRECTORY

Feature differences

Oracle database

Configure the directory to be operated, using the CREATE DIRECTORY statement or the initialization parameter UTL_FILE_DIR.

Fujitsu Enterprise Postgres

The directory to be operated cannot be configured using the CREATE DIRECTORY statement or the initialization parameter UTL_FILE_DIR.

Conversion procedure

Configure the target directory information in the UTL_FILE.UTL_FILE_DIR table using the INSERT statement. Note that this conversion procedure should be performed only once before executing the PL/pgSQL function.

- When using the initialization parameter UTL_FILE_DIR:

  1. Check the initialization parameter UTL_FILE_DIR value ('/home/fsep' in the example).
  2. Using the INSERT statement, specify and execute the directory name checked in step 1.
     - Specify UTL_FILE.UTL_FILE_DIR(dir) for the INTO clause.
     - Using the character string literal ('/home/fsep' in the example), specify the target directory name for the VALUES clause.
     - If multiple directories are specified, execute the INSERT statement for each directory.

- When using the CREATE DIRECTORY statement:

  1. Check the directory name ('/home/fsep' in the example) registered with the CREATE DIRECTORY statement. To check, log in SQL*Plus as a user with DBA privileges, and execute "show ALL_DIRECTORIES;".
  2. Using the INSERT statement, specify and execute the directory name checked in step 1. Same steps are used to specify the INSERT statement as when using the initialization parameter UTL_FILE_DIR.

B.6.2 Checking File Information

Oracle database

```
CREATE PROCEDURE read_file(fname VARCHAR2) AS

    v_file      UTL_FILE.FILE_TYPE;
    v_exists    BOOLEAN;
    v_length    NUMBER;
    v_bsize     INTEGER;
    v_rbuff     VARCHAR2(1024);
BEGIN

    UTL_FILE.FGETATTR('DIR', fname, v_exists, v_length, v_bsize); ...(2)

    IF v_exists <> true THEN
        DBMS_OUTPUT.PUT_LINE('-- FILE NOT FOUND --');
        RETURN;
    END IF;
```

```
    DBMS_OUTPUT.PUT_LINE('-- FILE DATA --');

    v_file := UTL_FILE.FOPEN('DIR', fname, 'r', 1024); ...(3)
    FOR i IN 1..3 LOOP
        UTL_FILE.GET_LINE(v_file, v_rbuff, 1024); ...(4)
        DBMS_OUTPUT.PUT_LINE(v_rbuff);
    END LOOP;
    DBMS_OUTPUT.PUT_LINE('... more');
    DBMS_OUTPUT.PUT_LINE('-- READ END --');

    UTL_FILE.FCLOSE(v_file); ...(5)
    RETURN;

EXCEPTION
    WHEN NO_DATA_FOUND THEN
        DBMS_OUTPUT.PUT_LINE('-- FILE END --');

        UTL_FILE.FCLOSE(v_file);
        RETURN;
    WHEN OTHERS THEN
        DBMS_OUTPUT.PUT_LINE('-- SQL Error --');

        DBMS_OUTPUT.PUT_LINE('ERROR : ' || SQLERRM );
        UTL_FILE.FCLOSE_ALL; ...(6)
        RETURN;
END;
/

set serveroutput on

call read_file('file01.txt');
```

Fujitsu Enterprise Postgres

```
CREATE FUNCTION read_file(fname VARCHAR) RETURNS void AS $$
DECLARE
    v_file      UTL_FILE.FILE_TYPE;
    v_exists    BOOLEAN;
    v_length    NUMERIC;
    v_bsize     INTEGER;
    v_rbuff     VARCHAR(1024);
BEGIN
    PERFORM DBMS_OUTPUT.SERVEROUTPUT(TRUE);

    SELECT fexists, file_length, blocksize
       INTO v_exists, v_length, v_bsize
       FROM UTL_FILE.FGETATTR('/home/fsep', fname); ...(2)
    IF v_exists <> true THEN
        PERFORM DBMS_OUTPUT.PUT_LINE('-- FILE NOT FOUND --');
        RETURN;
    END IF;

    PERFORM DBMS_OUTPUT.PUT_LINE('-- FILE DATA --');
    v_file := UTL_FILE.FOPEN('/home/fsep', fname, 'w', 1024); ...(3)
    FOR i IN 1..3 LOOP
        v_rbuff := UTL_FILE.GET_LINE(v_file, 1024); ...(4)
        PERFORM DBMS_OUTPUT.PUT_LINE(v_rbuff);
    END LOOP;
    PERFORM DBMS_OUTPUT.PUT_LINE('... more');
    PERFORM DBMS_OUTPUT.PUT_LINE('-- READ END --');

    v_file := UTL_FILE.FCLOSE(v_file); ...(5)
```

```
    RETURN;

EXCEPTION
    WHEN NO_DATA_FOUND THEN
        PERFORM DBMS_OUTPUT.PUT_LINE('-- FILE END --');
        v_file := UTL_FILE.FCLOSE(v_file);
        RETURN;
    WHEN OTHERS THEN
        PERFORM DBMS_OUTPUT.PUT_LINE('-- SQL Error --');
        PERFORM DBMS_OUTPUT.PUT_LINE('ERROR : ' || SQLERRM );
        PERFORM UTL_FILE.FCLOSE_ALL(); ...(6)
        RETURN;
END;
$$
LANGUAGE plpgsql;

SELECT read_file('file01.txt');
```

(2) FGETATTR

Specification format for Oracle database

UTL_FILE.FGETATTR(*firstArg, secondArg*, *thirdArg*, *fourthArg*, *fifthArg*)

Feature differences

Oracle database

If using a CREATE DIRECTORY statement (Oracle9.2i or later), specify a directory object name for the directory name.

Fujitsu Enterprise Postgres

A directory object name cannot be specified for the directory name.

Specification differences

Oracle database

Obtained values are received with variables specified for arguments.

Fujitsu Enterprise Postgres

Since obtained values are the search results for UTL_FILE.FGETATTR, they are received with variables specified for the INTO clause of the SELECT statement.

Conversion procedure

Convert using the following procedure. Refer to UTL_FILE_DIR/CREATE DIRECTORY for information on how to check if the directory object name corresponds to the actual directory name.

1. Locate the places where the keyword "UTL_FILE.FOPEN" is used in the stored procedure.
2. Check the actual directory name ('/home/fsep' in the example) that corresponds to the directory object name ('DIR' in the example).
3. Replace the directory object name ('DIR' in the example) in *firstArg* with the actual directory name ('/home/fsep' in the example) verified in step 2.
4. Replace the UTL_FILE.FGETATTR location called with a SELECT INTO statement.
   - Use the literal "fexists, file_length, blocksize" in the select list.
   - Specify *thirdArg*, *fourthArg*, and *fifthArg* (v_exists, v_length, v_bsize, in the example) specified for UTL_FILE.FGETATTR to the INTO clause in the same order as that of the arguments.
   - Use UTL_FILE.FGETATTR in the FROM clause. Specify only the actual directory name for *firstArg* ('/home/fsep' in the example) and *secondArg* (fname in the example) before modification for the arguments.

(3) FOPEN

Specification format for Oracle

UTL_FILE.FOPEN(*firstArg, secondArg*, *thirdArg*, *fourthArg*, *fifthArg*)

Feature differences

Oracle database

If using a CREATE DIRECTORY statement (Oracle9.2i or later), specify a directory object name for the directory name.

Fujitsu Enterprise Postgres

A directory object name cannot be specified for the directory name.

Conversion procedure

Convert using the following procedure. Refer to UTL_FILE_DIR/CREATE DIRECTORY for information on how to check if the directory object name corresponds to the actual directory name.

1. Locate the places where the keyword "UTL_FILE.FOPEN" is used in the stored procedure.
2. Check the actual directory name ('/home/fsep' in the example) that corresponds to the directory object name ('DIR' in the example).
3. Replace the directory object name ('DIR' in the example) in *firstArg* with the actual directory name ('/home/fsep' in the example) checked in step 1.

(4) GET_LINE

Specification format for Oracle database

UTL_FILE.GET_LINE(*firstArg, secondArg*, *thirdArg*, *fourthArg*)

Specification differences

Oracle database

Obtained values are received with variables specified for arguments.

Fujitsu Enterprise Postgres

Since obtained values are the returned value of UTL_FILE.GET_LINE, they are received with variables specified for substitution statement.

Conversion procedure

Convert using the following procedure:

1. Locate the places where the keyword "UTL_FILE.GET_LINE" is used in the stored procedure.
2. Replace the UTL_FILE.GET_LINE location called with a value assignment (:=).
   - On the left-hand side, specify *secondArg* (v_rbuff in the example) specified for UTL_FILE.GET_LINE.
   - Use UTL_FILE.GET_LINE in the right-hand side. Specify only *firstArg* (v_file in the example) and *thirdArg* (1024 in the example) before modification.

(5) FCLOSE

Specification format for Oracle database

UTL_FILE.FCLOSE(*firstArg*)

Specification differences

Oracle database

After closing, the file handler specified for the argument becomes NULL.

Fujitsu Enterprise Postgres

After closing, set the file handler to NULL by assigning the return value of UTL_FILE.FCLOSE to it.

Conversion procedure

Convert using the following procedure:

1. Locate the places where the keyword "UTL_FILE.FCLOSE" is used in the stored procedure.
2. Replace the UTL_FILE.FCLOSE location called with a value assignment (:=) so that the file handler (v_file in the example) becomes NULL.
   - On the left-hand side, specify the argument (v_file in the example) specified for UTL_FILE.FCLOSE.
   - Use UTL_FILE.FCLOSE in the right-hand side. For the argument, specify the same value (v_file in the example) as before modification.

(6) FCLOSE_ALL

Same as NEW_LINE in the DBMS_OUTPUT package. Refer to NEW_LINE in the DBMS_OUTPUT for information on specification differences and conversion procedures associated with specification differences.

B.6.3 Copying Files

Oracle database

```
CREATE PROCEDURE copy_file(fromname VARCHAR2, toname VARCHAR2) AS
BEGIN

    UTL_FILE.FCOPY('DIR1', fromname, 'DIR2', toname, 1, NULL); ...(7)

    RETURN;

EXCEPTION
    WHEN OTHERS THEN
        DBMS_OUTPUT.PUT_LINE('-- SQL Error --');

        DBMS_OUTPUT.PUT_LINE('ERROR : ' || SQLERRM );
        RETURN;
END;
/

set serveroutput on

call copy_file('file01.txt','file01_bk.txt');
```

Fujitsu Enterprise Postgres

```
CREATE FUNCTION copy_file(fromname VARCHAR, toname VARCHAR) RETURNS void AS $$
BEGIN
    PERFORM DBMS_OUTPUT.SERVEROUTPUT(TRUE);

    PERFORM UTL_FILE.FCOPY('/home/fsep', fromname, '/home/backup', toname, 1, NULL); ...(7)
    RETURN;

EXCEPTION
    WHEN OTHERS THEN
        PERFORM DBMS_OUTPUT.PUT_LINE('-- SQL Error --');
        PERFORM DBMS_OUTPUT.PUT_LINE('ERROR : ' || SQLERRM );
        RETURN;
END;
```

```
$$
LANGUAGE plpgsql;

SELECT copy_file('file01.txt','file01_bk.txt');
```

(7) FCOPY

Specification format for Oracle database

UTL_FILE.FCOPY(*firstArg, secondArg*, *thirdArg*, *fourthArg, fifthArg, sixthArg*)

Feature differences

Oracle database

If using a CREATE DIRECTORY statement (Oracle9.2i or later), specify a directory object name for the directory name.

Fujitsu Enterprise Postgres

A directory object name cannot be specified for the directory name.

Conversion procedure

Convert using the following procedure. Refer to UTL_FILE_DIR/CREATE DIRECTORY for information on how to check if the directory object name corresponds to the actual directory name.

1. Locate the places where the keyword "UTL_FILE.FCOPY" is used in the stored procedure.
2. Check the actual directory names ('/home/fsep' and '/home/backup', in the example) that correspond to the directory object names ('DIR1' and 'DIR2', in the example) of *firstArg* and *thirdArg* argument.
3. Replace the directory object name ('DIR1' and 'DIR2', in the example) with the actual directory names ('/home/fsep' in the example) checked in step 1.

B.6.4 Moving/Renaming Files

Oracle database

```
CREATE PROCEDURE move_file(fromname VARCHAR2, toname VARCHAR2) AS
BEGIN

    UTL_FILE.FRENAME('DIR1', fromname, 'DIR2', toname, FALSE); ...(8)
    RETURN;

EXCEPTION
    WHEN OTHERS THEN
        DBMS_OUTPUT.PUT_LINE('-- SQL Error --');

        DBMS_OUTPUT.PUT_LINE('ERROR : ' || SQLERRM );
        RETURN;
END;
/

set serveroutput on

call move_file('file01.txt','file02.txt');
```

Fujitsu Enterprise Postgres

```
CREATE FUNCTION move_file(fromname VARCHAR, toname VARCHAR) RETURNS void AS $$
BEGIN
    PERFORM DBMS_OUTPUT.SERVEROUTPUT(TRUE);
```

```
    PERFORM UTL_FILE.FRENAME('/home/fsep', fromname, '/home/backup', toname, FALSE); ...(8)
    RETURN;

EXCEPTION
    WHEN OTHERS THEN
        PERFORM DBMS_OUTPUT.PUT_LINE('-- SQL Error --');
        PERFORM DBMS_OUTPUT.PUT_LINE('ERROR : ' || SQLERRM );
        RETURN;
END;
$$
LANGUAGE plpgsql;

SELECT move_file('file01.txt','file02.txt');
```

(8) FRENAME

Same as FCOPY for the UTL_FILE package. Refer to FCOPY in the UTL_FILE package for information on specification differences and conversion procedures associated with specification differences.

B.7 DBMS_SQL (Execute Dynamic SQL)

Features

For DBMS_SQL, dynamic SQL can be executed from PL/pgSQL.

B.7.1 Searching Using a Cursor

Oracle database

```
CREATE PROCEDURE search_test(h_where CLOB) AS

    str_sql     CLOB;
    v_cnt       INTEGER;
    v_array     DBMS_SQL.VARCHAR2A;
    v_cur       INTEGER;
    v_smpid     INTEGER;
    v_smpnm     VARCHAR2(20);
    v_addbuff   VARCHAR2(20);
    v_smpage    INTEGER;
    errcd       INTEGER;
    length      INTEGER;
    ret         INTEGER;
BEGIN

   str_sql    := 'SELECT smpid, smpnm FROM smp_tbl WHERE ' || h_where || ' ORDER BY smpid';
    v_smpid     := 0;
    v_smpnm     := '';
    v_smpage    := 0;

    v_cur := DBMS_SQL.OPEN_CURSOR; ...(1)

    v_cnt :=
      CEIL(DBMS_LOB.GETLENGTH(str_sql)/1000);
    FOR idx IN 1 .. v_cnt LOOP
        v_array(idx) :=
            DBMS_LOB.SUBSTR(str_sql,
                            1000,
                            (idx-1)*1000+1);
```

```
    END LOOP;
    DBMS_SQL.PARSE(v_cur, v_array, 1, v_cnt, FALSE, DBMS_SQL.NATIVE); ...(2)

    DBMS_SQL.DEFINE_COLUMN(v_cur, 1, v_smpid); ...(3)

    DBMS_SQL.DEFINE_COLUMN(v_cur, 2, v_smpnm, 10);

    ret := DBMS_SQL.EXECUTE(v_cur);
    LOOP
        v_addbuff := '';

        IF DBMS_SQL.FETCH_ROWS(v_cur) = 0 THEN
            EXIT;
        END IF;

        DBMS_OUTPUT.PUT_LINE('-----------------------------------------------------------');
        DBMS_SQL.COLUMN_VALUE(v_cur, 1, v_smpid, errcd, length); ...(4)

        IF errcd = 1405 THEN ...(4)

          DBMS_OUTPUT.PUT_LINE('smpid       = (NULL)');
        ELSE
          DBMS_OUTPUT.PUT_LINE('smpid       = ' || v_smpid);
        END IF;

        DBMS_SQL.COLUMN_VALUE(v_cur, 2, v_smpnm, errcd, length);

        IF errcd = 1406 THEN ...(4)
          v_addbuff := '... [len=' || length || ']';
        END IF;
        IF errcd = 1405 THEN
          DBMS_OUTPUT.PUT_LINE('v_smpnm     = (NULL)');
        ELSE
          DBMS_OUTPUT.PUT_LINE('v_smpnm     = ' || v_smpnm || v_addbuff );
        END IF;

DBMS_OUTPUT.PUT_LINE('-----------------------------------------------------------');

        DBMS_OUTPUT.NEW_LINE;
    END LOOP;

    DBMS_SQL.CLOSE_CURSOR(v_cur); ...(5)

    RETURN;
END;
/

Set serveroutput on

call search_test('smpid < 100');
```

Fujitsu Enterprise Postgres

```
CREATE FUNCTION search_test(h_where text) RETURNS void AS $$
DECLARE
    str_sql     text;

    v_cur       INTEGER;
```

```
    v_smpid     INTEGER;
    v_smpnm     VARCHAR(20);
    v_smpnm_max_length    INTEGER;
    v_addbuff   VARCHAR(20);
    v_smpage    INTEGER;
    errcd       INTEGER;
    length      INTEGER;
    ret         INTEGER;
BEGIN
    PERFORM DBMS_OUTPUT.SERVEROUTPUT(TRUE);
    str_sql     := 'SELECT smpid, smpnm FROM smp_tbl WHERE ' || h_where || ' ORDER BY smpid';
    v_smpid     := 0;
    v_smpnm     := '';
    v_smpage    := 0;

    v_cur := DBMS_SQL.OPEN_CURSOR(); ...(1)

    CALL DBMS_SQL.PARSE(v_cur, str_sql); ...(2)

    CALL DBMS_SQL.DEFINE_COLUMN(v_cur, 1, v_smpid); ...(3)
    CALL DBMS_SQL.DEFINE_COLUMN(v_cur, 2, v_smpnm);
    v_smpnm_max_length := 10;

    ret := DBMS_SQL.EXECUTE(v_cur);
    LOOP
        v_addbuff := '';

        IF DBMS_SQL.FETCH_ROWS(v_cur) = 0 THEN
            EXIT;
        END IF;

        PERFORM
DBMS_OUTPUT.PUT_LINE('-----------------------------------------------------------');
        CALL DBMS_SQL.COLUMN_VALUE(v_cur, 1, v_smpid); ... (4)

        errcd := 0; ・・・(4)
        IF v_smpid IS NULL THEN
          errcd := 1405;
        END IF;

        IF errcd = 1405 THEN
          PERFORM DBMS_OUTPUT.PUT_LINE('smpid       = (NULL)');
        ELSE
          PERFORM DBMS_OUTPUT.PUT_LINE('smpid       = ' || v_smpid);
        END IF;

        CALL DBMS_SQL.COLUMN_VALUE(v_cur, 2, v_smpnm); ... (4)

        errcd := 0;
        length := 0;
        IF v_smpnm IS NULL THEN
          errcd := 1405;
          length := 0;
        ELSE;
          length := LENGTH(v_smpnm);
          IF length > v_smpnm_max_length THEN
             errcd := 1406;
             length := v_smpnm_max_length;
             v_smpnm := LEFT(v_smpnm, v_smpnm_max_length);
          END IF;
        END IF;
```

```
        IF errcd = 1406 THEN
          v_addbuff := '... [len=' || length || ']';
        END IF;
        IF errcd = 1405 THEN
          PERFORM DBMS_OUTPUT.PUT_LINE('v_smpnm     = (NULL)');
        ELSE
          PERFORM DBMS_OUTPUT.PUT_LINE('v_smpnm     = ' || v_smpnm || v_addbuff );
        END IF;

        PERFORM
DBMS_OUTPUT.PUT_LINE('-----------------------------------------------------');
        PERFORM DBMS_OUTPUT.NEW_LINE();
    END LOOP;

    CALL DBMS_SQL.CLOSE_CURSOR();・・・(5)
    v_cur := NULL;
    RETURN;
END;
$$
LANGUAGE plpgsql;

SELECT search_test('smpid < 100');
```

(1) OPEN_CURSOR

Same as NEW_LINE in the DBMS_OUTPUT package. Refer to NEW_LINE in the DBMS_OUTPUT package for information on specification differences and conversion procedures associated with specification differences.

(2) PARSE

Specification format for Oracle database

DBMS_SQL.PARSE(*firstArg, secondArg*, *thirdArg*, *fourthArg*, *fifthArg*)

Feature differences

Oracle database

SQL statements can be specified with string table types (VARCHAR2A type, VARCHAR2S type). Specify this for *secondArg*.

DBMS_SQL.NATIVE, DBMS_SQL.V6, DBMS_SQL.V7 can be specified for processing SQL statements.

Fujitsu Enterprise Postgres

SQL statements cannot be specified with string table types.

DBMS_SQL.NATIVE, DBMS_SQL.V6, DBMS_SQL.V7 cannot be specified for processing SQL statements.

Conversion procedure

Convert using the following procedure:

1. Locate the places where the keyword "DBMS_SQL.PARSE" is used in the stored procedure.
2. Check the data type of the SQL statement specified for *secondArg* (v_array in the example).
   - If the data type is either DBMS_SQL.VARCHAR2A type or DBMS_SQL.VARCHAR2S type, then it is a table type specification. Execute step 3 and continue the conversion process.
   - If the data type is neither DBMS_SQL.VARCHAR2A type nor DBMS_SQL.VARCHAR2S type, then it is a string specification. Execute step 7 and continue the conversion process.
3. Check the SQL statement (str_sql in the example) before it was divided into DBMS_SQL.VARCHAR2A type and DBMS_SQL.VARCHAR2S type.

4. Delete the sequence of the processes (processes near FOR idx in the example) where SQL is divided into DBMS_SQL.VARCHAR2A type and DBMS_SQL.VARCHAR2S type.
5. Replace *secondArg* with the SQL statement (str_sql in the example) before it is divided, that was checked in step 2.
6. Delete *thirdArg*, *fourthArg*, and *fifthArg* (v_cnt, FALSE, DBMS_SQL.NATIVE, in the example).

(3) DEFINE_COLUMN

Specification format for Oracle database

DBMS_SQL.DEFINE_COLUMN(*firstArg, secondArg*, *thirdArg*, *fourthArg*)

Feature differences

Oracle database

fourthArg specifies the maximum length of the character string data to be returned. If specified, the character string will be truncated to the specified length when the character string data is subsequently retrieved with DBMS_SQL.COLUMN_VALUE.

You can also check whether truncation has occurred by checking the error code of DBMS_SQL.COLUMN_VALUE.

Fujitsu Enterprise Postgres

fourthArg specifies the maximum length of the character string data to be returned. If specified, the character string will be truncated to the specified length when the character string data is subsequently retrieved with DBMS_SQL.COLUMN_VALUE.

However, whether truncation has occurred cannot be determined at the time DBMS_SQL.COLUMN_VALUE is executed.

Conversion procedure

Convert using the following procedure:

1. Locate the places where the keyword "DBMS_SQL.DEFINE_COLUMN" is used in the stored procedure.
2. Check whether a numeric value is specified for the *fourthArg*.
3. If a numeric value is specified for the fourth argument, check whether the error code 1406 is evaluated when DBMS_SQL.COLUMN_VALUE is subsequently executed. If it is, take the following measures to ensure that the same evaluation can be performed.
   - Add an INTEGER variable declaration to store the *fourthArg* of DBMS_SQL.DEFINE_COLUMN.
   - Set the specified value of the *fourthArg* of DBMS_SQL.COLUMN_VALUE to the above variable, and delete the *fourthArg* of DBMS_SQL.DEFINE_COLUMN.
   - After the subsequent execution of DBMS_SQL.COLUMN_VALUE, use the above INTEGER variable to truncate the string and evaluate the error code 1406. For details, refer to "(4) COLUMN_VALUE".

(4) COLUMN_VALUE

Specification format for Oracle database

DBMS_SQL.COLUMN_VALUE(*firstArg, secondArg*, *thirdArg*, *fourthArg, fifthArg*)

Feature differences

Oracle database

The following error codes are returned for the *fourthArg*.

- 1405: fetched column value is NULL
- 1406: fetched column value was truncated

Fujitsu Enterprise Postgres

The *fourthArg* and *fifthArg* cannot be specified.

Therefore, it is not possible to determine the above error code using the *fourthArg*, nor is it possible to determine the length of the retrieved value that should be set in the *fifthArg*.

Specification differences

Oracle database

Obtained values are received with variables specified for arguments.

Fujitsu Enterprise Postgres

The retrieved value will be received in the variable specified in the argument.

However, because the *fourthArg* and *fifthArg* cannot be specified, the variables that could not be specified will be reset to appropriate values based on the processing results, allowing the transition to take place without changing the existing processing.

Conversion procedure

Convert using the following procedure:

1. Locate the places where the keyword "DBMS_SQL.COLUMN_VALUE" is used in the stored procedure.
2. When determining whether the value of the *fourthArg* of COLUMN_VALUE is 1405, a process is performed to check whether the obtained data value is NULL.
   The following support for the *fourthArg* will allow the existing process to be executed.
   - Add a process to check whether the obtained data value is NULL immediately before the process to determine the *fourthArg*. If the value is NULL, set 1405 to the variable of the *fourthArg*.
3. When determining whether the value of the *fourthArg* of COLUMN_VALUE is 1406, a process is performed to check whether the acquired data value has been truncated.
   Truncation of the acquired data value occurs when the maximum length of the returned character string data is specified in the *fourthArg* of DBMS_SQL.DEFINE_COLUMN, so it is necessary to deal with not only COLUMN_VALUE but also DBMS_SQL.DEFINE_COLUMN at the same time.
   - Handling DBMS_SQL.DEFINE_COLUMN
     The maximum length of the character string data must be saved. For details, rrefer to "(3) DEFINE_COLUMN".
   - Check whether the returned characters should be truncated
     The above DBMS_SQL.DEFINE_COLUMN handling returns the character string without truncation. Therefore, before checking whether the *fourthArg* is 1406, the length of the returned value (obtained with the LENGTH function) is compared with the maximum length of the character string data saved from DBMS_SQL.DEFINE_COLUMN to check whether the returned characters should have been truncated.
     If the length of the returned value is greater, set the *fourthArg* to 1406 so that the subsequent existing judgment process will be performed. At this time, it is also necessary to use the LEFT function to truncate the length to the maximum length of the string data.
4. If the *fifthArg* of COLUMN_VALUE is specified, you must set the length of the returned string.
   After executing COLUMN_VALUE, use the LENGTH function to obtain the length of the returned value and assign it to the variable of the *fifthArg*.

(5) CLOSE_CURSOR

Specification format for Oracle database

DBMS_SQL.CLOSE_CURSOR(*firstArg*)

Specification differences

Oracle database

After closing, the cursor specified in *firstArg* becomes NULL.

Fujitsu Enterprise Postgres

Even if you close it, the cursor specified in the argument does not become NULL. Set the cursor to NULL again.

Conversion procedure

Convert using the following procedure:

1. Locate the places where the keyword "DBMS_SQL.CLOSE_CURSOR" is used in the stored procedure.
2. Ensure that the cursor is null-valued after calling DBMS_SQL.CLOSE_CURSOR.

Appendix C Tables Used by the Features Compatible with Oracle Databases

This chapter describes the tables used by the features compatible with Oracle databases.

C.1 UTL_FILE.UTL_FILE_DIR

Register the directory handled by the UTL_FILE package in the UTL_FILE.UTL_FILE_DIR table.

Name	Type	Description
dir	text	Name of the directory handled by the UTL_FILE package

Appendix D ECOBPG - Embedded SQL in COBOL

This appendix describes application development using embedded SQL in COBOL.

D.1 Precautions when Using Functions and Operators

An embedded SQL program consists of code written in an ordinary programming language, in this case COBOL, mixed with SQL commands in specially marked sections. To build the program, the source code (*.pco) is first passed through the embedded SQL preprocessor, which converts it to an ordinary COBOL program (*.cob), and afterwards it can be processed by a COBOL compiler. (For details about the compiling and linking see "D.9 Processing Embedded SQL Programs".) Converted ECOBPG applications call functions in the libpq library through the embedded SQL library (ecpglib), and communicate with the PostgreSQL server using the normal frontend-backend protocol.

Embedded SQL has advantages over other methods for handling SQL commands from COBOL code. First, it takes care of the tedious passing of information to and from variables in your C program. Second, the SQL code in the program is checked at build time for syntactical correctness. Third, embedded SQL in COBOL is specified in the SQL standard and supported by many other SQL database systems. The PostgreSQL implementation is designed to match this standard as much as possible, and it is usually possible to port embedded SQL programs written for other SQL databases to PostgreSQL with relative ease.

As already stated, programs written for the embedded SQL interface are normal COBOL programs with special code inserted to perform database-related actions. This special code always has the form:

```
EXEC SQL ... END-EXEC
```

These statements syntactically take the place of a COBOL statement. Depending on the particular statement, they can appear at the data division or at the procedure division. Actual executable SQLs need to be placed at the procedure division, and host variable declarations need to be placed at data division. However, the precompiler does not validate their placements. Embedded SQL statements follow the case-sensitivity rules of normal SQL code, and not those of COBOL.

For COBOL code notation, "fixed' or "variable" can be used. In each line, columns 1 to 6 constitute the line number area, and column 7 is the indicator area. Embedded SQL programs also should be placed in area B (column 12 and beyond).

Note that sample code in this document omits indents for each area.

ECOBPG processes or outputs programs according to the COBOL code notation. COBOL code notation is specified using the ecobpg command. Note, however, that the following restrictions apply:

- For "fixed" notation, area B is from columns 12 to 72. Characters in column 73 and beyond are deleted in the precompiled source.
- For "variable" notation, area B is from column 12 to the last column of that record (up to column 251). Characters in column 252 and beyond are deleted in the precompiled source.

ECOBPG accepts as many COBOL statements as possible. Note, however, that the following restrictions apply:

- In declaring host variable section, you can't use debug line.
- Outside of declaring host variable section, you can use debug line, but you can't contain any SQL in debug lines.
- In declaring host variable section, you can't use commas or semicolons as separator. Use space instead.
- EXEC SQL VAR command, it can be used in ECPG, is not available in ECOBPG. Use REDEFINE clause of COBOL instead.

The following sections explain all the embedded SQL statements.

D.2 Managing Database Connections

This section describes how to open, close, and switch database connections.

D.2.1 Connecting to the Database Server

One connects to a database using the following statement:

```
EXEC SQL CONNECT TO target [AS connection-name] [USER user-name] END-EXEC.
```

The target can be specified in the following ways:

- dbname[@hostname][:port]
- tcp:postgresql://hostname[:port][/dbname][?options]
- unix:postgresql://hostname[:port][/dbname][?options]
- an SQL string literal containing one of the above forms
- a reference to a character variable containing one of the above forms (see examples)
- DEFAULT

If you specify the connection target literally (that is, not through a variable reference) and you don't quote the value, then the case-insensitivity rules of normal SQL are applied. In that case you can also double-quote the individual parameters separately as needed. In practice, it is probably less error-prone to use a (single-quoted) string literal or a variable reference. The connection target DEFAULT initiates a connection to the default database under the default user name. No separate user name or connection name can be specified in that case.

There are also different ways to specify the user name:

- username
- username/password
- username IDENTIFIED BY password
- username USING password

As above, the parameters username and password can be an SQL identifier, an SQL string literal, or a reference to a character variable.

The connection-name is used to handle multiple connections in one program. It can be omitted if a program uses only one connection. The most recently opened connection becomes the current connection, which is used by default when an SQL statement is to be executed (see later in this chapter).

Here are some examples of CONNECT statements:

```
EXEC SQL CONNECT TO mydb@sql.mydomain.com END-EXEC.
```

```
EXEC SQL CONNECT TO tcp:postgresql://sql.mydomain.com/mydb AS myconnection USER john END-
EXEC.
```

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 TARGET PIC X(25).
01 USER PIC X(5).
EXEC SQL END DECLARE SECTION END-EXEC.
 ...
MOVE "mydb@sql.mydomain.com" TO TARGET.
MOVE "john" TO USER.
EXEC SQL CONNECT TO :TARGET USER :USER END-EXEC.
```

The last form makes use of the variant referred to above as character variable reference. For this purpose, only fixed-length string(no VARYING) variable can be used. Trailing spaces are ignored. You will see in later sections how COBOL variables can be used in SQL statements when you prefix them with a colon.

Be advised that the format of the connection target is not specified in the SQL standard. So if you want to develop portable applications, you might want to use something based on the last example above to encapsulate the connection target string somewhere.

D.2.2 Choosing a Connection

SQL statements in embedded SQL programs are by default executed on the current connection, that is, the most recently opened one. If an application needs to manage multiple connections, then there are two ways to handle this.

The first option is to explicitly choose a connection for each SQL statement, for example:

```
EXEC SQL AT connection-name SELECT ... END-EXEC.
```

This option is particularly suitable if the application needs to use several connections in mixed order.

The second option is to execute a statement to switch the current connection. That statement is:

```
EXEC SQL SET CONNECTION connection-name END-EXEC.
```

This option is particularly convenient if many statements are to be executed on the same connection.

Here is an example program managing multiple database connections:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
    01 DBNAME PIC X(7).
EXEC SQL END DECLARE SECTION END-EXEC.

    EXEC SQL CONNECT TO testdb1 AS con1 USER testuser END-EXEC.
    EXEC SQL CONNECT TO testdb2 AS con2 USER testuser END-EXEC.
    EXEC SQL CONNECT TO testdb3 AS con3 USER testuser END-EXEC.

*   This query would be executed in the last opened database "testdb3".
    EXEC SQL SELECT current_database() INTO :DBNAME END-EXEC.
    DISPLAY "current=" DBNAME " (should be testdb3)".

*   Using "AT" to run a query in "testdb2"
    EXEC SQL AT con2 SELECT current_database() INTO :DBNAME END-EXEC.
    DISPLAY "current=" DBNAME " (should be testdb2)".

*   Switch the current connection to "testdb1".
    EXEC SQL SET CONNECTION con1 END-EXEC.

    EXEC SQL SELECT current_database() INTO :DBNAME END-EXEC.
    DISPLAY "current=" DBNAME " (should be testdb1)".

    EXEC SQL DISCONNECT ALL END-EXEC.
```

This example would produce this output:

```
current=testdb3 (should be testdb3)
current=testdb2 (should be testdb2)
current=testdb1 (should be testdb1)
```

D.2.3 Closing a Connection

To close a connection, use the following statement:

```
EXEC SQL DISCONNECT [connection] END-EXEC.
```

The connection can be specified in the following ways:

- connection-name
- DEFAULT
- CURRENT
- ALL

If no connection name is specified, the current connection is closed.

It is good style that an application always explicitly disconnect from every connection it opened.

D.3 Running SQL Commands

Any SQL command can be run from within an embedded SQL application. Below are some examples of how to do that.

D.3.1 Executing SQL Statements

Creating a table:

```
EXEC SQL CREATE TABLE foo (number integer, ascii char(16)) END-EXEC.
EXEC SQL CREATE UNIQUE INDEX num1 ON foo(number) END-EXEC.
EXEC SQL COMMIT END-EXEC.
```

Inserting rows:

```
EXEC SQL INSERT INTO foo (number, ascii) VALUES (9999, 'doodad') END-EXEC.
EXEC SQL COMMIT END-EXEC.
```

Deleting rows:

```
EXEC SQL DELETE FROM foo WHERE number = 9999 END-EXEC.
EXEC SQL COMMIT END-EXEC.
```

Updates:

```
EXEC SQL UPDATE foo
    SET ascii = 'foobar'
    WHERE number = 9999 END-EXEC.
EXEC SQL COMMIT END-EXEC.
```

SELECT statements that return a single result row can also be executed using EXEC SQL directly. To handle result sets with multiple rows, an application has to use a cursor; see "D.3.2 Using Cursors" below. (As a special case, an application can fetch multiple rows at once into an array host variable; see "Arrays".)

Single-row select:

```
EXEC SQL SELECT foo INTO :FooBar FROM table1 WHERE ascii = 'doodad' END-EXEC.
```

Also, a configuration parameter can be retrieved with the SHOW command:

```
EXEC SQL SHOW search_path INTO :var END-EXEC.
```

The tokens of the form :something are *host variables*, that is, they refer to variables in the COBOL program. They are explained in "D.4 Using Host Variables".

D.3.2 Using Cursors

To retrieve a result set holding multiple rows, an application has to declare a cursor and fetch each row from the cursor. The steps to use a cursor are the following: declare a cursor, open it, fetch a row from the cursor, repeat, and finally close it.

Select using cursors:

```
EXEC SQL DECLARE foo_bar CURSOR FOR
    SELECT number, ascii FROM foo
    ORDER BY ascii END-EXEC.
EXEC SQL OPEN foo_bar END-EXEC.
EXEC SQL FETCH foo_bar INTO :FooBar, :DooDad END-EXEC.
...
EXEC SQL CLOSE foo_bar END-EXEC.
EXEC SQL COMMIT END-EXEC.
```

For more details about declaration of the cursor, see "D.11.4 DECLARE", and refer to "SQL Commands" in "Reference" in the PostgreSQL Documentation for information on FETCH command.

Note: The ECOBPG DECLARE command does not actually cause a statement to be sent to the PostgreSQL backend. The cursor is opened in the backend (using the backend's DECLARE command) at the point when the OPEN command is executed.

D.3.3 Managing Transactions

In the default mode, statements are committed only when EXEC SQL COMMIT is issued. The embedded SQL interface also supports autocommit of transactions (similar to libpq behavior) via the -t command-line option to ecobpg or via the EXEC SQL SET AUTOCOMMIT TO ON statement. In autocommit mode, each command is automatically committed unless it is inside an explicit transaction block. This mode can be explicitly turned off using EXEC SQL SET AUTOCOMMIT TO OFF.

See

Refer to "ecpg" in "PostgreSQL Client Applications" in the PostgreSQL Documentation for information on -t command-line option to ecobpg.

The following transaction management commands are available:

EXEC SQL COMMIT END-EXEC

Commit an in-progress transaction.

EXEC SQL ROLLBACK END-EXEC

Roll back an in-progress transaction.

EXEC SQL SET AUTOCOMMIT TO ON END-EXEC

Enable autocommit mode.

EXEC SQL SET AUTOCOMMIT TO OFF END-EXEC

Disable autocommit mode. This is the default.

D.3.4 Prepared Statements

When the values to be passed to an SQL statement are not known at compile time, or the same statement is going to be used many times, then prepared statements can be useful.

The statement is prepared using the command PREPARE. For the values that are not known yet, use the placeholder "?":

```
EXEC SQL PREPARE stmt1 FROM "SELECT oid, datname FROM pg_database WHERE oid = ?" END-EXEC.
```

If a statement returns a single row, the application can call EXECUTE after PREPARE to execute the statement, supplying the actual values for the placeholders with a USING clause:

```
EXEC SQL EXECUTE stmt1 INTO :dboid, :dbname USING 1 END-EXEC.
```

If a statement returns multiple rows, the application can use a cursor declared based on the prepared statement. To bind input parameters, the cursor must be opened with a USING clause:

```
EXEC SQL PREPARE stmt1 FROM "SELECT oid,datname FROM pg_database WHERE oid > ?" END-EXEC.
EXEC SQL DECLARE foo_bar CURSOR FOR stmt1 END-EXEC.

* when end of result set reached, break out of while loop
EXEC SQL WHENEVER NOT FOUND GOTO FETCH-END END-EXEC.

EXEC SQL OPEN foo_bar USING 100 END-EXEC.
...
PERFORM NO LIMIT
    EXEC SQL FETCH NEXT FROM foo_bar INTO :dboid, :dbname END-EXEC
END-PERFORM.

FETCH-END.
EXEC SQL CLOSE foo_bar END-EXEC.
```

When you don't need the prepared statement anymore, you should deallocate it:

```
EXEC SQL DEALLOCATE PREPARE name END-EXEC.
```

For more details about PREPARE, see "D.11.10 PREPARE". Also see "D.5 Dynamic SQL" for more details about using placeholders and input parameters.

D.4 Using Host Variables

In "D.3 Running SQL Commands" you saw how you can execute SQL statements from an embedded SQL program. Some of those statements only used fixed values and did not provide a way to insert user-supplied values into statements or have the program process the values returned by the query. Those kinds of statements are not really useful in real applications. This section explains in detail how you can pass data between your COBOL program and the embedded SQL statements using a simple mechanism called host variables. In an embedded SQL program we consider the SQL statements to be guests in the COBOL program code which is the host language. Therefore the variables of the COBOL program are called host variables.

Another way to exchange values between PostgreSQL backends and ECOBPG applications is the use of SQL descriptors, described in "D.6 Using Descriptor Areas".

D.4.1 Overview

Passing data between the COBOL program and the SQL statements is particularly simple in embedded SQL. Instead of having the program paste the data into the statement, which entails various complications, such as properly quoting the value, you can simply write the name of a COBOL variable into the SQL statement, prefixed by a colon. For example:

```
EXEC SQL INSERT INTO sometable VALUES (:v1, 'foo', :v2) END-EXEC.
```

This statements refers to two COBOL variables named v1 and v2 and also uses a regular SQL string literal, to illustrate that you are not restricted to use one kind of data or the other.

This style of inserting COBOL variables in SQL statements works anywhere a value expression is expected in an SQL statement.

D.4.2 Declare Sections

To pass data from the program to the database, for example as parameters in a query, or to pass data from the database back to the program, the COBOL variables that are intended to contain this data need to be declared in specially marked sections, so the embedded SQL preprocessor is made aware of them.

This section starts with:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
```

and ends with:

```
EXEC SQL END DECLARE SECTION END-EXEC.
```

Between those lines, there must be normal COBOL variable declarations, such as:

```
01 INTX PIC S9(9) COMP VALUE 4.
01 FOO PIC X(15).
01 BAR PIC X(15).
```

As you can see, you can optionally assign an initial value to the variable. The variable's scope is determined by the location of its declaring section within the program.

You can have as many declare sections in a program as you like.

The declarations are also echoed to the output file as normal COBOL variables, so there's no need to declare them again. Variables that are not intended to be used in SQL commands can be declared normally outside these special sections.

The definition of a group item also must be listed inside a DECLARE section. Otherwise the preprocessor cannot handle these types since it does not know the definition.

D.4.3 Retrieving Query Results

Now you should be able to pass data generated by your program into an SQL command. But how do you retrieve the results of a query? For that purpose, embedded SQL provides special variants of the usual commands SELECT and FETCH. These commands have a special INTO clause that specifies which host variables the retrieved values are to be stored in. SELECT is used for a query that returns only single row, and FETCH is used for a query that returns multiple rows, using a cursor.

Here is an example:

```
*
* assume this table:
* CREATE TABLE test (a int, b varchar(50));
*

 EXEC SQL BEGIN DECLARE SECTION END-EXEC.
 01 V1 PIC S9(9).
 01 V2 PIC X(50) VARYING.
 EXEC SQL END DECLARE SECTION END-EXEC.

 ...

 EXEC SQL SELECT a, b INTO :V1, :V2 FROM test END-EXEC.
```

So the INTO clause appears between the select list and the FROM clause. The number of elements in the select list and the list after INTO (also called the target list) must be equal.

Here is an example using the command FETCH:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 V1 PIC S9(9).
01 V2 PIC X(50) VARYING.
EXEC SQL END DECLARE SECTION END-EXEC.

 ...

EXEC SQL DECLARE foo CURSOR FOR SELECT a, b FROM test END-EXEC.

 ...

PERFORM WITH
    ...
    EXEC SQL FETCH NEXT FROM foo INTO :V1, :V2 END-EXEC
```

```
    ...
END-PERFORM.
```

Here the INTO clause appears after all the normal clauses.

D.4.4 Type Mapping

When ECOBPG applications exchange values between the PostgreSQL server and the COBOL application, such as when retrieving query results from the server or executing SQL statements with input parameters, the values need to be converted between PostgreSQL data types and host language variable types (specifically COBOL language data types). One of the main points of ECOBPG is that it takes care of this automatically in most cases.

In this respect, there are two kinds of data types: Some simple PostgreSQL data types, such as integer and text, can be read and written by the application directly. Other PostgreSQL data types, such as timestamp and date can only be accessed through character strings. special library functions does not exist in ecobpg. (pgtypes, exists in ECPG, for COBOL is not implemented yet)

"Table D.1 Mapping Between PostgreSQL Data Types and COBOL Variable Types" shows which PostgreSQL data types correspond to which COBOL data types. When you wish to send or receive a value of a given PostgreSQL data type, you should declare a COBOL variable of the corresponding COBOL data type in the declare section.

Table D.1 Mapping Between PostgreSQL Data Types and COBOL Variable Types

PostgreSQL data type	COBOL Host variable type
smallint	PIC S9([1-4]) {BINARY|COMP|COMP-5}
integer	PIC S9([5-9]) {BINARY|COMP|COMP-5}
bigint	PIC S9([10-18]) {BINARY|COMP|COMP-5}
decimal	PIC S9(m)V9(n) PACKED-DECIMAL PIC 9(m)V9(n) DISPLAY (*1) PIC S9(m)V9(n) DISPLAY PIC S9(m)V9(n) DISPLAY SIGN TRAILING [SEPARATE] PIC S9(m)V9(n) DISPLAY SIGN LEADING [SEPARATE]
numeric	(same with decimal)
real	COMP-1
double precision	COMP-2
small serial	PIC S9([1-4]) {BINARY|COMP|COMP-5}
serial	PIC S9([1-9]) {BINARY|COMP|COMP-5}
bigserial	PIC S9([10-18]) {BINARY|COMP|COMP-5}
oid	PIC 9(9) {BINARY|COMP|COMP-5}
character(*n*), varchar(*n*), text	PIC X(*n*), PIC X(*n*) VARYING
name	PIC X(NAMEDATALEN)
boolean	BOOL(*2)
bytea	BYTEA(n)
other types(e.g. timestamp)	PIC X(*n*), PIC X(*n*) VARYING
*1: If no USAGE is specified, host variable is regarded as DISPLAY. *2: Type definition is added automatically on pre-compiling. Body of BOOL is PIC X(1). '1' for true and '0' for false. You can use some pattern of digits for integer(see table), but if database sends big number with more digits than specified, behavior is undefined.	

PostgreSQL data type	COBOL Host variable type
VALUE clause can't be used with VARYING. (Can be used with other types) REDEFINE clause can be used, but it won't be validated on pre-compilation (The COBOL compiler will do this).	

Handling Character Strings

To handle SQL character string data types, such as varchar and text, there is a possible way to declare the host variables.

The way is using the PIC X(*n*) VARYING type (we call it VARCHAR type from now on), which is a special type provided by ECOBPG. The definition on type VARCHAR is converted into a group item consists of named variables. A declaration like:

```
01 VAR PIC X(180) VARYING.
```

is converted into:

```
01 VAR.
49 LEN PIC S9(4) COMP-5.
49 ARR PIC X(180).
```

if --varchar-with-named-member option is used, it is converted into:

```
01 VAR.
49 VAR-LEN PIC S9(4) COMP-5.
49 VAR-ARR PIC X(180).
```

You can use level 1 to 48 for VARCHAR. Don't use level 49 variable right after VARCHAR variable. To use a VARCHAR host variable as an input for SQL statement, LEN must be set the length of the string included in ARR.

To use a VARCHAR host variable as an output of SQL statement, the variable must be declared in a sufficient length. If the length is insufficient, it can cause a buffer overrun.

PIC X(*n*) and VARCHAR host variables can also hold values of other SQL types, which will be stored in their string forms.

Accessing Special Data Types

ECOBPG doesn't have special support for date, timestamp, and interval types.
(ECPG has pgtypes, but ECOBPG doesn't.)
You can use PIC X(*n*) or VARCHAR for DB I/O with these types. See "Data Types" section in PostgreSQL's document.

bytea

Handling of bytea types is similar to VARCHAR. The definition of an array of type bytea is converted into a group item consists of named variables.

A declaration like:

```
01 var bytea(100).
```

is converted into:

```
01 var .
49 LEN PIC S9(9) COMP-5 .
49 ARR PIC X(100) .
```

if bytea-with-named-member option is used, it is converted into:

```
01 var .
49 var-LEN PIC S9(9) COMP-5 .
49 var-ARR PIC X(100) .
```

The data item ARR holds binary format data. Unlike VARCHAR, it is not affected by the locale or character encoding when processing data.

Other usage and prohibitions are the same as VARCHAR.

Note

The bytea variable can only be used if byta_output is set to hex.

Host Variables with Nonprimitive Types

As a host variable you can also use arrays, typedefs, and group items.

Arrays

To create and use array variables, OCCURENCE syntax is provided by COBOL.

The typical use case is to retrieve multiple rows from a query result without using a cursor. Without an array, to process a query result consisting of multiple rows, it is required to use a cursor and the FETCH command. But with array host variables, multiple rows can be received at once. The length of the array has to be defined to be able to accommodate all rows, otherwise a buffer overrun will likely occur.

Following example scans the pg_database system table and shows all OIDs and names of the available databases:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 GROUP-ITEM.
    05 DBID PIC S9(9) COMP OCCURS 8.
    05 DBNAME PIC X(16) OCCURS 8.
01 I PIC S9(9) COMP.
EXEC SQL END DECLARE SECTION END-EXEC.

    EXEC SQL CONNECT TO testdb END-EXEC.

*   Retrieve multiple rows into arrays at once.
    EXEC SQL SELECT oid,datname INTO :DBID, :DBNAME FROM pg_database END-EXEC.

    PERFORM VARYING I FROM 1 BY 1 UNTIL I > 8
        DISPLAY "oid=" DBID(I) ", dbname=" DBNAME(I)
    END-PERFORM.

    EXEC SQL COMMIT END-EXEC.
    EXEC SQL DISCONNECT ALL END-EXEC.
```

You can use member of array as simple host variable by specifying subscript of array. For specifying subscript, use C-style "[1]", not COBOL-style "(1)". But subscript starts with 1, according to COBOL syntax.

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 GROUP-ITEM.
    05 DBID PIC S9(9) COMP OCCURS 8.
EXEC SQL END DECLARE SECTION END-EXEC.

    EXEC SQL CONNECT TO testdb END-EXEC.

    EXEC SQL SELECT oid INTO :DBID[1] FROM pg_database WHERE oid=1 END-EXEC.

        DISPLAY "oid=" DBID(1)

    EXEC SQL COMMIT END-EXEC.
    EXEC SQL DISCONNECT ALL END-EXEC.
```

Group Item

A group item whose subordinate item names match the column names of a query result, can be used to retrieve multiple columns at once. The group item enables handling multiple column values in a single host variable.

The following example retrieves OIDs, names, and sizes of the available databases from the pg_database system table by using the pg_database_size() function. In this example, a group item variable dbinfo_t with members whose names match each column in the SELECT result is used to retrieve one result row without putting multiple host variables in the FETCH statement.

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
    01 DBINFO-T TYPEDEF.
       02 OID PIC S9(9) COMP.
       02 DATNAME PIC X(65).
       02 DBSIZE PIC S9(18) COMP.

    01 DBVAL TYPE DBINFO-T.
EXEC SQL END DECLARE SECTION END-EXEC.

    EXEC SQL DECLARE cur1 CURSOR FOR SELECT oid, datname, pg_database_size(oid) AS size
FROM pg_database END-EXEC.
    EXEC SQL OPEN cur1 END-EXEC.

*   when end of result set reached, break out of loop
    EXEC SQL WHENEVER NOT FOUND GOTO END-FETCH END-EXEC.

    PERFORM NO LIMIT
*        Fetch multiple columns into one structure.
        EXEC SQL FETCH FROM cur1 INTO :DBVAL END-EXEC

*        Print members of the structure.
        DISPLAY "oid=" OID ", datname=" DATNAME ", size=" DBSIZE
    END-PERFORM.

    END-FETCH.
    EXEC SQL CLOSE cur1 END-EXEC.
```

group item host variables "absorb" as many columns as the group item as subordinate items. Additional columns can be assigned to other host variables. For example, the above program could also be restructured like this, with the size variable outside the group item:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
    01 DBINFO-T TYPEDEF.
       02 OID PIC S9(9) COMP.
       02 DATNAME PIC X(65).

    01 DBVAL TYPE DBINFO-T.
    01 DBSIZE PIC S9(18) COMP.
EXEC SQL END DECLARE SECTION END-EXEC.

    EXEC SQL DECLARE cur1 CURSOR FOR SELECT oid, datname, pg_database_size(oid) AS size
FROM pg_database END-EXEC.
    EXEC SQL OPEN cur1 END-EXEC.

*   when end of result set reached, break out of loop
    EXEC SQL WHENEVER NOT FOUND GOTO END-FETCH END-EXEC.

    PERFORM NO LIMIT
*       Fetch multiple columns into one structure.
        EXEC SQL FETCH FROM cur1 INTO :DBVAL, :DBSIZE END-EXEC

*       Print members of the structure.
        DISPLAY "oid=" OID ", datname=" DATNAME ", size=" DBSIZE
    END-PERFORM
```

```
    FETCH-END.
    EXEC SQL CLOSE cur1 END-EXEC.
```

You can use only non-nested group items for host variable of SQL statement. Declaration of nested group items are OK, but you must specify non-nested part of group items for SQL. (VARCHAR, is translated to group item on pre-compilation, is not considered as offense of this rule.) When using inner item of group item in SQL, use C-struct like period separated syntax(not COBOL's A OF B). Here is example.

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 NESTED-GROUP.
  02 CHILD1.
    03 A PIC X(10).
    03 B PIC S9(9) COMP.
  02 CHILD2.
    03 A PIC X(10).
    03 B PIC S9(9) COMP.
EXEC SQL END DECLARE SECTION END-EXEC.

* This SQL is valid. CHILD1 has no nested group items.
EXEC SQL SELECT * INTO :NESTED-GROUP.CHILD1 FROM TABLE1 END-EXEC.
```

For specifying basic item of group items, full specification is not needed if the specification is enough for identifying the item. This is from COBOL syntax. For more detail, see resources of COBOL syntax.

TYPEDEF

Use the typedef keyword to map new types to already existing types.

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
    01 MYCHARTYPE TYPEDEF PIC X(40).
    01 SERIAL-T TYPEDEF PIC S9(9) COMP.
EXEC SQL END DECLARE SECTION END-EXEC.
```

Note that you could also use:

```
EXEC SQL TYPE SERIAL-T IS PIC S9(9) COMP-5. END-EXEC.
```

This declaration does not need to be part of a declare section.

D.4.5 Handling Nonprimitive SQL Data Types

This section contains information on how to handle nonscalar and user-defined SQL-level data types in ECOBPG applications. Note that this is distinct from the handling of host variables of nonprimitive types, described in the previous section.

Arrays

SQL-level arrays are not directly supported in ECOBPG. It is not possible to simply map an SQL array into a COBOL array host variable. This will result in undefined behavior. Some workarounds exist, however.

If a query accesses elements of an array separately, then this avoids the use of arrays in ECOBPG. Then, a host variable with a type that can be mapped to the element type should be used. For example, if a column type is array of integer, a host variable of type PIC S9(9) COMP can be used. Also if the element type is varchar or text, a host variable of type VARCHAR can be used.

Here is an example. Assume the following table:

```
CREATE TABLE t3 (
    ii integer[]
);

testdb=> SELECT * FROM t3;
     ii
-------------
 {1,2,3,4,5}
(1 row)
```

The following example program retrieves the 4th element of the array and stores it into a host variable of type PIC S9(9) COMP-5:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 II PIC S9(9) COMP.
EXEC SQL END DECLARE SECTION END-EXEC.

EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii[4] FROM t3 END-EXEC.
EXEC SQL OPEN cur1 END-EXEC.

EXEC SQL WHENEVER NOT FOUND GOTO END-FETCH END-EXEC.

PERFORM NO LIMIT
    EXEC SQL FETCH FROM cur1 INTO :II  END-EXEC
    DISPLAY "ii=" II
END-PERFORM.

END-FETCH.
EXEC SQL CLOSE cur1 END-EXEC.
```

To map multiple array elements to the multiple elements in an array type host variables each element of array column and each element of the host variable array have to be managed separately, for example:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 GROUP-ITEM.
    05 II_A PIC S9(9) COMP OCCURS 8.
EXEC SQL END DECLARE SECTION END-EXEC.

EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii[1], ii[2], ii[3], ii[4] FROM t3 END-EXEC.
EXEC SQL OPEN cur1 END-EXEC.

EXEC SQL WHENEVER NOT FOUND GOTO END-FETCH END-EXEC.

PERFORM NO LIMIT
    EXEC SQL FETCH FROM cur1 INTO :II_A[1], :II_A[2], :II_A[3], :II_A[4] END-EXEC
    ...
END-PERFORM.
```

Note again that.

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 GROUP-ITEM.
    05 II_A PIC S9(9) COMP OCCURS 8.
EXEC SQL END DECLARE SECTION END-EXEC.

EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii FROM t3 END-EXEC.
EXEC SQL OPEN cur1 END-EXEC.
```

```
EXEC SQL WHENEVER NOT FOUND GOTO END-FETCH END-EXEC.

PERFORM NO LIMIT
*    WRONG
     EXEC SQL FETCH FROM cur1 INTO :II_A END-EXEC
     ...
END-PERFORM.
```

would not work correctly in this case, because you cannot map an array type column to an array host variable directly.

Another workaround is to store arrays in their external string representation in host variables of type VARCHAR. For more details about this representation.

See

Refer to "Arrays" in "Tutorial" in the PostgreSQL Documentation for information more details about this representation.

Note that this means that the array cannot be accessed naturally as an array in the host program (without further processing that parses the text representation).

Composite Types

Composite types are not directly supported in ECOBPG, but an easy workaround is possible. The available workarounds are similar to the ones described for arrays above: Either access each attribute separately or use the external string representation.

For the following examples, assume the following type and table:

```
CREATE TYPE comp_t AS (intval integer, textval varchar(32));
CREATE TABLE t4 (compval comp_t);
INSERT INTO t4 VALUES ( (256, 'PostgreSQL') );
```

The most obvious solution is to access each attribute separately. The following program retrieves data from the example table by selecting each attribute of the type comp_t separately:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 INTVAL PIC S9(9) COMP.
01 TEXTVAL PIC X(33) VARYING.
EXEC SQL END DECLARE SECTION END-EXEC.

* Put each element of the composite type column in the SELECT list.
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).intval, (compval).textval FROM t4 END-
EXEC.
EXEC SQL OPEN cur1 END-EXEC.

EXEC SQL WHENEVER NOT FOUND GOTO END-FETCH END-EXEC.

PERFORM NO LIMIT
*    Fetch each element of the composite type column into host variables.
     EXEC SQL FETCH FROM cur1 INTO :INTVAL, :TEXTVAL END-EXEC

     DISPLAY "intval=" INTVAL ", textval=" ARR OF TEXTVAL
END-PERFORM.

END-FETCH.
EXEC SQL CLOSE cur1 END-EXEC.
```

To enhance this example, the host variables to store values in the FETCH command can be gathered into one group item. For more details about the host variable in the group item form, see "Group Item". To switch to the group item, the example can be modified as below. The two host variables, intval and textval, become subordinate items of the comp_t group item, and the group item is specified on the FETCH command.

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 COMP-T TYPEDEF.
    02 INTVAL PIC S9(9) COMP.
    02 TEXTVAL PIC X(33) VARYING.

01 COMPVAL TYPE COMP-T.
EXEC SQL END DECLARE SECTION END-EXEC.

* Put each element of the composite type column in the SELECT list.
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).intval, (compval).textval FROM t4 END-
EXEC.
EXEC SQL OPEN cur1 END-EXEC.
EXEC SQL WHENEVER NOT FOUND GOTO END-FETCH END-EXEC.

PERFORM NO LIMIT
*   Put all values in the SELECT list into one structure.
    EXEC SQL FETCH FROM cur1 INTO :COMPVAL END-EXEC

    DISPLAY "intval=" INTVAL ", textval=" ARR OF TEXTVAL
END-PERFORM.

END-FETCH.
EXEC SQL CLOSE cur1 END-EXEC.
```

Although a group item is used in the FETCH command, the attribute names in the SELECT clause are specified one by one. This can be enhanced by using a * to ask for all attributes of the composite type value.

```
...
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).* FROM t4 END-EXEC.
EXEC SQL OPEN cur1 END-EXEC.
EXEC SQL WHENEVER NOT FOUND GOTO END-FETCH END-EXEC.

PERFORM NO LIMIT
*   Put all values in the SELECT list into one structure.
    EXEC SQL FETCH FROM cur1 INTO :COMPVAL END-EXEC

    DISPLAY "intval=" INTVAL ", textval=" ARR OF TEXTVAL
END-PERFORM.
```

This way, composite types can be mapped into structures almost seamlessly, even though ECOBPG does not understand the composite type itself.

Finally, it is also possible to store composite type values in their external string representation in host variables of type VARCHAR. But that way, it is not easily possible to access the fields of the value from the host program.

User-defined Base Types

New user-defined base types are not directly supported by ECOBPG. You can use the external string representation and host variables of type VARCHAR, and this solution is indeed appropriate and sufficient for many types.

Here is an example using the data type complex.

See

Refer to "User-defined Types" in "Server Programming" in the PostgreSQL Documentation for information on the data type complex.

The external string representation of that type is (%lf,%lf), which is defined in the functions complex_in() and complex_out() functions. The following example inserts the complex type values (1,1) and (3,3) into the columns a and b, and select them from the table after that.

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
    01 A PIC X(64) VARYING.
    01 B PIC X(64) VARYING.
EXEC SQL END DECLARE SECTION END-EXEC.

EXEC SQL INSERT INTO test_complex VALUES ('(1,1)', '(3,3)') END-EXEC.

EXEC SQL DECLARE cur1 CURSOR FOR SELECT a, b FROM test_complex END-EXEC.
EXEC SQL OPEN cur1 END-EXEC.

EXEC SQL WHENEVER NOT FOUND GOTO END-FETCH END-EXEC.

PERFORM NO LIMIT
    EXEC SQL FETCH FROM cur1 INTO :A, :B END-EXEC
    DISPLAY "a=" ARR OF A ", b=" ARR OF B
END-PERFORM.

END-FETCH.
EXEC SQL CLOSE cur1 END-EXEC.
```

Another workaround is avoiding the direct use of the user-defined types in ECOBPG and instead create a function or cast that converts between the user-defined type and a primitive type that ECOBPG can handle. Note, however, that type casts, especially implicit ones, should be introduced into the type system very carefully.

For example:

```
CREATE FUNCTION create_complex(r double precision, i double precision) RETURNS complex
LANGUAGE SQL
IMMUTABLE
AS $$ SELECT $1 * complex '(1,0)' + $2 * complex '(0,1)' $$;
```

After this definition, the following:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 A COMP-2.
01 B COMP-2.
01 C COMP-2.
01 D COMP-2.
EXEC SQL END DECLARE SECTION END-EXEC.

MOVE 1 TO A.
MOVE 2 TO B.
MOVE 3 TO C.
MOVE 4 TO D.

EXEC SQL INSERT INTO test_complex VALUES (create_complex(:A, :B), create_complex(:C, :D))
END-EXEC.
```

has the same effect as

```
EXEC SQL INSERT INTO test_complex VALUES ('(1,2)', '(3,4)') END-EXEC.
```

D.4.6 Indicators

The examples above do not handle null values. In fact, the retrieval examples will raise an error if they fetch a null value from the database. To be able to pass null values to the database or retrieve null values from the database, you need to append a second host variable specification to each host variable that contains data. This second host variable is called the *indicator* and contains a flag that tells whether the datum is null, in which case the value of the real host variable is ignored. Here is an example that handles the retrieval of null values correctly:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 VAL PIC X(50) VARYING.
01 VAL_IND PIC S9(9) COMP-5.
```

```
EXEC SQL END DECLARE SECTION END-EXEC.

 ...

EXEC SQL SELECT b INTO :VAL :VAL_IND FROM test1 END-EXEC.
```

The indicator variable val_ind will be zero if the value was not null, and it will be negative if the value was null.

The indicator has another function: if the indicator value is positive, it means that the value is not null, but it was truncated when it was stored in the host variable.

D.5 Dynamic SQL

In many cases, the particular SQL statements that an application has to execute are known at the time the application is written. In some cases, however, the SQL statements are composed at run time or provided by an external source. In these cases you cannot embed the SQL statements directly into the COBOL source code, but there is a facility that allows you to call arbitrary SQL statements that you provide in a string variable.

D.5.1 Executing Statements without a Result Set

The simplest way to execute an arbitrary SQL statement is to use the command EXECUTE IMMEDIATE. For example:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 STMT PIC X(30) VARYING.
EXEC SQL END DECLARE SECTION END-EXEC.

MOVE "CREATE TABLE test1 (...);" TO ARR OF STMT.
COMPUTE LEN OF STMT = FUNCTION STORED-CHAR-LENGTH (ARR OF STMT).
EXEC SQL EXECUTE IMMEDIATE :STMT END-EXEC.
```

EXECUTE IMMEDIATE can be used for SQL statements that do not return a result set (e.g., DDL, INSERT, UPDATE, DELETE). You cannot execute statements that retrieve data (e.g., SELECT) this way. The next section describes how to do that.

D.5.2 Executing a Statement with Input Parameters

A more powerful way to execute arbitrary SQL statements is to prepare them once and execute the prepared statement as often as you like. It is also possible to prepare a generalized version of a statement and then execute specific versions of it by substituting parameters. When preparing the statement, write question marks where you want to substitute parameters later. For example:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 STMT PIC X(40) VARYING.
EXEC SQL END DECLARE SECTION END-EXEC.

MOVE "INSERT INTO test1 VALUES(?, ?);" TO ARR OF STMT.
COMPUTE LEN OF STMT = FUNCTION STORED-CHAR-LENGTH (ARR OF STMT).
EXEC SQL PREPARE MYSTMT FROM :STMT END-EXEC.
 ...
EXEC SQL EXECUTE MYSTMT USING 42, 'foobar' END-EXEC.
```

When you don't need the prepared statement anymore, you should deallocate it:

```
EXEC SQL DEALLOCATE PREPARE name END-EXEC.
```

D.5.3 Executing a Statement with a Result Set

To execute an SQL statement with a single result row, EXECUTE can be used. To save the result, add an INTO clause.

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 STMT PIC X(50) VARYING.
```

```
01 V1 PIC S9(9) COMP.
01 V2 PIC S9(9) COMP.
01 V3 PIC X(50) VARYING.
EXEC SQL END DECLARE SECTION END-EXEC.

MOVE "SELECT a, b, c FROM test1 WHERE a > ?" TO ARR OF STMT.
COMPUTE LEN OF STMT = FUNCTION STORED-CHAR-LENGTH (ARR OF STMT).
EXEC SQL PREPARE MYSTMT FROM :STMT END-EXEC.
 ...
EXEC SQL EXECUTE MYSTMT INTO :V1, :V2, :V3 USING 37 END-EXEC.
```

An EXECUTE command can have an INTO clause, a USING clause, both, or neither.

If a query is expected to return more than one result row, a cursor should be used, as in the following example. (See "D.3.2 Using Cursors" for more details about the cursor.)

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 DBANAME PIC X(128) VARYING.
01 DATNAME PIC X(128) VARYING.
01 STMT PIC X(200) VARYING.
EXEC SQL END DECLARE SECTION END-EXEC.

MOVE "SELECT u.usename as dbaname, d.datname
-             "  FROM pg_database d, pg_user u
-             "  WHERE d.datdba = u.usesysid"
TO ARR OF STMT.
COMPUTE LEN OF STMT = FUNCTION STORED-CHAR-LENGTH (ARR OF STMT).

EXEC SQL CONNECT TO testdb AS con1 USER testuser END-EXEC.

EXEC SQL PREPARE STMT1 FROM :STMT END-EXEC.

EXEC SQL DECLARE cursor1 CURSOR FOR STMT1 END-EXEC.
EXEC SQL OPEN cursor1 END-EXEC.

EXEC SQL WHENEVER NOT FOUND GOTO FETCH-END END-EXEC.

PERFORM NO LIMIT
    EXEC SQL FETCH cursor1 INTO :DBANAME,:DATNAME END-EXEC
    DISPLAY "dbaname=" ARR OF DBANAME ", datname=" ARR OF DATNAME
END-PERFORM.

FETCH-END.

EXEC SQL CLOSE cursor1 END-EXEC.

EXEC SQL COMMIT END-EXEC.
EXEC SQL DISCONNECT ALL END-EXEC.
```

D.6 Using Descriptor Areas

An SQL descriptor area is a more sophisticated method for processing the result of a SELECT, FETCH or a DESCRIBE statement. An SQL descriptor area groups the data of one row of data together with metadata items into one data group item. The metadata is particularly useful when executing dynamic SQL statements, where the nature of the result columns might not be known ahead of time. PostgreSQL provides a way to use Descriptor Areas: the named SQL Descriptor Areas.

D.6.1 Named SQL Descriptor Areas

A named SQL descriptor area consists of a header, which contains information concerning the entire descriptor, and one or more item descriptor areas, which basically each describe one column in the result row.

Before you can use an SQL descriptor area, you need to allocate one:

```
EXEC SQL ALLOCATE DESCRIPTOR identifier END-EXEC.
```

The identifier serves as the "variable name" of the descriptor area. When you don't need the descriptor anymore, you should deallocate it:

```
EXEC SQL DEALLOCATE DESCRIPTOR identifier END-EXEC.
```

To use a descriptor area, specify it as the storage target in an INTO clause, instead of listing host variables:

```
EXEC SQL FETCH NEXT FROM mycursor INTO SQL DESCRIPTOR mydesc END-EXEC.
```

If the result set is empty, the Descriptor Area will still contain the metadata from the query, i.e. the field names.

For not yet executed prepared queries, the DESCRIBE statement can be used to get the metadata of the result set:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 SQL-STMT PIC X(30) VARYING.
EXEC SQL END DECLARE SECTION END-EXEC.

MOVE "SELECT * FROM table1" TO ARR OF SQL-STMT.
COMPUTE LEN OF SQL-STMT = FUNCTION STORED-CHAR-LENGTH ( ARR OF SQL-STMT ) .
EXEC SQL PREPARE STMT1 FROM :SQL-STMT END-EXEC.
EXEC SQL DESCRIBE STMT1 INTO SQL DESCRIPTOR MYDESC END-EXEC.
```

Before PostgreSQL 9.0, the SQL keyword was optional, so using DESCRIPTOR and SQL DESCRIPTOR produced named SQL Descriptor Areas. Now it is mandatory, omitting the SQL keyword is regarded as the syntax that produces SQLDA Descriptor Areas. However, ecobpg does not support SQLDA and it causes an error.

In DESCRIBE and FETCH statements, the INTO and USING keywords can be used to similarly: they produce the result set and the metadata in a Descriptor Area.

Now how do you get the data out of the descriptor area? You can think of the descriptor area as a group item with named fields. To retrieve the value of a field from the header and store it into a host variable, use the following command:

```
EXEC SQL GET DESCRIPTOR name :hostvar = field END-EXEC.
```

Currently, there is only one header field defined: COUNT, which tells how many item descriptor areas exist (that is, how many columns are contained in the result). The host variable needs to be of an integer type as PIC S9(9) COMP-5. To get a field from the item descriptor area, use the following command:

```
EXEC SQL GET DESCRIPTOR name VALUE num :hostvar = field END-EXEC.
```

num can be a host variable containing an integer as PIC S9(9) COMP-5.
hostvar must be PIC S9(9) COMP-5 if type of the field is integer. Possible fields are:

CARDINALITY (integer)

number of rows in the result set

DATA

actual data item (therefore, the data type of this field depends on the query)

DATETIME_INTERVAL_CODE (integer)

When TYPE is 9, DATETIME_INTERVAL_CODE will have a value of 1 for DATE, 2 for TIME, 3 for TIMESTAMP, 4 for TIME WITH TIME ZONE, or 5 for TIMESTAMP WITH TIME ZONE.

DATETIME_INTERVAL_PRECISION (integer)

not implemented

INDICATOR (integer)

the indicator (indicating a null value or a value truncation)

KEY_MEMBER (integer)

not implemented

LENGTH (integer)

length of the datum in characters

NAME (string)

name of the column

NULLABLE (integer)

not implemented

OCTET_LENGTH (integer)

length of the character representation of the datum in bytes

PRECISION (integer)

precision (for type numeric)

RETURNED_LENGTH (integer)

length of the datum in characters

RETURNED_OCTET_LENGTH (integer)

length of the character representation of the datum in bytes

SCALE (integer)

scale (for type numeric)

TYPE (integer)

numeric code of the data type of the column

In EXECUTE, DECLARE and OPEN statements, the effect of the INTO and USING keywords are different. A Descriptor Area can also be manually built to provide the input parameters for a query or a cursor and USING SQL DESCRIPTOR name is the way to pass the input parameters into a parametrized query. The statement to build a named SQL Descriptor Area is below:

```
EXEC SQL SET DESCRIPTOR name VALUE num field = :hostvar END-EXEC.
```

PostgreSQL supports retrieving more than one record in one FETCH statement and storing the data in host variables in this case assumes that the variable is an array. E.g.:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
01 GROUP-ITEM.
    05 IDNUM PIC S9(9) COMP OCCURS 5.
EXEC SQL END DECLARE SECTION END-EXEC.

EXEC SQL FETCH 5 FROM mycursor INTO SQL DESCRIPTOR mydesc END-EXEC.

EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :IDNUM = DATA END-EXEC.
```

D.7 Error Handling

This section describes how you can handle exceptional conditions and warnings in an embedded SQL program. There are two nonexclusive facilities for this.

- Callbacks can be configured to handle warning and error conditions using the WHENEVER command.
- Detailed information about the error or warning can be obtained from the sqlca variable.

D.7.1 Setting Callbacks

One simple method to catch errors and warnings is to set a specific action to be executed whenever a particular condition occurs. In general:

```
EXEC SQL WHENEVER condition action END-EXEC.
```

condition can be one of the following:

SQLERROR

The specified action is called whenever an error occurs during the execution of an SQL statement.

SQLWARNING

The specified action is called whenever a warning occurs during the execution of an SQL statement.

NOT FOUND

The specified action is called whenever an SQL statement retrieves or affects zero rows. (This condition is not an error, but you might be interested in handling it specially.)

action can be one of the following:

CONTINUE

This effectively means that the condition is ignored. This is the default.

GOTO label
GO TO label

Jump to the specified label (using a COBOL goto statement).

SQLPRINT

Print a message to standard error. This is useful for simple programs or during prototyping. The details of the message cannot be configured.

STOP

Call STOP, which will terminate the program.

CALL name usingargs
DO name usingargs

Call the specified functions with the following characters including arguments. Thus, syntaxes (including compiler depending) are able to be placed as well as the arguments. Though, there are some limitation as following:

- You can't use RETURNING, ON EXCEPTION or OVER FLOW clauses.
- In the called subprogram, you must specify CONTINUE for every action with WHENEVER statement.

The SQL standard only provides for the actions CONTINUE and GOTO (and GO TO).

Here is an example that you might want to use in a simple program. It prints a simple message when a warning occurs and aborts the program when an error happens:

```
EXEC SQL WHENEVER SQLWARNING SQLPRINT END-EXEC.
EXEC SQL WHENEVER SQLERROR STOP END-EXEC.
```

The statement EXEC SQL WHENEVER is a directive of the SQL preprocessor, not a COBOL statement. The error or warning actions that it sets apply to all embedded SQL statements that appear below the point where the handler is set, unless a different action was set for the same condition between the first EXEC SQL WHENEVER and the SQL statement causing the condition, regardless of the flow of control in the COBOL program. So neither of the two following COBOL program excerpts will have the desired effect:

```
*
*   WRONG
*
    ...
    IF VERBOSE = 1 THEN
        EXEC SQL WHENEVER SQLWARNING SQLPRINT END-EXEC
    END-IF.
```

```
    ...
    EXEC SQL SELECT ... END-EXEC.
    ...
*
*   WRONG
*
    ...
    CALL SET-ERROR-HANDLER.
*        (and execute "EXEC SQL WHENEVER SQLERROR STOP" in SET-ERROR-HANDLER)
    ...
    EXEC SQL SELECT ... END-EXEC.
    ...
```

D.7.2 sqlca

For more powerful error handling, the embedded SQL interface provides a global variable with the name sqlca (SQL communication area) that has the following group item:

```
01  sqlca_t.
    10 sqlcaid PIC X(8).
    10 sqlabc PIC S9(9) COMP-5.
    10 sqlcode PIC S9(9) COMP-5.
    10 sqlerrm.
        20 sqlerrml PIC S9(9) COMP-5.
        20 sqlerrmc PIC X(150).
    10 sqlerrp PIC X(8).
    10 sqlerrd PIC S9(9) COMP-5 OCCURS 6.
    10 sqlwarn PIC X(8).
    10 sqlstate PIC X(5).
```

sqlca covers both warnings and errors. If multiple warnings or errors occur during the execution of a statement, then sqlca will only contain information about the last one.

If no error occurred in the last SQL statement, SQLCODE will be 0 and SQLSTATE will be "00000". If a warning or error occurred, then SQLCODE will be negative and SQLSTATE will be different from "00000". A positive SQLCODE indicates a harmless condition, such as that the last query returned zero rows. SQLCODE and SQLSTATE are two different error code schemes; details appear below.

If the last SQL statement was successful, then SQLERRD(2) contains the OID of the processed row, if applicable, and SQLERRD(3) contains the number of processed or returned rows, if applicable to the command.

In case of an error or warning, SQLERRMC will contain a string that describes the error. The field SQLERRML contains the length of the error message that is stored in SQLERRMC (the result of FUNCTION STORED-CHAR-LENGTH. Note that some messages are too long to fit in the fixed-size sqlerrmc array; they will be truncated.

In case of a warning, the 3rd character of SQLWARN is set to W. (In all other cases, it is set to something different from W.) If the 2nd character of SQLWARN is set to W, then a value was truncated when it was stored in a host variable. The 1st character of SQLWARN is set to W if any of the other elements are set to indicate a warning.

The fields sqlcaid, sqlcabc, sqlerrp, and the remaining elements of sqlerrd and sqlwarn currently contain no useful information.

The structure sqlca is not defined in the SQL standard, but is implemented in several other SQL database systems. The definitions are similar at the core, but if you want to write portable applications, then you should investigate the different implementations carefully.

Here is one example that combines the use of WHENEVER and sqlca, printing out the contents of sqlca when an error occurs. This is perhaps useful for debugging or prototyping applications, before installing a more "user-friendly" error handler.

```
EXEC SQL WHENEVER SQLERROR GOTO PRINT_SQLCA END-EXEC.

PRINT_SQLCA.
    DISPLAY "==== sqlca ====".
    DISPLAY "SQLCODE: " SQLCODE.
```

```
    DISPLAY "SQLERRML: " SQLERRML.
    DISPLAY "SQLERRMC: " SQLERRMC.
    DISPLAY "SQLERRD: " SQLERRD(1) " " SQLERRD(2) " " SQLERRD(3)" " SQLERRD(4) " "
SQLERRD(5) " " SQLERRD(6).
    DISPLAY "SQLSTATE: " SQLSTATE.
    DISPLAY "===============".
```

The result could look as follows (here an error due to a misspelled table name):

```
==== sqlca ====
sqlcode: -000000400
SQLERRML: +000000064
SQLERRMC: relation "pg_databasep" does not exist (10292) on line 93
sqlerrd: +000000000 +000000000 +000000000 +000000000 +000000000 +000000000
sqlstate: 42P01
===============
```

D.7.3 SQLSTATE vs. SQLCODE

The fields SQLSTATE and SQLCODE are two different schemes that provide error codes. Both are derived from the SQL standard, but SQLCODE has been marked deprecated in the SQL-92 edition of the standard and has been dropped in later editions. Therefore, new applications are strongly encouraged to use SQLSTATE.

SQLSTATE is a five-character array. The five characters contain digits or upper-case letters that represent codes of various error and warning conditions. SQLSTATE has a hierarchical scheme: the first two characters indicate the general class of the condition, the last three characters indicate a subclass of the general condition. A successful state is indicated by the code 00000. The SQLSTATE codes are for the most part defined in the SQL standard. The PostgreSQL server natively supports SQLSTATE error codes; therefore a high degree of consistency can be achieved by using this error code scheme throughout all applications.

See

Refer to "PostgreSQL Error Codes" in "Appendixes" in the PostgreSQL Documentation for further information.

SQLCODE, the deprecated error code scheme, is a simple integer. A value of 0 indicates success, a positive value indicates success with additional information, and a negative value indicates an error. The SQL standard only defines the positive value +100, which indicates that the last command returned or affected zero rows, and no specific negative values. Therefore, this scheme can only achieve poor portability and does not have a hierarchical code assignment. Historically, the embedded SQL processor for PostgreSQL has assigned some specific SQLCODE values for its use, which are listed below with their numeric value and their symbolic name. Remember that these are not portable to other SQL implementations. To simplify the porting of applications to the SQLSTATE scheme, the corresponding SQLSTATE is also listed. There is, however, no one-to-one or one-to-many mapping between the two schemes (indeed it is many-to-many), so you should consult the global SQLSTATE in each case.

See

Refer to "PostgreSQL Error Codes" in "Appendixes" in the PostgreSQL Documentation.

These are the assigned SQLCODE values:

0

Indicates no error. (SQLSTATE 00000)

100

This is a harmless condition indicating that the last command retrieved or processed zero rows, or that you are at the end of the cursor. (SQLSTATE 02000)

When processing a cursor in a loop, you could use this code as a way to detect when to abort the loop, like this:

```
PERFORM NO LIMIT
    EXEC SQL FETCH ... END-EXEC
    IF SQLCODE = 100 THEN
        GO TO FETCH-END
    END-IF
END-PERFORM.
```

But WHENEVER NOT FOUND GOTO ... effectively does this internally, so there is usually no advantage in writing this out explicitly.

-12

Indicates that your virtual memory is exhausted. The numeric value is defined as -ENOMEM. (SQLSTATE YE001)

-200

Indicates the preprocessor has generated something that the library does not know about. Perhaps you are running incompatible versions of the preprocessor and the library. (SQLSTATE YE002)

-201

This means that the command specified more host variables than the command expected. (SQLSTATE 07001 or 07002)

-202

This means that the command specified fewer host variables than the command expected. (SQLSTATE 07001 or 07002)

-203

This means a query has returned multiple rows but the statement was only prepared to store one result row (for example, because the specified variables are not arrays). (SQLSTATE 21000)

-204

The host variable is of type signed int and the datum in the database is of a different type and contains a value that cannot be interpreted as a signed int. The library uses strtol() for this conversion. (SQLSTATE 42804)

-205

The host variable is of type unsigned int and the datum in the database is of a different type and contains a value that cannot be interpreted as an unsigned int. The library uses strtoul() for this conversion. (SQLSTATE 42804)

-206

The host variable is of type float and the datum in the database is of another type and contains a value that cannot be interpreted as a float. The library uses strtod() for this conversion. (SQLSTATE 42804)

-207

The host variable is of type DECIMAL and the datum in the database is of another type and contains a value that cannot be interpreted as a DECIMAL or DISPLAY value. For the case of DISPLAY, this error happens if values in the database is too large for converting to DISPLAY value. (SQLSTATE 42804)

-208

The host variable is of type interval and the datum in the database is of another type and contains a value that cannot be interpreted as an interval value. (SQLSTATE 42804)

-209

The host variable is of type date and the datum in the database is of another type and contains a value that cannot be interpreted as a date value. (SQLSTATE 42804)

-210

The host variable is of type timestamp and the datum in the database is of another type and contains a value that cannot be interpreted as a timestamp value. (SQLSTATE 42804)

-211

This means the host variable is of type bool and the datum in the database is neither 't' nor 'f'. (SQLSTATE 42804)

-212

The statement sent to the PostgreSQL server was empty. (This cannot normally happen in an embedded SQL program, so it might point to an internal error.) (SQLSTATE YE002)

-213

A null value was returned and no null indicator variable was supplied. (SQLSTATE 22002)

-214

An ordinary variable was used in a place that requires an array. (SQLSTATE 42804)

-215

The database returned an ordinary variable in a place that requires array value. (SQLSTATE 42804)

-220

The program tried to access a connection that does not exist. (SQLSTATE 08003)

-221

The program tried to access a connection that does exist but is not open. (This is an internal error.) (SQLSTATE YE002)

-230

The statement you are trying to use has not been prepared. (SQLSTATE 26000)

-240

The descriptor specified was not found. The statement you are trying to use has not been prepared. (SQLSTATE 33000)

-241

The descriptor index specified was out of range. (SQLSTATE 07009)

-242

An invalid descriptor item was requested. (This is an internal error.) (SQLSTATE YE002)

-243

During the execution of a dynamic statement, the database returned a numeric value and the host variable was not numeric. (SQLSTATE 07006)

-244

During the execution of a dynamic statement, the database returned a non-numeric value and the host variable was numeric. (SQLSTATE 07006)

-400

Some error caused by the PostgreSQL server. The message contains the error message from the PostgreSQL server.

-401

The PostgreSQL server signaled that we cannot start, commit, or rollback the transaction. (SQLSTATE 08007)

-402

The connection attempt to the database did not succeed. (SQLSTATE 08001)

-403

Duplicate key error, violation of unique constraint. (SQLSTATE 23505)

-404

A result for the subquery is not single row. (SQLSTATE 21000)

-602

An invalid cursor name was specified. (SQLSTATE 34000)

-603

Transaction is in progress. (SQLSTATE 25001)

-604

There is no active (in-progress) transaction. (SQLSTATE 25P01)

-605

An existing cursor name was specified. (SQLSTATE 42P03)

D.8 Preprocessor Directives

Several preprocessor directives are available that modify how the ecobpg preprocessor parses and processes a file.

D.8.1 Including Files

To include an external file into your embedded SQL program, use:

```
EXEC SQL INCLUDE filename END-EXEC.
EXEC SQL INCLUDE <filename> END-EXEC.
EXEC SQL INCLUDE "filename" END-EXEC.
```

The embedded SQL preprocessor will look for a file named filename.pco, preprocess it, and include it in the resulting COBOL output. Thus, embedded SQL statements in the included file are handled correctly.

By default, the ecobpg preprocessor will search a file at the current directory. This behavior can be changed by the ecobpg commandline option.

First, the preprocessor tries to locate a file by specified file name at the current directory. If it fails and the file name does not end with .pco, the preprocessor also tries to locate a file with the suffix at the same directory.

The difference between EXEC SQL INCLUDE and COPY statement is whether precompiler processes embedded SQLs in the file, or not. If the file contains embedded SQLs, use EXEC SQL INCLUDE.

Note

The include file name is case-sensitive, even though the rest of the EXEC SQL INCLUDE command follows the normal SQL case-sensitivity rules.

D.8.2 The define and undef Directives

Similar to the directive #define that is known from C, embedded SQL has a similar concept:

```
EXEC SQL DEFINE name END-EXEC.
EXEC SQL DEFINE name value END-EXEC.
```

So you can define a name:

```
EXEC SQL DEFINE HAVE_FEATURE END-EXEC.
```

And you can also define constants:

```
EXEC SQL DEFINE MYNUMBER 12 END-EXEC.
EXEC SQL DEFINE MYSTRING 'abc' END-EXEC.
```

Use undef to remove a previous definition:

```
EXEC SQL UNDEF MYNUMBER END-EXEC.
```

Note that a constant in the SQL statement is only replaced by EXEC SQL DEFINE. The replacement may change the number of characters in a line, but ecobpg does not validate it after the replacement. Pay attention to the limitation of the number of characters in a line.

D.8.3 ifdef, ifndef, else, elif, and endif Directives

You can use the following directives to compile code sections conditionally:

```
EXEC SQL ifdef name END-EXEC.
```

Checks a name and processes subsequent lines if name has been created with EXEC SQL define name.

```
EXEC SQL ifndef name END-EXEC.
```

Checks a name and processes subsequent lines if name has not been created with EXEC SQL define name.

```
EXEC SQL else END-EXEC.
```

Starts processing an alternative section to a section introduced by either EXEC SQL ifdef name or EXEC SQL ifndef name.

```
EXEC SQL elif name END-EXEC.
```

Checks name and starts an alternative section if name has been created with EXEC SQL define name.

```
EXEC SQL endif END-EXEC.
```

Ends an alternative section.

Example:

```
EXEC SQL ifndef TZVAR END-EXEC.
EXEC SQL SET TIMEZONE TO 'GMT' END-EXEC.
EXEC SQL elif TZNAME END-EXEC.
EXEC SQL SET TIMEZONE TO TZNAME END-EXEC.
EXEC SQL else END-EXEC.
EXEC SQL SET TIMEZONE TO TZVAR END-EXEC.
EXEC SQL endif END-EXEC.
```

D.9 Processing Embedded SQL Programs

Now that you have an idea how to form embedded SQL COBOL programs, you probably want to know how to compile them. Before compiling you run the file through the embedded SQL COBOL preprocessor, which converts the SQL statements you used to special function calls. After compiling, you must link with a special library that contains the needed functions. These functions fetch information from the arguments, perform the SQL command using the libpq interface, and put the result in the arguments specified for output.

The preprocessor program is called ecobpg and is included in a normal PostgreSQL installation. Embedded SQL programs are typically named with an extension .pco. If you have a program file called prog1.pco, you can preprocess it by simply calling:

```
ecobpg prog1.pco
```

This will create a file called prog1.cob. If your input files do not follow the suggested naming pattern, you can specify the output file explicitly using the -o option.

The preprocessed file can be compiled normally, following the usage of the compiler.

The generated COBOL source files include library files from the PostgreSQL installation, so if you installed PostgreSQL in a location that is not searched by default, you have to add an option such as -I/usr/local/pgsql/include to the compilation command line.

To link an embedded SQL program, you need to include the libecpg library.

Again, you might have to add an option for library search like -L/usr/local/pgsql/lib to that command line.

If you manage the build process of a larger project using make, it might be convenient to include the following implicit rule to your makefiles:

```
ECOBPG = ecobpg

%.cob: %.pco
        $(ECOBPG) $<
```

The complete syntax of the ecobpg command is detailed in "D.12.1 ecobpg".

Currently, ecobpg does not support multi threading.

D.10 Large Objects

Large objects are not supported by ECOBPG.

If you need to access large objects, use large objects interfaces of libpq instead.

D.11 Embedded SQL Commands

This section describes all SQL commands that are specific to embedded SQL.

Command	Description
ALLOCATE DESCRIPTOR	Allocate an SQL descriptor area
CONNECT	Establish a database connection
DEALLOCATE DESCRIPTOR	Deallocate an SQL descriptor area
DECLARE	Define a cursor
DESCRIBE	Obtain information about a prepared statement or result set
DISCONNECT	Terminate a database connection
EXECUTE IMMEDIATE	Dynamically prepare and execute a statement
GET DESCRIPTOR	Get information from an SQL descriptor area
OPEN	Open a dynamic cursor
PREPARE	Prepare a statement for execution
SET AUTOCOMMIT	Set the autocommit behavior of the current session
SET CONNECTION	Select a database connection
SET DESCRIPTOR	Set information in an SQL descriptor area
TYPE	Define a new data type
VAR	Define a variable
WHENEVER	Specify the action to be taken when an SQL statement causes a specific class condition to be raised

See

Refer to the SQL commands listed in "SQL Commands" under "Reference" in the PostgreSQL Documentation, which can also be used in embedded SQL, unless stated otherwise.

D.11.1 ALLOCATE DESCRIPTOR

Name

ALLOCATE DESCRIPTOR -- allocate an SQL descriptor area

Synopsis

```
ALLOCATE DESCRIPTOR name
```

Description

ALLOCATE DESCRIPTOR allocates a new named SQL descriptor area, which can be used to exchange data between the PostgreSQL server and the host program.

Descriptor areas should be freed after use using the DEALLOCATE DESCRIPTOR command.

Parameters

name

A name of SQL descriptor. This can be an SQL identifier or a host variable.

Examples

```
EXEC SQL ALLOCATE DESCRIPTOR mydesc END-EXEC.
```

Compatibility

ALLOCATE DESCRIPTOR is specified in the SQL standard.

See Also

DEALLOCATE DESCRIPTOR, GET DESCRIPTOR, SET DESCRIPTOR

D.11.2 CONNECT

Name

CONNECT -- establish a database connection

Synopsis

```
CONNECT TO connection_target [ AS connection_name ] [ USER connection_user_name ]

CONNECT TO DEFAULT

CONNECT connection_user_name

DATABASE connection_target
```

Description

The CONNECT command establishes a connection between the client and the PostgreSQL server.

Parameters

connection_target

connection_target specifies the target server of the connection on one of several forms.

[database_name] [@host] [:port]

Connect over TCP/IP

unix:postgresql://host [:port] / [database_name] [?connection_option]

Connect over Unix-domain sockets

tcp:postgresql://host [:port] / [database_name] [?connection_option]

Connect over TCP/IP

SQL string constant

containing a value in one of the above forms

host variable

host variable of fixed-length string (trailing spaces are ignored) containing a value in one of the above forms

connection_name

An optional identifier for the connection, so that it can be referred to in other commands. This can be an SQL identifier or a host variable.

connection_user_name

The user name for the database connection.

This parameter can also specify user name and password, using one the forms user_name/password, user_name IDENTIFIED BY password, or user_name USING password.

User name and password can be SQL identifiers, string constants, or host variables (fixed-length string, trailing spaces are ignored).

DEFAULT

Use all default connection parameters, as defined by libpq.

Examples

Here a several variants for specifying connection parameters:

```
EXEC SQL CONNECT TO "connectdb" AS main END-EXEC.
EXEC SQL CONNECT TO "connectdb" AS second END-EXEC.
EXEC SQL CONNECT TO "unix:postgresql://localhost/connectdb" AS main USER connectuser END-
EXEC.
EXEC SQL CONNECT TO 'connectdb' AS main END-EXEC.
EXEC SQL CONNECT TO 'unix:postgresql://localhost/connectdb' AS main USER :user END-EXEC.
EXEC SQL CONNECT TO :dbn AS :idt END-EXEC.
EXEC SQL CONNECT TO :dbn USER connectuser USING :pw END-EXEC.
EXEC SQL CONNECT TO @localhost AS main USER connectdb END-EXEC.
EXEC SQL CONNECT TO REGRESSDB1 as main END-EXEC.
EXEC SQL CONNECT TO connectdb AS :idt END-EXEC.
EXEC SQL CONNECT TO connectdb AS main USER connectuser/connectdb END-EXEC.
EXEC SQL CONNECT TO connectdb AS main END-EXEC.
EXEC SQL CONNECT TO connectdb@localhost AS main END-EXEC.
EXEC SQL CONNECT TO tcp:postgresql://localhost/ USER connectdb END-EXEC.
EXEC SQL CONNECT TO tcp:postgresql://localhost/connectdb USER connectuser IDENTIFIED BY
connectpw END-EXEC.
EXEC SQL CONNECT TO tcp:postgresql://localhost:20/connectdb USER connectuser IDENTIFIED BY
connectpw END-EXEC.
EXEC SQL CONNECT TO unix:postgresql://localhost/ AS main USER connectdb END-EXEC.
EXEC SQL CONNECT TO unix:postgresql://localhost/connectdb AS main USER connectuser END-
EXEC.
EXEC SQL CONNECT TO unix:postgresql://localhost/connectdb USER connectuser IDENTIFIED BY
"connectpw" END-EXEC.
EXEC SQL CONNECT TO unix:postgresql://localhost/connectdb USER connectuser USING
"connectpw" END-EXEC.
EXEC SQL CONNECT TO unix:postgresql://localhost/connectdb?connect_timeout=14 USER
connectuser END-EXEC.
```

Here is an example program that illustrates the use of host variables to specify connection parameters:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
*   database name
    01 DBNAME PIC X(6).
*   connection user name
```

```
    01 USER PIC X(8).
*   connection string
    01 CONNECTION PIC X(38).

    01 VER PIC X(256).
EXEC SQL END DECLARE SECTION END-EXEC.

    MOVE "testdb" TO DBNAME.
    MOVE "testuser" TO USER.
    MOVE "tcp:postgresql://localhost:5432/testdb" TO CONNECTION.

    EXEC SQL CONNECT TO :DBNAME USER :USER END-EXEC.
    EXEC SQL SELECT version() INTO :VER END-EXEC.
    EXEC SQL DISCONNECT END-EXEC.

    DISPLAY "version: " VER.

    EXEC SQL CONNECT TO :CONNECTION USER :USER END-EXEC.
    EXEC SQL SELECT version() INTO :VER END-EXEC.
    EXEC SQL DISCONNECT END-EXEC.

    DISPLAY "version: " VER.
```

Compatibility

CONNECT is specified in the SQL standard, but the format of the connection parameters is implementation-specific.

See Also

DISCONNECT, SET CONNECTION

D.11.3 DEALLOCATE DESCRIPTOR

Name

DEALLOCATE DESCRIPTOR -- deallocate an SQL descriptor area

Synopsis

```
DEALLOCATE DESCRIPTOR name
```

Description

DEALLOCATE DESCRIPTOR deallocates a named SQL descriptor area.

Parameters

name

The name of the descriptor which is going to be deallocated. This can be an SQL identifier or a host variable.

Examples

EXEC SQL DEALLOCATE DESCRIPTOR mydesc END-EXEC.

Compatibility

DEALLOCATE DESCRIPTOR is specified in the SQL standard.

See Also

ALLOCATE DESCRIPTOR, GET DESCRIPTOR, SET DESCRIPTOR

D.11.4 DECLARE

Name

DECLARE -- define a cursor

Synopsis

```
DECLARE cursor_name [ BINARY ] [ INSENSITIVE ] [ [ NO ] SCROLL ] CURSOR [ { WITH | WITHOUT }
HOLD ] FOR prepared_name

DECLARE cursor_name [ BINARY ] [ INSENSITIVE ] [ [ NO ] SCROLL ] CURSOR [ { WITH | WITHOUT }
HOLD ] FOR query
```

Description

DECLARE declares a cursor for iterating over the result set of a prepared statement. This command has slightly different semantics from the direct SQL command DECLARE: Whereas the latter executes a query and prepares the result set for retrieval, this embedded SQL command merely declares a name as a "loop variable" for iterating over the result set of a query; the actual execution happens when the cursor is opened with the OPEN command.

Parameters

cursor_name

A cursor name. This can be an SQL identifier or a host variable.

prepared_name

The name of a prepared query, either as an SQL identifier or a host variable.

query

A SELECT or VALUES command which will provide the rows to be returned by the cursor.

For the meaning of the cursor options, see DECLARE.

See

Refer to "SQL Commands" in "Reference" in the PostgreSQL Documentation for information on the SELECT, VALUES and DECLARE command.

Examples

Examples declaring a cursor for a query:

```
EXEC SQL DECLARE C CURSOR FOR SELECT * FROM My_Table END-EXEC.
EXEC SQL DECLARE C CURSOR FOR SELECT Item1 FROM T END-EXEC.
EXEC SQL DECLARE cur1 CURSOR FOR SELECT version() END-EXEC.
```

An example declaring a cursor for a prepared statement:

```
EXEC SQL PREPARE stmt1 AS SELECT version() END-EXEC.
EXEC SQL DECLARE cur1 CURSOR FOR stmt1 END-EXEC.
```

Compatibility

DECLARE is specified in the SQL standard.

See Also

OPEN, CLOSE, DECLARE

See

Refer to "SQL Commands" in "Reference" in the PostgreSQL Documentation for information on the CLOSE and DECLARE command.

D.11.5 DESCRIBE

Name

DESCRIBE -- obtain information about a prepared statement or result set

Synopsis

```
DESCRIBE [ OUTPUT ] prepared_name USING SQL DESCRIPTOR descriptor_name

DESCRIBE [ OUTPUT ] prepared_name INTO SQL DESCRIPTOR descriptor_name
```

Description

DESCRIBE retrieves metadata information about the result columns contained in a prepared statement, without actually fetching a row.

Parameters

prepared_name

The name of a prepared statement. This can be an SQL identifier or a host variable.

descriptor_name

A descriptor name. It can be an SQL identifier or a host variable.

Examples

```
EXEC SQL ALLOCATE DESCRIPTOR mydesc END-EXEC.
EXEC SQL PREPARE stmt1 FROM :sql_stmt END-EXEC.
EXEC SQL DESCRIBE stmt1 INTO SQL DESCRIPTOR mydesc END-EXEC.
EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :charvar = NAME END-EXEC.
EXEC SQL DEALLOCATE DESCRIPTOR mydesc END-EXEC.
```

Compatibility

DESCRIBE is specified in the SQL standard.

See Also

ALLOCATE DESCRIPTOR, GET DESCRIPTOR

D.11.6 DISCONNECT

Name

DISCONNECT -- terminate a database connection

Synopsis

```
DISCONNECT connection_name

DISCONNECT [ CURRENT ]

DISCONNECT DEFAULT
```

```
DISCONNECT ALL
```

Description

DISCONNECT closes a connection (or all connections) to the database.

Parameters

connection_name

A database connection name established by the CONNECT command.

CURRENT

Close the "current" connection, which is either the most recently opened connection, or the connection set by the SET CONNECTION command. This is also the default if no argument is given to the DISCONNECT command.

DEFAULT

Close the default connection.

ALL

Close all open connections.

Examples

```
    EXEC SQL CONNECT TO testdb AS DEFAULT USER testuser END-EXEC.
    EXEC SQL CONNECT TO testdb AS con1 USER testuser END-EXEC.
    EXEC SQL CONNECT TO testdb AS con2 USER testuser END-EXEC.
    EXEC SQL CONNECT TO testdb AS con3 USER testuser END-EXEC.

*   close con3
    EXEC SQL DISCONNECT CURRENT END-EXEC.
*   close DEFAULT
    EXEC SQL DISCONNECT DEFAULT END-EXEC.
*   close con2 and con1
    EXEC SQL DISCONNECT ALL END-EXEC.
```

Compatibility

DISCONNECT is specified in the SQL standard.

See Also

CONNECT, SET CONNECTION

D.11.7 EXECUTE IMMEDIATE

Name

EXECUTE IMMEDIATE -- dynamically prepare and execute a statement

Synopsis

```
EXECUTE IMMEDIATE string
```

Description

EXECUTE IMMEDIATE immediately prepares and executes a dynamically specified SQL statement, without retrieving result rows.

Parameters

string

A literal string or a host variable containing the SQL statement to be executed.

Examples

Here is an example that executes an INSERT statement using EXECUTE IMMEDIATE and a host variable named command:

```
MOVE "INSERT INTO test (name, amount, letter) VALUES ('db: ''r1''', 1, 'f')" TO ARR OF cmd.
COMPUTE LEN OF cmd = FUNCTION STORED-CHAR-LENGTH(ARR OF cmd).
EXEC SQL EXECUTE IMMEDIATE :cmd END-EXEC.
```

Compatibility

EXECUTE IMMEDIATE is specified in the SQL standard.

D.11.8 GET DESCRIPTOR

Name

GET DESCRIPTOR -- get information from an SQL descriptor area

Synopsis

```
GET DESCRIPTOR descriptor_name :hostvariable = descriptor_header_item [, ... ]

GET DESCRIPTOR descriptor_name VALUE column_number :hostvariable = descriptor_item [, ... ]
```

Description

GET DESCRIPTOR retrieves information about a query result set from an SQL descriptor area and stores it into host variables. A descriptor area is typically populated using FETCH or SELECT before using this command to transfer the information into host language variables.

This command has two forms: The first form retrieves descriptor "header" items, which apply to the result set in its entirety. One example is the row count. The second form, which requires the column number as additional parameter, retrieves information about a particular column. Examples are the column name and the actual column value.

Parameters

descriptor_name

A descriptor name.

descriptor_header_item

A token identifying which header information item to retrieve. Only COUNT, to get the number of columns in the result set, is currently supported.

column_number

The number of the column about which information is to be retrieved. The count starts at 1.

descriptor_item

A token identifying which item of information about a column to retrieve. See Section 33.7.1 for a list of supported items.

hostvariable

A host variable that will receive the data retrieved from the descriptor area.

Examples

An example to retrieve the number of columns in a result set:

```
EXEC SQL GET DESCRIPTOR d :d_count = COUNT END-EXEC.
```

An example to retrieve a data length in the first column:

```
EXEC SQL GET DESCRIPTOR d VALUE 1 :d_returned_octet_length = RETURNED_OCTET_LENGTH END-
EXEC.
```

An example to retrieve the data body of the second column as a string:

```
EXEC SQL GET DESCRIPTOR d VALUE 2 :d_data = DATA END-EXEC.
```

Here is an example for a whole procedure of executing SELECT current_database(); and showing the number of columns, the column data length, and the column data:

```
EXEC SQL BEGIN DECLARE SECTION END-EXEC.
    01 D-COUNT PIC S9(9) COMP-5.
    01 D-DATA PIC X(1024).
    01 D-RETURNED-OCTET-LENGTH PIC S9(9) COMP.
EXEC SQL END DECLARE SECTION END-EXEC.

    EXEC SQL CONNECT TO testdb AS con1 USER testuser END-EXEC.
    EXEC SQL ALLOCATE DESCRIPTOR d END-EXEC.

*   Declare, open a cursor, and assign a descriptor to the cursor
    EXEC SQL DECLARE cur CURSOR FOR SELECT current_database() END-EXEC.
    EXEC SQL OPEN cur END-EXEC.
    EXEC SQL FETCH NEXT FROM cur INTO SQL DESCRIPTOR d END-EXEC.

*   Get a number of total columns
    EXEC SQL GET DESCRIPTOR d :D-COUNT = COUNT END-EXEC.
    DISPLAY "d_count                = " D-COUNT.

*   Get length of a returned column
    EXEC SQL GET DESCRIPTOR d VALUE 1 :D-RETURNED-OCTET-LENGTH = RETURNED_OCTET_LENGTH END-
EXEC.
    DISPLAY "d_returned_octet_length = " D-RETURNED-OCTET-LENGTH.

*   Fetch the returned column as a string
    EXEC SQL GET DESCRIPTOR d VALUE 1 :D-DATA = DATA END-EXEC.
    DISPLAY "d_data                  = " D-DATA.

*   Closing
    EXEC SQL CLOSE cur END-EXEC.
    EXEC SQL COMMIT END-EXEC.

    EXEC SQL DEALLOCATE DESCRIPTOR d END-EXEC.
    EXEC SQL DISCONNECT ALL END-EXEC.
```

When the example is executed, the result will look like this:

```
d_count                = +000000001
d_returned_octet_length = +000000006
d_data                 = testdb
```

Compatibility

GET DESCRIPTOR is specified in the SQL standard.

See Also

ALLOCATE DESCRIPTOR, SET DESCRIPTOR

D.11.9 OPEN

Name

OPEN -- open a dynamic cursor

Synopsis

```
OPEN cursor_name

OPEN cursor_name USING value [, ... ]

OPEN cursor_name USING SQL DESCRIPTOR descriptor_name
```

Description

OPEN opens a cursor and optionally binds actual values to the placeholders in the cursor's declaration. The cursor must previously have been declared with the DECLARE command. The execution of OPEN causes the query to start executing on the server.

Parameters

cursor_name

The name of the cursor to be opened. This can be an SQL identifier or a host variable.

value

A value to be bound to a placeholder in the cursor. This can be an SQL constant, a host variable, or a host variable with indicator.

descriptor_name

The name of a descriptor containing values to be bound to the placeholders in the cursor. This can be an SQL identifier or a host variable.

Examples

```
EXEC SQL OPEN a END-EXEC.
EXEC SQL OPEN d USING 1, 'test' END-EXEC.
EXEC SQL OPEN c1 USING SQL DESCRIPTOR mydesc END-EXEC.
EXEC SQL OPEN :curname1 END-EXEC.
```

Compatibility

OPEN is specified in the SQL standard.

See Also

DECLARE, CLOSE

Refer to "SQL Commands" in "Reference" in the PostgreSQL Documentation for information on the CLOSE command.

D.11.10 PREPARE

Name

PREPARE -- prepare a statement for execution

Synopsis

```
PREPARE name FROM string
```

Description

PREPARE prepares a statement dynamically specified as a string for execution. This is different from the direct SQL statement PREPARE, which can also be used in embedded programs. The EXECUTE command is used to execute either kind of prepared statement.

Parameters

prepared_name

An identifier for the prepared query.

string

A literal string or a host variable containing a preparable statement, one of the SELECT, INSERT, UPDATE, or DELETE.

Examples

```
MOVE "SELECT * FROM test1 WHERE a = ? AND b = ?" TO ARR OF STMT.
COMPUTE LEN OF STMT = FUNCTION STORED-CHAR-LENGTH (ARR OF STMT).
EXEC SQL ALLOCATE DESCRIPTOR indesc END-EXEC.
EXEC SQL ALLOCATE DESCRIPTOR outdesc END-EXEC.
EXEC SQL PREPARE foo FROM :STMT END-EXEC.

EXEC SQL EXECUTE foo USING SQL DESCRIPTOR indesc INTO SQL DESCRIPTOR outdesc END-EXEC.
```

Compatibility

PREPARE is specified in the SQL standard.

See Also

EXECUTE

Refer to "SQL Commands" in "Reference" in the PostgreSQL Documentation for information on the EXECUTE command.

D.11.11 SET AUTOCOMMIT

Name

SET AUTOCOMMIT -- set the autocommit behavior of the current session

Synopsis

```
SET AUTOCOMMIT { = | TO } { ON | OFF }
```

Description

SET AUTOCOMMIT sets the autocommit behavior of the current database session. By default, embedded SQL programs are not in autocommit mode, so COMMIT needs to be issued explicitly when desired. This command can change the session to autocommit mode, where each individual statement is committed implicitly.

Compatibility

SET AUTOCOMMIT is an extension of PostgreSQL ECOBPG.

D.11.12 SET CONNECTION

Name

SET CONNECTION -- select a database connection

Synopsis

```
SET CONNECTION [ TO | = ] connection_name
```

Description

SET CONNECTION sets the "current" database connection, which is the one that all commands use unless overridden.

Parameters

connection_name

A database connection name established by the CONNECT command.

DEFAULT

Set the connection to the default connection.

Examples

```
EXEC SQL SET CONNECTION TO con2 END-EXEC.
EXEC SQL SET CONNECTION = con1 END-EXEC.
```

Compatibility

SET CONNECTION is specified in the SQL standard.

See Also

CONNECT, DISCONNECT

D.11.13 SET DESCRIPTOR

Name

SET DESCRIPTOR -- set information in an SQL descriptor area

Synopsis

```
SET DESCRIPTOR descriptor_name descriptor_header_item = value [, ... ]

SET DESCRIPTOR descriptor_name VALUE number descriptor_item = value [, ...]
```

Description

SET DESCRIPTOR populates an SQL descriptor area with values. The descriptor area is then typically used to bind parameters in a prepared query execution.

This command has two forms: The first form applies to the descriptor "header", which is independent of a particular datum. The second form assigns values to particular datums, identified by number.

Parameters

descriptor_name

A descriptor name.

descriptor_header_item

A token identifying which header information item to set. Only COUNT, to set the number of descriptor items, is currently supported.

number

The number of the descriptor item to set. The count starts at 1.

descriptor_item

A token identifying which item of information to set in the descriptor. See Section 33.7.1 for a list of supported items.

value

A value to store into the descriptor item. This can be an SQL constant or a host variable.

Examples

```
EXEC SQL SET DESCRIPTOR indesc COUNT = 1 END-EXEC.
EXEC SQL SET DESCRIPTOR indesc VALUE 1 DATA = 2 END-EXEC.
EXEC SQL SET DESCRIPTOR indesc VALUE 1 DATA = :val1 END-EXEC.
EXEC SQL SET DESCRIPTOR indesc VALUE 2 DATA = 'some string', INDICATOR = :val1 END-EXEC.
EXEC SQL SET DESCRIPTOR indesc VALUE 2 INDICATOR = :val2null, DATA = :val2 END-EXEC.
```

Compatibility

SET DESCRIPTOR is specified in the SQL standard.

See Also

ALLOCATE DESCRIPTOR, GET DESCRIPTOR

D.11.14 TYPE

Name

TYPE -- define a new data type

Synopsis

`TYPE` *`type_name`* `IS` *`ctype`*

Description

The TYPE command defines a new COBOL type. It is equivalent to putting a typedef into a declare section.

This command is only recognized when ecobpgpg is run with the -c option.

A level number of 01 is automatically added to type_name item. Thus, the level number must not to be specified externally. To define a group item, a level number needs to be specified to the each subordinate items.

For reasons of internal implementation, "TYPE" must be placed just after "EXEC SQL", without containing newline. For other place, you can use newline.

Parameters

type_name

The name for the new type. It must be a valid COBOL type name.

ctype

A COBOL type specification (including expression format specification).

Examples

```
EXEC SQL TYPE CUSTOMER IS
      02  NAME PIC X(50) VARYING.
      02 PHONE PIC S9(9) COMP. END-EXEC.

EXEC SQL TYPE CUST-IND IS
      02  NAME_IND PIC S9(4) COMP.
      02 PHONE_IND PIC S9(4) COMP. END-EXEC.

EXEC SQL TYPE INTARRAY IS
      02 INT PIC S9(9) OCCURS 20. END-EXEC.
EXEC SQL TYPE STR IS PIC X(50) VARYING. END-EXEC.
EXEC SQL TYPE STRING IS PIC X(10). END-EXEC.
```

Here is an example program that uses EXEC SQL TYPE:

```
EXEC SQL TYPE TT IS
     02 V PIC X(256) VARYING.
     02 I PIC S9(9) COMP. END-EXEC.

EXEC SQL TYPE TT-IND IS
     02 V-IND PIC S9(4) COMP.
     02 I-IND PIC S9(4) COMP. END-EXEC.

EXEC SQL BEGIN DECLARE SECTION END-EXEC.
    01 T TYPE TT.
    01 T-IND TYPE TT-IND.
EXEC SQL END DECLARE SECTION END-EXEC.

    EXEC SQL CONNECT TO testdb AS con1 END-EXEC.

    EXEC SQL SELECT current_database(), 256 INTO :T :T-IND LIMIT 1 END-EXEC.

    DISPLAY "t.v = " ARR OF V OF T.
    DISPLAY "t.i = " I OF T.

    DISPLAY "t_ind.v_ind = " V-IND OF T-IND.
    DISPLAY "t_ind.i_ind = " I-IND OF T-IND.

    EXEC SQL DISCONNECT con1 END-EXEC.
```

Compatibility

The TYPE command is a PostgreSQL extension.

D.11.15 VAR

Name

VAR─ define a variable

Synopsis

```
VAR varname IS ctype
```

Description

The VAR command defines a host variable. It is equivalent to an ordinary COBOL variable definition inside a declare section.

When translating, a level number 01 is added. Thus, the level number must not to be specified externally.

To define a group item, a level number needs to be specified to the each subordinate items.

For reasons of internal implementation, "VAR" must be placed just after "EXEC SQL", without containing newline. For other place, you can use newline.

Parameters

varname

A COBOL variable name.

ctype

A COBOL type specification.

Examples

```
EXEC SQL VAR VC IS PIC X(10) VARYING. END-EXEC.
EXEC SQL VAR BOOL-VAR IS BOOL. END-EXEC.
```

Compatibility

The VAR command is a PostgreSQL extension.

D.11.16 WHENEVER

Name

WHENEVER -- specify the action to be taken when an SQL statement causes a specific class condition to be raised

Synopsis

```
WHENEVER { NOT FOUND | SQLERROR | SQLWARNING } action
```

Description

Define a behavior which is called on the special cases (Rows not found, SQL warnings or errors) in the result of SQL execution.

Parameters

See Section "D.7.1 Setting Callbacks" or a description of the parameters.

Examples

```
EXEC SQL WHENEVER NOT FOUND CONTINUE END-EXEC.
EXEC SQL WHENEVER SQLWARNING SQLPRINT END-EXEC.
EXEC SQL WHENEVER SQLWARNING DO "warn" END-EXEC.
EXEC SQL WHENEVER SQLERROR sqlprint END-EXEC.
EXEC SQL WHENEVER SQLERROR CALL "print2" END-EXEC.
EXEC SQL WHENEVER SQLERROR DO handle_error USING "select" END-EXEC.
EXEC SQL WHENEVER SQLERROR DO sqlnotice USING 0 1 END-EXEC.
EXEC SQL WHENEVER SQLERROR DO "sqlprint" END-EXEC.
EXEC SQL WHENEVER SQLERROR GOTO error_label END-EXEC.
EXEC SQL WHENEVER SQLERROR STOP END-EXEC.
```

A typical application is the use of WHENEVER NOT FOUND GOTO to handle looping through result sets:

```
    EXEC SQL CONNECT TO testdb AS con1 END-EXEC.
    EXEC SQL ALLOCATE DESCRIPTOR d END-EXEC.
    EXEC SQL DECLARE cur CURSOR FOR SELECT current_database(), 'hoge', 256 END-EXEC.
    EXEC SQL OPEN cur END-EXEC.

*   when end of result set reached, break out of while loop
    EXEC SQL WHENEVER NOT FOUND GOTO NOTFOUND END-EXEC.

    PERFORM NO LIMIT
        EXEC SQL FETCH NEXT FROM cur INTO SQL DESCRIPTOR d END-EXEC
        ...
    END-PERFORM.

    NOTFOUND.
    EXEC SQL CLOSE cur END-EXEC.
    EXEC SQL COMMIT END-EXEC.

    EXEC SQL DEALLOCATE DESCRIPTOR d END-EXEC.
    EXEC SQL DISCONNECT ALL END-EXEC.
```

Compatibility

WHENEVER is specified in the SQL standard, but most of the actions are PostgreSQL extensions.

D.12 PostgreSQL Client Applications

This part contains reference information for PostgreSQL client applications and utilities. Not all of these commands are of general utility; some might require special privileges. The common feature of these applications is that they can be run on any host, independent of where the database server resides.

When specified on the command line, user and database names have their case preserved—the presence of spaces or special characters might require quoting. Table names and other identifiers do not have their case preserved, except where documented, and might require quoting.

D.12.1 ecobpg

Name

ecobpg -- embedded SQL COBOL preprocessor

Synopsis

ecobpg [*option*...] *file*...

Description

ecobpg is the embedded SQL preprocessor for COBOL programs. It converts COBOL programs with embedded SQL statements to normal COBOL code by replacing the SQL invocations with special function calls. The output files can then be processed with any COBOL compiler tool chain.

ecobpg will convert each input file given on the command line to the corresponding COBOL output file. Input files preferably have the extension .pco, in which case the extension will be replaced by .cob to determine the output file name. If the extension of the input file is not .pco, then the output file name is computed by appending .cob to the full file name. The output file name can also be overridden using the -o option.

Options

ecobpg accepts the following command-line arguments:

`-c`

Automatically generate certain COBOL code from SQL code. Currently, this works for EXEC SQL TYPE.

-I directory

Specify an additional include path, used to find files included via EXEC SQL INCLUDE. Defaults are: (current directory), /usr/local/include, the PostgreSQL include directory which is defined at compile time (default: /usr/local/pgsql/include), and /usr/include, in that order.

-o filename

Specifies that ecobpg should write all its output to the given filename.

-f format

Specifies the COBOL code notation. For "format", specify either of the following. If omitted, "fixed" is used.

fixed

Specifies fixed format notation. Up to 72 columns can be specified for area B. Characters in column 73 and beyond are deleted in the precompiled source.

variable

Specifies variable format notation. Up to 251 columns can be specified for area B. Characters in column 252 and beyond are deleted in the precompiled source.

-r option

Selects run-time behavior. Option can be one of the following:

prepare

Prepare all statements before using them. Libecpg will keep a cache of prepared statements and reuse a statement if it gets executed again. If the cache runs full, libecpg will free the least used statement.

questionmarks

Allow question mark as placeholder for compatibility reasons. This used to be the default long ago.

-t

Turn on autocommit of transactions. In this mode, each SQL command is automatically committed unless it is inside an explicit transaction block. In the default mode, commands are committed only when EXEC SQL COMMIT is issued.

--varchar-with-named-member

When converting VARCHAR host variable, adding name of the variable to members as prefix. Instead of LEN and ARR, (varname)-ARR and (varname)-LEN will be used.

--bytea-with-named-member

When converting bytea host variable, adding name of the variable to members as prefix. Instead of LEN and ARR, (varname)-ARR and (varname)-LEN will be used.

-E encode

Specify the COBOL source encoding: "UTF8", "SJIS", or "EUC_JP".

If this option is omitted, the encoding is processed based on the locale.

--enable-hint

Enables the optimizer hint block comment (hereafter, referred to as the "hint clause"). If this option is not specified, the hint clause will be removed as a result of the ecobpg precompile and be disabled.

The SQL statements that can be specified in the hint clause are SELECT, INSERT, UPDATE, and DELETE.

The locations in which the hint clause can be specified are immediately after one of the SELECT, INSERT, UPDATE, DELETE, or WITH keywords. A syntax error will occur if it is specified in any other location.

-v

Print additional information including the version and the "include" path.

--version

Print the ecobpg version and exit.

-?
--help

Show help about ecobpg command line arguments, and exit.

Notes

When compiling the preprocessed COBOL code files, the compiler needs to be able to find the library files in the PostgreSQL include directory.

Programs using COBOL code with embedded SQL have to be linked against the libecpg library, for example using the linker options.

The value of either of these directories that is appropriate for the installation can be found out using pg_config.

See

Refer to "pg_config" in "Reference" in the PostgreSQL Documentation.

Examples

If you have an embedded SQL COBOL source file named prog1.pco, you can create an executable program using the following command:

```
ecobpg prog1.pco
```

Appendix E Quantitative Limits

This appendix lists the quantitative limits of Fujitsu Enterprise Postgres.

Table E.1 Length of identifier

Item	Limit
Database name	Up to 63 bytes (*1) (*2)
Schema name	Up to 63 bytes (*1) (*2)
Table name	Up to 63 bytes (*1) (*2)
View name	Up to 63 bytes (*1) (*2)
Index name	Up to 63 bytes (*1) (*2)
Table space name	Up to 63 bytes (*1) (*2)
Cursor name	Up to 63 bytes (*1) (*2)
Function name	Up to 63 bytes (*1) (*2)
Aggregate function name	Up to 63 bytes (*1) (*2)
Trigger name	Up to 63 bytes (*1) (*2)
Constraint name	Up to 63 bytes (*1) (*2)
Conversion name	Up to 63 bytes (*1) (*2)
Role name	Up to 63 bytes (*1) (*2)
Cast name	Up to 63 bytes (*1) (*2)
Collation sequence name	Up to 63 bytes (*1) (*2)
Encoding method conversion name	Up to 63 bytes (*1) (*2)
Domain name	Up to 63 bytes (*1) (*2)
Extension name	Up to 63 bytes (*1) (*2)
Operator name	Up to 63 bytes (*1) (*2)
Operator class name	Up to 63 bytes (*1) (*2)
Operator family name	Up to 63 bytes (*1) (*2)
Rewrite rule name	Up to 63 bytes (*1) (*2)
Sequence name	Up to 63 bytes (*1) (*2)
Text search settings name	Up to 63 bytes (*1) (*2)
Text search dictionary name	Up to 63 bytes (*1) (*2)
Text search parser name	Up to 63 bytes (*1) (*2)
Text search template name	Up to 63 bytes (*1) (*2)
Data type name	Up to 63 bytes (*1) (*2)
Enumerator type label	Up to 63 bytes (*1) (*2)

*1: This is the character string byte length when converted by the server character set character code.

*2: If an identifier that exceeds 63 bytes in length is specified, the excess characters are truncated and it is processed.

Table E.2 Database object

Item	Limit
Number of databases	Less than 4,294,967,296 (*1)

Item	Limit
Number of schemas	Less than 4,294,967,296 (*1)
Number of tables	Less than 4,294,967,296 (*1)
Number of views	Less than 4,294,967,296 (*1)
Number of indexes	Less than 4,294,967,296 (*1)
Number of table spaces	Less than 4,294,967,296 (*1)
Number of functions	Less than 4,294,967,296 (*1)
Number of aggregate functions	Less than 4,294,967,296 (*1)
Number of triggers	Less than 4,294,967,296 (*1)
Number of constraints	Less than 4,294,967,296 (*1)
Number of conversion	Less than 4,294,967,296 (*1)
Number of roles	Less than 4,294,967,296 (*1)
Number of casts	Less than 4,294,967,296 (*1)
Number of collation sequences	Less than 4,294,967,296 (*1)
Number of encoding method conversions	Less than 4,294,967,296 (*1)
Number of domains	Less than 4,294,967,296 (*1)
Number of extensions	Less than 4,294,967,296 (*1)
Number of operators	Less than 4,294,967,296 (*1)
Number of operator classes	Less than 4,294,967,296 (*1)
Number of operator families	Less than 4,294,967,296 (*1)
Number of rewrite rules	Less than 4,294,967,296 (*1)
Number of sequences	Less than 4,294,967,296 (*1)
Number of text search settings	Less than 4,294,967,296 (*1)
Number of text search dictionaries	Less than 4,294,967,296 (*1)
Number of text search parsers	Less than 4,294,967,296 (*1)
Number of text search templates	Less than 4,294,967,296 (*1)
Number of data types	Less than 4,294,967,296 (*1)
Number of enumerator type labels	Less than 4,294,967,296 (*1)
Number of default access privileges defined in the ALTER DEFAULT PRIVILEGES statement	Less than 4,294,967,296 (*1)
Number of large objects	Less than 4,294,967,296 (*1)
Number of index access methods	Less than 4,294,967,296 (*1)

*1: The total number of all database objects must be less than 4,294,967,296.

Table E.3 Schema element

Item	Limit
Number of columns that can be defined in one table	From 250 to 1600 (according to the data type)
Table row length	Up to 400 gigabytes
Number of columns comprising a unique constraint	Up to 32 columns
Data length comprising a unique constraint	Less than 2,000 bytes (*1) (*2)

Item	Limit
Table size	Up to one terabyte
Search condition character string length in a trigger definition statement	Up to 800 megabytes (*1) (*2)
Item size	Up to 1 gigabyte

*1: Operation might proceed correctly even if operations are performed with a quantity outside the limits.

*2: This is the character string byte length when converted by the server character set character code.

Table E.4 Index

Item	Limit
Number of columns comprising a key (including VCI)	Up to 32 columns
Key length (other than VCI)	Less than 2,000 bytes (*1)

*1: This is the character string byte length when converted by the server character set character code.

Table E.5 Data types and attributes that can be handled

Item			Limit
Character	Data length		Data types and attributes that can be handled (*1)
	Specification length (*n*)		Up to 10,485,760 characters (*1)
Numeric	External decimal expression		Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point
	Internal binary expression	2 bytes	From -32,768 to 32,767
		4 bytes	From -2,147,483,648 to 2,147,483,647
		8 bytes	From -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807
	Internal decimal expression		Up to 13,1072 digits before the decimal point, and up to 16,383 digits after the decimal point
	Floating point expression	4 bytes	From -3.4E+38 to -7.1E-46, 0, or from 7.1E-46 to 3.4E+38
		8 bytes	From -1.7E+308 to -2.5E-324, 0, or from 2.5E-324 to 1.7E+308
bytea			Up to one gigabyte minus 53 bytes
Large object			Up to two gigabytes

*1: This is the character string byte length when converted by the server character set character code.

Table E.6 Function definition

Item	Limit
Number of arguments that can be specified	Up to 100
Number of variable names that can be specified in the declarations section	No limit

Item	Limit
Number of SQL statements or control statements that can be specified in a function processing implementation	No limit

Table E.7 Data operation statement

Item	Limit
Maximum number of connections for one process in an application (remote access)	4,000 connections
Number of expressions that can be specified in a selection list	Up to 1,664
Number of tables that can be specified in a FROM clause	No limit
Number of unique expressions that can be specified in a selection list/DISTINCT clause/ORDER BY clause/GROUP BY clause within one SELECT statement	Up to 1,664
Number of expressions that can be specified in a GROUP BY clause	No limit
Number of expressions that can be specified in an ORDER BY clause	No limit
Number of SELECT statements that can be specified in a UNION clause/INTERSECT clause/EXCEPT clause	Up to 4,000 (*1)
Number of nestings in joined tables that can be specified in one view	Up to 4,000 (*1)
Number of functions or operator expressions that can be specified in one expression	Up to 4,000 (*1)
Number of expressions that can be specified in one row constructor	Up to 1,664
Number of expressions that can be specified in an UPDATE statement SET clause	Up to 1,664
Number of expressions that can be specified in one row of a VALUES list	Up to 1,664
Number of expressions that can be specified in a RETURNING clause	Up to 1,664
Total expression length that can be specified in the argument list of one function specification	Up to 800 megabytes (*2)
Number of cursors that can be processed simultaneously by one session	No limit
Character string length of one SQL statement	Up to 800 megabytes (*1) (*3)
Number of input parameter specifications that can be specified in one dynamic SQL statement	No limit
Number of tokens that can be specified in one SQL statement	Up to 10,000
Number of values that can be specified as a list in a WHERE clause IN syntax	No limit
Number of expressions that can be specified in a USING clause	No limit
Number of JOINs that can be specified in a joined table	Up to 4,000 (*1)
Number of expressions that can be specified in COALESCE	No limit
Number of WHEN clauses that can be specified for CASE in a simple format or a searched format	No limit

Item	Limit
Data size per record that can be updated or inserted by one SQL statement	Up to one gigabyte minus 53 bytes
Number of objects that can share a lock simultaneously	Up to 256,000 (*1)

*1: Operation might proceed correctly even if operations are performed with a quantity outside the limits.

*2: The total number of all database objects must be less than 4,294,967,296.

*3: This is the character string byte length when converted by the server character set character code.

Table E.8 Data sizes

Item	Limit
Data size per record for input data files (COPY statement, psql command \copy meta command)	Up to 800 megabytes (*1)
Data size per record for output data files (COPY statement, psql command \copy meta command)	Up to 800 megabytes (*1)

*1: Operation might proceed correctly even if operations are performed with a quantity outside the limits.

Appendix F Reference

F.1 JDBC Driver

See

Refer to the Java API Reference for information on PostgreSQL JDBC driver.

F.2 ODBC Driver

F.2.1 List of Supported APIs

The following table shows the support status of APIs:

Function name	Support status
SQLAllocConnect	Y
SQLAllocEnv	Y
SQLAllocHandle	Y
SQLAllocStmt	Y
SQLBindCol	Y
SQLBindParameter	Y
SQLBindParam	Y
SQLBrowseConnect	Y
SQLBulkOperations	Y
SQLCancel	Y
SQLCancelHandle	N
SQLCloseCursor	Y
SQLColAttribute	Y

SQLTransact	Y

Y: Supported
N: Not supported

F.3 .NET Data Provider

There are the following ways to develop applications using Fujitsu Npgsql .NET Data Provider:

- Use the Fujitsu Npgsql.NET Data Provider API (classes and methods) directly.

  Fujitsu Npgsql .NET Data Provider is created based on the open source software Npgsql. Refer to the "Npgsql - .Net Data Provider for Postgresql" for information on the APIs:

  See

  Refer to the Installation and Setup Guide for Client for the version of Npgsql that Fujitsu Npgsql .NET Data Provider is based on.

- Use the API of the .NET System.Data.Common namespace

  It is possible to create applications that do not rely on a provider when you use the System.Data.Common namespace. Refer to the "Writing Provider-Independent Code in ADO.NET" in MSDN Library for information.

See

Refer to the Npgsql API Reference for information on Npgsql API classes and methods.

F.4 C Library (libpq)

See

Refer to "libpq - C Library" in "Client Interfaces" in the PostgreSQL Documentation.

F.5 Embedded SQL in C

See

Refer to "ECPG - Embedded SQL in C" in "Client Interfaces" in the PostgreSQL Documentation.

Appendix G DBMS_SQL Package

Describes the DBMS_SQL package.

"z" of SPz used in this appendix indicates the number at which the product is upgraded.

G.1 When using the DBMS_SQL package compatible with Fujitsu Enterprise Postgres 16 SPz or earlier

Note

The DBMS_SQL package for Fujitsu Enterprise Postgres 16 SPz and earlier is provided as a deprecated feature for compatibility reasons, and will not be supported in the future. Please check the support status in advance when upgrading your system in the future.

If you want to continue using applications that use the DBMS_SQL packages from Fujitsu Enterprise Postgres 16 SPz or earlier, after upgrading the product, you must run the following to change your environment to one that allows the DBMS_SQL packages from Fujitsu Enterprise Postgres 16 SPz or earlier to be used.

```
ALTER EXTENSION oracle_compatible UPDATE TO 'pgx4.12'
```

For information on how to update the extensions, Refer to "Notes on Upgrading Database Instances" in the Operations Guide.

G.2 How to Migrate Applications that Use the DBMS_SQL Package

Describes the procedure for migrating applications that use the DBMS_SQL package (hereinafter referred to as the old package) from Fujitsu Enterprise Postgres 16 SPz or earlier to the DBMS_SQL package (hereinafter referred to as the new package) provided in Fujitsu Enterprise Postgres 17. If the application migration is not completed, an error will occur when the application is executed due to differences in the interface.

G.2.1 Differences

All the functions from the old package are available in the new package, but due to differences in the definition of arguments, etc., it is necessary to change the calling method when executing each function. Below is an overview of the changes to each function. Note that all the names are the same.

Feature	Type in old package	Type in new package	Number of arguments	Other points to note
BIND_VARIABLE	function	procedure or function	different	
CLOSE_CURSOR	function	procedure	same	
COLUMN_VALUE	function	procedure or function	same	Be careful how you select columns
DEFINE_COLUMN	function	procedure	same	
EXECUTE	function	function	same	
FETCH_ROWS	function	function	same	
OPEN_CURSOR	function	function	different	
PARSE	function	procedure	different	

Due to the above differences, the following actions are required when migrating from the old package. For details, please refer to the modification method for each feature.

- Differences in types

  If the new calling method is a procedure, the following changes will be required:

How to call in old package	How to call in new package
perform *function name* Example: perform BIND_VARIABLE	Call *procedure name* Example: Call BIND_VARIABLE

  Also, if you want to use a function in a feature that provides both procedures and functions, you will need to change the function name.

How to call in old package	How to call in new package
perform *function name* Example: perform BIND_VARIABLE	perform *procedure name*_f Example: perform BIND_VARIABLE_f

- Differences in arguments

  There are optional arguments that can only be specified in the old package. If they are omitted, no action is required. If they are set, you will need to delete the argument or add alternative processing for that argument.

G.2.2 Correction Method

Describes how to modify each feature.

Note that <datatype> in the text indicates the data type listed in "G.3 DBMS_SQL Package for Fujitsu Enterprise Postgres 16 SPz and earlier".

BIND_VARIABLE

[Feature]

Binds a given value or set of values to a given variable in a cursor, based on the name of the variable in the statement.

[How to use]

	Type	Argument types
Old package	function	integer, text, <datatype> [, integer]
New package	procedure	integer, oracle.varchar2, "any"
	function (bind_variable_f)	

[Migrating to new package]

- The execution method needs to be turned into the procedure or function.
- If you are specifying the fourth argument, before using this function, use the LEFT function to cut out the second argument string so that it can be specified with the length of the fourth argument.

CLOSE_CURSOR

[Feature]

Closes the specified cursor and frees memory.

[How to use]

	Type	Argument types
Old package	function	integer
New package	procedure	integer

[Migrating to new package]

- The execution method needs to be turned into a procedure.

COLUMN_VALUE

[Feature]

The value of the cursor element at the specified position within the cursor is assigned to the variable specified in the third argument.

[How to use]

	Type	Argument types
Old package	function	integer, integer, INOUT <datatype>
New package	procedure	integer, integer, INOUT anyelement
	function (column_value_f)	

[Migrating to new package]

- The execution method needs to be turned into the procedure or function.
- If you need the length of the resulting string, after using this feature, add a process to get the length using the LENGTH function.
- You cannot obtain error codes (22001, 22002) for the processing results. You need to add processing depending on the type of error code you are judging.

[When you need to judge error code 22002]
It judges whether the result string is a NULL value or not.
In the new COLUMN_VALUE package, please either "change the judgment process for error code 22002 to the NULL value judgment process for the result string" or "perform a NULL value judgment on the result string in advance, and if it is a NULL value, set the error code 22002 yourself".

[When you need to judge error code 22001]
It judges whether the result string was truncated to the maximum string length previously specified in DEFINE_COLUMN. In addition, the maximum string length is the value of the fourth argument of DEFINE_COLUMN executed beforehand. Therefore, in order to obtain the same result as error code 22001 with the new package's COLUMN_VALUE, the following measures are required.

- Prepare a separate INTEGER type variable, set the value of the fourth argument of DEFINE_COLUMN to that variable, and omit the fourth argument.
- Compare the length of the result string with the saved maximum string length, and take either of the following measures: "If the length of the result string is greater, execute the judgment process for error code 22001" or "Set the error code 22001 yourself to make it possible to execute the subsequent error code judgment process"

Example) Below is an example of how to handle error code judgment process for NULL values and truncation at the maximum string length.

```
max_length INTEGER;
errcd INTEGER;
length INTEGER;

. . .

max_length := 10;
CALL DEFINE_COLUMN(v_cursor, 1, v_string_values1);

. . .

errcd := 0;
length := 0;
CALL COLUMN_VALUE(v_cursor, 1, v_string_values1);
```

```
-- Setting errcd
IF v_string_values1 IS NULL THEN
  errcd := 22002;
ELSE
  IF LENGTH(v_string_values1) > max_length THEN
    errcd := 22001;
    v_string_values1 := LEFT(v_string_values1, max_length);
  END IF;
END IF;

-- Setting length
length := LENGTH(v_string_values1);

IF errcd = 22001 THEN
  -- Handling errcd 22001

  . . .

END IF;

IF errcd = 22002 THEN
  -- Handling errcd 22002

  . . .

END IF;
```

DEFINE_COLUMN

[Feature]

Defines the columns to be selected from the given cursor.

[How to use]

	Type	Argument types
Old package	function	integer, integer, <datatype> [, integer]
New package	procedure	integer, integer, "any" [, integer]

[Migrating to new package]

- The execution method needs to be turned into a procedure.
- If the fourth argument is specified and the subsequent COLUMN_VALUE is used to determine whether the string has been truncated (error code: 22001), save the value in the fourth argument as an INTEGER variable and omit the fourth argument. For information on how COLUMN_VALUE works, refer to "COLUMN_VALUE".
- This feature must be executed for all columns specified in SELECT. If EXECUTE is executed with any columns missing or omitted, an error will occur.

Old package

You can get only some columns with DEFINE_COLUMN.

Example) To get the second column
SQL := 'SELECT id, data, val1 FROM test WHERE data=:x';
perform DBMS_SQL.DEFINE_COLUMN(CURSOR, 2, COL2, 10);

New package

Even if you only need some of the columns, you need to get all the columns with DEFINE_COLUMN. Therefore, please do one of the following:

Example 1) Execute DEFINE_COLUMN for all columns.
SQL := 'SELECT id, data, va1 FROM test WHERE data=:x';

call DBMS_SQL.DEFINE_COLUMN(CURSOR, 1, COL1, 10);
call DBMS_SQL.DEFINE_COLUMN(CURSOR, 2, COL2, 10);
call DBMS_SQL.DEFINE_COLUMN(CURSOR, 3, COL3, 10);

Example 2) Modify your SELECT statement to retrieve only the columns you need.
SQL := 'SELECT data FROM test WHERE data=:x';
call DBMS_SQL.DEFINE_COLUMN(CURSOR, 1, COL2, 10);

EXECUTE

[Feature]

Executes the specified cursor.

[How to use]

There is no difference.

FETCH_ROWS

[Feature]

Fetches rows from the given cursor.

[How to use]

There is no difference.

OPEN_CURSOR

[Feature]

Opens a new cursor.

[How to use]

	Type	Argument types
Old package	function	[integer]
New package	function	void

[Migrating to new package]

- The argument is not necessary, so if it is specified, delete it.

PARSE

[Feature]

Parses the specified statement in the specified cursor. All statements are parsed immediately. In addition, DDL statements are executed immediately when they are parsed.

[How to use]

	Type	Argument types
Old package	function	integer, text [, integer, text DEFAULT '', text DEFAULT '', Boolean DEFAULT false]
New package	procedure	integer, oracle.varchar2

[Migrating to new package]

- The execution method needs to be turned into a procedure.

Example) Programs in old packages

```
CREATE FUNCTION search_test(h_where text) RETURNS void AS $$
DECLARE
    str_sql     text;
```

```
    v_cur       INTEGER;
    v_smpid     INTEGER;
    v_smpnm     VARCHAR(20);
    v_addbuff   VARCHAR(20);
    v_smpage    INTEGER;
    errcd       INTEGER;
    length      INTEGER;
    ret         INTEGER;
BEGIN
    PERFORM DBMS_OUTPUT.SERVEROUTPUT(TRUE);
    str_sql    := 'SELECT smpid, smpnm FROM smp_tbl WHERE ' || h_where || ' ORDER BY smpid';
    v_smpid     := 0;
    v_smpnm     := '';
    v_smpage    := 0;

    v_cur := DBMS_SQL.OPEN_CURSOR();

    PERFORM DBMS_SQL.PARSE(v_cur, str_sql, 1);
    PERFORM DBMS_SQL.DEFINE_COLUMN(v_cur, 1, v_smpid);
    PERFORM DBMS_SQL.DEFINE_COLUMN(v_cur, 2, v_smpnm, 10);

    ret := DBMS_SQL.EXECUTE(v_cur);
    LOOP
        v_addbuff := '';

        IF DBMS_SQL.FETCH_ROWS(v_cur) = 0 THEN
            EXIT;
        END IF;

        PERFORM
DBMS_OUTPUT.PUT_LINE('-------------------------------------------------------');
        SELECT value,column_error,actual_length
          INTO v_smpid, errcd, length
          FROM DBMS_SQL.COLUMN_VALUE(v_cur,
                                     1,
                                     v_smpid);
        IF errcd = 22002 THEN
          PERFORM DBMS_OUTPUT.PUT_LINE('smpid       = (NULL)');
        ELSE
          PERFORM DBMS_OUTPUT.PUT_LINE('smpid       = ' || v_smpid);
        END IF;

        SELECT value,column_error,actual_length INTO v_smpnm, errcd, length FROM
DBMS_SQL.COLUMN_VALUE(v_cur, 2, v_smpnm);
        IF errcd = 22001 THEN
          v_addbuff := '... [len=' || length || ']';
        END IF;
        IF errcd = 22002 THEN
          PERFORM DBMS_OUTPUT.PUT_LINE('v_smpnm     = (NULL)');
        ELSE
          PERFORM DBMS_OUTPUT.PUT_LINE('v_smpnm     = ' || v_smpnm || v_addbuff );
        END IF;

        PERFORM
DBMS_OUTPUT.PUT_LINE('-------------------------------------------------------');
        PERFORM DBMS_OUTPUT.NEW_LINE();
    END LOOP;

    v_cur := DBMS_SQL.CLOSE_CURSOR(v_cur);
    RETURN;
END;
```

```
$$
LANGUAGE plpgsql;
```

Example) Programs after migration to new packaging
The corrections are in red.

```
CREATE FUNCTION search_test(h_where text) RETURNS void AS $$
DECLARE
    str_sql     text;

    v_cur       INTEGER;
    v_smpid     INTEGER;
    v_smpnm     VARCHAR(20);
    v_smpnm_max_length    INTEGER;
    v_addbuff   VARCHAR(20);
    v_smpage    INTEGER;
    errcd       INTEGER;
    length      INTEGER;
    ret         INTEGER;
BEGIN
    PERFORM DBMS_OUTPUT.SERVEROUTPUT(TRUE);
   str_sql    := 'SELECT smpid, smpnm FROM smp_tbl WHERE ' || h_where || ' ORDER BY smpid';
    v_smpid     := 0;
    v_smpnm     := '';
    v_smpage    := 0;

    v_cur := DBMS_SQL.OPEN_CURSOR();

    CALL DBMS_SQL.PARSE(v_cur, str_sql);
    CALL DBMS_SQL.DEFINE_COLUMN(v_cur, 1, v_smpid);
    CALL DBMS_SQL.DEFINE_COLUMN(v_cur, 2, v_smpnm);
    v_smpnm_max_length := 10;

    ret := DBMS_SQL.EXECUTE(v_cur);
    LOOP
        v_addbuff := '';

        IF DBMS_SQL.FETCH_ROWS(v_cur) = 0 THEN
            EXIT;
        END IF;

        PERFORM
DBMS_OUTPUT.PUT_LINE('-------------------------------------------------------');

        errcd := 0;
        length := 0;
        CALL DBMS_SQL.COLUMN_VALUE(v_cur, 1, v_smpid);

        IF v_smpid IS NULL THEN
          errcd := 22002;
        END IF;

        IF errcd = 22002 THEN
          PERFORM DBMS_OUTPUT.PUT_LINE('smpid       = (NULL)');
        ELSE
          PERFORM DBMS_OUTPUT.PUT_LINE('smpid       = ' || v_smpid);
        END IF;

        CALL DBMS_SQL.COLUMN_VALUE(v_cur, 2, v_smpnm);

        errcd := 0;
```

```
        length := 0;
        IF v_smpnm IS NULL THEN
          errcd := 22002;
        ELSE;
          length := LENGTH(v_smpnm);
          IF length > v_smpnm_max_length THEN
             errcd := 22001;
             length := v_smpnm_max_length;
             v_smpnm := LEFT(v_smpnm, v_smpnm_max_length);
          END IF;
        END IF;

        IF errcd = 22001 THEN
          v_addbuff := '... [len=' || length || ']';
        END IF;
        IF errcd = 22002 THEN
          PERFORM DBMS_OUTPUT.PUT_LINE('v_smpnm     = (NULL)');
        ELSE
          PERFORM DBMS_OUTPUT.PUT_LINE('v_smpnm     = ' || v_smpnm || v_addbuff );
        END IF;

        PERFORM
DBMS_OUTPUT.PUT_LINE('------------------------------------------------------------');
        PERFORM DBMS_OUTPUT.NEW_LINE();
    END LOOP;

    CALL DBMS_SQL.CLOSE_CURSOR(v_cur);
    v_cur := NULL;
    RETURN;
END;
$$
LANGUAGE plpgsql;
```

G.3 DBMS_SQL Package for Fujitsu Enterprise Postgres 16 SPz and earlier

Describes the DBMS_SQL package that was provided prior to Fujitsu Enterprise Postgres 16 SPz.

The interface described here is a compatibility interface for applications prior to Fujitsu Enterprise Postgres 16 SPz. As it will no longer be supported in the future, do not use it for any purpose other than application compatibility.

Feature	Description
BIND_VARIABLE	Sets values in the host variable within the SQL statement.
CLOSE_CURSOR	Closes the cursor.
COLUMN_VALUE	Retrieves the value of the column in the select list extracted with FETCH_ROWS.
DEFINE_COLUMN	Defines the column from which values are extracted and the storage destination.
EXECUTE	Executes SQL statements.
FETCH_ROWS	Positions the specified cursor at the next row and extracts values from the row.
OPEN_CURSOR	Opens a new cursor.
PARSE	Parses SQL statements.

Note

- In DBMS_SQL, the data types supported in dynamic SQL are limited, and therefore the user must consider this. The supported data types are:
  - INTEGER
  - DECIMAL
  - NUMERIC
  - REAL
  - DOUBLE PRECISION
  - CHAR(*1)
  - VARCHAR(*1)
  - NCHAR(*1)
  - NCHAR VARYING(*1)
  - TEXT
  - DATE
  - TIMESTAMP WITHOUT TIME ZONE
  - TIMESTAMP WITH TIME ZONE
  - INTERVAL(*2)
  - SMALLINT
  - BIGINT

  *1:
  The host variables with CHAR, VARCHAR, NCHAR, and NCHAR VARYING data types are treated as TEXT, to match the string function arguments and return values. Refer to "String Functions and Operators" in "Functions and Operators" in "The SQL Language" in the PostgreSQL Documentation for information on string functions.
  When specifying the arguments of the features compatible with Oracle databases NVL and/or DECODE, use CAST to convert the data types of the host variables to ensure that data types between arguments are the same.

  *2:
  When using COLUMN_VALUE to obtain an INTERVAL type value specified in the select list, use an INTERVAL type variable with a wide range such as when no interval qualifier is specified, or with a range that matches that of the variable in the select list. If an interval qualifier variable with a narrow range is specified, then the value within the interval qualifier range will be obtained, but an error that the values outside the range have been truncated will not occur.

Example

This example illustrates where a value expression that returns an INTERVAL value is set in the select list and the result is received with COLUMN_VALUE. Note that the SQL statement operation result returns a value within the INTERVAL DAY TO SECOND range.

[Bad example]

Values of MINUTE, and those after MINUTE, are truncated, because the variable(v_interval) is INTERVAL DAY TO HOUR.

```
    v_interval     INTERVAL DAY TO HOUR;
...
    PERFORM DBMS_SQL.PARSE(cursor, 'SELECT CURRENT_TIMESTAMP - ''2010-01-01'' FROM
DUAL', 1);
...
```

```
    SELECT value INTO v_interval FROM DBMS_SQL.COLUMN_VALUE(cursor, 1, v_interval);
    result:1324 days 09:00:00
```

[Good example]

By ensuring that the variable(v_interval) is INTERVAL, the values are received correctly.

```
    v_interval     INTERVAL;
...
    PERFORM DBMS_SQL.PARSE(cursor, 'SELECT CURRENT_TIMESTAMP - ''2010-01-01'' FROM
DUAL', 1);
...
    SELECT value INTO v_interval FROM DBMS_SQL.COLUMN_VALUE(cursor, 1, v_interval);
    result:1324 days 09:04:37.530623
```

Syntax

```
{ BIND_VARIABLE(cursor, varName, val [, len ])
| CLOSE_CURSOR(cursor)
| COLUMN_VALUE(cursor, colPos, varName)
| DEFINE_COLUMN(cursor, colPos, varName [, len ])
| EXECUTE(cursor)
| FETCH_ROWS(cursor)
| OPEN_CURSOR([parm1 ])
| PARSE(cursor, sqlStmt, parm1 [, parm2, parm3, parm4 ])
}
```

G.3.1 Description

This section explains each feature of DBMS_SQL.

BIND_VARIABLE

- BIND_VARIABLE sets values in the host variable within the SQL statement.
- Specify the cursor number to be processed.
- Specify the name of the host variable within the SQL statement using a string for the host variable name.
- Specify the value set in the host variable. The data type of the host variable is the same as that of the value expression - it is implicitly converted in accordance with its position within the SQL statement. Refer to "A.3 Implicit Data Type Conversions" for information on implicit conversions.
- If the value is a character type, the string length is the number of characters. If the string length is not specified, the size is the total length of the string.
- It is necessary to place a colon at the beginning of the host variable in SQL statements to identify the host variable. The colon does not have to be added to the host variable names specified at BIND_VARIABLE. The following shows examples of host variable names specified with SQL statements and host variable names specified with BIND_VARIABLE:

```
PERFORM DBMS_SQL.PARSE(cursor, 'SELECT emp_name FROM emp WHERE sal > :x', 1);
```

In this example, BIND_VARIABLE will be as follows:

```
PERFORM DBMS_SQL.BIND_VARIABLE(cursor, ':x', 3500);
```

Or,

```
PERFORM DBMS_SQL.BIND_VARIABLE(cursor, 'x', 3500);
```

- The length of the host variable name can be up to 30 bytes (excluding colons).

- If the data type of the set value is string, specify the effective size of the column value as the fourth argument.

Example

If the data type of the value to be set is not a string:

```
PERFORM DBMS_SQL.BIND_VARIABLE(cursor, ':NO', 1);
```

If the data type of the value to be set is a string:

```
PERFORM DBMS_SQL.BIND_VARIABLE(cursor, ':NAME', h_memid, 5);
```

CLOSE_CURSOR

- CLOSE_CURSOR closes the cursor.
- Specify the cursor number to be processed.
- The value returned is a NULL value.

Example

```
cursor := DBMS_SQL.CLOSE_CURSOR(cursor);
```

COLUMN_VALUE

- COLUMN_VALUE retrieves the value of the column in the select list extracted with FETCH_ROWS.
- Specify the cursor number to be processed.
- Specify the position of the column of the select list in the SELECT statement. The position of the first column is 1.
- Specify the destination variable name.
- Use a SELECT statement to obtain the values of the value, column_error, and actual_length columns.
- The value column returns the value of the column specified at the column position. The data type of the variable name must match that of the column. If the data type of the column in the SELECT statement specified in PARSE is not compatible with DBMS_SQL, use CAST to convert to a compatible data type.
- The data type of the column_error column is NUMERIC. If the column value could not be set correctly in the value column, a value other than 0 will be returned:
  22001: The extracted string has been truncated
  22002: The extracted value contains a NULL value
- The data type of the actual_length column is INTEGER. If the extracted value is a character type, the number of characters will be returned (if the value was truncated, the number of characters prior to the truncation will be returned), otherwise, the number of bytes will be returned.

Example

When retrieving the value of the column, the error code, and the actual length of the column value:

```
SELECT value, column_error, actual_length INTO v_memid, v_col_err, v_act_len FROM
DBMS_SQL.COLUMN_VALUE(cursor, 1, v_memid);
```

When retrieving just the value of the column:

```
SELECT value INTO v_memid FROM DBMS_SQL.COLUMN_VALUE(cursor, 1, v_memid);
```

DEFINE_COLUMN

- DEFINE_COLUMN defines the column from which values are extracted and the storage destination.
- Specify the cursor number to be processed.
- Specify the position of the column in the select list in the SELECT statement. The position of the first column is 1.
- Specify the destination variable name. The data type should be match with the data type of the column from which the value is to be extracted. If the data type of the column in the SELECT statement specified in PARSE is not compatible with DBMS_SQL, use CAST to convert to a compatible data type.
- Specify the maximum number of characters of character type column values.
- If the data type of the column value is string, specify the effective size of the column value as the fourth argument.

Example

When the data type of the column value is not a string:

```
PERFORM DBMS_SQL.DEFINE_COLUMN(cursor, 1, v_memid);
```

When the data type of the column value is a string:

```
PERFORM DBMS_SQL.DEFINE_COLUMN(cursor, 1, v_memid, 10);
```

EXECUTE

- EXECUTE executes SQL statements.
- Specify the cursor number to be processed.
- The return value is an INTEGER type, is valid only with INSERT statement, UPDATE statement, and DELETE statement, and is the number of rows processed. Anything else is invalid.

Example

```
ret := DBMS_SQL.EXECUTE(cursor);
```

FETCH_ROWS

- FETCH_ROWS positions at the next row and extracts values from the row.
- Specify the cursor number to be processed.
- The return value is an INTEGER type and is the number of rows extracted. 0 is returned if all are extracted.
- The extracted information is retrieved with COLUMN_VALUE.

Example

```
LOOP
    IF DBMS_SQL.FETCH_ROWS(cursor) = 0 THEN
        EXIT;
    END IF;
```

```
...

END LOOP;
```

OPEN_CURSOR

- OPEN_CURSOR opens a new cursor.
- The parameter is used for compatibility with Oracle databases only, and is ignored by Fujitsu Enterprise Postgres. An INTEGER type can be specified, but it will be ignored. If migrating from an Oracle database, specify 1.
- Close unnecessary cursors by executing CLOSE_CURSOR.
- The return value is an INTEGER type and is the cursor number.

Example

```
cursor := DBMS_SQL.OPEN_CURSOR();
```

PARSE

- PARSE analyzes dynamic SQL statements.
- Specify the cursor number to be processed.
- Specify the SQL statement to be parsed.
- Parameters 1, 2, 3, and 4 are used for compatibility with Oracle databases only, and are ignored by Fujitsu Enterprise Postgres. If you are specifying values anyway, specify the following:
  - Parameter 1 is an INTEGER type. Specify 1.
  - Parameters 2 and 3 are TEXT types. Specify NULL.
  - Parameter 4 is a BOOLEAN type. Specify TRUE.

  If migrating from an Oracle database, the specified values for parameters 2, 3, and 4 do not need to be changed.
- Add a colon to the beginning of host variables in SQL statements.
- The DDL statement is executed when PARSE is issued. EXECUTE is not required for the DDL statement.
- If PARSE is called again for opened cursors, the content in the data regions within the cursors is reset, and the SQL statement is parsed anew.

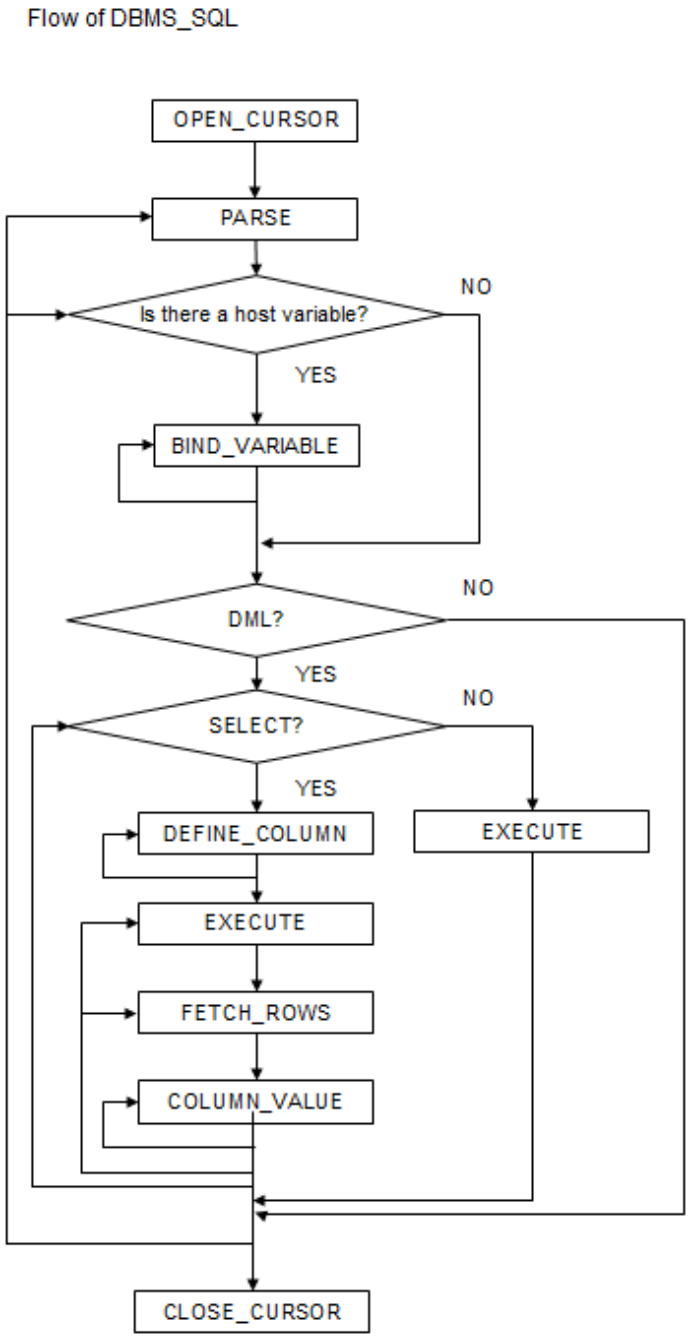
Example

```
PERFORM DBMS_SQL.PARSE(cursor, 'SELECT memid, memnm FROM member WHERE memid = :NO', 1);
```

G.3.2 Example

This section explains the flow of DBMS_SQL and provides an example.

Flow of DBMS_SQL



Example

```
CREATE FUNCTION smp_00()
RETURNS INTEGER
AS $$
DECLARE
    str_sql     VARCHAR(255);
    cursor      INTEGER;
    h_smpid     INTEGER;
    v_smpid     INTEGER;
    v_smpnm     VARCHAR(20);
    v_smpage    INTEGER;
    errcd       INTEGER;
```

```
    length      INTEGER;
    ret         INTEGER;
BEGIN
   str_sql    := 'SELECT smpid, smpnm, smpage FROM smp_tbl WHERE smpid < :H_SMPID ORDER BY
smpid';
    h_smpid     := 3;
    v_smpid     := 0;
    v_smpnm     := '';

FUJITSU

Fujitsu Enterprise Postgres 18SP1 for x86

Operation Guide

Windows/Linux

March-2026

FUJITSU

Fujitsu Enterprise Postgres 18SP1 for x86

Operation Guide

Linux

J2UL-3057-02ENZ0(00)

March-2026

Preface

Purpose of this document

The Fujitsu Enterprise Postgres database system extends the PostgreSQL features and runs on the Linux platform.

This document is the Fujitsu Enterprise Postgres Operation Guide.

Intended readers

This document is intended for those who install and operate Fujitsu Enterprise Postgres.

Readers of this document are assumed to have general knowledge of:

- PostgreSQL
- SQL
- Linux

Structure of this document

This document is structured as follows:

Chapter 1 Operating Fujitsu Enterprise Postgres

Describes how to operate Fujitsu Enterprise Postgres.

Chapter 2 Starting an Instance and Creating a Database

Describes how to start a Fujitsu Enterprise Postgres instance, and how to create a database.

Chapter 3 Backing Up the Database

Describes how to back up the database.

Chapter 4 Configuring Secure Communication Using Secure Sockets Layer

Describes communication data encryption between the client and the server.

Chapter 5 Protecting Storage Data Using Transparent Data Encryption

Describes how to encrypt the data to be stored in the database.

Chapter 6 Using Transparent Data Encryption with Key Management Systems as Keystores

Describes the operation of transparent data encryption when a key management system is used as a keystore.

Chapter 7 Policy-based Login Security

Describes how to apply login security policies to users.

Chapter 8 Data Masking

Describes the data masking feature.

Chapter 9 Periodic Operations

Describes the periodic database operations that must be performed on Fujitsu Enterprise Postgres.

Chapter 10 Building a Cluster System Using Patroni

Describes how to build a cluster system using Patroni.

Chapter 11 Autoscale of Replica Servers through Amazon EC2 Auto Scaling Integration

Describes the autoscale of replica servers through Amazon EC2 Auto Scaling Integration.

Chapter 12 Streaming Replication Using WebAdmin

Describes how to create a streaming replication cluster using WebAdmin.

Chapter 13 Installing and Operating the In-memory Feature

Describes how to install and operate the in-memory feature.

Chapter 14 Parallel Query

Describes the factors taken into consideration by Fujitsu Enterprise Postgres when performing parallel queries.

Chapter 15 High-Speed Data Load

Describes how to install and operate high-speed data load.

Chapter 16 Global Meta Cache

Describes how to use Grobal Meta Cache feature.

Chapter 17 Local Meta Cache Limit

Describes how to use Local Meta Cache Limit feature.

Chapter 18 Backup/Recovery Using the Copy Command

Describes backup and recovery using the copy command created by the user.

Chapter 19 Actions when an Error Occurs

Describes how to perform recovery when disk failure or data corruption occurs.

Appendix A Parameters

Describes the Fujitsu Enterprise Postgres parameters.

Appendix B System Administration Functions

Describes the system administration functions of Fujitsu Enterprise Postgres.

Appendix C System Catalogs

Describes the system catalog used by Fujitsu Enterprise Postgres.

Appendix D System Views

Describes the system view used by Fujitsu Enterprise Postgres.

Appendix E Tables Used by Transparent Data Encryption

Describes the tables used by the transparent data encryption feature.

Appendix F Tables Used by Data Masking

Describes the tables used by the data masking feature.

Appendix G Tables Used by Aggressive Freeze for Tuples

Describes the tables used by the agressive freeze for tuples.

Appendix H Tables Used by High-Speed Data Load

Describes the tables used by high-speed data load.

Appendix I Starting and Stopping the Web Server Feature of WebAdmin

Describes how to start and stop WebAdmin (Web server feature).

Appendix J WebAdmin Wallet

Describes how to use the Wallet feature of WebAdmin.

Appendix K WebAdmin Disallow User Inputs Containing Hazardous Characters

Describes characters not allowed in WebAdmin.

Appendix L Copy Command Samples that Use the Advanced Copy Feature of the ETERNUS Disk Array

Describes copy command samples that use the advanced copy feature of the ETERNUS disk array.

Appendix M Collecting Failure Investigation Data

Describes how to collect information for initial investigation.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Chapter 1 Operating Fujitsu Enterprise Postgres....1
1.1 Operating Methods....1
1.2 Starting WebAdmin....2
1.2.1 Logging in to WebAdmin....2
1.3 Starting pgAdmin....3
1.3.1 Starting pgAdmin....3
1.3.2 Adding an Instance....3
1.3.3 Connecting/Disconnecting an Instance....4
1.3.4 Changing the pgAdmin Display Language....5
1.4 Operations Using Commands....5
1.5 Operating Environment of Fujitsu Enterprise Postgres....6
1.5.1 Operating Environment....6
1.5.2 File Composition....8
1.5.3 Precautions when Using Antivirus Software....8
1.6 Notes on Compatibility of Applications Used for Operations....9
1.7 Notes on Upgrading Database Instances....9
1.7.1 Additional Steps for upgrading to Fujitsu Enterprise Postgres with Vertical Clustered Index (VCI) Enabled....10
1.7.2 Additional Steps to upgrading to Fujitsu Enterprise Postgres with Transparent Data Encryption (TDE) Enabled....11

Chapter 2 Starting an Instance and Creating a Database....12
2.1 Starting and Stopping an Instance....12
2.1.1 Using WebAdmin....12
2.1.2 Using Server Commands....13
2.2 Creating a Database....15
2.2.1 Using pgAdmin....15
2.2.2 Using Client Commands....15

Chapter 3 Backing Up the Database....16
3.1 Periodic Backup....18
3.2 Backup Methods....18
3.2.1 Using WebAdmin....18
3.2.2 Using Server Commands....18

Chapter 4 Configuring Secure Communication Using Secure Sockets Layer....22
4.1 Configuring Communication Data Encryption....22
4.1.1 Issuing a Certificate....23
4.1.2 Deploying a Server Certificate File and a Server Private Key File....23
4.1.3 Distributing a CA Certificate File to the Client....23
4.1.4 Configuring the Operating Environment for the Database Server....23
4.1.5 Configuring the Operating Environment for the Client....23
4.1.6 Performing Database Multiplexing....24

Chapter 5 Protecting Storage Data Using Transparent Data Encryption....25
5.1 Protecting Data Using Encryption....25
5.2 Setting the Master Encryption Key....26
5.3 Opening the Keystore....27
5.4 Encrypting a Tablespace....27
5.5 Checking an Encrypted Tablespace....28
5.6 Managing the Keystore....29
5.6.1 Changing the Master Encryption Key....29
5.6.2 Changing the Keystore Passphrase....29
5.6.3 Enabling Automatic Opening of the Keystore....30
5.6.4 Backing Up and Recovering the Keystore....30
5.7 Backing Up and Restoring/Recovering the Database....32
5.8 Importing and Exporting the Database....34
5.9 Encrypting Existing Data....34

5.10 Operations in Cluster Systems....34
5.10.1 HA Clusters that do not Use Database Multiplexing....35
5.10.2 Database Multiplexing Mode....35
5.11 Security-Related Notes....36
5.12 Tips for Installing Built Applications....37

Chapter 6 Using Transparent Data Encryption with Key Management Systems as Keystores....38
6.1 Protecting Data Using Encryption....38
6.2 Setting the Master Encryption Key....40
6.3 Opening the Keystore....41
6.4 Encrypting a Tablespace....41
6.5 Checking an Encrypted Tablespace....42
6.6 Managing the Keystore....42
6.6.1 Changing the Master Encryption Key....42
6.6.2 Enabling Automatic Opening of the Keystore....42
6.6.3 Changing Credentials for Key Management Systems....42
6.6.4 Verifying the Master Encryption Key....42
6.6.5 Changes to the Key Management System....43
6.7 Backing Up and Restoring/Recovering the Database....43
6.8 Importing and Exporting the Database....44
6.9 Encrypting Existing Data....45
6.10 Operations in Cluster Systems....45
6.10.1 HA Clusters that do not Use Database Multiplexing....45
6.10.2 Database Multiplexing Mode....45
6.11 Security-Related Notes....46
6.12 Tips for Installing Built Applications....46
6.13 Reference Information for Linking Key Management Systems Using Sample Plugins....46

Chapter 7 Policy-based Login Security....48
7.1 Advance Preparation....48
7.2 Changing the Contents of the default Profile....48
7.3 Creating and Assigning Profiles....49
7.4 Actions to be Taken in the Event of Deviation from Policy....49
7.5 Settings in Streaming Replication Configuration....50
7.6 Backup and Recovery....50
7.7 Profile parameters....51
7.8 Worker Processes....54

Chapter 8 Data Masking....55
8.1 Masking Policy....55
8.1.1 Masking Target....55
8.1.2 Masking Type....56
8.1.3 Masking Condition....56
8.1.4 Masking Format....56
8.2 Usage Method....59
8.2.1 Creating a Masking Policy....60
8.2.2 Changing a Masking Policy....60
8.2.3 Confirming a Masking Policy....61
8.2.4 Enabling and Disabling a Masking Policy....61
8.2.5 Deleting a Masking Policy....62
8.3 Data Types for Masking....63
8.4 Security Notes....63

Chapter 9 Periodic Operations....64
9.1 Configuring and Monitoring the Log....64
9.2 Monitoring Disk Usage and Securing Free Space....64
9.2.1 Monitoring Disk Usage....64
9.2.2 Securing Free Disk Space....65

9.3 Automatically Closing Connections ... 65
9.4 Monitoring the Connection State of an Application ... 65
9.4.1 Using the View (pg_stat_activity) ... 66
9.4.2 Using pgAdmin ... 67
9.5 Reorganizing Indexes ... 67
9.6 Monitoring Database Activity ... 68
9.6.1 Information that can be Collected ... 69
9.6.2 Collection Configuration ... 70
9.6.3 Information Reset ... 70
9.7 Scheduling of an Aggressive Freeze for Tuples (VACUUM FREEZE) ... 71
9.7.1 Monitoring Trends in Transaction ID Usage ... 71
9.7.2 How to Schedule Aggressive Freeze for Tuples ... 72
9.7.3 Tuning the Allocation Time for Aggressive Freeze for Tuples ... 72
9.8 Database Monitoring with Amazon CloudWatch ... 73
9.8.1 Metrics Collection ... 73
9.8.2 Log Collection ... 74
9.8.3 Metrics Collected by the Sample Script ... 74
9.9 Monitoring Deferred SQL and Periodically Backing up statistics ... 75
9.10 Performance Tuning ... 79
9.10.1 Enhanced Query Plan Stability ... 79
9.10.1.1 Fixing the Height of a Btree Index ... 79

Chapter 10 Building a Cluster System Using Patroni ... 81

Chapter 11 Autoscale of Replica Servers through Amazon EC2 Auto Scaling Integration ... 82
11.1 Autoscale Setup ... 82
11.1.1 Building a Cluster System ... 82
11.1.1.1 Preparation ... 82
11.1.1.2 Building a Cluster System Using a Mirroring Controller ... 83
11.1.1.3 Acquiring Snapshots to Restore Data when Deploying Replica Servers ... 83
11.1.1.4 Settings for Name Resolution of the Standby Server, which will be the Replica Source Server ... 84
11.1.2 Building a Replica Server ... 84
11.1.2.1 Installation of Fujitsu Enterprise Postgres on EC2 ... 84
11.1.2.2 Creation of Startup Script for Replica Server Deployment ... 85
11.1.2.3 Volume Mount Definition ... 87
11.1.2.4 Creation of AMI for Replica Server ... 87
11.1.3 Enable Autoscale ... 87
11.1.4 Preparation for Scale in ... 88
11.2 Operations for Autoscale ... 89
11.2.1 Customizing Scaling Policies ... 89
11.2.2 Scale in of Replica Servers ... 91
11.2.3 Switching/Failback of the Cascade Replication Source for the Replica Server ... 91
11.2.4 Updating an Existing AMI ... 92
11.2.5 Storage Scale up ... 92
11.2.6 Backup/Restore ... 95

Chapter 12 Streaming Replication Using WebAdmin ... 96
12.1 Creating a Standby Instance ... 96
12.2 Promoting a Standby Instance ... 97
12.3 Converting an Asynchronous Replication to Synchronous ... 97
12.4 Converting a Synchronous Replication to Asynchronous ... 98
12.5 Joining a Replication Cluster ... 98

Chapter 13 Installing and Operating the In-memory Feature ... 100
13.1 Installing Vertical Clustered Index (VCI) ... 100
13.1.1 Evaluating whether to Install VCI ... 100
13.1.2 Estimating Resources ... 101
13.1.3 Setting up ... 101

13.1.3.1 Setting Parameters ... 101
13.1.3.2 Installing the Extensions ... 102
13.1.3.3 Creating a VCI ... 102
13.1.3.4 Confirming that the VCI has been Created ... 103
13.1.4 Data that can Use VCI ... 103
13.1.4.1 Relation Types ... 103
13.1.4.2 Data Types ... 104
13.2 Operating VCI ... 105
13.2.1 Commands that cannot be Used for VCI ... 105
13.2.2 Data Preload Feature ... 107

Chapter 14 Parallel Query ... 108
14.1 CPU Load Calculation ... 108
14.2 Increase of Workers during Runtime ... 108
14.3 Statistics View Displays the Action State ... 108

Chapter 15 High-Speed Data Load ... 110
15.1 Installing High-Speed Data Load ... 110
15.1.1 Deciding whether to Install ... 110
15.1.2 Estimating Resources ... 110
15.1.3 Setup ... 111
15.1.3.1 Setting Parameters ... 111
15.1.3.2 Installing the Extension ... 112
15.2 Using High-Speed Data Load ... 112
15.2.1 Loading Data ... 112
15.2.2 Checking Progress ... 113
15.2.3 Recovering from a Data Load that Ended Abnormally ... 114
15.3 Removing High-Speed Data Load ... 115
15.3.1 Removing the Extension ... 115

Chapter 16 Global Meta Cache ... 116
16.1 Usage ... 116
16.1.1 Deciding Whether to Enable the Global Meta Cache Feature ... 116
16.1.2 Estimating Memory for Global Meta Cache ... 116
16.1.3 How the GMC Memory Area Is Used ... 116
16.1.4 Enabling the Global Meta Cache Feature ... 116
16.1.5 Estimating Resources ... 117
16.2 Statistics ... 117
16.2.1 System View ... 117

Chapter 17 Local Meta Cache Limit ... 118
17.1 Usage ... 118
17.1.1 Deciding Whether to Enable the Local Meta Cache Limit Feature ... 118
17.1.2 How to Set Parameters for the Local Meta Cache Limit Feature ... 118
17.1.3 Cache Removal when Local Meta Cache Limit is Enabled ... 118
17.1.4 Performance Impact and Parameter Tuning of the Local Meta Cache Limit Feature ... 119

Chapter 18 Backup/Recovery Using the Copy Command ... 121
18.1 Configuration of the Copy Command ... 121
18.2 Backup Using the Copy Command ... 124
18.3 Recovery Using the Copy Command ... 125
18.4 Copy Command Interface ... 126
18.4.1 Copy Command for Backup ... 126
18.4.2 Copy Command for Recovery ... 128

Chapter 19 Actions when an Error Occurs ... 130
19.1 Recovering from Disk Failure (Hardware) ... 131
19.1.1 Using WebAdmin ... 131
19.1.2 Using Server Command ... 132

19.2 Recovering from Data Corruption ... 136
19.2.1 Using WebAdmin ... 137
19.2.2 Using the pgx_rcvall Command ... 137
19.3 Recovering from an Incorrect User Operation ... 138
19.3.1 Using WebAdmin ... 138
19.3.2 Using the pgx_rcvall Command ... 139
19.4 Actions in Response to an Application Error ... 140
19.4.1 When using the view (pg_stat_activity) ... 141
19.4.2 Using the ps Command ... 141
19.4.3 Using pgAdmin ... 142
19.5 Actions in Response to an Access Error ... 142
19.6 Actions in Response to Insufficient Space on the Data Storage Destination ... 143
19.6.1 Using a Tablespace ... 143
19.6.2 Replacing the Disk with a Larger Capacity Disk ... 143
19.6.2.1 Using WebAdmin ... 144
19.6.2.2 Using Server Commands ... 144
19.7 Actions in Response to Insufficient Space on the Backup Data Storage Destination ... 146
19.7.1 Temporarily Saving Backup Data ... 146
19.7.1.1 Using WebAdmin ... 146
19.7.1.2 Using Server Commands ... 146
19.7.2 Replacing the Disk with a Larger Capacity Disk ... 149
19.7.2.1 Using WebAdmin ... 149
19.7.2.2 Using Server Commands ... 150
19.8 Actions in Response to Insufficient Space on the Transaction Log Storage Destination ... 154
19.8.1 Replacing the Disk with a Larger Capacity Disk ... 154
19.8.1.1 Using WebAdmin ... 154
19.8.1.2 Using Server Commands ... 155
19.9 Errors in More Than One Storage Disk ... 157
19.10 Actions in Response to Instance Startup Failure ... 157
19.10.1 Errors in the Configuration File ... 157
19.10.2 Errors Caused by Power Failure or Mounting Issues ... 157
19.10.3 Other Errors ... 157
19.10.3.1 Using WebAdmin ... 158
19.10.3.2 Using Server Commands ... 158
19.11 Actions in Response to Failure to Stop an Instance ... 158
19.11.1 Using WebAdmin ... 158
19.11.2 Using Server Commands ... 158
19.11.2.1 Stopping the Instance Using the Fast Mode ... 159
19.11.2.2 Stopping the Instance Using the Immediate Mode ... 159
19.11.2.3 Forcibly Stopping the Server Process ... 159
19.12 Actions in Response to Failure to Create a Streaming Replication Standby Instance ... 160
19.13 Actions in Response to Error in a Distributed Transaction ... 160
19.14 I/O Errors Other than Disk Failure ... 161
19.14.1 Network Error with an External Disk ... 161
19.14.2 Errors Caused by Power Failure or Mounting Issues ... 162
19.15 Anomaly Detection and Resolution ... 162
19.15.1 Port Number and Backup Storage Path Anomalies ... 162
19.15.2 Mirroring Controller Anomalies ... 163

Appendix A Parameters ... 164

Appendix B System Administration Functions ... 174
B.1 WAL Mirroring Control Functions ... 174
B.2 Transparent Data Encryption Control Functions ... 174
B.2.1 pgx_open_keystore ... 174
B.2.2 pgx_set_master_key ... 175
B.2.3 pgx_declare_external_master_key ... 175
B.2.4 pgx_set_keystore_passphrase ... 176

B.3 Profile Management Functions and User Management Functions ... 176
B.3.1 Profile Management Functions ... 176
B.3.2 User Management Functions ... 177
B.4 Data Masking Control Functions ... 178
B.4.1 pgx_alter_confidential_policy ... 178
B.4.2 pgx_create_confidential_policy ... 184
B.4.3 pgx_drop_confidential_policy ... 187
B.4.4 pgx_enable_confidential_policy ... 188
B.4.5 pgx_update_confidential_values ... 189
B.5 VCI Data Load Control Function ... 190
B.6 High-Speed Data Load Control Functions ... 191

Appendix C System Catalogs ... 192
C.1 pgx_profile ... 192
C.2 pgx_user_profile ... 192
C.3 pgx_auth_password ... 193
C.4 pgx_password_history ... 193

Appendix D System Views ... 195
D.1 pgx_tablespaces ... 195
D.2 pgx_stat_lwlock ... 195
D.3 pgx_stat_latch ... 195
D.4 pgx_stat_walwriter ... 196

Chapter 1 Operating Fujitsu Enterprise Postgres

This chapter describes how to operate Fujitsu Enterprise Postgres.

1.1 Operating Methods

There are two methods of managing Fujitsu Enterprise Postgres operations:

- Operation management using GUI tools
- Operation management using commands

Operation management using GUI tools

This involves managing operations using the WebAdmin and pgAdmin GUI tools.

- Management using WebAdmin

  This removes the requirement for complex environment settings and operational design for backup and recovery that is usually required for running a database. It enables you to easily and reliably monitor the state of the database, create a streaming replication cluster, back up the database, and restore it even if you do not have expert knowledge of databases.

- Management using pgAdmin

  When developing applications and maintaining the database, you can use pgAdmin to perform simple operations on database objects, such as:

  - Rebuild indexes and update statistics
  - Create, delete, and update database objects

  In addition, from pgAdmin of Fujitsu Enterprise Postgres, you can use the expanded features provided by Fujitsu Enterprise Postgres on the PostgreSQL SQL commands.

See

Refer to pgAdmin Help for information on the expanded features of pgAdmin provided by Fujitsu Enterprise Postgres.

Operation management using commands

You can use commands for configuring and operating the database and managing operations.

Points to consider when choosing an operation method

- You cannot combine WebAdmin and server commands to perform the following operations:
  - Use commands to operate an instance created using WebAdmin.
  - Use WebAdmin to recover a database backed up using commands.

  For instances created with WebAdmin, however, backup can be obtained with the pgx_dmpall command. Also, WebAdmin can perform recovery by using the backup obtained with the pgx_dmpall command.

- To operate an instance created using the initdb command in WebAdmin, the instance needs to be imported using WebAdmin.
- You can perform backup and restoration in pgAdmin, but the backup data obtained with WebAdmin and pgx_dmpall is not compatible with the backup data obtained with pgAdmin.

Features used in each phase

The following table lists the features used in each phase for GUI-based operations and command-based operations.

Operation		Operation with the GUI	Operation with commands
Setup	Creating an instance	WebAdmin is used. The server machine capacity, and the optimum parameter for operations using WebAdmin, are set automatically.	The configuration file is edited directly using the initdb command.
	Creating a standby instance	WebAdmin is used. WebAdmin performs a base backup of the source instance and creates a standby instance.	A standby instance is created using the pg_basebackup command.
	Changing the configuration files	WebAdmin is used.	The configuration file is edited directly.
Starting and stopping an instance		WebAdmin is used.	The pg_ctl command is used.
Creating a database		This is defined using pgAdmin of the GUI tool, or using the psql command or the application after specifying the DDL statement.	
Backing up the database		WebAdmin, or the pgx_dmpall command, is used.	It is recommended that the pgx_dmpall command be used. Recovery to the latest database can be performed.
Database recovery		WebAdmin is used.	To use the backup that was performed using the pgx_dmpall command, the pgx_rcvall command is used.
Monitoring	Database errors	The status in the WebAdmin window can be checked. (*1)	The messages that are output to the database server log are monitored (*1)
	Disk space	The status in the WebAdmin window can be checked. A warning will be displayed if the free space falls below 20%. (*1)	This is monitored using the df command of the operating system, for example. (*1)
	Connection status	This can be checked using pgAdmin of the GUI tool, or referencing pg_stat_activity of the standard statistics view from psql or the application.	

*1: This can be used together with system log monitoring using operations management middleware (Systemwalker Centric Manager, for example).

1.2 Starting WebAdmin

This section describes how to start and log in to WebAdmin.

About using WebAdmin

- It is recommended to use the following browsers with WebAdmin:
  - Microsoft Edge

    WebAdmin will work with other browsers, such as Firefox and Chrome, however, the look and feel may be slightly different.
- You must start the Web server feature of WebAdmin before using WebAdmin. Refer to "Appendix I Starting and Stopping the Web Server Feature of WebAdmin" for information on how to start the Web server feature of WebAdmin.

1.2.1 Logging in to WebAdmin

This section describes how to log in to WebAdmin.

Startup URL for WebAdmin

In the browser address bar, type the startup URL of the WebAdmin window in the following format:

```
http://hostNameOrIpAddress:portNumber/
```

- *hostNameOrIpAddress*: The host name or IP address of the server where WebAdmin is installed.
- *portNumber*: The port number of WebAdmin. The default port number is 27515.

Example

For a server with IP address "192.0.2.0" and port number "27515"

```
http://192.0.2.0:27515/
```

Display the startup windows. From this window you can log in to WebAdmin or access the product documentation.

Log in to WebAdmin

Click [Launch WebAdmin] in the startup URL window to start WebAdmin and display the login window.

To log in, specify the following values:

- [User name]: User name (OS user account) of the instance administrator
- [Password]: Password corresponding to the user name

1.3 Starting pgAdmin

This section describes how to start pgAdmin, how to add an instance required for managing a database, and how to connect to and disconnect from the instance.

You can use pgAdmin on the Windows client.

About using pgAdmin

- You must start the instance to be connected to before using pgAdmin. Refer to "2.1 Starting and Stopping an Instance" for information on how to start an instance.
- When using pgAdmin4 with Microsoft Edge, enable network access by loopback in Microsoft Edge. Also, add Microsoft Edge to the loopback exclusion list.

1.3.1 Starting pgAdmin

Click [Start] >> [All apps] >> [Fujitsu Enterprise Postgres Client(64bit) <*x*>] and start [pgAdmin 4 (64bit) (<*x*>)].

Note that "<x>" indicates the product version. Also, the shortcuts displayed in the [Start] menu may be arranged differently depending on the operating system.

1.3.2 Adding an Instance

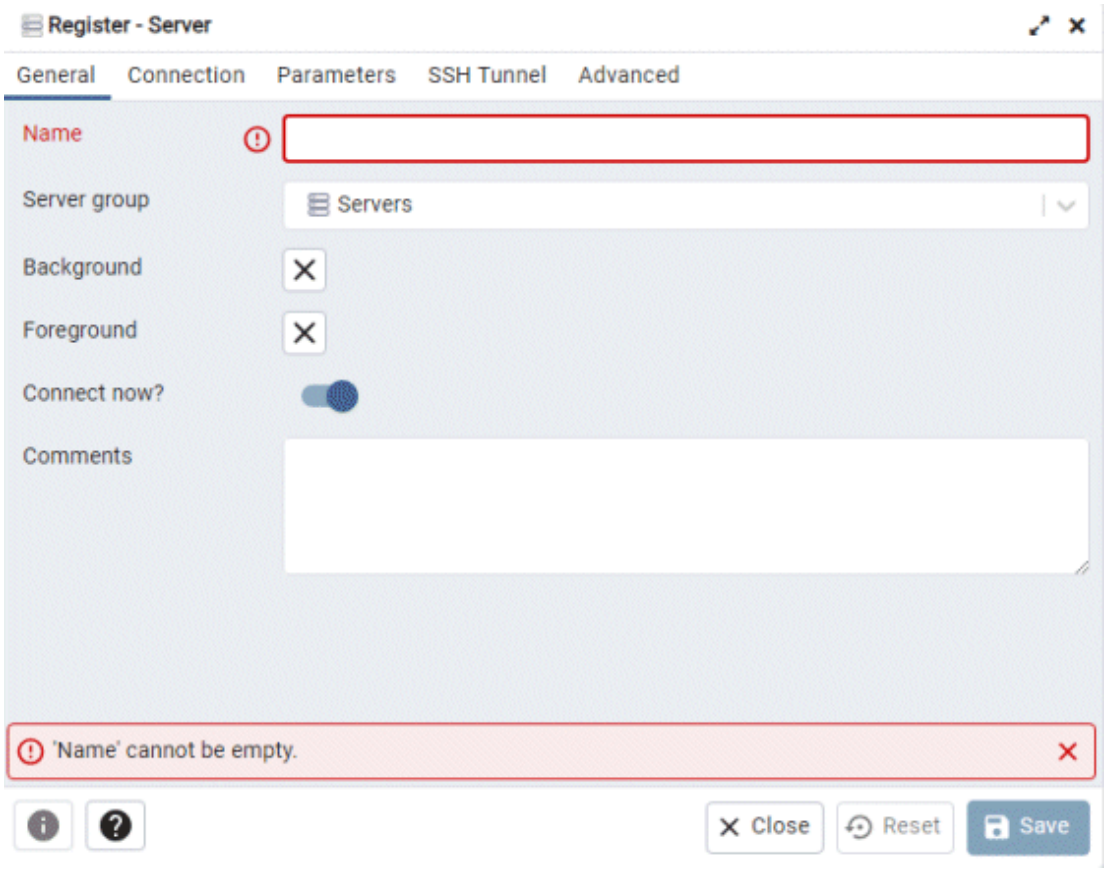
This section describes how to add an instance to be connected to.

If you use a link-local address with version 6 of the TCP/IP protocol, you may encounter the following error when registering the server with pgAdmin. Therefore, do not use link-local addresses.

```
unsupported format character '"' (0x22) at index 96
```

1. In the [Browser] pane, right-click [Servers], and then click [Register] >> [Server...].

2. In the [Register - Server] window, specify a value for each item.



[General] tab

- [Name]: Name of the instance to be managed

[Connection] tab

- [Host name/address]: Host name or IP address of the server where Fujitsu Enterprise Postgres is installed
- [Port]: Port number of the instance
- [Maintenance database]: Database name to which the client will connect
- [Username]: User name of the instance administrator
- [Password]: Password for the user name specified in [Username]

Point

If you select [Save password], the Fujitsu Enterprise Postgres connection password is stored in the following location. Set the appropriate access permissions for the password file to protect it from unauthorized access.

- %APPDATA%\Roaming\pgAdmin\pgadmin4.db

1.3.3 Connecting/Disconnecting an Instance

This section describes how to connect pgAdmin to an instance, and how to disconnect it.

To connect to an instance created using WebAdmin, you must first configure the settings in the [Client authentication] window of WebAdmin to permit connection from pgAdmin.

See

Refer to "Changing the settings" in the Installation and Setup Guide for Server for information on the [Client authentication] window of WebAdmin.

Connecting to an instance

Starting pgAdmin does not connect it to any instance.

To connect to an instance, in the [Browser] pane, right-click the server, and then click [Connect Server].

If a password was not saved when the instance was added, enter a password in the password entry window that is displayed.

Disconnecting from an instance

To disconnect from an instance, in the [Browser] pane, right-click the server, and then click [Disconnect from Server].

1.3.4 Changing the pgAdmin Display Language

This section describes the procedure for changing the display language of pgAdmin.

1. Start pgAdmin.
2. Click [File] >> [Preferences].
3. Click [Miscellaneous] >> [User language] in the left pane of the [Preferences] dialog.
4. Select the language you want to display from the [User language] drop-down list displayed in the right pane, and click the [Save] button.
5. Refresh page by clicking the [Refresh] button.

1.4 Operations Using Commands

You can operate and manage the database using the following commands:

- Server commands

  This group of commands includes commands for creating a database cluster and controlling the database. You can run these commands on the server where the database is operating.

  To use these commands, you must configure the environment variables.

  See

  - Refer to "PostgreSQL Server Applications" under "Reference" in the PostgreSQL Documentation, or "Reference" for information on server commands.
  - Refer to "Configure the environment variables" in the procedure to create instances in "Using the initdb Command" in the Installation and Setup Guide for Server for information on configuring the environment variables.

- Client commands

  This group of commands includes the psql command and commands for extracting the database cluster to a script file. These commands can be executed on the client that can connect to the database, or on the server on which the database is running.

  To use these commands, you must configure the environment variables.

  See

  - Refer to "PostgreSQL Client Applications" under "Reference" in the PostgreSQL Documentation, or "Reference" for information on client commands.

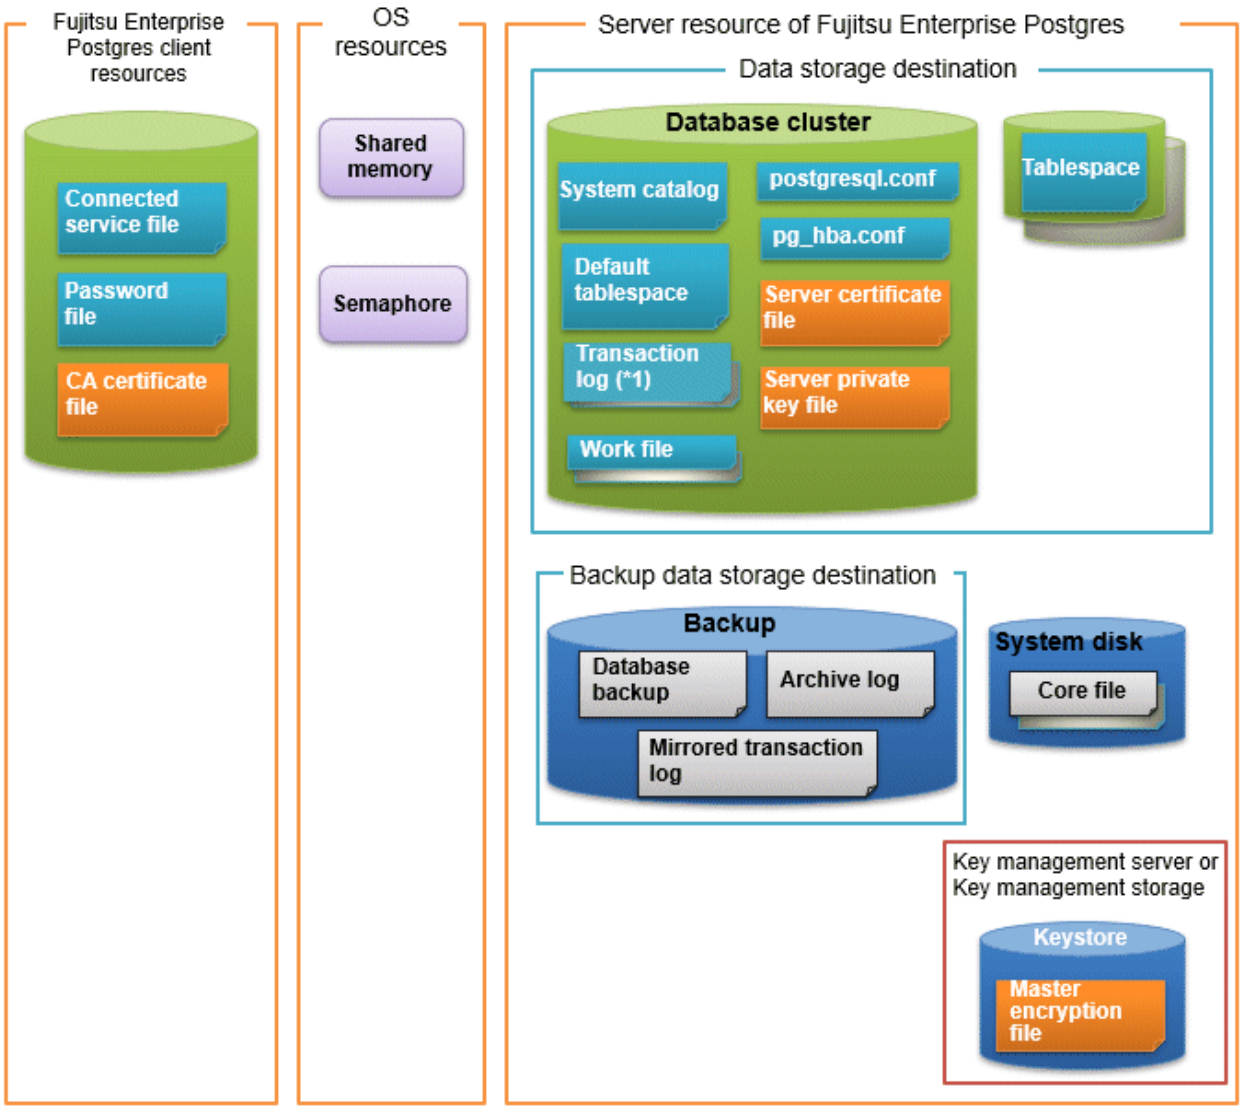
- Refer to "Configuring Environment Variables" in the Installation and Setup Guide for Client for information on the values to be set in the environment variables.

1.5 Operating Environment of Fujitsu Enterprise Postgres

This section describes the operating environment and the file composition of Fujitsu Enterprise Postgres.

1.5.1 Operating Environment

The following figure shows the configuration of the Fujitsu Enterprise Postgres operating environment. The tables given below list the roles of the OS resources and Fujitsu Enterprise Postgres resources.



*1: To distribute the I/O load, place the transaction log on a different disk from the data storage destination.

Table 1.1 OS resources

Type	Role
Shared memory	Used when a database process exchanges information with an external process.
Semaphore	

Table 1.2 Fujitsu Enterprise Postgres client resources

Type	Role
Connection service file	Specifies information, such as the host name, user name, and password, for connecting to Fujitsu Enterprise Postgres.
Password file	Securely manages the password for connecting to Fujitsu Enterprise Postgres.
CA certificate file	CA (certificate authority) certificate used for server authentication when encrypting communication data.

Table 1.3 Server resources of Fujitsu Enterprise Postgres

Type	Role
Database cluster	Database storage area on the database storage disk. It is a collection of databases managed by an instance.
System catalog	Contains information required for the system to run, including the database definition information and the operation information created by the user.
Default tablespace	Contains table files and index files stored by default.
Transaction log	Contains log information in case of a crash recovery or rollback. This is the same as the WAL (Write Ahead Log).
Work file	Work file used when executing applications or commands.
postgresql.conf	Contains information that defines the operating environment of Fujitsu Enterprise Postgres.
pg_hba.conf	Fujitsu Enterprise Postgres uses this file to authenticate individual client hosts.
Server certificate file	Contains information about the server certificate to be used when encrypting communication data and authenticating a server.
Server private key file	Contains information about the server private key to be used when encrypting communication data and authenticating a server
Tablespace	Stores table files and index files in a separate area from the database cluster. Specify a space other than that under the database cluster.
Backup	Stores the data required for recovering the database when an error, such as disk failure, occurs.
Database backup	Contains the backup data for the database.
Archive log	Contains the log information for recovery.
Mirrored transaction log (mirrored WAL)	Enables a database cluster to be restored to the state immediately before an error even if both the database cluster and transaction log fail when performing backup/recovery operations using the pgx_dmpall command or WebAdmin. Mirrored WALs can be used only for backup/recovery using the pgx_dmpall command or WebAdmin.
Core file	Fujitsu Enterprise Postgres process core file that is output when an error occurs during a Fujitsu Enterprise Postgres process.
Key management server or key management storage	Server or storage where the master encryption key file is located.
Master encryption key file	Contains the master encryption key to be used when encrypting storage data. The master encryption key file is managed on the key management server or key management storage.

1.5.2 File Composition

Fujitsu Enterprise Postgres consists of the following files for controlling and storing the database. The table below shows the relationship between the number of such files and their location within a single instance.

Do not place files for use with Fujitsu Enterprise Postgres in a directory mounted over the network except when creating a database space in a storage device on a network. Examples include NFS (Network File System) and CIFS (Common Internet File System). This is because the database might hang if the network fails.

Table 1.4 Number of files within a single instance and how to specify their location

File type	Required	Quantity	How to specify the location
Program files	Y	Multiple	Note that "<*x*>" indicates the product version. /opt/fsepv<*x*>server64
Database cluster	Y	1	Specify using WebAdmin or server commands.
Tablespace	Y	Multiple	Specify a space other than that under the database cluster, using pgAdmin or the DDL statement.
Backup	Y	Multiple	Specify using WebAdmin or server commands.
Core file	Y	Multiple	Specify using WebAdmin, server commands, or postgresql.conf.
Server certificate file (*1)	N	1	Specify using postgresql.conf.
Server private key file (*1)	N	1	Specify using postgresql.conf.
Master encryption key file (*1)	N	1	Specify the directory created as the key store using postgresql.conf.
Connection service file (*1)	N	1	Specify using environment variables.
Password file (*1)	N	1	Specify using environment variables.
CA certificate file (*1)	N	1	Specify using environment variables.

Y: Mandatory
N: Optional

*1: Set manually when using the applicable feature.

Information

If you are using antivirus software, refer to "1.5.3 Precautions when Using Antivirus Software".

1.5.3 Precautions when Using Antivirus Software

If anti-virus software is used, the instance might not start or not respond during operation, and proper operation of the database might not be guaranteed. To avoid such troubles, it is necessary to change the settings of the antivirus software so that virus scans are not executed on the active database.

Do scan exclusion for directories so that all files that comprise Fujitsu Enterprise Postgres are excluded from virus scanning. Alternatively, if the files that comprise Fujitsu Enterprise Postgres are to be scanned for viruses, stop Fujitsu Enterprise Postgres and perform the scan when tasks that use Fujitsu Enterprise Postgres are not operating.

However, setting exclusions for scans poses a risk of missing malware that should be detected by antivirus software. To meet the security requirements necessary for system operation, implement risk countermeasures against malware threats across the entire system. Consider the following measures, for example:

- Introduce WAF, IPS, and IDS to prevent unauthorized access to the database server across the entire system.
- Disable unnecessary features, services, and protocols in the OS and network you use, and always obtain and apply the latest patches to prevent malware intrusion.
- Enable access log acquisition for the OS and database to detect data tampering or leakage caused by malware.
- Perform regular backups to ensure recovery from backups in case data is tampered with.
  For backup methods of Fujitsu Enterprise Postgres, refer to "Chapter 3 Backing Up the Database".

1.6 Notes on Compatibility of Applications Used for Operations

When you upgrade Fujitsu Enterprise Postgres to a newer version, there may be some effect on applications due to improvements or enhancements in functionality.

Take this into account when creating applications so that you can maintain compatibility after upgrading to a newer version of Fujitsu Enterprise Postgres.

See

Refer to "Notes on Application Compatibility" in the Application Development Guide for details.

1.7 Notes on Upgrading Database Instances

If you are upgrading a database instance that uses the extensions, follow the procedure below to upgrade according to the source product version.

When migrating from a database instance of FUJITSU Enterprise Postgres 10 or later

If you are using pg_upgrade to upgrade a database instance from FUJITSU Enterprise Postgres 10 or later that uses the extensions, follow the procedure below to upgrade.

It is strongly recommended to back up the database using pg_dump before performing pg_upgrade.

1. Create a database cluster at the destination
2. Stop the source and destination instances
3. Run the pg_upgrade command
4. Start the destination instance
5. Update the extensions used with ALTER EXTENSION to the latest version at the destination

   ```
   ALTER EXTENSION extensionName UPDATE;
   ```

   If you are using multiple extensions, update each extension separately.

See

For information about pg_upgrade and ALTER EXTENSION, refer to "Reference" in the PostgreSQL Documentation.

When migrating from a database instance of FUJITSU Enterprise Postgres 9.x

The following describes the tasks required to upgrade a database instance of FUJITSU Enterprise Postgres 9.x using the extension with pg_upgrade.

It is strongly recommended to back up the database using pg_dump before performing pg_upgrade or using DROP EXTENSION.

Before running pg_upgrade, remove the following extensions from all databases of the instance, except for "template0". If a column was created in the user table using the following extended data types, "DROP EXTENSION" will also drop that column:. In such cases you might need to consider alternative upgrade methods rather than pg_upgrade. In that case, consider using pg_dump or pg_restore.

- pg_stat_statements
- pgx_io
- pgx_paging
- pgx_network
- pgx_network_err
- pgx_cpu
- pgx_memory
- pgx_swap
- pgx_disk
- pgx_process
- pgx_log
- oracle_compatible
- pg_dbms_stats
- pg_hint_plan

For all databases except "template0", execute the following command to remove these extensions:

```
DROP EXTENSION extensionName;
```

Once the pg_upgrade operation is complete, for all databases except "template0", execute the following command to re-create these extensions as required:

```
CREATE EXTENSION extensionName;
```

See

For information about pg_upgrade, DROP EXTENSION and CREATE EXTENSION, refer to "Reference" in the PostgreSQL Documentation.

1.7.1 Additional Steps for upgrading to Fujitsu Enterprise Postgres with Vertical Clustered Index (VCI) Enabled

When upgrading FUJITSU Enterprise Postgres 11.0 or earlier instances that are using the VCI extension to FUJITSU Enterprise Postgres 12 or later using pg_upgrade, additional steps must be performed because of the incompatibility of the VCI extension between FUJITSU Enterprise Postgres 12 or later and FUJITSU Enterprise Postgres 11 or earlier.

Follow the procedure below in all databases in the FUJITSU Enterprise Postgres 11 or earlier instance, except "template0".

Before upgrading

1. Obtain the CREATE INDEX Definitions

   Run the query below to list all the VCI indexes created in the database. Ensure that these indexes are re-created in the FUJITSU Enterprise Postgres 12 or later instance after pg_upgrade has finished.

   ```
   SELECT nspname || '.' || relname AS index_relname,* FROM pg_class, pg_namespace
     WHERE relnamespace = pg_namespace.oid AND relam IN (SELECT oid FROM pg_am WHERE amname='vci');
   ```

   For each index_relname listed above, execute the commands below to obtain the CREATE INDEX definition (to use the same SQL syntax while re-creating the indexes on the FUJITSU Enterprise Postgres 12 or later instance).

   ```
   SELECT pg_get_indexdef('indexName'::regclass);
   ```

2. Drop the VCI indexes and VCI extension along with all its dependencies.

   To remove all the VCI indexes and VCI internal objects that are created in Fujitsu Enterprise Postgres, execute the commands below. VCI internal objects will be created in FUJITSU Enterprise Postgres 12 or later automatically when CREATE EXTENSION for VCI is executed.

   ```
   DROP EXTENSION VCI CASCADE;
   ```

   Information

   To restore the VCI extension in the FUJITSU Enterprise Postgres 11 or earlier instance, execute CREATE EXTENSION.

After upgrading

Once the pg_upgrade operation is complete, for all databases except "template0", execute CREATE EXTENSION to create the VCI extension, and then execute CREATE INDEX for all the VCI indexes as required.

1.7.2 Additional Steps to upgrading to Fujitsu Enterprise Postgres with Transparent Data Encryption (TDE) Enabled

If you are using pg_upgrade to upgrade an instance of Fujitsu Enterprise Postgres that uses Transparent Data Encryption (TDE), there are steps you can take before upgrading.

If your old cluster operation was an HA cluster operation without database multiplexing operations, and you shared a single keystore file, see "Before upgrading if you shared a keystore file". For other operations, see "Before upgrading"

Before upgrading

Before upgrading, perform the following steps.

This is not necessary if you are using the old cluster keystore file location as the new cluster keystore file location. In that case, the old cluster cannot continue to be used. Enable automatic keystore opening for old and new clusters.

1. Copy Master Encryption Key

   Copy the keystore file from the old cluster to the new cluster.

   You do not need to use the pgx_set_master_key function to generate a new master encryption key on the new cluster; you must copy the keystore file from the old cluster.

   As a database superuser, do the following:

   ```
   $ mkdir <NEW-KEY-STORE>/
   $ cp -p <OLD-KEY-STORE>/keystore.ks  <NEW-KEY-STORE>/
   ```

   NEW-KEY-STORE: The directory specified by the keystore_location parameter in postgresql.conf for the new cluster

   OLD-KEY-STORE: The directory specified by the keystore_location parameter in postgresql.conf on the old cluster

Before upgrading if you shared a keystore file

If the primary and standby servers shared the same keystore file, copy the keystore file from the old environment and share it as the keystore file from the new environment.

For more secure management of keystore files, place them on a secure, isolated key management server or key management storage.

Enable automatic keystore opening for old and new clusters.

Chapter 2 Starting an Instance and Creating a Database

This chapter describes basic operations, from starting an instance to creating a database.

2.1 Starting and Stopping an Instance

This section describes how to start and stop an instance.

- 2.1.1 Using WebAdmin
- 2.1.2 Using Server Commands

Point

- To automatically start or stop an instance when the operating system on the database server is started or stopped, refer to "Configuring Automatic Start and Stop of an Instance" in the Installation and Setup Guide for Server and configure the settings.
- The collected statistics are initialized if an instance is stopped in the "Immediate" mode or if it is abnormally terminated. To prepare for such initialization of statistics, consider regular collection of the statistics by using the SELECT statement. Refer to "The Statistics Collector" in "Server Administration" in the PostgreSQL Documentation for information on the statistics.

2.1.1 Using WebAdmin

WebAdmin enables you to start or stop an instance and check its operating status.

Starting an instance

Start an instance by using the [Instances] tab in WebAdmin.

is displayed when an instance is stopped.

To start a stopped instance, click .

Stopping an instance

Stop an instance by using the [Instances] tab in WebAdmin.

is displayed when an instance is active.

To stop an active instance, click .

Stop mode

Select the mode in which to stop the instance. The following describes the operations of the modes:

Stop mode	Connected clients	Backup being executed using the command
Smart mode (*1)	Waits for all connected clients to be disconnected.	Waits for backups being executed using the command to finish.
Fast mode	Rolls back all transactions being executed and forcibly disconnects clients.	Terminates backups being executed using the command.
Immediate mode	All server processes are terminated immediately. Crash recovery is executed the next time the instance is started.	
Kill process mode	Send SIGKILL to the process and abort all active transactions. This will lead to a crash-recovery run at the next restart.	

*1: When the processing to stop the instance in the Smart mode has started and you want to stop immediately, use the following procedure:

1. Restart the Web server feature of WebAdmin.
2. In the [Instances] tab, click .
3. In the [Instances] tab, click , and select the Immediate mode to stop the instance.

Checking the operating status of an instance

You can check the operating status of an instance by using the [Instances] tab. The following indicators are used to show the status of a resource.

Status indicator	Explanation
	The resource is operating normally.
	The resource is stopped.
	There is an error in the resource.
	An operation is in progress on this resource or the status is being checked.
	The resource is not operating optimally and needs intervention.

If an instance stops abnormally, remove the cause of the stoppage and start the instance by using WebAdmin.

When operating WebAdmin, click to update the status. WebAdmin will reflect the latest status of the operation or the instance resources from the server.

If an error occurs while communicating with the server, there may be no response from WebAdmin. When this happens, close the browser and then log in again. If this does not resolve the issue, check the system log of the server and confirm whether a communication error has occurred.

The following message is output during startup of an instance when the startup process is operating normally, therefore, the user does not need to be aware of this message:

```
FATAL:  the database system is starting up
```

2.1.2 Using Server Commands

Server commands enable you to start or stop an instance and check its operating status.

To use sever commands, configure the environment variables.

See

Refer to " Configure the environment variables" in the procedure to create instances in " Using the initdb Command" in the Installation and Setup Guide for Server for information on configuring the environment variables.

Starting an instance

Use the pg_ctl command to start an instance.

Specify the following values in the pg_ctl command:

- Specify "start" as the mode.
- Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

Example

```
> pg_ctl start -D /database/inst1
```

The message FATAL:the database system is starting up(11189)" may be output in the following cases. This is output by the pg_ctl command to see if the instance's processes have finished starting. Therefore, if there are no other applications, commands, or processes connecting to the database, ignore this message.

- If an application, command, or process connects to the database while the instance is starting up
- If the instance is started without specifying the -W option

If the -W option is specified, the command will return without waiting for the instance to finish starting. Therefore, you need to check the server log to see if the instance has started successfully.

Stopping an instance

Use the pg_ctl command to stop an instance.

Specify the following values in the pg_ctl command:

- Specify "stop" as the mode.
- Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

Example

```
> pg_ctl stop -D /database/inst1
```

Checking the operating status of an instance

Use the pg_ctl command to check the operating status of an instance.

Specify the following values in the pg_ctl command:

- Specify "status" as the mode.
- Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

Example

When the instance is active:

```
> pg_ctl status -D /database/inst1
pg_ctl: server is running (PID: 1234)
```

When the instance is inactive:

```
> pg_ctl status -D /database/inst1
pg_ctl: no server running.
```

See

Refer to "pg_ctl" under "Reference" in the PostgreSQL Documentation for information on pg_ctl command.

2.2 Creating a Database

This section explains how to create a database.

- 2.2.1 Using pgAdmin
- 2.2.2 Using Client Commands

2.2.1 Using pgAdmin

Follow the procedure below to define a database using pgAdmin.

1. In the pgAdmin window, right-click [Databases] in the [Browser] pane, and then click [Create] >> [Database...] to display a [Create - Database] window.
2. Specify appropriate values for the following items in the [Create - Database] window.
   - [General] tab
     - [Database]: Name of the database to be managed
3. Click [Save] to create the database.

2.2.2 Using Client Commands

Follow the procedure below to define a database using client commands.

An example of operations on the server is shown below.

1. Use psql command to connect to the postgres database.
   Execute psql postgres.

```
> psql postgres
psql (<x>) (*1)
Type "help" for help.
```

   *1: *<x>* indicates the PostgreSQL version on which this product is based.

2. Create the database.
   To create the database, execute the CREATE DATABASE databaseName; statement.

```
postgres=# CREATE DATABASE db01;
CREATE DATABASE
```

3. Confirm that the database is created.
   Execute \l+, and confirm that the name of the database created in step 2 is displayed.

```
postgres=# \l+
```

4. Disconnect from the postgres database.
   Execute \q to terminate the psql command.

```
postgres=# \q
```

You can create a database using the createdb command.

See

Refer to "Creating a Database" in "Tutorial" in the PostgreSQL Documentation for information on creating a database using the createdb command.

Chapter 3 Backing Up the Database

This chapter describes how to back up the database.

Backup methods

The following backup methods enable you to recover data to a backup point or to the state immediately preceding disk physical breakdown or data logical failure.

- Backup using WebAdmin

  This method enables you to back up data through intuitive window operations using the GUI.

  WebAdmin is used for recovery.

- Backup using the pgx_dmpall command

  Execute the pgx_dmpall command with a script to perform automatic backup.To back up data automatically, you must register the process in the automation software of the operating system. Follow the procedure given in the documentation for your operating system.

  Additionally, you can also take backups periodically by using any external scheduler.

  The pgx_rcvall command is used for recovery.

Use the selected backup method continuously.There are several differences, such as the data format, across the backup methods. For this reason, the following restrictions apply:

- It is not possible to use one method for backup and another for recovery.
- It is not possible to convert one type of backup data to a different type of backup data.

Information

By using a copy command created by the user, the pgx_dmpall command and the pgx_rcvall command can back up database clusters and tablespaces to any destination and recover them from any destination using any copy method. Refer to "Chapter 18 Backup/Recovery Using the Copy Command" for details.

Approximate backup time

The formula for deriving the approximate backup time when you use WebAdmin or the pgx_dmpall command is as follows:

```
backupTime = dataStorageDestinationUsage / diskWritePerformance x 1.5
```

- *dataStorageDestinationUsage*: Disk usage at the data storage destination
- *diskWritePerformance*: Maximum data volume (bytes/second) that can be written per second in the system environment where operation is performed
- 1.5: Coefficient to factor in tasks other than disk write (which is the most time-consuming step)

If using the copy command with the pgx_dmpall command, the backup time will depend on the implementation of the copy command.

When defining a tablespace

If you have defined a tablespace, back it up. If you do not back it up, directories for the tablespace are not created during recovery, which may cause the recovery to fail. If the recovery fails, refer to the system log, create the tablespace, and then perform the recovery process again.

When encrypting data stored in the database

There are several considerations for the backup of the keystore and backup of the database in case the data stored in the database is encrypted. Refer to the following for details:

- 5.6.4 Backing Up and Recovering the Keystore
- 5.7 Backing Up and Restoring/Recovering the Database

Information

The following methods can also be used to perform backup. Performing a backup using these methods allows you to restore to the point when the backup was performed.

- Backup using an SQL-based dump

  Dump the data by using SQL. This backup method also enables data migration.

- File system level backup

  This backup method requires you to stop the instance and use OS commands to backup database resources as files.

- Backup by continuous archiving

  This is the standard backup method for PostgreSQL.

Refer to "Backup and Restore" in "Server Administration" in the PostgreSQL Documentation for information on these backup methods.

The following backup methods are available for the features provided by Enterprise Postgres:

Category	Backup method	Backup target	Enterprise Postgres					
			Transparent Data Encryption	Policy-based Login Security	Data Masking	Confidentiality Management	Audit Log Feature	Database Multiplexing
Physical Backup	WebAdmin	Database cluster	Y	Y	Y	Y	Y	Y
	pgx_dmpall command		Y	Y	Y	Y	Y	Y
	Backup by continuous archiving		Y	Y	Y	Y	Y	Y
	File system level backup		Y	Y	Y	Y	Y	Y
Logical backup	pg_dumpall command		N	Y	N	Y	N	Y
	pg_dump command	Database	N	N	N	Y	N	Y
	COPY command	Table	N	N	N	N	N	N

Y: Can be used

N: Cannot be used

In a logical backup, the restore process recreates the indexes. For example, if the index size is large, such as for vector data handled by pgvector, the restoration time may be long. If you want to restore quickly, use a physical backup.

To export large amounts of data from multiple tables at high speed, use multiple executions to export data in parallel.

Some features are important to keep in mind when backing up. For information about the features, see the following:

Transparent Data Encryption : "5.7 Backing Up and Restoring/Recovering the Database"

Policy-based Login Security : "7.6 Backup and Recovery"

Confidentiality Management : "Backup/Restore" in the Security Operation Guide

Database Multiplexing : "Backup Operation" in the Cluster Operation Guide(Database Multiplexing)

3.1 Periodic Backup

It is recommended that you perform backup periodically.

Backing up data periodically using WebAdmin or the pgx_dmpall command has the following advantages:

- This method reduces disk usage, because obsolete archive logs (transaction logs copied to the backup data storage destination) are deleted. It also minimizes the recovery time when an error occurs.

Backup cycle

The time interval when backup is performed periodically is called the backup cycle. For example, if backup is performed every morning, the backup cycle is 1 day.
The backup cycle depends on the jobs being run, but on Fujitsu Enterprise Postgres it is recommended that operations are run with a backup cycle of at least once per day.

3.2 Backup Methods

This section describes the methods for backing up the database.

- 3.2.1 Using WebAdmin
- 3.2.2 Using Server Commands

3.2.1 Using WebAdmin

You can use WebAdmin to perform backup and check the backup status.

Backup operation

Follow the procedure below to back up the database.

1. Select the database to back up

   In the [Instances] tab, select the instance to be backed up and click .

2. Back up the database

   The [Backup] dialog box is displayed. To perform backup, click [Yes].
   An instance is automatically started when backup is performed.

Backup status

If an error occurs and backup fails, [Error] is displayed adjacent to [Data storage status] or [Backup storage status] in the [Instances] tab. An error message is also displayed in the message list.

In this case, the backup data is not optimized. Ensure that you check the backup result whenever you perform backup. If backup fails, [Solution] appears to the right of the error message. Clicking this button displays information explaining how to resolve the cause of the error. Remove the cause of failure, and perform backup again.

When encrypting data stored in the database

If the data to be stored in the database is to be encrypted, it is necessary to enable the automatic opening of the keystore before doing so. Refer to "5.6.3 Enabling Automatic Opening of the Keystore" for details.

3.2.2 Using Server Commands

Use the pgx_dmpall command and pgx_rcvall command to perform backup and check the backup result.

Preparing for backup

You must prepare for backup before actually starting the backup process.

Follow the procedure below.

See

Refer to "Preparing Directories to Deploy Resources" in the Installation and Setup Guide for Server for information on the location of directories required for backup and for points to take into account.

1. Prepare the backup data storage disk

   For backup, prepare a separate disk unit from the database storage disk and mount it using the operating system commands.

2. Create a directory where the backup data will be stored

   Create an empty directory.

   Set appropriate permissions so that only the instance administrator can access the directory.

   Example

   ```
   # mkdir /backup/inst1
   # chown fsepuser:fsepuser /backup/inst1
   # chmod 700 /backup/inst1
   ```

3. Specify the settings required for backup

   Stop the instance, and set the following parameters in the postgresql.conf file.

   Start the instance after editing the postgresql.conf file.

Parameter name	Setting	Description
backup_destination	Name of the directory where the backup data will be stored	Specify the name of the directory where the backup data will be stored. Appropriate privileges that allow only the instance administrator to access the directory must already be set. Place the backup data storage destination directory outside the data storage destination directory, the tablespace directory, and the transaction log storage destination directory.
archive_mode	on	Specify the archive log mode. Specify [on] (execute).
archive_command	'*installationDirectory*/bin/pgx_walcopy.cmd "%p" "*backupDataStorageDestinationDirectory*/archived_wal/%f"'	Specify the path name of the command that will save the transaction log and the storage destination.
archive_library	"(default)	Specify the archive library. Specify ["](default).

   Refer to "Appendix A Parameters" and "Write Ahead Log" under "Server Administration" in the PostgreSQL Documentation for information on the parameters.

Backup operation (file backup)

Use the pgx_dmpall command to perform file backup. You can even embed the pgx_dmpall command in OS automation software to perform backup.

The backup data is stored in the directory specified in the backup_destination parameter of postgresql.conf.

Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

Example

```
> pgx_dmpall -D /database/inst1
```

Backup stores the data obtained during the backup and the backup data of the data obtained during previous backup.

If the data to be stored in the database is encrypted, refer to the following and back up the keystore:

- 5.6.4 Backing Up and Recovering the Keystore

Backup status

Use the pgx_rcvall command to check the backup status.

Specify the following values in the pgx_rcvall command:

- The -l option indicates backup data information.
- Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

```
> pgx_rcvall -l -D /database/inst1
Date                    Status          Dir
2022-03-01 13:30:40     COMPLETE        /backup/inst1/2022-03-01_13-30-40
```

If an error occurs and backup fails, a message is output to the system log.

In this case, the backup data is not optimized. Ensure that you check the backup result whenever you perform backup. If backup fails, remove the cause of failure and perform backup again.

See

Refer to "pgx_dmpall" and "pgx_rcvall" in the Reference for information on the pgx_dmpall command and pgx_rcvall command.

Setting a restore point

In case you want to recover your database to a certain point in time, you can name this particular point in time, which is referred to as the restore point, by using the psql command.

By setting a restore point before executing an application, it becomes easy to identify up to which point in time the data will be reverted.

A restore point can be set to any point in time after a backup is executed. However, if a restore point is set before a backup is executed, the database cannot be recovered to that point in time. This is because restore points are recorded in the archive logs, and the archive logs are discarded when backups are executed.

Name restore points so that they are unique within the database. Add the date and time of setting a restore point to distinguish it from other restore points, as shown below:

- YYMMDD_HHMMSS
  - YYMMDD: Indicates the date
  - HHMMSS: Indicates the time
- There is no way to check restore points you have set. Keep a record in, for example, a file.

Example

The following example uses the psql command to connect to the database and execute the SQL statement to set a restore point.

However, when considering continued compatibility of applications, do not use functions directly in SQL statements. Refer to "Notes on Application Compatibility" in the Application Development Guide for details.

```
postgres=# SELECT pg_create_restore_point('batch_20220303_1');
LOG:  restore point "batch_20220303_1" created at 0/20000E8
STATEMENT:  select pg_create_restore_point('batch_20220303_1');
 pg_create_restore_point
-------------------------
 0/20000E8
(1 row)
```

Refer to "19.3.2 Using the pgx_rcvall Command" for information on using a restore point to recover the database.

See

Refer to "System Administration Functions" under "Functions and Operators" in the PostgreSQL Documentation for information on pg_create_restore_point.

Chapter 4 Configuring Secure Communication Using Secure Sockets Layer

If communication data transferred between a client and a server contains confidential information, encrypting the communication data can protect it against threats, such as eavesdropping on the network.

4.1 Configuring Communication Data Encryption

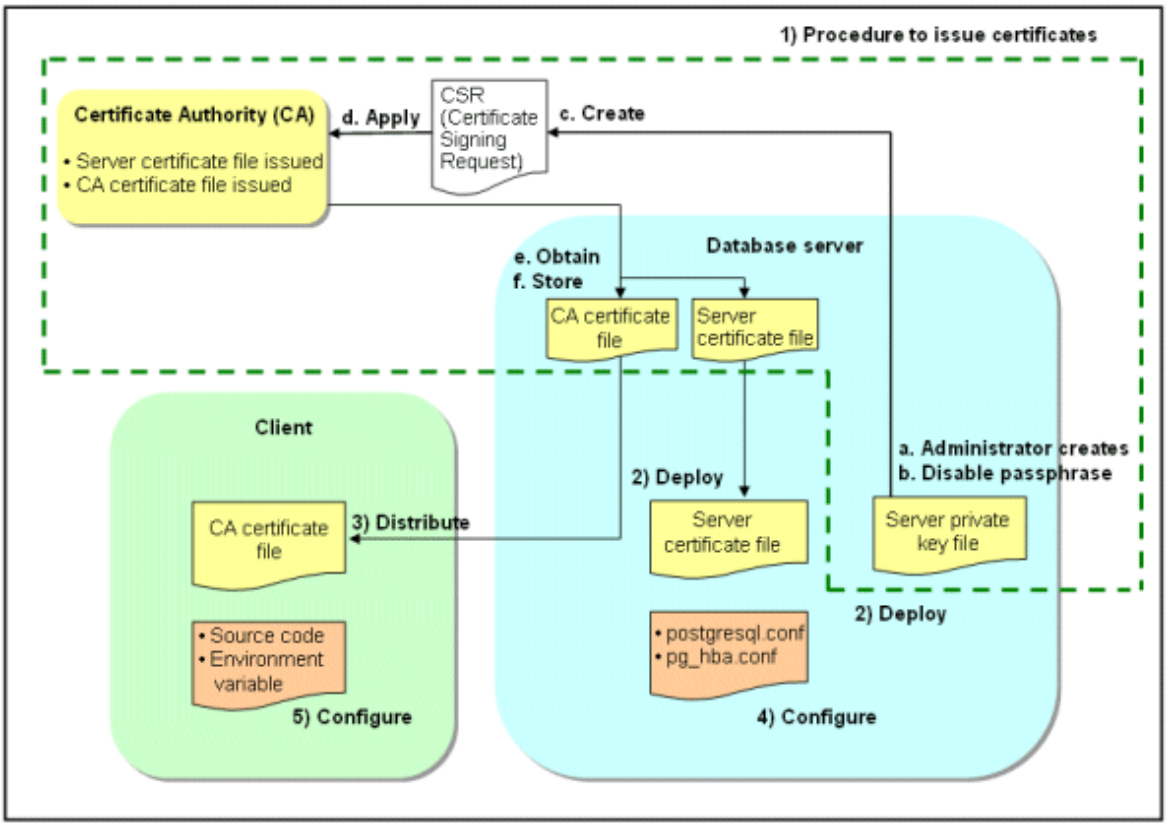
To encrypt communication data transferred between a client and a server, configure communication data encryption as described below. Communication data encryption not only protects the communication content, but it also guards against man-in-the-middle (MITM) attacks (for example, data and password theft through server impersonation).

Table 4.1 Configuration procedure

Configuration procedure
1) Issue a certificate
2) Deploy a server certificate file and a server private key file
3) Distribute a CA certificate file to the client
4) Configure the operating environment for the database server
5) Configure the operating environment for the client

The following figure illustrates the environment for communication data encryption.

Figure 4.1 Environment for communication data encryption



4.1.1 Issuing a Certificate

For authenticating servers, you must acquire a certificate issued by the certificate authority (CA).
Fujitsu Enterprise Postgres supports X.509 standard PEM format files. If the certificate authority issues a file in DER format, use a tool such as the openssl command to convert the DER format file to PEM format.

The following provides an overview of the procedure. Refer to the procedure published by the public or independent certificate authority (CA) that provides the certificate file for details.

a. Create a server private key file

b. Disable the passphrase for the server private key file

c. Create a CSR (signing request for obtaining a server certificate) from the server private key file

d. Apply to the certificate authority (CA) for a server certificate

e. Obtain a server certificate file and a CA certificate file from the certificate authority (CA)

f. Store the server certificate file and the CA certificate file
   Note: If you lose or destroy the certificates, you will need to have them re-issued.

The above procedure enables you to prepare the following files:

- Server private key file
- Server certificate file
- CA certificate file

4.1.2 Deploying a Server Certificate File and a Server Private Key File

Create a directory on the local disk of the database server and store the server certificate file and the server private key file in it.
Use the operating system features to set access privileges for the server certificate file and the server private key file so that only the database administrator has load privileges.
Back up the server certificate file and the server private key file in the event that data corruption occurs and store them securely.

4.1.3 Distributing a CA Certificate File to the Client

Create a directory on the local disk of the client and place the distributed CA certificate file there. Use the operating system features to set load privileges to protect the CA certificate file against accidental deletion.

4.1.4 Configuring the Operating Environment for the Database Server

See

Refer to "Secure TCP/IP Connections with SSL" under "Server Administration" in the PostgreSQL Documentation for details.

4.1.5 Configuring the Operating Environment for the Client

See

Refer to the following sections in the Application Development Guide for details, depending on your application development environment:

- "Settings for Encrypting Communication Data" under "Setup" in "JDBC Driver"
- "Settings for Encrypting Communication Data" under "Setup" in "C Library (libpq)"
- "Settings for Encrypting Communication Data" under "Setup" in "Embedded SQL in C"

4.1.6 Performing Database Multiplexing

When you perform communication that uses database multiplexing and a Secure Socket Layer server certificate, certificates with the same "Common Name" must be used. To ensure this, take one of the following actions:

- Create one server certificate, replicate it, and place a copy on each server used for database multiplexing.
- Create a server certificate with the same "Common Name" for each server used for database multiplexing.

See

Refer to "Using the Application Connection Switch Feature" in the Application Development Guide for information on how to specify applications on the client.

Chapter 5 Protecting Storage Data Using Transparent Data Encryption

This chapter describes how to encrypt data to be stored in the database.

See

If you want to use an external key management system as the storage location for the encryption key, refer to "Chapter 6 Using Transparent Data Encryption with Key Management Systems as Keystores".

5.1 Protecting Data Using Encryption

With PostgreSQL, data in a database is protected from access by unauthorized database users through the use of authentication and access controls. However, the OS file is not protected from attackers who bypass the database server's authentication and access controls.

With Fujitsu Enterprise Postgres, data inside the OS file is encrypted, so valuable information is protected even if the file or disk is stolen.

Data to be stored in a database is encrypted when it is written to the data file, and decrypted when it is read.

This is performed automatically by the instance, so the user and the application need not be aware of key management and encryption or decryption. This process is called TDE (Transparent Data Encryption).

The characteristics of TDE are described below.

Encryption mechanisms

Two-layer encryption key and the keystore

In each tablespace, there is a tablespace encryption key that encrypts and decrypts all the data within. The tablespace encryption key is encrypted by the master encryption key and saved.
Only one master encryption key exists in a database cluster. It is encrypted based on a passphrase specified by the user and stored in a keystore. Fujitsu Enterprise Postgres provides a file-based keystore. Attackers who do not know the passphrase cannot read the master encryption key from the keystore.

Strong encryption algorithms

TDE uses the Advanced Encryption Standard (AES) as its encryption algorithm. AES was adopted as a standard in 2002 by the United States Federal Government, and is used throughout the world.

Faster encryption and decryption based on hardware

TDE minimizes the overhead of encryption and decryption by using the AES-NI (Advanced Encryption Standard New Instructions) built into Intel(R) Xeon(R) processors since the 5600 series. This means that even in situations where previously the minimum encryption target was selected as a tradeoff between performance and security, it is now possible to encrypt all the data of an application.

Refer to the Intel Corporation's website for information on the list of processors equipped with AES-NI.

Zero overhead storage areas

Encryption does not change the size of data stored in tables, indexes, or WAL. There is, therefore, no need for additional estimates or disks.

Scope of encryption

All user data within the specified tablespace

The tablespace is the unit for specifying encryption. All tables, indexes, temporary tables, and temporary indexes created in the encrypted tablespace are encrypted. There is no need for the user to consider which tables and strings to encrypt.

Refer to "5.4 Encrypting a Tablespace" for details.

Backup data

The pgx_dmpall command and pg_basebackup command create backup data by copying the OS file. Backups of the encrypted data are, therefore, also encrypted. Information is protected from leakage even if the backup medium is stolen.

Refer to "5.7 Backing Up and Restoring/Recovering the Database" after enabling or reconfiguring encryption to back up the database.

WAL and temporary files

WAL, which is created by updating encrypted tables and indexes, is encrypted with the same security strength as the update target. When large merges and sorts are performed, the encrypted data is written to a temporary file in encrypted format.

Streaming replication support

You can combine streaming replication and transparent data encryption. The data and WAL encrypted on the primary server is transferred to the standby server in its encrypted format and stored.

The following are not encrypted:

- pg_dump and pg_dumpall output files
- Files output by the COPY command
- Notification event payloads that communicate using the LISTEN or NOTIFY command
- Checksum validation is not performed on encrypted tablespaces during backup and when using the pg_checksum utility.

5.2 Setting the Master Encryption Key

To use transparent data encryption, you must create a keystore and set the master encryption key.

1. In the keystore_location parameter of postgresql.conf, specify the directory to store the keystore.

   Specify a different location for each database cluster. Specify a different directory from those below as the keystore storage destination:

   - Data storage destination
   - Tablespace storage destination
   - Transaction log storage destination
   - Backup data storage destination

   ```
   keystore_location = '/key/store/location'
   ```

   Refer to "Appendix A Parameters" for information on postgresql.conf.

   After editing the postgresql.conf file, either start or restart the instance.

   - Using WebAdmin

     Refer to "2.1.1 Using WebAdmin", and restart the instance.

   - Using the pg_ctl command

     Specify the following in the pg_ctl command:

     - Specify "restart" as the mode.
     - Specify the data storage destination directory in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
     - Specify the -w option. This means that the command returns after waiting for the instance to start. If the -w option is not specified, it may not be possible to determine if the starting of the instance completed successfully or if it failed.

     Example

     ```
     > pg_ctl restart -w -D /database/inst1
     ```

2. Execute the pgx_set_master_key function to set the master encryption key.

   Execute it as the database superuser.

   ```
   SELECT pgx_set_master_key('passphrase');
   ```

The value "passphrase" is the passphrase that will be used to open the keystore. The master encryption key is protected by this passphrase, so avoid specifying a short simple string that is easy to guess.

The pgx_set_master_key function creates a file with the name keystore.ks in the keystore storage destination. It also creates a master encryption key from random bit strings, encrypts it with the specified passphrase, and stores it in keystore.ks. At this point, the keystore is open.

Refer to "B.2 Transparent Data Encryption Control Functions" for information on the pgx_set_master_key function.

Note that if you forget the passphrase, you will not be able to access the encrypted data. There is no method to retrieve a forgotten passphrase and decrypt data. Do not, under any circumstances, forget the passphrase.

5.3 Opening the Keystore

To create encrypted tablespaces and access the encrypted data, you must first open the keystore. When you open the keystore, the master encryption key is loaded into the database server memory and becomes usable for encryption and decryption.

You need to open the keystore each time you start the instance. To open the keystore, the database superuser must execute the following SQL function.

```
SELECT pgx_open_keystore('passphrase');
```

The value "passphrase" is the passphrase specified during creation of the keystore.

Refer to "B.2 Transparent Data Encryption Control Functions" for information on the pgx_open_keystore function.

Note that, in the following cases, the passphrase must be entered when starting the instance, because the encrypted WAL must be decrypted for recovery. In this case, the above-mentioned pgx_open_keystore function cannot be executed.

- If performing crash recovery at the time of starting the instance
- If performing recovery using continuous archiving

For the above cases, specify the --keystore-passphrase option in the pg_ctl command, and then start the instance. This will display the prompt for the passphrase to be entered, as shown below.

```
> pg_ctl --keystore-passphrase start
Enter the passphrase:
The server is starting
>
```

When using an automatically opening keystore, you do not need to enter the passphrase and you can automatically open the keystore when the database server starts. Refer to "5.6.3 Enabling Automatic Opening of the Keystore" for details.

5.4 Encrypting a Tablespace

The keystore must be open before you can create an encrypted tablespace.

When creating a tablespace that will be encrypted, configure the encryption algorithm in the runtime parameters. For example, to create a tablespace with the name secure_tablespace using AES with a key length of 256 bits as the encryption algorithm, configure as shown below.

```
-- Specify the encryption algorithm for the tablespace to be created below
SET tablespace_encryption_algorithm = 'AES256';
CREATE TABLESPACE secure_tablespace LOCATION '/My/Data/Dir';
-- Specify that the tablespace to be created below is not to be encrypted
SET tablespace_encryption_algorithm = 'none';
```

Or

```
CREATE TABLESPACE secure_tablespace LOCATION '/My/Data/Dir' WITH (tablespace_encryption_algorithm =
'AES256' );
```

When the tablespace is empty, the encryption algorithm can be modified with the command below.

```
ALTER TABLESPACE secure_tablespace SET (tablespace_encryption_algorithm=AES256);
```

Trying to set the encryption algorithm for a non-empty tablespace causes an error.

You can use AES with a key length of 128 bits or 256 bits as the encryption algorithm. It is recommended that you use 256-bit AES. Refer to "Appendix A Parameters" for information on how to specify the runtime parameters.

If user provides both GUC and command line options while creating the tablespace, the preference is given to the command line option.

The pg_default and pg_global tablespaces cannot be encrypted.

Create tables and indexes in the encrypted tablespace that you created. Relations created in the encrypted tablespace are automatically encrypted.

Example

Example 1: Specifying an encrypted tablespace when creating it

```
CREATE TABLE my_table (...)
    TABLESPACE secure_tablespace;
```

Example 2: Not explicitly specifying a tablespace when creating it and instead using the default tablespace

```
SET default_tablespace = 'secure_tablespace';
CREATE TABLE my_table (...);
```

The process is the same for encrypting temporary tables and temporary indexes. In other words, either explicitly specify the TABLESPACE clause or list encrypted tablespaces in the temp_tablespaces parameter, and then execute CREATE TEMPORARY TABLE or CREATE INDEX.

Point

If an encrypted tablespace is specified in the TABLESPACE clause of the CREATE DATABASE statement, relations created in the database without explicitly specifying a tablespace will be encrypted. Furthermore, the system catalog will also be encrypted, so the source code of user-defined functions is also protected.

Example: Specifying a tablespace in a database definition statement

```
CREATE DATABASE DB01 TABLESPACE=SP01 ... ;
```

Part of the data is also stored in the system catalog - to encrypt this data as well, specify an encrypted tablespace as above and create a database.

An encrypted tablespace cannot be created from the window used for creating the pgAdmin tablespace, or from the query tool using a multi-command string. To create an encrypted tablespace, use psql console or a single command in the query tool such as that shown in the example below.

```
CREATE TABLESPACE tspace LOCATION '/some/dir/in/the/path' WITH
(tablespace_encryption_algorithm='AES256')
```

5.5 Checking an Encrypted Tablespace

The pgx_tablespaces system view displays information about whether each tablespace has been encrypted, and about the encryption algorithm. Refer to "D.1 pgx_tablespaces" for information on strings.

You can discover which tablespaces have been encrypted by executing the following SQL statements.

However, when considering continued compatibility of applications, do not reference system catalogs (pg_tablespace) directly in SQL statements.

```
SELECT spcname, spcencalgo
FROM pg_tablespace ts, pgx_tablespaces tsx
WHERE ts.oid = tsx.spctablespace;
```

Example

```
postgres=# SELECT spcname, spcencalgo FROM pg_tablespace ts, pgx_tablespaces tsx WHERE ts.oid =
tsx.spctablespace;
      spcname      | spcencalgo
-------------------+------------
 pg_default        | none
 pg_global         | none
 secure_tablespace | AES256
(3 rows)
```

See

Refer to "Notes on Application Compatibility" in the Application Development Guide for information on how to maintain application compatibility.

5.6 Managing the Keystore

This section describes how to manage the keystore and the master encryption key to guard against the threat of theft.

5.6.1 Changing the Master Encryption Key

Using the same encryption key for an extended period gives attackers an opportunity to decipher the encrypted data. It is recommended that you change the key at regular intervals, or whenever the key is exposed to risk.

Adhere to the industry's best practices for encryption algorithms and key management when considering how often the key should be changed. For example, the NIST in the United States has published "NIST Special Publication 800-57". The PCI DSS also refers to this publication. This publication recommends changing the master encryption key once a year.

To change the master encryption key, execute the pgx_set_master_key function, which is the same function used for configuring the key. Refer to "5.2 Setting the Master Encryption Key" for details.

After changing the master encryption key, you must immediately back up the keystore.

5.6.2 Changing the Keystore Passphrase

In security policies for organizations, it is usually a requirement that the passphrase be changed whenever a security administrator who knows the passphrase is removed from duties due to transfer or retirement. It is also recommended that the passphrase be changed if it is ever exposed to risks due to deception such as social engineering.

To change the keystore passphrase, execute the following SQL function as a superuser.

```
SELECT pgx_set_keystore_passphrase('oldPassphrase', 'newPassphrase');
```

After changing the passphrase, you must immediately back up the keystore.

Refer to "B.2 Transparent Data Encryption Control Functions" for information on the pgx_set_keystore_passphrase function.

5.6.3 Enabling Automatic Opening of the Keystore

When using an automatically opening keystore, you do not need to enter the passphrase and you can automatically open the keystore when the instance starts. Execute the pgx_keystore command to enable automatic opening of the keystore.

```
> pgx_keystore --enable-auto-open /key/store/location/keystore.ks
Enter the passphrase:
Automatic opening of the keystore is now enabled
>
```

See

Refer to "pgx_keystore" in the Reference for information on pgx_keystore command.

When automatic opening is enabled, an automatically opening keystore is created in the same directory as the original keystore. The file name of the automatically opening keystore is keystore.aks. The file keystore.aks is an obfuscated copy of the decrypted content of the keystore.ks file. As long as this file exists, there is no need to enter the passphrase to open the keystore when starting the instance.

Do not delete the original keystore file, keystore.ks. It is required for changing the master encryption key and the passphrase. When you change the master encryption key and the passphrase, keystore.aks is recreated from the original keystore file, keystore.ks.

Protect keystore.ks, keystore.aks, and the directory that stores the keystore so that only the user who starts the instance can access them.

Configure the permission of the files so that only the user who starts the instance can access the SQL functions and commands that create these files. Accordingly, manually configure the same permission mode if the files are restored.

Example

```
# chown -R fsepuser:fsepuser /key/store/location
# chmod 700 /key/store/location
# chmod 600 /key/store/location/keystore.ks
# chmod 600 /key/store/location/keystore.aks
```

To use WebAdmin for backup and recovery, you must enable automatic opening of the keystore.

An automatically opening keystore will only open on the computer where it was created.

To disable automatic opening of the keystore, delete keystore.aks.

5.6.4 Backing Up and Recovering the Keystore

Back up the keystore at the following times in case it is corrupted or lost. Note that you must store the database and the keystore on separate data storage media. Storing both on the same data storage medium risks the danger of the encrypted data being deciphered if the medium is stolen. A passphrase is not required to open an automatically opening keystore, so store this type of keystore in a safe location.

- When the master encryption key is first configured
- When the master encryption key is changed
- When the database is backed up
- When the keystore passphrase is changed

Point

Do not overwrite an old keystore when backing up a keystore. This is because during database recovery, you must restore the keystore to its state at the time of database backup. When the backup data of the database is no longer required, delete the corresponding keystore.

Example

- Back up the database and the keystore on March 1, 2022.

```
> pgx_dmpall -D /database/inst1
> cp -p /key/store/location/keystore.ks /keybackup/keystore_20220301.ks
```

  Specify the following in the pgx_dmpall command:

  - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

- Change the master encryption key, and back up the keystore on March 5, 2022.

```
> psql -c "SELECT pgx_set_master_key('passphrase')" postgres
> cp -p /key/store/location/keystore.ks /keybackup/keystore_20220305.ks
```

  Specify the following in the psql command:

  - Specify the SQL function that sets the master encryption key in the -c option.
  - Specify the name of the database to be connected to as the argument.

If the keystore is corrupted or lost, restore the keystore containing the latest master encryption key. If there is no keystore containing the latest master encryption key, restore the keystore to its state at the time of database backup, and recover the database from the database backup. This action recovers the keystore to its latest state.

Example

- Restore the keystore containing the latest master encryption key as of March 5, 2022.

```
> cp -p /keybackup/keystore_20220305.ks /key/store/location/keystore.ks
```

- If there is no backup of the keystore containing the latest master encryption key, recover the keystore by restoring the keystore that was backed up along with the database on 1 March 2022.

```
> cp -p /keybackup/keystore_20220301.ks /key/store/location/keystore.ks
> pgx_rcvall -B /backup/inst1 -D /database/inst1 --keystore-passphrase
```

  Specify the following in the pgx_rcvall command:

  - Specify the data storage directory in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
  - Specify the backup data storage directory in the -B option.
  - The --keystore-passphrase option prompts you to enter the passphrase to open the keystore.

If you have restored the keystore, repeat the process of enabling automatic opening of the keystore. This ensures that the contents of the automatically opening keystore (keystore.aks) are identical to the contents of the restored keystore.

It is recommended that you do not back up the automatically opening keystore file, keystore.aks. If the database backup medium and the backup medium storing the automatically opening keystore are both stolen, the attacker will be able to read the data even without knowing the passphrase.

If the automatically opening keystore is corrupted or lost, you must again enable automatic opening. The keystore.aks file will be recreated from keystore.ks at this time.

See

Refer to "pgx_rcvall" and "pgx_dmpall" in the Reference for information on the pgx_rcvall and pgx_dmpall commands.

Refer to "psql" under "Reference" in the PostgreSQL Documentation for information on the psql command.

Refer to "B.2 Transparent Data Encryption Control Functions" for information on the pgx_set_master_key function.

Refer to "5.6.3 Enabling Automatic Opening of the Keystore" for information on how to enable automatic opening of the keystore.

5.7 Backing Up and Restoring/Recovering the Database

Fujitsu Enterprise Postgres enables you to use the five backup and recovery methods described below. Regardless of the method you use, you must back up the keystore at the same time.

Note that you must store the database and the keystore on separate data storage media. Storing both on the same data storage medium risks the danger of the encrypted data being deciphered if the medium is stolen.

Backup and recovery using WebAdmin

- Backup

  WebAdmin backs up encrypted data.

  Back up the key store after backing up the database.

- Recovery

  Restore the keystore to its state at the time of database backup. Refer to "5.6.4 Backing Up and Recovering the Keystore" for details.

  Enable automatic opening of the keystore in accordance with the procedure described in "5.6.3 Enabling Automatic Opening of the Keystore". Then, use WebAdmin to recover the database.

Backup and recovery using the pgx_dmpall and pgx_rcvall commands

- Backup

  The pgx_dmpall command backs up the encrypted data.

  Back up the key store after backing up the database.

- Recovery

  Restore the keystore to its state at the time of the database backup.

  Configure automatic opening of the key store as necessary.

  If automatic opening of the keystore is not enabled, execute the pgx_rcvall command with the --keystore-passphrase option specified. This will display the prompt for the passphrase to be entered.

Example

- Back up the database and the keystore on March 1, 2022.

```
> pgx_dmpall -D /database/inst1
> cp -p /key/store/location/keystore.ks /keybackup/keystore_20220301.ks
```

  Specify the following in the pgx_dmpall command:

  - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

- Recover the database and the keystore from the backup taken on March 1, 2022.

```
> cp -p /keybackup/keystore_20220301.ks /key/store/location/keystore.ks
> pgx_keystore --enable-auto-open /key/store/location/keystore.ks  (Execute only when enabling
automatic opening)
> pgx_rcvall -B /backup/inst1 -D /database/inst1 --keystore-passphrase
```

  Specify the following in the pgx_rcvall command:

  - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

- Specify the backup data storage directory in the -B option.
- The --keystore-passphrase option prompts you to enter the passphrase to open the keystore.

Dump and restore using SQL

- Backup

  The files output by the pg_dump and pg_dumpall commands are not encrypted. You should, therefore, encrypt the files using OpenSSL commands or other means before saving them, as described in "5.8 Importing and Exporting the Database" below.

  Back up the key store after backing up the database.

- Restore

  If the backup data has been encrypted using, for example Open SSL commands, decrypt that data.

  The data generated by the pg_dumpall command includes a specification to encrypt tablespaces by default. For this reason, the psql command encrypts tablespaces during restoration.

File system level backup and restore

- Backup

  Stop the instance and backup the data directory and the tablespace directory using the file copy command of the operating system. The files of encrypted tablespaces are backed up in the encrypted state.

  Back up the key store after performing the backup.

- Restore

  Restore the keystore to its state at the time of the database backup.

  Stop the instance and restore the data directory and the tablespace directory using the file copy command of the operating system.

Continuous archiving and point-in-time recovery

- Backup

  The pg_basebackup command backs up the encrypted data as is.

  Back up the key store after performing the backup.

- Recovery

  Restore the keystore to its state at the time of the database backup.

  Configure automatic opening of the key store as necessary.

  If automatic opening of the keystore is not enabled, execute the pg_ctl command to start the instance with the --keystore-passphrase option specified. This will display the prompt for the passphrase to be entered.

See

- Refer to "pg_ctl" under "Reference" in the PostgreSQL Documentation for information on the pg_ctl command.
- Refer to "Reference" in the PostgreSQL Documentation for information on the following commands:
  - psql
  - pg_dump
  - pg_basebackup
- Refer to the Reference for information on the following commands:
  - pgx_rcvall
  - pgx_dmpall

- pg_dumpall

If you have restored the keystore, repeat the process of enabling automatic opening of the keystore This ensures that the contents of the automatically opening keystore (keystore.aks) are identical to the contents of the restored keystore.

Refer to "5.6.3 Enabling Automatic Opening of the Keystore" for information on how to enable automatic opening of the keystore.

5.8 Importing and Exporting the Database

The files output by the COPY TO command are not encrypted. Therefore, when transferring files to other systems, you should encrypt files using OpenSSL commands or other means and use scp or sftp to encrypt the data being transferred.

Use a safe method to delete obsolete plain text files.

You can use the following methods to safely delete files:

- shred command

Example

```
# Export the contents of the table my_table to a CSV file.
> psql -c "COPY my_table TO '/tmp/my_table.csv' (FORMAT CSV)" postgres

# Encrypt the exported file.
> openssl enc -e -aes256 -in my_table.csv -out my_table.csv.enc
(The user is prompted to enter the passphrase to be used for encryption)

# Safely delete plain text files.
> shred -u -x my_table.csv
 (Transfer encrypted files to other systems)

# Decrypt the encrypted files on other systems.
> openssl enc -d -aes256 -in my_table.csv.enc -out my_table.csv
(The user is prompted to enter the passphrase to be used for decryption)
```

If you use COPY FROM to import data to tables and indexes in an encrypted tablespace, the imported data is automatically encrypted before being stored.

5.9 Encrypting Existing Data

You cannot encrypt existing unencrypted tablespaces. In addition, you cannot change encrypted tablespaces so that they do not encrypt.

As an alternative, transfer the tables and indexes to other tablespaces. You can use the following SQL commands for this.

```
ALTER TABLE table_name SET TABLESPACE new_tablespace;
ALTER INDEX index_name SET TABLESPACE new_tablespace;
ALTER DATABASE database_name SET TABLESPACE new_tablespace;
```

See

Refer to "SQL Commands" under "Reference" in the PostgreSQL Documentation for information on SQL commands.

5.10 Operations in Cluster Systems

This section describes how to use transparent data encryption on cluster systems such as high-availability systems, streaming replication, and database multiplexing.

5.10.1 HA Clusters that do not Use Database Multiplexing

Take the following points into account when using transparent data encryption in an HA cluster environment that does not use database multiplexing.

Placement and automatic opening of the keystore file

There are two alternatives for placing the keystore file:

- Sharing the keystore file
- Placing a copy of the keystore file

Sharing the keystore file

This involves using the same keystore file on the primary server and the standby server.

As the standby server is not active while the primary server is running, this file would not be accessed simultaneously, and therefore, it can be shared.

To manage the keystore file in a more secure manner, place it on the key management server or the key management storage isolated in a secure location.

Enable the automatic opening of the keystore on both the primary and standby servers.

Placing a copy of the keystore file

This involves placing a copy of the primary server keystore file on the standby server.

You can do this if you cannot prepare a shared server or disk device that can be accessed from both the primary and standby servers.

However, if you change the master encryption key and the passphrase on the primary server, you must copy the keystore file to the standby server again.

To manage the keystore file in a more secure manner, prepare the key management server or the key management storage isolated in a secure location for both the primary and standby servers, and place the keystore files there.

Enable the automatic opening of the keystore on both the primary and standby servers. Note that copying the automatically opening keystore file (keystore.aks) to the standby server does not enable the automatic opening of the keystore.

See

Refer to the Cluster Operation Guide (PRIMECLUSTER) for information on building a cluster system environment for performing failover using the failover feature integrated with the cluster software.

5.10.2 Database Multiplexing Mode

Note the following when using transparent data encryption in environments that use streaming replication, or database multiplexing with streaming replication.

Placing the keystore file

Place a copy of the primary server keystore file on the standby server.

This is required as the keystore file cannot be shared, and both servers may need to access it simultaneously.

Point

To manage the keystore file in a more secure manner, place it on the key management server or the key management storage isolated in a secure location. A keystore used by both the primary and standby servers can be managed on the same key management server or key management storage.

However, create different directories for the keystores to be used by the primary server and the standby server. Then copy the keystore for the primary server to the directory used on the standby server.

Automatically opening the keystore

You must enable automatic opening of the keystore.

To do this, enable automatic opening of the keystore in all servers that make up database multiplexing. The settings for automatic opening of the keystore include information unique to each server, so simply copying the file does not enable it.

Changing the passphrase

Changes to the passphrase are reflected in all servers that make up database multiplexing, so no special operation is required.

Building and starting a standby server

Before using the pg_basebackup command or pgx_rcvall command to build a standby server, copy the keystore file from the primary server to the standby server. When using an automatically opening keystore, use the copied keystore file to enable automatic opening on the standby server.

Open the keystore each time you start the standby server. This step is necessary for decrypting and restoring encrypted WAL received from the primary server. To open the keystore, specify the --keystore-passphrase option in the pg_ctl command or pgx_rcvall command and enter the passphrase, or use an automatically opening keystore.

Changing the master encryption key and the passphrase

Change the master encryption key and the passphrase on the primary server. You need not copy the keystore from the primary server to the standby server. You need not even restart the standby server or reopen the keystore. Changes to the master encryption key and the passphrase are reflected in the keystore on the standby server.

See

Refer to "pgx_rcvall " in the Reference for information on pgx_rcvall command.

Refer to "pg_ctl" under "Reference" in the PostgreSQL Documentation for information on pg_ctl command.

Refer to "pg_basebackup" under "Reference" in the PostgreSQL Documentation for information on pg_basebackup command.

Refer to "High Availability, Load Balancing, and Replication" under "Server Administration" in the PostgreSQL Documentation for information on how to set up streaming replication.

5.11 Security-Related Notes

- Decrypted data is cached in the database server memory (shared buffer). As a result, unencrypted data is stored in a core file, which is a process memory dump. You should, therefore, safely delete the memory dump.
  You can safely delete files by using the following command:
  - shred command
- Unencrypted data may be written from the database server memory to the operating system's swap area. To prevent leakage of information from the swap area, consider either disabling the use of swap area or encrypting the swap area using a full-disk encryption product.
- The content of the server log file is not encrypted. Therefore, in some cases the value of a constant specified in a SQL statement is output to the server log file. To prevent this, consider setting a parameter such as log_min_error_statement.
- When executing an SQL function that opens the keystore and modifies the master encryption key, ensure that the SQL statement containing the passphrase is not output to the server log file. To prevent this, consider setting a parameter such as log_min_error_statement. If you are executing this type of SQL function on a different computer from the database server, encrypt the communication between the client and the database server with SSL.
- Starting with FEP 10, logical replication is available, which allows non-backed up clusters to subscribe to databases where transparent data encryption is enabled. Logical replication does not need to have the same encryption strategy between publisher and subscriber.

  In this scenario, if the user wants to encrypt the subscribed copy of data as well, then it is the user's responsibility to create encryption policies to the subscribed databases. By default, published encrypted tablespace data will not be encrypted in the subscriber side.

5.12 Tips for Installing Built Applications

With transparent data encryption, you can easily encrypt all the data in an application without modifying the application. Database administrators install built applications in the following manner. However, this procedure stores data to the default tablespace, so take necessary action if processing differs from the original design.

1. (Normal procedure) Create an owner and a database for the built application.

```
CREATE USER crm_admin ...;
CREATE DATABASE crm_db ...;
```

2. (Procedure for encryption) Create an encrypted tablespace to store the data for the built application.

```
SET tablespace_encryption_algorithm = 'AES256';
CREATE TABLESPACE crm_tablespace LOCATION '/crm/data';
```

3. (Procedure for encryption) Configure an encrypted tablespace as the default tablespace for the owner of the built application.

```
ALTER USER crm_admin SET default_tablespace = 'crm_tablespace';
ALTER USER crm_admin SET temp_tablespaces = 'crm_tablespace';
```

4. (Normal procedure) Install the built application. The application installer prompts you to enter the host name and the port number of the database server, the user name, and the database name. The installer uses the entered information to connect to the database server and execute the SQL script. For applications that do not have an installer, the database administrator must manually execute the SQL script.

Normally, the application's SQL script includes logic definition SQL statements, such as CREATE TABLE, CREATE INDEX, and GRANT or REVOKE, converted from the entity-relationship diagram. It does not include SQL statements that create databases, users, and tablespaces. Configuring the default tablespace of the users who will execute the SQL script deploys the objects generated by the SQL script to the tablespace.

Chapter 6 Using Transparent Data Encryption with Key Management Systems as Keystores

This chapter describes the operation of transparent data encryption when a key management system is used as a keystore.

See

Refer to "Key Management System Requirements" in the Installation and Setup Guide for Server for the key management system requirements that can be used with Fujitsu Enterprise Postgres.

6.1 Protecting Data Using Encryption

Refer to "5.1 Protecting Data Using Encryption". The following describes the differences from the transparent data encryption operation in the file-based keystore described in "5.1 Protecting Data Using Encryption".

Encryption mechanisms

Two-layer encryption key and the keystore

Each tablespace has a tablespace encryption key that encrypts/decrypts all data in it. Tablespace encryption keys are stored encrypted with the master encryption key.
Use an encryption key stored in a key management system as a common master encryption key for your database cluster. Fujitsu Enterprise Postgres refers to the key management system as a keystore for master encryption keys.

Type of key management system

Two types of key management systems are available:

- kmip

  It is a key management system that can be used using a protocol called KMIP (Key Management Interoperability Protocol) standardized by OASIS (Organization for the Advancement of Structured Information Standards).

- custom

  It is a key management system that cooperates using an adapter that converts the request format without adopting the KMIP protocol.

  A sample of the adapter plugin required for this type is stored in the following location under the Fujitsu Enterprise Postgres installation directory.

  - For Amazon Web Services (AWS)

    <*Install directory*>/share/aw-kms-plugin.sh.sample

  - For Microsoft Azure (Azure)

    <*Install directory*>/share/az-kms-plugin.sh.sample

  If you use the provided AWS sample plug-in as is, the following conditions apply.

Item	Contens
Available services	By using the AWS adapter, you can use encryption keys on the Key Management Service (KMS) provided by AWS. There are no regional restrictions as long as the region is supported by AWS KMS.
Available AWS KMS keys	The key spec for a KMS key (key spec) must be a symmetric cryptographic key. Asymmetric cryptographic keys cannot be used. Also, the KMS key usage (key usage) must be ENCRYPT_DECRYPT.
Required permissions	The user accessing AWS KMS must be permitted to perform the following operations for the KMS key to be used.

Item	Contens
	- Encrypt - Decrypt - DescribeKey
Key ID	The following can be specified as the key ID. - Key ARN
Dependent package	Install AWS CLI on the Fujitsu Enterprise Postgres server. For details, refer to the AWS CLI manual. In addition, the following packages are required. - jq The plugin is executed by the OS user who starts the Fujitsu Enterprise Postgres server. You must set the PATH or modify the script file so that the OS user can execute the aws command and jq command.
CLI configuration	Configure the CLI so that aws commands executed by the OS user that starts the Fujitsu Enterprise Postgres server can access the AWS key management service without entering additional credentials. Configuring in this way allows keystores that use this plugin to be opened without entering a KMS secret.

If you use the provided Azure sample plug-in as is, the following conditions apply.

Item	Contens
Available services	The Azure adapter allows you to use any key management service that is accessible through the Azure Key Vault API and that can use symmetric keys.
Available keys	Symmetric key is available.
Available algorithms	The following algorithms are available for encryption/decryption operations. - A256GCM
Key operations	The user accessing the Azure key management service must be permitted to perform the following operations for the key to be used. - encrypt - decrypt - get
Key ID	The following can be specified as the key ID. - Key object identifier
Dependent package	Install Azure CLI on the Fujitsu Enterprise Postgres server. For details, refer to the Azure CLI manual. In addition, the following packages are required. - jq The plugin is executed by the OS user who starts the Fujitsu Enterprise Postgres server. You must set the PATH or modify the script file so that the OS user can execute the az command and jq command.
Sign in	Sign in to Azure using a service principal. You need the application ID, tenant ID, and credentials to sign in. The available authentication methods are password authentication and certificate-based authentication.
Opening the Keystore	To open the keystore, you must specify the following as the KMS secret: - Password (for password authentication)

Item	Contens
	- Private key passphrase (for certificate-based authentication)

See

Refer to "Key Management System Requirements" in the Installation and Setup Guide for Server for the key management system requirements that can be used with Fujitsu Enterprise Postgres.

Sharing tablespace encryption keys

When using an adapter to link with a key management system, encryption and decryption of the tablespace encryption key using the master encryption key are performed on the key management system side.

Tablespace encryption keys can be shared within a database cluster so that you do not need to access the key management system each time you want to use the tablespace encryption key.

The cost of encryption/decryption using the master encryption key becomes an issue in the following cases:

- Multiple connections to the database access encrypted tablespaces
- Connections accessing encrypted tablespaces are repeated and connection pooling is disabled

Encryption key identifier

Key IDs are used as identifiers to identify encryption keys stored on the key management system.

Key ID

Information that identifies the encryption key on the key management system, and is unique within the key management system. The correspondence between the encryption key substance (byte string) and the key ID does not change throughout the life cycle of the encryption key.

The name of the identifier differs depending on each key management system, but in this feature, such information is called the key ID.

Changes to the key management system

After starting operation of the transparent data encryption function, the key management system to be used can be changed to another key management system.

6.2 Setting the Master Encryption Key

To use transparent data encryption, you must create a keystore and set the master encryption key.

1. Load the shared_preload_libraries parameter in postgresql.conf with the library name "tde _ kms"

```
shared_preload_libraries = 'tde_kms'
```

2. When using an adapter, register the adapter as a plug-in. Specify the directory where the plugin is stored in the tde_kms.plugin_path parameter in postgresql.conf. Store your plugins in this directory. If you want to use the samples, copy them into this directory. The plugin file requires execution privilege for the OS user that starts the Fujitsu Enterprise Postgres server.

```
tde_kms.plugin_path = '/home/fsepuser/plugin/'
```

3. To share the tablespace encryption key, set the tde_kms.enable_shared_dek parameter in postgresql.conf to "on".

```
tde_kms.enable_shared_dek = on
```

4. Set the tde_kms.kms_conninfo_file parameter in postgresql.conf to a file that contains key management system connection information. Refer to "Appendix A Parameters" for information.

   Example for the key management system connection information file kms_conninfo.conf

```
tde_kms.kms_conninfo_file = 'kms_conninfo.conf'
```

Example of key management system connection information file

For type kmip

```
kmip   mykmipsvr  mykmipsvr.example.com   5696   cert   sslcert=postgres.crt
sslkey=postgres.key sslrootcert=root.crt
```

For type custom (When using the AWS sample plugin)

```
custom   mykms   aw-kms-plugin.sh   arg=--profile arg=user1
```

For type custom (When using the Azure sample plugin)

```
custom   mykms   az-kms-plugin.sh  kms-secret-obf=password.ksc arg=--auth-method arg=password
arg=--user-id arg=ApplicationId arg=--tenant arg=TenantId arg=--algorithm arg=A256GCM
```

5. Execute a CREATE EXTENSION statement to install the extension.

```
CREATE EXTENSION tde_kms;
```

6. To enable transparent data encryption, call the pgx_declare_external_master_key function to declare the encryption key to use as the master encryption key. Specify a key ID as an identifier to identify the encryption key. Refer to "B.2.3 pgx_declare_external_master_key" for information on the pgx_declare_external_master_key function.

```
SELECT pgx_declare_external_master_key( kms_name => 'mykmipsvr', key_id =>
'a0eebc99-9c0b-0000-0000-000000000000', sslpassphrase => 'mykmippassphrase' );
```

6.3 Opening the Keystore

To create encrypted tablespaces and access the encrypted data, you must first open the keystore. When you open the keystore, the master encryption key is available for encryption and decryption.

You need to open the keystore each time you start the instance. To open the keystore, the database superuser must execute the following SQL function.

```
SELECT pgx_open_keystore( sslpassphrase => 'passphrase');
```

passphrase is the passphrase of the private key file for the client certificate.

Refer to "B.2 Transparent Data Encryption Control Functions" for information on the pgx_open_keystore function.

Note that, in the following cases, the passphrase must be entered when starting the instance, because the encrypted WAL must be decrypted for recovery. In this case, the above-mentioned pgx_open_keystore function cannot be executed.

- If performing crash recovery at the time of starting the instance
- If performing recovery using continuous archiving

For the above cases, specify the --kms-secret option in the pg_ctl command, and then start the instance. This will display the prompt for the passphrase to be entered, as shown below.

```
> pg_ctl --kms-secret start
Enter secret:
```

Point

When using an automatically opening keystore, you do not need to enter the passphrase and you can automatically open the keystore when the database server starts. Refer to "6.6.2 Enabling Automatic Opening of the Keystore" for details.

6.4 Encrypting a Tablespace

Refer to "5.4 Encrypting a Tablespace".

6.5 Checking an Encrypted Tablespace

Refer to "5.5 Checking an Encrypted Tablespace".

6.6 Managing the Keystore

Describes how to manage master encryption keys when a key management system is used.

6.6.1 Changing the Master Encryption Key

To change the master encryption key, run the pgx_declare_external_master_key function as you originally set it. Refer to "6.2 Setting the Master Encryption Key" for more information.

Also, by specifying a different key management system name than the key management system name specified during installation, you can change the key management system to be used. Refer to"6.6.5 Changes to the Key Management System" for details.

6.6.2 Enabling Automatic Opening of the Keystore

You can automatically open a keystore at instance startup without entering a passphrase by specifying all credentials, including those that should be kept secret, in the key management system connection information file. To enable automatic keystore opening, run the pgx_keystore command.

Example of storing obfuscated credentials in the file sslkeypasprase.ksc

```
> pgx_keystore -s -o sslkeypassphrase.ksc
Enter secret:
```

Specify obfuscated credentials in the key management system connection information file.

```
kmip    mykmipsvr    kmip.example.com    5696    cert    sslcert=postgres.crt    sslkey=postgres.key
sslrootcert=root.crt    sslkeypassphrase-obf=sslkeypassphrase.ksc
```

The key management system connection information file is valid only on the computer on which it was created.

To disable automatic keystore opening, delete the file containing obfuscated credentials for the private key specified in sslkeypasserase-obf and delete the sslkeypasserase-obf option in the key management system connection information file.

See

Refer to "pgx_keystore" in the Reference for information on pgx_keystore command.

Refer to "Appendix A Parameters" for information on the key management system connection information file.

6.6.3 Changing Credentials for Key Management Systems

If the credentials for the key management service change, you must also change the credentials that Fujitsu Enterprise Postgres uses to connect to the key management system.

You can change the credentials used by Fujitsu Enterprise Postgres using the pgx_open_keystore function. The new credentials are used to connect to the new key management system.

If you have a streaming replication configuration, you must change credentials on all replicas.

Refer to "B.2.1 pgx_open_keystore" for information on the pgx_open_keystore function.

6.6.4 Verifying the Master Encryption Key

The view pgx_tde_master_key shows information about your master encryption key. For more information about columns, Refer to "E.1 pgx_tde_master_key" for more information about columns..

6.6.5 Changes to the Key Management System

If you need to change the linked key management system after installing the transparent data encryption function that uses the key management system, you can do so by following the procedure below.

After this step, data in Fujitsu Enterprise Postgres will be encrypted using encryption keys on the new key management system.

Defining a new key management system

If the new key management system is not listed in the key management system's connection information file, add a definition to that configuration file. Give the old key management system and the new key management system different key management system names.

Reload the configuration file for the changes to take effect.

Declaring the master encryption key to use

Use the pgx_dexlare_external_master_key function to declare a new encryption key to use. Specify the name you gave the new key management system as the key management system name. Other arguments required are the key ID to use on the new key management system and credentials. Upon successful completion, it will be encrypted using the encryption key on the new key management system.

Information

The master encryption key that encrypts the backup data before changing the key management system exists only on the old key management system. As such, you need the old key management system and the encryption keys residing there for any period of time when you might restore backup data from before the change. If you delete the encryption key on the old key management system, destroy the old key management system, cancel the key management service, etc., you will not be able to decrypt the backup data and you will not be able to use the data.

6.7 Backing Up and Restoring/Recovering the Database

Fujitsu Enterprise Postgres enables you to use the five backup and recovery methods described below.

Backup and recovery using WebAdmin

- Backup

  WebAdmin backs up encrypted data.

- Recovery

  If you recover to a point in time when the old master encryption key was in use, change to the most recent master encryption key immediately after recovery.

  Enable automatic opening of the keystore in accordance with the procedure described in "6.6.2 Enabling Automatic Opening of the Keystore". Then, use WebAdmin to recover the database.

Backup and recovery using the pgx_dmpall and pgx_rcvall commands

- Backup

  The pgx_dmpall command backs up the encrypted data.

- Recovery

  If you recover to a point in time when the old master encryption key was in use, change to the most recent master encryption key immediately after recovery.

  Configure automatic opening of the key store as necessary.

  If automatic opening of the keystore is not enabled, execute the pgx_rcvall command with the --kms-secret option specified. This will display the prompt for the passphrase to be entered.

Dump and restore using SQL

- Backup

  The files output by the pg_dump and pg_dumpall commands are not encrypted. You should, therefore, encrypt the files using OpenSSL commands or other means before saving them, as described in "5.8 Importing and Exporting the Database" below.

- Restore

  If the backup data has been encrypted using, for example Open SSL commands, decrypt that data.

  The data generated by the pg_dumpall command includes a specification to encrypt tablespaces by default. For this reason, the psql command encrypts tablespaces during restoration.

File system level backup and restore

- Backup

  Stop the instance and backup the data directory and the tablespace directory using the file copy command of the operating system. The files of encrypted tablespaces are backed up in the encrypted state.

- Restore

  Stop the instance and use the OS file copy command to restore the data storage directory or tablespace directory.

  If you recover to a point in time when the old master encryption key was in use, change to the most recent master encryption key immediately after recovery.

Continuous archiving and point-in-time recovery

- Backup

  The pg_basebackup command backs up the encrypted data as is.

- Recovery

  If you recover to a point in time when the old master encryption key was in use, change to the most recent master encryption key immediately after recovery.

  Configure automatic opening of the key store as necessary.

  If automatic opening of the keystore is not enabled, execute the pg_ctl command to start the instance with the --kms-secret option specified. This will display the prompt for the passphrase to be entered.

See

- Refer to "pg_ctl" under "Reference" in the PostgreSQL Documentation for information on the pg_ctl command.
- Refer to "Reference" in the PostgreSQL Documentation for information on the following commands:
  - psql
  - pg_dump
  - pg_basebackup
- Refer to the Reference for information on the following commands:
  - pgx_rcvall
  - pgx_dmpall
  - pg_dumpall

6.8 Importing and Exporting the Database

Refer to "5.8 Importing and Exporting the Database**".**

6.9 Encrypting Existing Data

Refer to "5.9 Encrypting Existing Data".

6.10 Operations in Cluster Systems

This section describes how to use transparent data encryption on cluster systems such as high-availability systems, streaming replication, and database multiplexing.

6.10.1 HA Clusters that do not Use Database Multiplexing

Take the following points when using transparent data encryption with a key management system as a key store in an HA cluster environment that does not use database multiplexing.

Placement and automatic opening of the connection information file of the key management system

The file that describes the connection information of the key management system specified in the tde_kms.kms_conninfo_file parameter of the postgresql.conf file, and the files such as certificates that are referenced from that file can be shared by the primary server and the standby server. However, the obfuscated credential file used to enable automatic opening of the keystore must be created and placed on each server according to the instructions for enabling automatic opening.

If not shared, it must be possible to connect to the key management system used from the standby server with the same key management system name as the key management system name set on the primary server. Place the connection information file and files such as certificates referenced from the connection information file on the standby server. The obfuscated credential file used to enable automatic opening of the keystore must be created and placed on each server according to the instructions in enabling automatic opening.

Changing credentials for key management systems

If the credentials for the key management system have changed, use the pgx_open_keystore function on the primary server to change the credentials. Re-enable automatic opening of the keystore on the standby server.

See

Refer to the Cluster Operation Guide (PRIMECLUSTER) for information on building a cluster system environment for performing failover operations linked to cluster software.

6.10.2 Database Multiplexing Mode

Note the following when using transparent data encryption with a key management system as a key store in environments that use streaming replication, or database multiplexing with streaming replication.

Placement and automatic opening of the connection information file of the key management system

The file that describes the connection information of the key management system specified in the tde_kms.kms_conninfo_file parameter of the postgresql.conf file, and the files such as certificates that are referenced from that file can be shared by the primary server and the standby server. However, the obfuscated credential file used to enable automatic opening of the keystore must be created and placed on each server according to the instructions for enabling automatic opening.

If not shared, it must be possible to connect to the key management system to be used with the same key management system name as the key management system name set on the primary server. Place the connection information file and files such as certificates referenced from the connection information file on all servers that configure database multiplexing mode. The obfuscated credential file used to enable automatic opening of the keystore must be created and placed on each server according to the instructions in enabling automatic opening.

Changing credentials for key management systems

If the credentials for the key management system are changed, use the pgx_open_keystore function on all servers that configure database multiplexing to change the credentials.

Starting a standby server

Open the keystore when starting the standby server. This is required to decrypt and replay the encrypted WAL received from the primary server. To open a keystore, use the pg_ctl or pgx_rcvall command with --kms-secret and provide your credentials, or enable automatic opening of the keystore.

Changing the master encryption key

Change the master encryption key on the primary server. No need to restart the standby server or reopen the keystore. Changes to the master encryption key are also reflected on the standby server.

Refer to "pgx_rcvall " in the Reference for information on pgx_rcvall command.

Refer to "pg_ctl" under "Reference" in the PostgreSQL Documentation for information on pg_ctl command.

Refer to "High Availability, Load Balancing, and Replication" under "Server Administration" in the PostgreSQL Documentation for information on how to set up streaming replication.

6.12 Tips for Installing Built Applications

Refer to "5.12 Tips for Installing Built Applications**".**

6.13 Reference Information for Linking Key Management Systems Using Sample Plugins

Sample Plugin for AWS

See below for CLI configuration:

https://docs.aws.amazon.com/cli/latest/userguide/cli-configure-files.html

Sample Plugin for Azure

For key management services that support symmetric keys, see below.

https://learn.microsoft.com/en-us/azure/key-vault/keys/about-keys#key-types-and-protection-methods

For more information about Azure Key Management Services, see below.

https://learn.microsoft.com/en-us/azure/security/fundamentals/key-management#azure-key-management-services

For more information about service principals, see below.

https://learn.microsoft.com/en-us/cli/azure/create-an-azure-service-principal-azure-cli#4-sign-in-using-a-service-principal

Options that can be specified for AWS plugin

The following additional options can be specified for the plugin. These options can be specified as extra-args in the KMS connection information file.

--config config-file: Specify the path of the AWS CLI configuration file. If omitted, the default path of the AWS CLI will be used.

--credentials credentials-file: Specify the path to the AWS CLI authentication information file. If omitted, the default path of the AWS CLI will be used.

--profile profile-name: Specify the profile to use in the AWS CLI configuration file and credentials file. If omitted, the AWS CLI default profile will be used.

Options that can be specified for the Azure plugin

The following additional options can be specified for the plugin. These options can be specified as extra-args in the KMS connection information file.

--auth-method (password|cert): Specify the authentication method. (password: Password authentication, cert: Certificate-Based Authentication)

--user-id user-id: Specify the application ID.

--user-cert cert-file: For certificate-based authentication, specify the path to the certificate file.

--tenant tenant-id: Specify the tenant ID.

--algorithm algorithm: Specify the algorithm to be used.

Plugin Errors

If an error occurs in the operation of the plugin, a message will be output to the server log.

Verifying access to encryption keys

You can view information about the encryption key being used by executing the following command as the OS user running the Fujitsu Enterprise Postgres server.

- When using the sample plug-in for AWS

  aws kms describe-key --key-id *Key ID*

- When using the sample plug-in for Azure

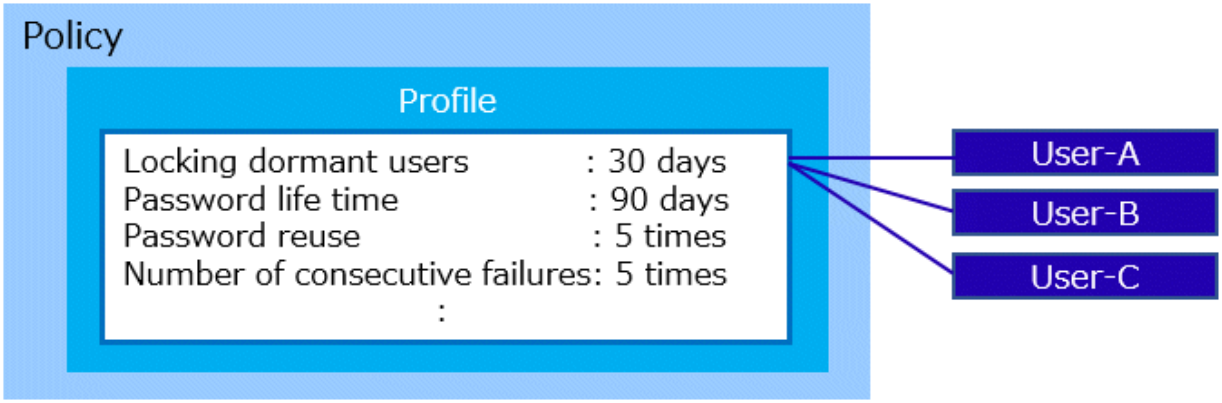
  az keyvault key show --id *Key ID*

Notes on using the Azure sample plug-in

The service principal may need to sign in periodically. If the OS user who starts the Fujitsu Enterprise Postgres server is already signed in to Azure due to the environment settings, the credentials passed from Fujitsu Enterprise Postgres will not be used when using the plugin. They will only be used when periodic sign-in becomes necessary. If the KMS secret specified when opening the KMS connection information file or keystore is incorrect, the error will be detected when periodic sign-in becomes necessary, so check in advance that the specified information is correct.

Chapter 7 Policy-based Login Security

To apply a policy for login security to a user, define the policy as a profile and assign the profile to the user. The contents of the profile are saved as database objects.



The items that can be set for a profile are described below.

Managing Dormant Users

You can automatically lock users who have not been connected to the database for a long time.

This setting is for users with the LOGIN attribute.

Managing Policies When Using Password Authentication

You can set the following policies for users who use password authentication (password, md5, scram-sha-256).

- Set a password life time
- Restrict password reuse
- Lock accounts that have failed to login continuously
- Allow passwords to be set in encrypted form
- Set the gradual password rollover time

  Gradual password rollover is when you change a password and then keep the old password in effect for a while.
  This setting specifies the valid period.
  This is useful, for example, if it is difficult to make a new password available system-wide instantly.

7.1 Advance Preparation

Ensure that the postgres database exists and that you can connect to it.

If no connections are possible, and if using a database other than the default postgres database, specify the name of the database to which you can connect in the userprofile_database parameter in the postgresql.conf file.

Refer to "Parameters for the Policy-based Login Security" for parameters.

7.2 Changing the Contents of the default Profile

When you create a database user with CREATE ROLE, the database user is assigned the default profile. When you create the default profile, all password configuration and authentication restrictions and the gradual password rollover feature are disabled, so change the parameter values to suit your policy. Change the value with the pgx_alter_profile function.

Users with CREATEROLE privilege can modify the contents of a profile.

Refer to "B.3.1 Profile Management Functions" for functions.

Refer to "7.7 Profile parameters" for more information on parameters.

[Example]

```
SELECT pgx_alter_profile('default',
'{
    "INACTIVE_USER_TIME": 30,
    "PASSWORD_LIFE_TIME": 50,
    "PASSWORD_GRACE_TIME": 10,
    "PASSWORD_REUSE_MAX": 5,
    "PASSWORD_LOCK_TIME": 0.5,
    "PASSWORD_ALLOW_HASHED": true,
    "PASSWORD_ROLLOVER_TIME": 0.125
}');
```

7.3 Creating and Assigning Profiles

If you want to apply a different policy than the default profile, create a new profile and assign it to the user.

The pgx_create_profile function creates a profile.

To assign a profile to a user, use the pgx_assign_profile_to_user function.

Users with CREATEROLE privilege can create and assign profiles.

Refer to "B.3.1 Profile Management Functions" and "B.3.2 User Management Functions" for functions.

7.4 Actions to be Taken in the Event of Deviation from Policy

When a user is locked

Locked in the following cases:

- Restriction by INACTIVE_USER_TIME
- Restriction by FAILED_LOGIN_ATTEMPTS

If you want to allow a locked user to login again, unlock the user. Unlocking is performed using the pgx_unlock_user function. Operations can be performed by users with CREATEROLE privilege.

Refer to "B.3.2 User Management Functions" for functions.

[Example]

```
SELECT pgx_unlock_user('user1');
```

To release a lock when a database administrator is locked, users other than the locked user with CREATEROLE privilege can do so. If the user does not exist, Fujitsu Enterprise Postgres must be started in single-user mode and the lock released.

You can set PASSWORD_LOCK_TIME to automatically release locks due to FAILED_LOGIN_ATTEMPTS.

When the password expires

When a password life time is over, the password expires and cannot be used to connect to and operate on the database until the password is changed.

The password can be changed by the expired user itself, or by a user who has the CREATEROLE privilege and who is an administrator of that user (who has ADMIN privilege for that user).

7.5 Settings in Streaming Replication Configuration

For streaming replication, the policy is enabled on both the primary and standby servers.

Perform changing the contents of the profile, creating and assigning profiles, unlock, and change the password can only be done on the primary server.

This section describes how to setting streaming replication configuration.

1. Grant privilege to users for streaming replication

   The standby server connects to the primary server and propagates any state changes it detects to the primary server. The used users for streaming replication (specified in primary_conninfo) is used to connect for state change. Grant privilege to this user. Allow the user to SET ROLE directly to the group role pgx_update_profile_status.

   [Example]

   ```
   # GRANT pgx_update_profile_status TO repluser WITH SET TRUE;
   ```

   This action enables users for streaming replication to lock all other database users or unlock the lock state due to policy deviations. Also, membership in the pgx_update_profile_status group role should only be granted to users for streaming replication.

2. Add a record to pg_hba.conf

   Add a record to accept connections from the standby server. Duplicate the record for streaming replication and specify the database name in the userprofile_database parameter as the destination database name. Authentication methods other than password authentication are recommended.

   ```
   host  replication  repluser  standbyServerAddress authenticationMethod    # For Streaming
   Replication
   host  postgres     repluser  standbyServerAddress authenticationMethod    # For state change
   propagation
   ```

Information

- If the primary and standby servers are disconnected, profile-based restrictions still apply on each server. However, the standby server itself cannot change its password or unlock it explicitly. After removing the cause of the disconnect, restore the connection to the primary server and business operations, and then change the password or explicitly unlock.
- Connection information for reflecting status changes to the primary server or standby server is output as "User profile status sender" to application_name in the pg_stat_replication view. When monitoring the streaming replication status with the pg_stat_replication view, exclude the "User profile status sender" line from the monitoring target.

7.6 Backup and Recovery

Backup

Profile contents, user and profile assignment status, and password history can be backed up with physical backups and the pg_dumpall command.

When dumping with SQL statements using the pg_dumpall command, database role information is backed up at the same time it is dumped.

Information

When the pg_dumpall command is run without the --no-role-passwords option, the database user's password is included in the backup file in the form of a encrypted form. Therefore, when recovering the database user's password, temporarily set this parameter to true in the default profile of the restore destination. If the restore is successful, the contents of the default profile are restored to the contents at the time of the backup.

Recovery

If you recover using older backup data, you may be considered a dormant user at the time of recovery, or your password may have expired. In this case, unlock or change the password after recovery.

7.7 Profile parameters

Details of the parameters set in the profile are explained.

INACTIVE_USER_TIME

Number of days before auto-locking users who have not been connected to the database for a long time (users who cannot see their sessions)

[Supported values]

integer: A INTEGER value greater than or equal to 1

The unit is days. The maximum value is 24855 days.

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: No auto lock

This setting is for users with the LOGIN attribute.

If a session to the database cannot be verified for at least INACTIVE_USER_TIME, the user is locked out and cannot log in.

Sessions are checked into the database every hour and the information is saved.

If the system shuts down before the save, it is assumed that there were no logins between the last save and the shutdown. As a result, the lock period might be shorter than the value specified in this parameter.

When using streaming replication, the session confirmation to the database is performed every hour on each server. The primary server makes a locking decision while the standby server sends session confirmation information to the upstream server. This can cause a time lag of several hours before the session confirmation information from the standby server is communicated to the primary server. This lag can result in locking even when connected to a standby server.

You can determine when each user's session was last seen by the system by looking at the value of the userprlastactivetime column in the pgx_user_profile system catalog.

If the device is locked by the setting of this parameter, use the pgx_unlock_user function to unlock the device. Automatic cancellation by PASSWORD_LOCK_TIME is not performed.

When a logged-in user changes to another role with SET ROLE, the new role is not considered logged in to the database. It is assumed that the old role is still logged in to the database.

PASSWORD_LIFE_TIME

Number of days the same password can be used for authentication

[Supported values]

numeric: A NUMERIC value greater than or equal to 0

The unit is days. Hours and seconds can be specified with decimal places (e.g. 4.5 is equivalent to "4 days and 12 hours"). Precision is 1 second. The maximum value is 24855 days.

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: No life time (same password can be used indefinitely)

The password life time will be over after PASSWORD_LIFE_TIME days from the last time the password was updated for the target user. The timing of updating the profile is not the starting point. Therefore, if you specify an extremely short number of days (such as 1 day), it may already be past the life time at the time of renewal.

It is possible to specify when a password becomes invalid using the VALID UNTIL clause of CREATE ROLE or ALTER ROLE. If you specify both the VALID UNTIL clause and PASSWORD_LIFE_TIME, both values are valid. Note that in this case, you can login only if both constraints are met.

If there is no grace period, the password expires when the password life time is over. If you login using password authentication in this state, you will receive a "password expired" warning and you will not be able to execute commands other than changing your password. You can change the password to resume normal operations. Other than password authentication, you can connect to and work with the database.

For streaming replication, users will not be able to connect to the standby server after the password life time is over. There is no grace period for password expiration on standby servers. Password changes must be made on the primary server.

PASSWORD_GRACE_TIME

The number of days after a password life time is over before the password expires.

[Supported values]

numeric: A NUMERIC value greater than or equal to 0

The unit is days. Hours and seconds can be specified with decimal places (e.g. 4.5 is equivalent to "4 days and 12 hours"). Precision is 1 second. The maximum value is 24855 days.

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: Indefinite period

The password expiration grace period is PASSWORD_GRACE_TIME days from the first login time after the password life time is over. You can login with your current password during the grace period, but a warning prompts you to change your password. You can operate normally except that a warning is displayed. If specified as UNLIMITED, the grace period is infinite and you will be warned to change your password at every login. Once transitioned to the grace period, even if you change the profile value after that, you cannot go back to before the grace period, and you cannot change the life time. If 0 is specified, there is no grace period and the password expires at the first login after the password life time is over. In this case, you can perform normal operations again by changing the password.

Because the standby server does not have a grace period before the password expires, users cannot connect to the standby server after the password life time is over. Password changes must be made on the primary server.

PASSWORD_REUSE_TIME

Number of days the same password cannot be reused

The password cannot be reused by the same user for this period from the time the password is updated.

This parameter must be set in combination with PASSWORD_REUSE_MAX.

[Supported values]

numeric: A NUMERIC value greater than or equal to 0

The unit is days. Hours and seconds can be specified with decimal places (e.g. 4.5 is equivalent to "4 days and 12 hours"). Precision is 1 second. The maximum value is 24855 days.

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: Not reusable (However, if PASSWORD_REUSE_MAX is also UNLIMITED, the password can be reused without restriction)

PASSWORD_REUSE_MAX

Number of password changes required before the same password can be reused

This parameter must be set in combination with PASSWORD_REUSE_TIME.

[Supported values]

integer: An INTEGER value greater than or equal to 0

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: Not reusable (However, if PASSWORD_REUSE_TIME is also UNLIMITED, the password can be reused without restriction)

Both PASSWORD_REUSE_TIME and PASSWORD_REUSE_MAX constraints must be met to reuse passwords.

For example, if you specify PASSWORD_REUSE_TIME = 30, PASSWORD_REUSE_MAX = 10, a certain password can be reused if 30 days have passed since the update time and the password has been updated 10 times or more. When password update fails due to these parameters, the SQLSTATE will be "22023: invalid_parameter_value".

Also, if one parameter has a value and the other parameter specifies UNLIMITED, the password cannot be reused. If you want to use only one condition for reuse judgment, you need to set the value of the unused parameter to 0. However, if UNLIMITED is specified for both, these parameters are ignored and passwords can be reused without restriction.

When changing a password, if the password is specified in MD5 or SCRAM encrypted format, you cannot check that the password is being reused.

PASSWORD_ALLOW_HASHED

Whether to allow passwords to be specified in MD5 or SCRAM encrypted form when changing passwords Allow if true.

[Supported values]

boolean: true or false

DEFAULT: The value of the same parameter in the default profile

If true, there are no restrictions on how to set or change passwords.

However, note the following when changing passwords in encrypted form:

- Unable to check for password reuse (PASSWORD_REUSE_TIME, PASSWORD_REUSE_MAX)
- Password rollover disabled (PASSWORD_ROLLOVER_TIME)
- Inability to check password complexity using the extension passwordcheck

If false, the password can only be set or changed by specifying the password in clear text in the PASSWORD clause of a CREATE ROLE or ALTER ROLE statement. You cannot change the password using the psql command \password meta-command.

In this case, all password checks that cannot be performed in encrypted form are possible.

Note

Passwords specified in CREATE ROLE or ALTER ROLE statements may, depending on configuration, be logged in the psql command history and the server log.

FAILED_LOGIN_ATTEMPTS

Number of consecutive failed login attempts allowed by the user

[Supported values]

integer: An INTEGER value greater than 0

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: Indefinite period (Can fail any number of times)

If password authentication fails consecutively for the number of times specified by this parameter, the user is locked and cannot login.

The number of failed login attempts is counted separately on each server.

PASSWORD_LOCK_TIME

Number of days after a user is locked due to consecutive login failures before the user is unlocked

[Supported values]

numeric: A NUMERIC value greater than or equal to 0

The unit is days. Hours and seconds can be specified with decimal places (e.g. 4.5 is equivalent to "4 days and 12 hours"). Precision is 1 second. The maximum value is 24855 days.

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: Locked indefinitely

If set to UNLIMITED, the user will be locked indefinitely and will not be automatically unlocked. Unlocking requires an explicit pgx_unlock_user function call by a user with CREATEROLE privilege.

PASSWORD_ROLLOVER_TIME

Number of days after password change before old password expires

[Supported values]

numeric: A NUMERIC value greater than or equal to 0

The unit is days. Hours and seconds can be specified with decimal places (e.g. 4.5 is equivalent to "4 days and 12 hours"). Precision is 1 second. The maximum value is 60 days. The minimum value is 0.0416 days (approximately 1 hour).

DEFAULT: The value of the same parameter in the default profile

From the time the user changes the password until PASSWORD_ROLLOVER_TIME has elapsed, the user can login using the old password.

Specify a value equal to or less than the lesser of the PASSWORD_GRACE_TIME (except when 0 is specified) or PASSWORD_LIFE_TIME. If a larger value is specified, the smaller of these parameters is used. For example, if PASSWORD_GRACE_TIME is 10 and PASSWORD_LIFE_TIME is 50, specify 10 or less for this parameter. If 15 is specified in this parameter, 10 is assumed to be specified.

If 0 is specified, the user cannot login with the old password. The default profile has an initial value of 0.

To expire the combinable period immediately before PASSWORD_ROLLOVER_TIME expires, a user or a user with CREATEROLE privilege can call the pgx_make_password_rollover_expire function.

If you execute the ALTER ROLE statement with PASSWORD NULL, password authentication is disabled. Therefore, you cannot log in with the old password.

In either of the following cases, the password rollover is disabled and the previous password expires immediately:

- When changing the password, the password is specified in MD5 or SCRAM encrypted format.
- The password method has changed since the last time the password was set.
  The relevant parameters are:
  - password_encryption
  - scram_iterations

7.8 Worker Processes

This feature allows up to two background worker processes to reside. This information is displayed in the statistics view pg_stat_activity when it needs to be processed by a worker process. The worker processes added by this feature are those with column backend_type values of "user profile status writer" and "user profile status sender".

These processes may wait on the wait event "UserProFileWorkerMain" of type "Activity".

Chapter 8 Data Masking

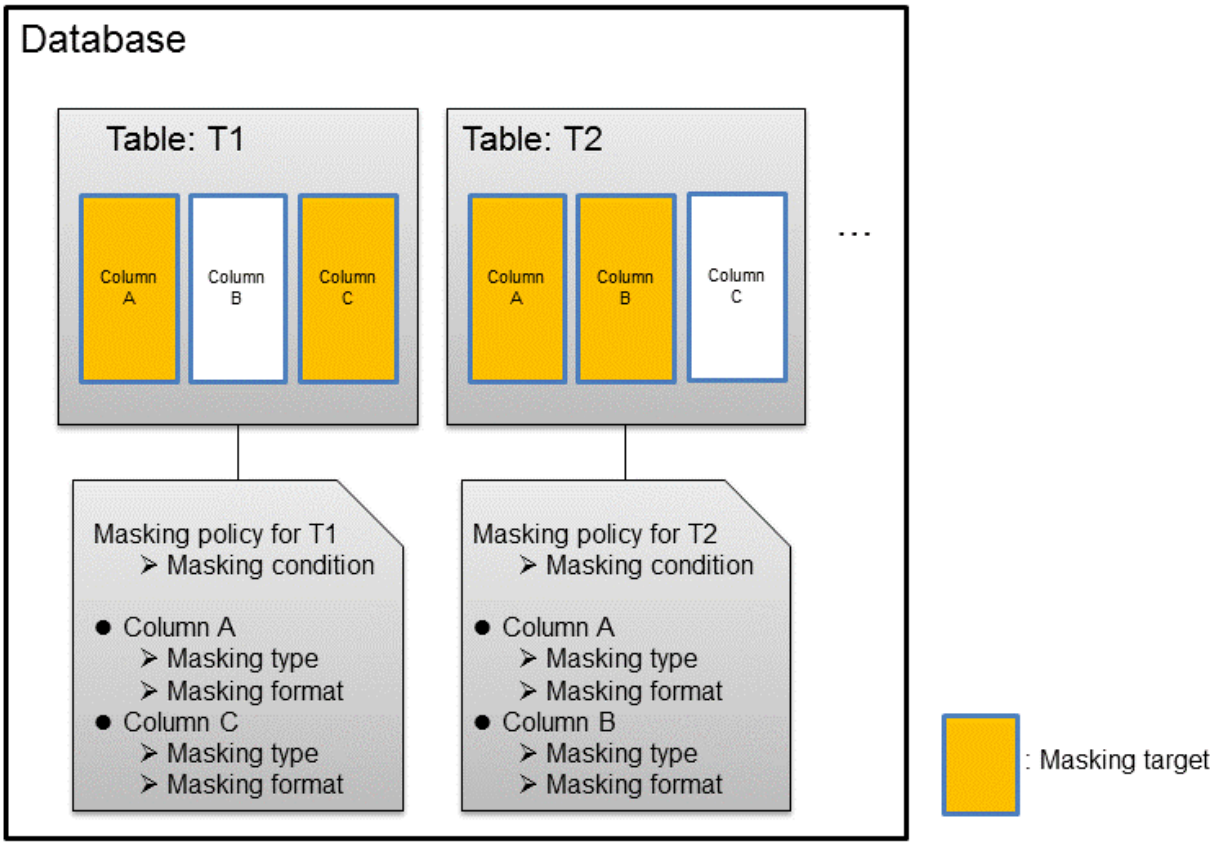
Data masking is a feature that can change the returned data for queries generated by applications, so that it can be referenced by users. For example, for a query of employee data, digits except the last four digits of an eight-digit employee number can be changed to "*" so that it can be used for reference.

When using this feature, it is recommended that the changed data be transferred to another medium for users to reference. This is because, if users directly access the database to extract the masked data, there is a possibility that they can deduce the original data by analyzing the masking policy or query result to the masking target column.

8.1 Masking Policy

Masking policy is a method of changing data under specific conditions when it is returned for a query from an application. One masking policy can be created per table. You can configure masking target, masking type, masking condition and masking format in a masking policy.

Figure 8.1 Masking policy



Information

When a masking policy is defined, the search performance for the corresponding table may deteriorate.

8.1.1 Masking Target

Masking target refers to a column to which a masking policy will be applied. When referring to a masking target or a function that includes a masking target, the execution result will be changed and obtained.

The following commands can change the execution result:

- SELECT
- COPY
- pg_dump
- pg_dumpall

Information

- If a masking target is specified to INSERT...SELECT target columns, processing will be performed using data before change.
- If a masking target other than SELECT target columns is specified, processing will be performed using data before change.
- If a masking target is specified in a function where the data type will be converted, an error will occur.

8.1.2 Masking Type

Masking type is a method to change column data that is returned from queries. Specify the masking type in the function_type parameter.

If multiple valid masking targets are specified for a function, the masking type for the left-most masking target will be applied. For example, if "SELECT GREATEST(c1, c2) FROM t1" is executed for numeric type masking target c1 and c2, the masking type for c1 will be applied.

The following masking types can be specified and selected depending on the masking target data type. When masking the data that includes multibyte characters, do not specify partial masking for masking type. The result may not be as expected.

Full masking

All the data in the specified column is changed. The changed value returned to the application that made the query varies depending on the column data type.
For example, 0 is used for a numeric type column and a space is used for a character type column.

Partial masking

The data in the specified column is partially changed.
For example, digits except the last four digits of an employee number can be changed to "*".

Regular expression masking

The data in the specified column is changed via a search that uses a regular expression.
For example, for strings such as email address that can have variable length, "*" can be used to change characters preceding "@" by using a regular expression. Regular expression masking can only be used for character type data.

8.1.3 Masking Condition

Masking condition refers to the conditions configured to perform masking. Specify the masking condition in the expression parameter. Changed or actual data can be displayed for different users by defining masking condition. An expression that returns a boolean type result needs to be specified in masking condition and masking is performed only when TRUE is returned. Refer to "Value Expressions" in the PostgreSQL Documentation for information on the expressions that can be specified. Note that expressions that include a column cannot be specified.
For example, when masking data only for "postgres" users, specify 'current_user = "postgres"' in the masking condition.

Information

Specify '1=1' so the masking condition is always evaluated to be TRUE and masking is performed all the time.

8.1.4 Masking Format

Masking format is a combination of change method and displayed characters when the masking condition is met. Masking format varies depending on the masking type. The following describes the masking format.

Full masking

With full masking, all characters are changed to values as determined by the database. Changed characters can be referenced in the pgx_confidential_values table. Also, replacement characters can be changed using the pgx_update_confidential_values system management function.

See

Refer to "8.3 Data Types for Masking" for information on the data types for which data masking can be performed.

Partial masking

With partial masking, data is changed according to the content in the function_parameters parameter. The method of specifying function_parameters varies depending on the data type.

Category	Method of specifying function_parameters
Numeric type	'*replacementCharacter*, *startPosition*, *endPosition*' - *replacementCharacter*: Specify the number to display. Specify a value from 0 to 9. - *startPosition*: Specify the start position of masking. Specify a positive integer. - *endPosition*: Specify the end position of masking. Specify a positive integer that is greater than *startPosition*. Example Specify as below to change the values from the 1st to 5th digits to 9. function_parameters := '9, 1, 5' In this example, if the original data is "123456789", it will be changed to "999996789".
Character type	*'inputFormat*, *outputFormat*, *replacementCharacter*, *startPosition*, *endPosition'* - *inputFormat*: Specify the current format of the data. Specify "V" for characters that will potentially be masked, and specify "F" for values such as spaces or hyphens that will not be masked. - *outputFormat*: Define the method to format the displayed data. Specify "V" for characters that will potentially be masked. Any character to be output can be specified for each character "F" in *inputFormat*. If you want to output a single quotation mark, specify two of them consecutively. - *replacementCharacter*: Specify any single character. If you want to output a single quotation mark, specify two of them consecutively. - *startPosition*: Specify the position of "V" as the start position of masking. For example, to specify the position of the 4th "V" from the left, specify 4. Specify a positive integer. - *endPosition*: Specify the position of "V" as an end position of masking. When working out the end position, do not include positions of "F". For example, to specify the position of the 11th "V" from the left, specify 11. Specify a positive integer that is greater than *startPosition*. Example Specify as below to mask a telephone number other than the first three digits using *. function_parameters := 'VVVFVVVVFVVVV, VVV-VVVV-VVVV, *, 4, 11' In this example, if the original data is "012-3156-7890", it will be changed to "012-****-****".
Date/timestamp type	'MDYHMS'

Category	Method of specifying function_parameters
	- M: Masks month. To mask month, enter the month from 1 to 12 after a lowercase letter m. Specify an uppercase letter M to not mask month. - D: Masks date. To mask date, enter the date from 1 to 31 after a lowercase letter d. If a value bigger than the last day of the month is entered, the last day of the month will be displayed. Specify an uppercase letter D to not mask date. - Y: Masks year. To mask year, enter the year from 1 to 9999 after a lowercase letter y. Specify an uppercase letter Y to not mask year. - H: Masks hour. To mask hour, enter the hour from 0 to 23 after a lowercase letter h. Specify an uppercase letter H to not mask hour. - M: Masks minute. To mask minute, enter the minute from 0 to 59 after a lowercase letter m. Specify an uppercase letter M to not mask minute. - S: Masks second. To mask second, enter the second from 0 to 59 after a lowercase letter s. Specify an uppercase letter S to not mask second. **Example** Specify as below to mask hour, minute, and second and display 00:00:00. function_parameters := 'MDYh0m0s0' In this example, if the original data is "2022-02-10 10:10:10", it will be changed to "2022-02-10 00:00:00".

See

- Refer to "B.4.2 pgx_create_confidential_policy" for information on function_parameters.
- Refer to "8.3 Data Types for Masking" for information on the data types for which masking can be performed.

Regular expression masking

With regular expression masking, data is changed according to the content of the regexp_pattern, regexp_replacement and regexp_flags parameters. For regexp_pattern, specify the search pattern using a regular expression. For regexp_replacement, specify the replacement character to use when data matches the search pattern. For regexp_flags, specify the regular expression flags.

When column data type is character(*n*) or char(*n*) and if the string length after change exceeds n, the extra characters will be truncated and only characters up to the nth character will be displayed.

When column data type is character varying(*n*) or varchar(*n*) and if the string length after change exceeds the length before the change, the extra characters will be truncated and only characters up to the length before change will be displayed.

Example

Specify as below to change all three characters starting from b to X.

regexp_pattern := 'b..'

regexp_replacement:= 'X'

regexp_flags := 'g'

In this example, if the original data is "foobarbaz", it will be changed to "fooXX".

See

- Refer to "POSIX Regular Expressions" in the PostgreSQL Documentation and check pattern, replacement, and flags for information on the values that can be specified for regexp_pattern, regexp_replacement, and regexp_flags.
- Refer to "8.3 Data Types for Masking" for information on the data types for which masking can be performed.

8.2 Usage Method

Preparation

The following preparation is required to use this feature.

1. Set the postgresql.conf file parameters.

   Prepend "pgx_datamasking" to the shared_preload_libraries parameter.

   Be sure to add "pgx_datamasking" to the beginning of the parameter "shared_preload_libraries".

2. Restart the instance.
3. Execute CREATE EXTENSION for the database that will use this feature.

   The target database is described as "postgres" here.

   Use the psql command to connect to the "postgres" database.

   Example

```
postgres=# CREATE EXTENSION pgx_datamasking;
CREATE EXTENSION
```

   Information

   - Specify "false" for pgx_datamasking.enable to not use this feature. Data will not be masked even if a masking policy is configured. This feature becomes available again once "true" is specified for pgx_datamasking.enable. This setting can be made by specifying a SET statement or specifying a parameter in the postgresql.conf file.
     Example

```
postgres=# SET pgx_datamasking.enable=false;
```

   - Hereafter, also perform this preparatory task for the "template1" database, so that this feature can be used by default when creating a new database.

Usage

To perform masking, a masking policy needs to be configured. Only database superusers can configure masking policies.

The masking policy setting is explained in the following steps using an example.

1. Creating a masking policy
2. Changing a masking policy
3. Confirming a masking policy
4. Enabling and disabling a masking policy
5. Deleting a masking policy

8.2.1 Creating a Masking Policy

Create a masking policy. Only one masking policy can be created per table.

All users can view the masking policy created, so do not grant the login privilege of the database where this feature is set to the users who refer to the changed data. Masking policies are defined in the "pgx_confidential_columns", "pgx_confidential_policies" and "pgx_confidential_values" tables.

An example of the operation on the server is shown below.

1. Create a masking policy
   Execute the pgx_create_confidential_policy system management function to create a masking policy.
   The following values are configured in this example.
   - Masking target: Numeric type c1
   - Masking type: FULL
   - Masking condition: '1=1'

```
postgres=# select pgx_create_confidential_policy(table_name := 't1', policy_name := 'p1',
expression := '1=1', column_name := 'c1', function_type := 'FULL');
 pgx_create_confidential_policy
--------------------------------
 t
(1 row)
```

2. Confirm the displayed data
   Confirm that the masking target data (column c1) has been correctly changed.

```
postgres=# select * from t1;
 c1 |      c2
----+--------------
  0 | 012-3456-7890
  0 | 012-3456-7891
  0 | 012-3456-7892
(3 row)
```

See

- Refer to "B.4.2 pgx_create_confidential_policy" for information on the pgx_create_confidential_policy system management function.

8.2.2 Changing a Masking Policy

An example of the operation on the server is shown below.

1. Change a masking policy
   Execute the pgx_alter_confidential_policy system management function to change a masking policy.
   The following values are changed in this example.
   - Content of change: Add a masking target
   - Masking target: Character type c2
   - Masking type: PARTIAL
   - Masking condition: 'VVVFVVVVFVVVV, VVV-VVVV-VVVV, *, 4, 11'

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1',
action := 'ADD_COLUMN', column_name := 'c2', function_type := 'PARTIAL', function_parameters :=
'VVVFVVVVFVVVV, VVV-VVVV-VVVV, *, 4, 11');
 pgx_alter_confidential_policy
--------------------------------
 t
(1 row)
```

2. Confirm the displayed data
   Confirm that the masking target data has been correctly changed.

```
postgres=# select * from t1;
 c1 |      c2
----+--------------
  0 | 012-****-****
  0 | 012-****-****
  0 | 012-****-****
(3 row)
```

See

- Refer to "B.4.1 pgx_alter_confidential_policy" for information on the pgx_alter_confidential_policy system management function.

8.2.3 Confirming a Masking Policy

An example of the operation on the server is shown below.

1. Confirm information about a masking target where a masking policy is set
   Refer to the pgx_confidential_columns table to confirm the masking target where the masking policy is set.

```
postgres=# select * from pgx_confidential_columns;
 schema_name | table_name | policy_name | column_name | function_type |
function_parameters           | regexp_pattern | regexp_replacement | regexp_flags |
column_description
-------------+------------+-------------+-------------+---------------
+---------------------------------------+----------------+--------------------+-------------
+--------------------
 public      | t1         | p1          | c1          | FULL
|                                        |                |                    |             |
 public      | t1         | p1          | c2          | PARTIAL       | VVVFVVVVFVVVV, VVV-VVVV-
VVVV, *, 4, 11 |                |                    |             |
(2 row)
```

2. Confirm information about the masking policy content
   Refer to pgx_confidential_policies to confirm the masking policy content.

```
postgres=# select * from pgx_confidential_policies;
 schema_name | table_name | policy_name | expression | enable | policy_description
-------------+------------+-------------+------------+--------+--------------------
 public      | t1         | p1          | 1=1        | t      |
(1 row)
```

See

- Refer to "F.1 pgx_confidential_columns" for information on the pgx_confidential_columns table.
- Refer to "F.2 pgx_confidential_policies" for information on the pgx_confidential_policies table.

8.2.4 Enabling and Disabling a Masking Policy

An example of the operation on the server is shown below.

1. Disable a masking policy
   Execute the pgx_enable_confidential_policy system management function to disable a masking policy.

```
postgres=# select pgx_enable_confidential_policy(table_name := 't1', policy_name := 'p1',
enable := 'f');
```

```
 pgx_enable_confidential_policy
--------------------------------
 t
(1 row)
```

2. Confirm the displayed data
   Confirm that the original data is displayed by disabling the masking policy.

```
postgres=# select * from t1;
 c1 |      c2
----+--------------
  1 | 012-3456-7890
  2 | 012-3456-7891
  3 | 012-3456-7892
(3 row)
```

3. Enable a masking policy
   Execute the pgx_enable_confidential_policy system management function to enable a masking policy.

```
postgres=# select pgx_enable_confidential_policy(table_name := 't1', policy_name := 'p1',
enable := 't');
 pgx_enable_confidential_policy
--------------------------------
 t
(1 row)
```

4. Confirm the displayed data
   Confirm that the masking target data has been correctly changed.

```
postgres=# select * from t1;
 c1 |      c2
----+--------------
  0 | 012-****-****
  0 | 012-****-****
  0 | 012-****-****
(3 row)
```

See

- Refer to "B.4.4 pgx_enable_confidential_policy" for information on the pgx_enable_confidential_policy system management function.

8.2.5 Deleting a Masking Policy

An example of the operation on the server is shown below.

1. Delete a masking policy
   Execute the pgx_drop_confidential_policy system management function to delete a masking policy.

```
postgres=# select pgx_drop_confidential_policy(table_name := 't1', policy_name := 'p1');
 pgx_drop_confidential_policy
--------------------------------
 t
(1 row)
```

2. Confirm the displayed data
   Confirm that the original data is displayed by deleting the masking policy.

```
postgres=# select * from t1;
 c1 |      c2
----+--------------
```

```
  1 | 012-3456-7890
  2 | 012-3456-7891
  3 | 012-3456-7892
(3 row)
```

See

- Refer to "B.4.3 pgx_drop_confidential_policy" for information on the gx_drop_confidential_policy function.

8.3 Data Types for Masking

The data types for which data masking can be performed are shown below.

Even if the data type can be masking, if the data is a special value (NaN, Infinity, -Infinity), it is not.

Category	Data type	Masking type		
		Full masking	Partial masking	Regular expression masking
Numeric type	smallint	Y	Y	N
	integer	Y	Y	N
	bigint	Y	Y	N
	decimal	Y	Y	N
	numeric	Y	Y	N
	float	Y	Y	N
	real	Y	Y	N
	double precision	Y	Y	N
Character type	character varying(*n*)	Y	Y	Y
	varchar(*n*)	Y	Y	Y
	character(*n*)	Y	Y	Y
	char(*n*)	Y	Y	Y
Date/timestamp type	date	Y	Y	N
	timestamp	Y	Y	N

8.4 Security Notes

- Starting with FEP 10, logical replication is available, which allows non-backed up clusters to subscribe to databases where data masking policies are enabled. Logical replication allows publisher and subscriber databases to have their own or the same data masking policies.

  In this scenario, the user must disable data masking on the publisher database whenever a subscription is created. This ensures that subscribers are able to obtain the original data (initial copy) instead of the masked version. Then, it is the user's responsibility to set masking policies to each subscribed database.

- Take strong caution in publishing data masking's confidential tables (pgx_confidential_policies, pgx_confidential_columns, etc.) unless the user is publishing all tables of the database and wants to apply the same data masking's policies on the subscribed database for all of them.

  Otherwise, as these confidential tables contain the masking policies for all tables of the database, confidential policies of unpublished tables may be unintentionally published. Additionally, it is not possible to apply different data masking policies on the subscriber database.

Chapter 9 Periodic Operations

This chapter describes the operations that must be performed periodically when running daily database jobs.

Information

Among routine operations, those that can be implemented with scripts can be automated using cron, while those that can be implemented as SQL statements or stored procedures can be automated using pg_cron.

9.1 Configuring and Monitoring the Log

Fujitsu Enterprise Postgres enables you to output database errors and warnings to a log file.

This information is useful for identifying if errors have occurred and the causes of those errors.

By default, this information is output to the system log. It is recommended that you configure Fujitsu Enterprise Postgres to collect logs from its log files (for example, log_destination) before operating Fujitsu Enterprise Postgres.

Periodically monitor the log files to check if any errors have occurred.

See

- Refer to "Error Reporting and Logging" under "Server Administration" in the PostgreSQL Documentation for information on logs.
- Refer to "Configuring Parameters" in the Installation and Setup Guide for Server for information on log settings when operating with WebAdmin.

9.2 Monitoring Disk Usage and Securing Free Space

When a database is used for an extended period, free space on the disk is continuously consumed and in some cases the disk space runs out. When this happens, database jobs may stop and no longer run.

You should, therefore, periodically monitor the usage of disk space, and delete obsolete files located in the disk.

Monitor the disk usage of the disk where the following directories are located:

- Data storage destination directory
- Transaction log storage destination (if the transaction log is stored in a different directory from the data storage destination directory)
- Backup data storage destination directory
- Tablespace storage destination directory

9.2.1 Monitoring Disk Usage

To check the disk usage, use the following operating system commands:

- df command

You can even use SQL statements to check tables and indexes individually.

Refer to "Determining Disk Usage" under "Server Administration" in the PostgreSQL Documentation for information on this method.

Information

If you are using WebAdmin for operations, a warning is displayed when disk usage reaches 80%

9.2.2 Securing Free Disk Space

Secure free disk space by using the following operating system commands to delete unnecessary files, other than the database, from the same disk unit.

- rm command

You can also secure disk space by performing the following tasks periodically:

- To secure space on the data storage destination disk:

  Execute the REINDEX statement. Refer to "9.5 Reorganizing Indexes" for details.

- To secure space on the backup data storage destination disk:

  Execute backup using WebAdmin or the pgx_dmpall command.

9.3 Automatically Closing Connections

If an application stops responding and abnormally terminates for any reason, the connection from the application may remain active on the database server. If this situation continues for an extended period, other applications attempting to connect to the database server may encounter an error, or an error indicating that the tables are unavailable may occur.

It is, therefore, recommended that idle connections be closed automatically at regular intervals.

Set the following parameters in the postgresql.conf file to indicate the time permitted to elapse before a connection is closed.

Parameter name	Setting	Description
tcp_keepalives_idle	Time until keepalive is sent (seconds) If 0, the default value of the system is used.	Sends keepalive to an idle connection at the specified interval in seconds It is recommended to specify 30 seconds.
tcp_keepalives_interval	keepalive send interval (seconds) If 0, the default value of the system is used.	Sends keepalive at the specified interval It is recommended to specify 10 seconds.
tcp_user_timeout	Time to wait for a response from the server (milliseconds) If 0, the default value of the system is used. If not set, the behavior is the same as if 0 were specified. If a value other than 0 is specified, the waiting time set by the tcp_keepalives_idle parameter and tcp_keepalives_interval parameter will be invalid and the waiting time specified by the tcp_user_timeout parameter will be used.	After establishing the connection, when sending from the client to the server, if the TCP resend process operates, specify the time until it is considered to be disconnected. If a value other than 0 is specified in this parameter, the time until automatic disconnection is determined by the waiting time specified in this parameter. The actual wait time is until the timing of the first keepalive retransmission after the time specified by this parameter has elapsed.

See

Refer to "Connection Settings" under "Server Administration" in the PostgreSQL Documentation for information on the parameters.

9.4 Monitoring the Connection State of an Application

Fujitsu Enterprise Postgres does not immediately delete the updated or deleted data. If the VACUUM determines there are no transactions that reference the database, Fujitsu Enterprise Postgres collects obsolete data.

However, obsolete data is not collected if there are connections that have remained active for an extended period or connections occupying resources. In this case the database may expand, causing performance degradation.

See

Refer to "Routine Vacuuming" under "Server Administration" in the PostgreSQL Documentation for information on the VACUUM command.

In such cases, you can minimize performance degradation of the database by monitoring problematic connections.

The following methods are supported for monitoring connections that have been in the waiting status for an extended period:

- 9.4.1 Using the View (pg_stat_activity)
- 9.4.2 Using pgAdmin

9.4.1 Using the View (pg_stat_activity)

Use the view (pg_stat_activity) to identify and monitor connections where the client has been in the waiting status for an extended period.

Example

The example below shows connections where the client has been in the waiting status for at least 60 minutes.

However, when considering continued compatibility of applications, do not reference system catalogs directly in the following SQL statements.

```
postgres=# select * from pg_stat_activity where backend_type = 'client backend' and state='idle in
transaction' and current_timestamp > cast(query_start + interval '60 minutes' as timestamp);
-[ RECORD 1 ]----+------------------------------
datid            | 13003
datname          | db01
pid              | 4638
leader_pid       |
usesysid         | 10
usename          | fsep
application_name | apl01
client_addr      | 192.33.44.15
client_hostname  |
client_port      | 27500
backend_start    | 2022-02-24 09:09:21.730641+09
xact_start       | 2022-02-24 09:09:23.858727+09
query_start      | 2022-02-24 09:09:23.858727+09
state_change     | 2022-02-24 09:09:23.858834+09
wait_event_type  | Client
wait_event       | ClientRead
state            | idle in transaction
backend_xid      |
backend_xmin     |
query_id         |
query            | begin;
backend_type     | client backend
```

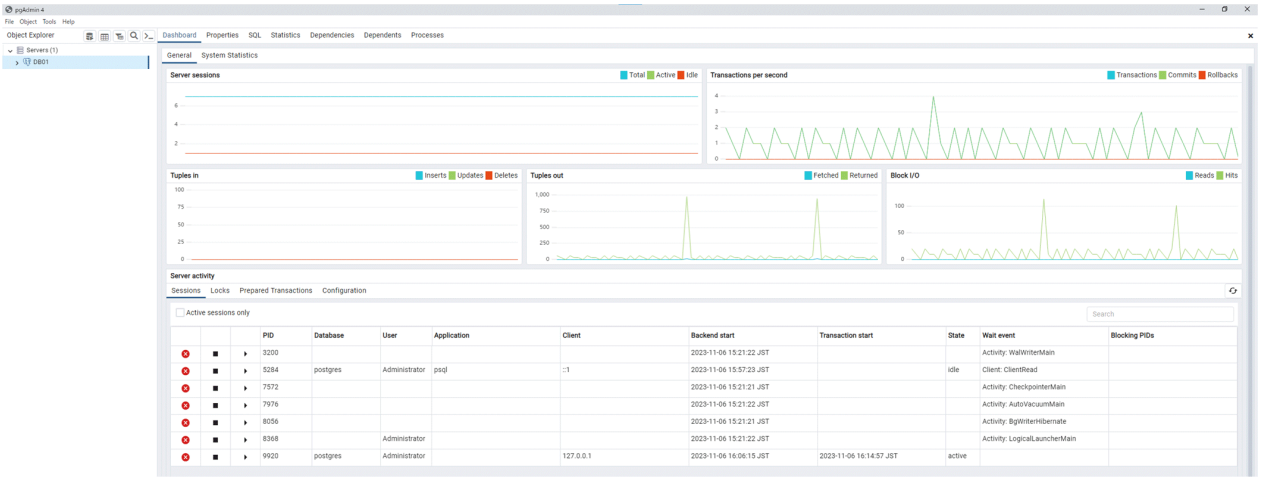
See

- Refer to "Notes on Application Compatibility" in the Application Development Guide for information on maintaining application compatibility.
- Refer to "The Statistics Collector" under "Server Administration" in the PostgreSQL Documentation for information on pg_stat_activity.

9.4.2 Using pgAdmin

This section describes the procedure for monitoring connections using [Server Status] in pgAdmin.

1. In the [Browser] pane, click the database server for monitoring.
2. In the [Dashboard] tab, identify client connections that have been in the waiting state for an extended period.



9.5 Reorganizing Indexes

Normally, a database defines indexes in tables, but if data is frequently updated, indexes can no longer use free space in the disk efficiently. This situation can also cause a gradual decline in database access performance.

To rearrange used space on the disk and prevent the database access performance from declining, it is recommended that you periodically execute the REINDEX command to reorganize indexes. Because the REINDEX command retrieves the exclusive lock for an index being processed and locks writing of tables that are the source of the index, other processes that access these may stop while waiting to be locked. Therefore, it is necessary to consider measures such as executing the command after the task is completed.

Check the disk usage of the data storage destination using the method described in "9.2 Monitoring Disk Usage and Securing Free Space".

See

Refer to "Routine Reindexing" under "Server Administration" in the PostgreSQL Documentation for information on reorganizing indexes by periodically executing the REINDEX command.

Point

Typically, reorganize indexes once a month at a suitable time such as when conducting database maintenance. Use SQL statements to check index usage. If this usage is increasing on a daily basis, adjust the frequency of recreating the index as compared to the free disk space.

The following example shows the SQL statements and the output.

However, when considering continued compatibility of applications, do not reference system catalogs and functions directly in the following SQL statements. Refer to "Notes on Application Compatibility" in the Application Development Guide for details.

[SQL statements]

```
SELECT
  nspname AS schema_name,
  relname AS index_name,
  round(100 * pg_relation_size(indexrelid) / pg_relation_size(indrelid)) / 100 AS index_ratio,
  pg_size_pretty(pg_relation_size(indexrelid)) AS index_size,
  pg_size_pretty(pg_relation_size(indrelid)) AS table_size
FROM pg_index I
```

```
  LEFT JOIN pg_class C ON (C.oid = I.indexrelid)
  LEFT JOIN pg_namespace N ON (N.oid = C.relnamespace)
WHERE
  C.relkind = 'i' AND
  pg_relation_size(indrelid) > 0
ORDER BY pg_relation_size(indexrelid) DESC, index_ratio DESC;
```

[Output]

```
 schema_name |            index_name            | index_ratio | index_size | table_size
-------------+----------------------------------+-------------+------------+------------
 public      | pgbench_accounts_pkey            |        0.16 | 2208 KB    | 13 MB
 pg_catalog  | pg_depend_depender_index         |         0.6 | 224 KB     | 368 KB
 pg_catalog  | pg_depend_reference_index        |        0.58 | 216 KB     | 368 KB
...
```

See

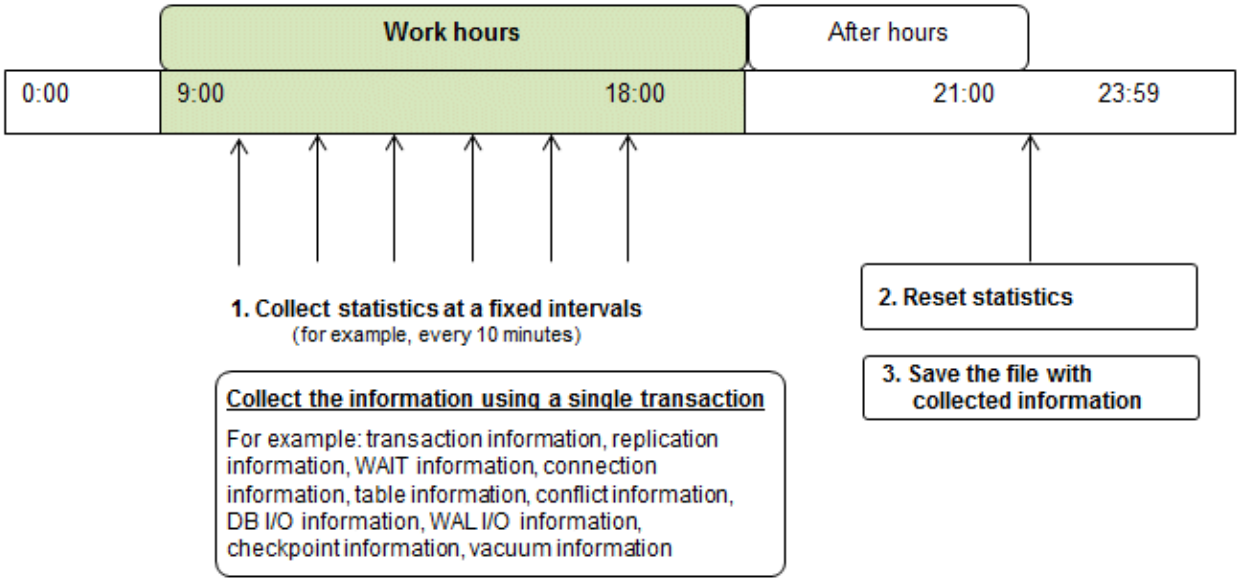
Refer to "Notes on Application Compatibility" in the Application Development Guide for information on maintaining application compatibility.

9.6 Monitoring Database Activity

Fujitsu Enterprise Postgres enables you to collect information related to database activity. By monitoring this information, you can check changes in the database status.

This information includes wait information for resources such as internal locks, and is useful for detecting performance bottlenecks. Furthermore, you should collect this information in case you need to request Fujitsu technical support for an investigation.

Figure 9.1 Overview of information collection



1. Collect statistics at fixed intervals during work hours.

   Accumulate the collected information into a file.

   Wherever possible, collect data from the various statistics views using a single transaction, because it enables you to take a snapshot of system performance at a given moment.

   Refer to "9.6.1 Information that can be Collected" for information on the system views that can be collected.

2. Reset statistics after work hours, that is, after jobs have finished.

   Refer to "9.6.3 Information Reset" for information on how to reset statistics.

3. Save the file with collected information.

   Keep the file with collected information for at least two days, in order to check daily changes in performance and to ensure that the information is not deleted until you have sent a query to Fujitsu technical support.

Where jobs run 24 hours a day, reset statistics and save the file with collected information when the workload is low, for example, at night. Statistics cumulatively add the daily database value, so if you do not reset them, the values will exceed the upper limit, and therefore will not provide accurate information.

The subsections below explain the following:

- Information that can be collected
- Collection configuration
- Information reset

9.6.1 Information that can be Collected

Information that can be collected is categorized into the following types:

- Information common to PostgreSQL
- Information added by Fujitsu Enterprise Postgres

Information common to PostgreSQL

Refer to "Monitoring Database Activity" under "Server Administration" in the PostgreSQL Documentation for information on information common to PostgreSQL.

Information added by Fujitsu Enterprise Postgres

You can collect the following information added by Fujitsu Enterprise Postgres.

Table 9.1 Information added by Fujitsu Enterprise Postgres

View name	Description
pgx_stat_lwlock	Displays statistic related to lightweight lock, with each type of content displayed on a separate line. This information helps to detect bottlenecks. Refer to "D.2 pgx_stat_lwlock" for details.
pgx_stat_latch	Displays statistics related latches, with each type of wait information within Fujitsu Enterprise Postgres displayed on a separate line. This information helps to detect bottlenecks. Refer to "D.3 pgx_stat_latch" for details.
pgx_stat_walwriter	Displays statistics related to WAL writing, in a single line. Refer to "D.4 pgx_stat_walwriter" for details.
pgx_stat_sql	Displays statistics related to SQL statement executions, with each type of SQL statement displayed on a separate line. Refer to "D.5 pgx_stat_sql" for details.
pgx_stat_gmc	Displays statistics related to Global Meta Cache hit ration and used memory size. Refer to “D.6 pgx_stat_gmc” for detail. Also refer to Chapter 16 Global Meta Cache" for information on the Global Meta Cache.

9.6.2 Collection Configuration

The procedure for configuring collection depends on the information content.

- Information common to PostgreSQL
- Information added by Fujitsu Enterprise Postgres

Information common to PostgreSQL

See

Refer to "The Statistics Collector" in "Monitoring Database Activity" under "Server Administration" in the PostgreSQL Documentation for information on information common to PostgreSQL.

Information added by Fujitsu Enterprise Postgres

Information added by Fujitsu Enterprise Postgres is collected by default.

To enable or disable information collection, change the configuration parameters in postgresql.conf. The following table lists the views for which you can enable or disable information collection, and the configuration parameters.

View name	Parameter
pgx_stat_lwlock pgx_stat_latch	track_waits (*1)
pgx_stat_sql	track_sql
pgx_stat_gmc	track_gmc

Remarks: You cannot change the collection status for pgx_stat_walwriter.

*1: When executing the SQL statement with EXPLAIN ANALYZE, processing time may increase because of this information collection. It is recommended to set this parameter to "off" when executing EXPLAIN ANALYZE to check the processing time.

Refer to "Appendix A Parameters" for information on the parameters.

9.6.3 Information Reset

This section describes how to reset information.

Information added by Fujitsu Enterprise Postgres

You can reset information added by Fujitsu Enterprise Postgres by using the pg_stat_reset_shared function in the same way as for information common to PostgreSQL.

Configure the following parameters in the pg_stat_reset_shared function:

Function	Type of return value	Description
pg_stat_reset_shared(text)	void	Reset some cluster-wide statistics counters to zero, depending on the argument (requires superuser privileges). Calling pg_stat_reset_shared('lwlock') will zero all counters shown in pgx_stat_lwlock. Similarly, in the following cases, all values of the pertinent statistics counter are reset: - If pg_stat_reset_shared('latch') is called: All values displayed in pgx_stat_latch

Function	Type of return value	Description
		- If pg_stat_reset_shared('walwriter') is called: All values displayed in pgx_stat_walwriter - If pg_stat_reset_shared('sql') is called: All values displayed in pgx_stat_sql - If pg_stat_reset_shared('gmc') is called: All values except size column in pgx_stat_gmc

See

Refer to "Statistics Functions" in "Monitoring Database Activity" under "Server Administration" in the PostgreSQL Documentation for information on other parameters of the pg_stat_reset_shared function.

9.7 Scheduling of an Aggressive Freeze for Tuples (VACUUM FREEZE)

An architectural limitation of PostgreSQL is that it requires transaction ID reclamation via tuple freezing to avoid the problem of disruptive transaction wraparound. For more information about transaction wraparound issues, refer to "Preventing Transaction ID Wraparound Failures" in the PostgreSQL Documentation.

Tuple freezing works with autovacuum and VACUUM FREEZE(aggressive freeze for tuples). However, on a system that consumes transactions quickly, autovacuum alone might be enough to run into wraparound problems. This is because autovacuum is slow to reduce frequency of collisions with applications and increase system load. Such systems must perform an aggressive tuple freeze at the appropriate time.

Fujitsu Enterprise Postgres provides scripts to perform efficient aggressive freeze for tuples.

This section describes how to monitor whether the freezing process is on time in a running system, and how to estimate the running time of the script.

Point

If you insert or update a large amount of data at once, the next freeze process will take a long time, so be sure to perform aggressive freeze for tuples after such operations.

9.7.1 Monitoring Trends in Transaction ID Usage

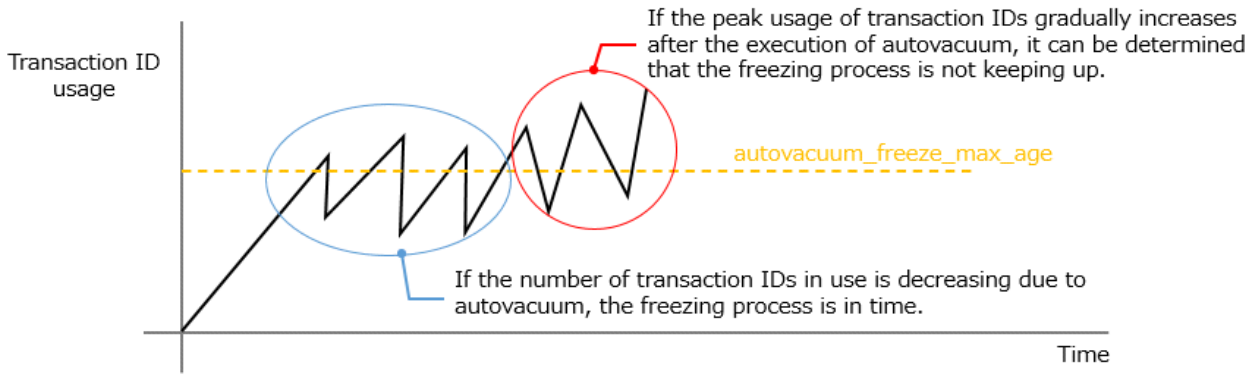
Execute the following SQL to monitor the trend in transaction ID usage.

```
# SELECT max(age(datfrozenxid)) FROM pg_database WHERE datallowconn = true;
```

If autovacuum does not sufficiently reduce transaction ID usage, schedule aggressive freeze for tuples.

Determine whether the amount of waste reduced by automatic vacuum is sufficient

Looking at the entire interval that includes several autovacuum freeze processes, the transaction ID usage will be graphed like a sawtooth, sandwiching the autovacuum_freeze_max_age setting value, depending on the start and end of the autovacuum operation. If the usage peaks are gradually getting larger, the reduction may be insufficient. In particular, if it no longer falls below autovacuum_freeze_max_age, the reduction is definitely insufficient.



9.7.2 How to Schedule Aggressive Freeze for Tuples

1. Determine a time period with low business load when aggressive freeze for tuples will have minaimal impact.
2. Copy the script that implements aggressive freeze for tuples and set the connection information, multiplicity, and timeout value parameters.

   For streaming replication configuration, specify multiple connection destinations in PGHOST and PGPORT, and specify "read-write" or "primary" in PGTARGETSESSIONATTRS to connect to the primary server.

   The scripts are stored in the following location under the Fujitsu Enterprise Postgres installation directory:

   ```
   <Install directory>/share/execute_freeze.sh.sample
   ```

3. Register the script from step 2 in the job scheduler.
   Specify the execution timing according to the planned time period.

   Example: Use cron to run a script called execute_freeze.sh at 2:05 AM

   ```
   5 2 * * 0 sh /path/to/execute_freeze.sh
   ```

When a schedule review is required

Even after aggressive freeze for tuples is scheduled, continue to monitor the trend in transaction ID usage. If you determine that the freezing process is not keeping up, the schedule must be reviewed. To collect the statistical information required for the review, enable the extended functionality for aggressive freeze for tuples using the following procedure.

1. Modify the shared_preload_libraries parameter in postgresql.conf

   ```
   shared_preload_libraries = 'pgx_stat_vacuum_freeze'
   ```

2. Execute the following SQL

   ```
   SELECT datname FROM pg_database WHERE datallowconn = true;
   ```

   Execute the following CREATE EXTENSION for all databases to be output and define the extension.

   ```
   CREATE EXTENSION pgx_stat_vacuum_freeze;
   ```

Monitor the trends in transaction usage, and if you determine that the freezing process is not keeping up, refer to "9.7.3 Tuning the Allocation Time for Aggressive Freeze for Tuples" to calculate the time required for freezing tuples and add more allocation time.

9.7.3 Tuning the Allocation Time for Aggressive Freeze for Tuples

The interval between autovacuum runs is treated as one interval, and aggressive freeze for tuples is scheduled to be completed before the next autovacuum run. For example, if your environment is one week where freezing by autovacuum occurs, determine the required time within that interval.

Calculate the time required for aggressive freeze for tuples as follows, based on the time it took to freeze transaction IDs by past autovacuums stored in the pgx_stat_freeze_results table for each database you are using.

In this example, the interval for autovacuum freezing is set to one week. Perform this for each database you operate and calculate the total.

```
# SELECT sum(total_elapsed_time) - sum(sleep_times) as total_time FROM pgx_stat_freeze_results WHERE
measurement_start_time >= '2024/10/21 00:00:00' AND measurement_end_time < '2024/10/28 00:00:00' AND
autovacuum = true;
```

If you are unable to secure sufficient time when the workload is low, increase the degree of parallelism. You can specify the degree of parallelism in the script.

9.8 Database Monitoring with Amazon CloudWatch

Amazon CloudWatch is a monitoring tool provided by Amazon Web Services (hereinafter referred to as AWS). Fujitsu Enterprise Postgres works with Amazon CloudWatch to collect database-related metrics and logs. The collected metrics can be used to monitor the status of the database and create alert notifications when thresholds are exceeded. In addition, by analyzing the collected logs on CloudWatch, it is possible to detect abnormalities in logins and operations.

9.8.1 Metrics Collection

Metrics collection uses psql commands to retrieve metrics and the AWS CLI to forward metrics to Amazon CloudWatch.

1. Preparation

   Refer to the AWS documentation, install the AWS CLI, and configure it to transfer metrics to Amazon CloudWatch.

2. Create a metrics collection script

   Sample scripts for collecting metrics are stored in the following location under the Fujitsu Enterprise Postgres installation directory. Create a script for collecting metrics by referring to the sample script. For the metrics collected by the sample script, refer to "9.8.3 Metrics Collected by the Sample Script".

   ```
   <Install directory>/share/putting-metrics-to-monitoring-tool.sh.sample
   ```

   Edit the following connection information defined in the sample script.

   - Amazon CloudWatch connection destination to store metrics

     Define the Amazon CloudWatch Namespace to collect metrics in “NAMESPACE”.

     ```
     NAMESPACE="YOUR Cloud Watch NAMESPACE"
     ```

   - Database connection destination for collecting metrics

     Edit the variables below to define the PostgreSQL information for retrieving metrics.

     PGHOST: Specify the host name to connect to.

     PGPORT: Specify the port to connect to.

     PGDATABASE: Specify the database name to connect to.

     PGUSER: Specify the PostgreSQL user to use for connection. To view all statistical information for all sessions, specify a superuser or a role with the built-in role pg_read_all_stats privileges.

3. Setting environment variables

   To run the metrics collection script, you must set the path where the Fujitsu Enterprise Postgres server feature and AWS CLI are installed in the environment variable PATH.

   The following is an example of how to set environment variables when the AWS CLI is installed in /awscli/bin.
   If you want to set environment variables within a script, write them at the beginning of the script before the environment variable for the database connection destination.

   ```
   export PATH=/opt/fsepv<x>server64/bin:/awscli/bin:$PATH
   ```

4. Define the database connection credentials

   If necessary, define the password and the storage location of the SSL communication certificate in an environment variable or configuration file.

5. Periodically run metrics collection scripts

   Use crontab or similar to periodically run the metrics collection script as the OS user who can transfer metrics using the aws cloudwatch put-metric-data command.

   Below is an example of a crontab definition for collecting metrics every 10 minutes.

```
$ cat /var/spool/cron/<Running User>
*/10 * * * * /<Script placement destination>/putting-metrics-to-monitoring-tool.sh
```

   Edit the script to run periodically using the "crontab -e" command.

   When running with crontab, you can use rsyslog to output the script's standard output to a log file and detect whether the script is running normally or abnormally.

   The metrics collection interval should be determined based on the purpose of collection. The following are examples of collection intervals.

   - Long intervals, such as once every 10 minutes or once an hour, are recommended when monitoring to check operational trends.
   - Short intervals, such as once a minute, are recommended when monitoring to quickly respond to increases in load, such as a sudden increase in the number of connections.

   If the collection interval is short, the load may increase because the number of queries to the database increases accordingly. Consider the business load when deciding on the execution interval and the queries to be executed for metric collection.

9.8.2 Log Collection

You can collect logs using the CloudWatch agent. For instructions on how to collect logs, see the Amazon CloudWatch manual.

9.8.3 Metrics Collected by the Sample Script

In the sample script, metrics items are created from the following perspectives to regularly check whether the database cluster is operating properly.

- Is the database capacity sufficient?
- Are your SQL performance and connections adequate?
- Are each node operating normally?

Table 9.2 List of metrics collected by the sample script

Metrics name	Metrics
pg_stat_bgwriter_*	Maps displayed in statistics collection
pg_stat_database_*	Maps displayed in statistics collection
pg_stat_database_conflicts_*	Maps displayed in statistics collection
pg_stat_archiver_*	Maps displayed in statistics collection
pg_stat_activity_*	Maps displayed in statistics collection
pg_stat_replication_*	Maps displayed in statistics collection
pg_replication_slots_*	Mapping to the pg_replication_slots system catalog
pg_locks_*	Mapping to the pg_locks system catalog
pg_capacity_connection_*	Connection metrics (e.g. txns running for 1 hour)
pg_capacity_schema_*	Schema disk space metrics
pg_capacity_tblspace_*	Tablespace disk space metrics

Metrics name	Metrics
pg_capacity_tblvacuum_*	Metrics for tables that haven't been vacuumed in days
pg_capacity_longtx_*	Number of transactions running for more than 5 minutes
pg_capacity_datfrozenxid_*	Trends in transaction ID usage (Used for scheduling aggressive freeze for tuples (VACUUM FREEZE))
pg_performance_locking_detail_*	Blocked process details
pg_performance_locking_*	Number of blocked processes
pg_stat_user_tables_*	Vital statistics from pg_stat_user_tables
pg_statio_user_tables_*	Vital statistics from pg_statio_user_tables
pg_stat_statements_*	Statistics for SQL statements executed by the server
pg_capacity_tblbloat_*	Table fetch bloat

9.9 Monitoring Deferred SQL and Periodically Backing up statistics

After production starts, SQL execution can be delayed due to a variety of factors, including unexpected system load and data bias. You can detect delays early by monitoring for delays that affect operations. Monitoring can also reduce the time required for recovery tasks, such as determining the cause and resolving delays.

One cause of deferred SQL is a change in statistics. Some delays caused by statistics can be resolved by restoring the statistics before the delay occurred. For this reason, back up your statistics periodically to guard against delays.

Operational workflow

The workflow required to monitor delayed SQL and back up statistics is shown below.

Corresponding time	Work item	Work details
During environment construction	(1) Enabling the pg_dbms_stats extension	Enable the pg_dbms_stats extension with the Create Extension statement.
	(2) Logging settings for delayed SQL monitoring	Set the log_min_duration_statement parameter etc. in postgresql.conf.
During system development	(3) Creating and reviewing a script for backing up statistics (*1)	Provide a script to back up statistics according to the statistics and Vacuum operation.
During operation	(4) Periodic backup of statistics	Execute the script created in (3) to back up the statistics.
	(5) Monitoring delayed SQL and adjusting the allowable delay time	Monitor the occurrence of delayed SQL and adjust the allowable delay time to find the optimal settings for operation.
When delayed SQL occurs	(6) Investigating the cause of delayed SQL	If a delayed SQL occurs, we will investigate the cause of the SQL delay and consider countermeasures.
	(7) Restoring statistics (*2)	Delayed SQL is eliminated by restoring and fixing the backed up statistics.

*1: Although it is possible to perform the work during operation, please consider the impact on operation and perform the work before starting operation.

*2: If it is determined that the cause is not statistics, take appropriate measures according to the cause.

The specific work content is shown below.

(1) Enabling the pg_dbms_stats extension

To back up and restore statistics, you need the export and import functions of the pg_dbms_stats extension, so enable the pg_dbms_stats extension.

For instructions on how to enable it, refer to " Setting Up pg_dbms_stats" in the Installation and Setup Guide for Server.

(2) Logging settings for delayed SQL monitoring

Database logs are used to monitor delayed SQL.

Make the following settings in postgresql.conf. Note that the date and time are important when investigating the cause of delayed SQL, set the format and file name to include the date and time.

Parameter	Specified value
logging_collector	on
log_line_prefix	Specify the following format and add information required for investigation, such as the time and executed application. [%t]%u %d %p[%l]
log_filename	Since you will need to check past execution records, set it so that you can see the date and time. postgresql.%Y-%m-%d
log_min_duration_statement	300000

Point

If the value specified for the log_min_duration_statement parameter is small, even SQL that does not need to be considered delayed will be output to the log, and if it is too large, delayed SQL cannot be detected. Therefore, if the setting value cannot be estimated, set it small at the start of operation, and adjust it to a larger value as necessary while monitoring during operation.

(3) Creating and reviewing a script for backing up statistics

To back up statistics, use the export function of the pg_dbms_stats extension.

The backup is used not only for restoration but also for identifying the cause of delayed SQL, so the time the backup was performed is important. Therefore, be sure to create a script like the one below so that the backup time is known.

We also provide a sample script that uses the export function to export on a database basis. This allows users to respond more flexibly by making modifications themselves, such as making changes on a schema basis, so copy the script to the execution current before using it.

The sample script is stored below. Also, "<*x*>" indicates the product version.

```
/opt/fsepv<x>server64/share/doc/extension/export_plain_stats-<x>.sql.sample
```

The following is an example of a file created when it is copied to the current execution directory as "export_plain_stats-<x>.sql".

```
expprt PATH=/opt/fsepv<x>server64/bin:$PATH
export CURRENTDIR=/pg_dbms_stats/backup

pushd "${CURRENTDIR}"

# make file name
EXECDATE=`date '+%Y%m%d%H%M%S'`
FILENAME=pg_dbms_stats_back.${EXECDATE}.dmp

# export
psql -d database1 -f export_plain_stats-<x>.sql

# rename dump file
```

```
mv export_stats.dmp ${FILENAME}
popd
```

(4) Periodic backup of statistics

Execute the script created in "(3) Creating and reviewing a script for backing up statistics" to back up the statistics information on a regular basis.

Backup execution interval

Perform backup at the following timings according to the statistics update method.

When statistics is automatically updated (autovacuum is enabled)

Statistics are updated when autovacuum is run.

Therefore, use the OS's cron command or schedule function of the task manager to periodically execute the export function and back up the statistics to a file.

Therefore, use the OS's cron command or a scheduler such as task manager to periodically execute the script created in "(3) Creating and reviewing a script for backing up statistics" and back up the statistics information to a file.

Obtain the shortest autovacuum execution interval from the log, and back up the statistics at an interval shorter than the obtained autovacuum execution interval. autovacuum logs can be obtained by setting the log_autovacuum_min_duration parameter to 0.

When users update statistics

If the user controls the updating of statistics using the ANALYZE command, etc.,back up the statistics at the same time as updating the statistics.

Backup retention period

The backed up statistics will be used as investigation material to determine the cause of delayed SQL if a performance problem occurs. Therefore, keep it for the period of time expected to be required from the occurrence of the operational problem to its resolution.

Point

- The capacity required for backup mainly depends on the number of objects (schemas, tables, etc.) contained in the database. Estimate the required capacity from the backup file when checking the operation of the script and secure this space.
- To restore backed up statistics, the names of objects such as schemas and tables in the backup source must match. If you change the name of an object during operation, change the backup file name or storage location so that you can check whether it matches the object definition when restoring statistics.

(5) Monitoring delayed SQL and adjusting the allowable delay time

Monitors SQL that is delayed beyond the time set in the log_min_duration_statement parameter.

The settings in this section will be output in the following format.

```
[2024-04-30 10:20:11 JST]user1 postgres 3414[1]LOG: duration: 301001.541 ms  statement: SELECT
pg_sleep(301)
[2024-04-30 10:26:12 JST]user1 postgres 3414[1]LOG: duration: 302002.321 ms  statement: SELECT
pg_sleep(302)
```

When detected SQL is deemed to be delayed more than expected

Refer to "(6) Investigating the cause of delayed SQL" to determine the cause and take appropriate measures.

When SQL with execution time that does not affect operation is detected

The current setting just outputs redundant logs, so make major changes to the log_min_duration_statement parameter and then reload to enable it.

(6) Investigating the cause of delayed SQL

There are many factors that can cause SQL delays, so you must first identify the cause.

Here we will show you how to investigate SQL delays caused by changes in statistics.

Note that in the following cases, delays caused by statistics are unlikely, so recommend investigating from a different perspective (I/O, system load, etc.).

- When the SQL statement does not contain a search condition
- When the SQL statement uses the pg_hint_plan extension

1. Check the delayed SQL from the server log and identify the schema used by that SQL.
2. In a database cluster (such as a development environment) separate from the production environment, create an environment (hereafter referred to as the reproduction environment) with the same database name and table definition as the environment where the problem occurred. The reproduction environment also requires the pg_dbms_stats extension, so enable the pg_dbms_stats extension.
3. Use the pg_dump command from the production environment to obtain the target table definition.
   Since the data is not needed at this time, use the -s option of the pg_dump command from the production environment and use the extracted table definition.

   The following is an example of output to the file ddl_schema.dmp when the schema to be investigated is schema_1 in database database1.

   ```
   pg_dump -d database1 -s schema_1 > ddl_schema.dmp
   ```

   Using ddl_schema.dmp, create a research schema named schema_1 in the database named database1 in the reproduction environment.

   ```
   psql -d database1 -f ddl_schema.dmp
   ```

4. In order to identify the cause of the SQL delay, use the backed up statistics to check whether there is a cause of the delay in the statistics. Import the statistics into the schema in the reproduction environment using the pg_dbms_stats import function (dbms_stats.import_schema_stats).
   The following is an example of restoring statistics for schema schema_1 from the backup file "pg_dbms_stats_back.20240422011223.dmp".

   ```
   psql -d database1 -c
   "SELECT dbms_stats.import_schema_stats('schema_1','pg_dbms_stats_back.20240422011223.dmp')"
   ```

   Then, execute the EXPLAIN command for the deferred SQL to obtain the execution result (query plan).

5. Restore the statistics by separately importing the statistics that were backed up during the previous time period when deferred SQL was running stably.
   For example, if the target SQL is executed daily as part of regular batch processing, use the data from the same time the previous day.
   For online processing, use the data from a previous time period when a similar business application is expected to be executed.
   The following is an example of restoring the statistics from the backup file "pg_dbms_stats_back.20240421010001.dmp" from one day ago, assuming the SQL is used in batch processing.

   ```
   psql -d database1 -c
   "SELECT dbms_stats.import_schema_stats('schema_1','pg_dbms_stats_back.20240421010001.dmp')"
   ```

   It likewise obtains the result of executing the EXPLAIN command on deferred SQL (query plan).

6. Compare the execution results (query plans) of 4. and 5., and take the following action based on the results.

   - If the query plans are the same or the expected execution time of the query plan in 5. is longer

     This may be a problem other than statistics (system load, index imbalance, I/O, etc.), so investigate from a different perspective.

   - Other than the above

     The problem is likely that the optimal query plan was not selected due to updated statistics.

     Refer to "(7) Restoring statistics" and import the statistics from the period when the system was operating stably into the production environment to restore the system.

(7) Restoring statistics

Restore the production environment statistics to the state they were in before the delay occurred. The procedure is the same as for verification, but it is as follows:

```
psql -d database1 -c
"SELECT dbms_stats.import_schema_stats('schema_1','pg_dbms_stats_back.20240422000000')"
```

9.10 Performance Tuning

9.10.1 Enhanced Query Plan Stability

Fujitsu Enterprise Postgres estimates the cost of query plans based on SQL statements and database statistics, and selects the least expensive query plan. However, like other databases, Fujitsu Enterprise Postgres does not necessarily select the most suitable query plan. For example, it may suddenly select unsuitable query plan due to changes in the data conditions.

If you know that the statistics will not change significantly, you can control the selection of the same query plan by directly specifying which query plan to select in pg_hint_plan, or by fixing the statistics referenced by the planner in pg_dbms_stats.

Also, pg_dbms_stats from Fujitsu Enterprise Postgres can fix statistics (height of Btree indexes) that OSS pg_dbms_stats cannot account for. Refer to "9.10.1.1 Fixing the Height of a Btree Index".

See

- For information about setting up pg_hint_plan and pg_dbms_stats, refer to "pg_hint_plan" and "pg_dbms_stats" in the Installation and Setup Guide for Server.
- For basic usage of pg_hint_plan and pg_dbms_stats, refer to below.
  - Control execution plans with pg_hint_plan

    https://www.postgresql.fastware.com/postgresql-insider-tun-hint-plan
  - Control execution plans by fixing statistics with pg_dbms_stats

    https://www.postgresql.fastware.com/postgresql-insider-tun-dbms-stt
- For more information about pg_hint_plan and pg_dbms_stats, refer to the OSS web page.

9.10.1.1 Fixing the Height of a Btree Index

When PostgreSQL creates a query plan, it also references the height of the Btree index to be used as part of the statistics. However, OSS pg_dbms_stats does not include the height of the Btree index in its fixed statistics. The height of a Btree index is also fixed in pg_dbms_stats for Fujitsu Enterprise Postgres.

Fixing the height of a Btree index covers Fujitsu Enterprise Postgres 16 and later, so to maintain compatibility with earlier versions, specify something like:

- PostgreSQL 9.2 and earlier compatibility

```
pg_dbms_stats.use_tree_height = off
```

- Fujitsu Enterprise Postgres 15 SP2 and earlier compatibility

```
pg_dbms_stats.lock_tree_height = off
```

See the table below for details on each parameter. If you want the parameter value to be valid for all sessions, specify it in postgresql.conf and then reload.

Parameter	Specified value	Default
pg_dbms_stats.use_tree_height	Specify whether to include the Btree index height in cost calculation and plan generation when statistics are fixed. on: Includes Btree index height in cost calculations and plan generation. off: Do not include Btree index height in cost calculation or plan generation.	on
pg_dbms_stats.lock_tree_height	Specify whether to also fix the height of the Btree index when you fix the statistics. Note that this is valid only when the specified value of pg_dbms_stats.use_tree_height is "on". on: Fixes the height of the Btree index at the height when locked. off: The height of the Btree index is not fixed and varies depending on the amount of data in the index.	on

When you want to import statistics from your legacy environment

The format of files handled by the import/export functions of this version of pg_dbms_stats is different from the format of pg_dbms_stats in OSS or Fujitsu Enterprise Postgres 15SP2 or earlier. Therefore, statistics exported from pg_dbms_stats for OSS or Fujitsu Enterprise Postgres 15SP2 or earlier should be imported using the dbms_stats.import_<obj>_stats_no_tree_height function.

How to specify the dbms_stats.import_<obj>_stats_no_tree_height function

```
dbms_stats.import_<obj>_stats_no_tree_height('Absolute path of export file')
```

<obj> indicates a database (currently connected), schema, table, or column.

Import using the dbms_stats.import_<obj>_stats function provided by OSS is not possible.

If you use the wrong import function, an error message containing the following HINT will be output. Check the combination of input file and import function type, and use the correct import function.

```
HINT:  The import function may be incorrectly combined with the format of the exported data. Please
check the documentation for the relationship between the import function and the available data.
```

Chapter 10 Building a Cluster System Using Patroni

Fujitsu Enterprise Postgres can build a cluster system in cooperation with Patroni and etcd.

For information on how to build and operate a cluster system, refer to the Patroni and etcd documentation.

For information on how to install Patroni and etcd, refer to the following.

- Patroni: "Patroni" in the Installation and Setup Guide for Server
- etcd: "etcd" in the Installation and Setup Guide for Server Assistant

System configuration

Regarding the etcd cluster configuration, a major choice is whether to place Patroni and etcd on different servers or not.

Placing etcd on the same server as Patroni can save on the number of servers, but for example, in the following cases, it is recommended to place Patroni and etcd on different servers to avoid trouble.

- Assuming operation to dynamically change the number of replica nodes

  Placing etcd on all nodes might be excessive. However, placing etcd on only some nodes makes the system configuration a bit more complex.

- The number of replica nodes is large

  This is to avoid resource contention between etcd and the database server.

- Share the same DCS (etcd) with other system.

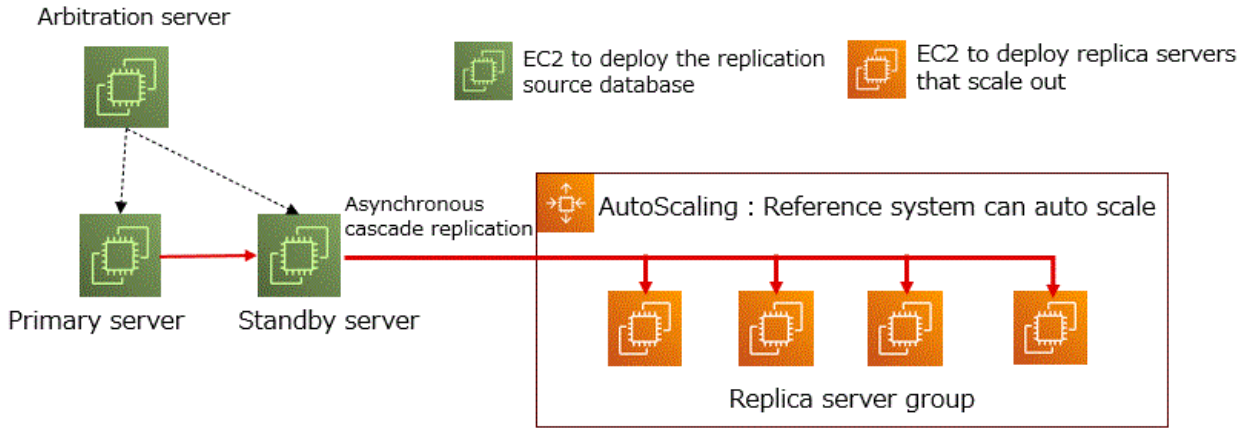
Regarding the Patroni cluster configuration, various configurations are possible depending on the system requirements, so please decide on your own. However, please note that depending on the configuration method, a single server failure could cause Patroni to demote the primary server to a standby server and halt update operations.

How to configure PostgreSQL

To enable Patroni to manage the configuration of PostgreSQL's streaming replication, all PostgreSQL data directories and settings are described in patroni.yml. In particular, do not directly edit postgresql.conf.

Chapter 11 Autoscale of Replica Servers through Amazon EC2 Auto Scaling Integration

By using Amazon EC2 Auto Scaling (Auto Scaling), you can scale out/scale in a group of replica servers that are cascaded and replicated from standby servers in a multiplexed database operation, depending on the database load.



11.1 Autoscale Setup

Describes the autoscale setup.

11.1.1 Building a Cluster System

Describes how to build a cluster system that will be the replication source for autoscaling.

11.1.1.1 Preparation

Refer to the AWS documentation to install the AWS Command Line Interface (AWS CLI) and configure the necessary settings for the following operations.

Operations	Example IAM policies to assign
Take an EBS snapshot	"ec2:DescribeInstances" "ec2:CreateTags" "ec2:CreateSnapshot"
Store WAL archives in S3	"s3:PutObject" "s3:AbortMultipartUpload" "s3:ListBucket"
Update the launch template for snapshot restoration	ec2:CreateLaunchTemplateVersion ec2:DescribeLaunchTemplates ec2:DescribeLaunchTemplateVersions
Edit the Route53 Private Hosted Zone to enable updating replica server connections	"route53:ChangeResourceRecordSets" "route53:GetChange"
Enable storage expansion via SSM	AmazonSSMManagedInstanceCore
Enable metric collection via the CloudWatch Agent	CloudWatchAgentServerPolicy

Point

To use AWS commands in the script that takes snapshots, you need to set the path where AWS CLI is installed in the PATH environment variable. Specify the PATH environment variable either as a global environment variable or in the sample script.

11.1.1.2 Building a Cluster System Using a Mirroring Controller

Refer to the Cluster Operation Guide(Database Multiplexing) to build a streaming replication configuration on Amazon EC2 (EC2).

To quickly copy data during scale out, we will use the Amazon Elastic Block Store (EBS) restore feature. Therefore, mount EBS to the EC2 instance where Fujitsu Enterprise Postgres server features are installed, and specify the folder where EBS is mounted as the storage location for the database cluster with initdb. Similarly, create tablespaces by specifying a folder where EBS is mounted.

11.1.1.3 Acquiring Snapshots to Restore Data when Deploying Replica Servers

When scaling out, a snapshot of the database cluster's data area is taken to restore data when deploying replica servers.

Creating a script to take snapshots

Create a script to take snapshots of the EBS volume storing data, in order to restore data when scaling out. On the primary server, use OS Cron or similar tools to regularly execute the created script and take snapshots.

Sample scripts for taking snapshots are stored under the Fujitsu Enterprise Postgres installation directory below.

```
<Install directory>/share/get-storage-snapshot-for-autoscaling.sh.sample
```

The sample script takes a snapshot between the pg_backup_start() and pg_backup_stop() functions. EBS processes the data at the time the snapshot command is executed in the background, allowing read/write access to the volume immediately after the snapshot command is executed.

The sample script waits for the background snapshot process to complete, ensuring the snapshot finishes successfully. Since EBS snapshots capture incremental data since the last snapshot, the wait time varies depending on the amount of data changed since the previous snapshot. The first EBS snapshot captures all data stored on EBS. Therefore, it is recommended to take the snapshot after building the streaming replication cluster and storing the necessary data before starting database operations.

Additionally, when restoring data to a replica server from a snapshot, the WAL archives created after the snapshot was taken are applied. The time required to apply the WAL varies depending on the amount of database changes since the snapshot was taken. Therefore, determine the snapshot interval based on the startup time settings for the replica server.

1. Edit the EBS volume ID to take a snapshot.

   Specify the ID, device name to be specified in the launch template and mount path of the EBS volume to be snapshotted.

   Specify all EBS volumes that store data and tablespaces.

```
# Specify the mount path of the EBS storing the data.
declare -A volumes
volumes=(
    ["vol-xxxxxxxxxxxxxx"]="/dev/sdf:/data"
    ["vol-yyyyyyyyyyyyyy"]="/dev/sdg:/tablespace"
)
```

Information

You can check the ID of an EBS volume mounted to a specific instance with a command like the following.

```
$ aws ec2 describe-volumes --filters Name=attachment.instance-id,Values=<your-instance-id> --
query "Volumes[*].{ID:VolumeId}" --output text
```

2. Editing PostgreSQL database connection information

   PostgreSQL connection information is specified to execute pg_backup_start() and pg_backup_stop() functions before and after creating a snapshot. If necessary, add and define environment variables related to authentication, such as passwords and SSL communication certificates.

```
# PostgreSQL database connection information
export PGHOST=localhost
export PGPORT=27500
export PGDATABASE=postgres
export PGUSER=fsepuser
```

3. Edit istallation path

   Specify the installation path for Fujitsu Enterprise Postgres and AWS CLI. "<*x*>" indicates the product version.

```
export FEP_INSTALL_DIR=/opt/fsepv<x>server64
export AWSCLI_BIN_DIR=/usr/local/bin
```

4. When updating the definition of the launch template for the snapshot restore destination, specify the following variables.

   Replace the snapshot ID to restore to the EBS volume defined in the specified launch template with the ID of the most recent snapshot. Utilizing the most recent snapshot reduces the time required to apply the WAL to the data restored to replica servers deployed in a scale out configuration.

```
# Define if you want to update the snapshot restore source for the volume of the launch template.
export LAUNCH_TEMPLATE_NAME=your-launch-template-name
export LAUNTH_TEMPLATE_SOURCE_VERSION=1
```

Editing postgresql.conf

When restoring EBS from a snapshot during scale out, we restore to the latest data using archived WALs stored in Amazon Simple Storage Service (S3). Therefore, we enable archive_mode in postgresql.conf and archive WALs to S3.

The following is an example of archiving WALs to the S3 bucket "primary-wal-bucket".

```
archive_mode = on
archive_command = 'aws s3 cp %p s3://primary-wal-backet/%f'
```

11.1.1.4 Settings for Name Resolution of the Standby Server, which will be the Replica Source Server

Use Amazon Route 53 private hosted zones to resolve names from replica servers to standby servers.

Private hosted zones allow you to configure DNS records for resources within your Virtual Private Cloud (VPC). You can set an arbitrary domain name (e.g., standby-server.com) and associate it with the private IP address of the standby server's EC2 instance.

While EC2 instances are assigned a private IP DNS name upon creation, by simply rewriting the Route 53 DNS record, it becomes easier to switch the replication connection destination for multiple replica servers when replacing standby servers or switching between primary and standby.

11.1.2 Building a Replica Server

Describes the procedure for creating an Amazon Machine Image (AMI) that will be the source for replica server instances.

Set up the necessary startup scripts for AMI deployment on the instance where Fujitsu Enterprise Postgres server is installed.

11.1.2.1 Installation of Fujitsu Enterprise Postgres on EC2

Install the Fujitsu Enterprise Postgres server on any EC2 instance and create an OS user who will be the instance administrator.

Database initialization and volume attachment are not required at this time. These will be performed when deploying the replica server.

11.1.2.2 Creation of Startup Script for Replica Server Deployment

Create a launch script that runs when replica servers are deployed by Auto Scaling. Specify the created script to run in the launch template.

During script execution, heartbeats are continuously sent to extend the Auto Scaling group's lifecycle hooks. During this period, connections from the load balancer are disabled. Once data restoration completes and replication catches up on the standby server, the lifecycle hooks conclude, and connections from the load balancer become possible again.

The script to be created will perform the following processes:

- Modify postgresql.conf (define replication settings, restore_command, etc.)
- Start the database
- Wait until replication catch-up is complete, then transition to a state where connections from the load balancer are accepted

Preparation

1. Refer to the AWS documentation to install the AWS Command Line Interface (AWS CLI) and configure it as needed for the following steps.

Operations	Example IAM policies to assign
Manipulate lifecycle hooks until database startup	"autoscaling:RecordLifecycleActionHeartbeat" "autoscaling:DescribeAutoScalingInstances" "autoscaling:CompleteLifecycleAction"
Retrieve WAL archives stored in S3	"s3:PutObject" "s3:GetObject" "s3:ListBucket"
Apply tags to mounted EBS volumes	"ec2:DescribeInstances" "ec2:DescribeVolumes" "ec2:DescribeVolumeStatus" "ec2:CreateTags"
Collect metrics via the CloudWatch Agent	CloudWatchAgentServerPolicy
Perform remote operations via SSM during storage expansion and scale in	AmazonSSMManagedInstanceCore

2. Refer to the WS documentation to install the SSM Agent.

   The SSM Agent is required to stop the database before instances are deleted during scale in.

Creating a startup script

Sample script for database startup is stored under the Fujitsu Enterprise Postgres installation directory below.

```
<Install directory>/share/start-replica-database-for-autoscaling.sh.sample
```

1. Edit the EBS volume ID for taking snapshots.

   Specify the ID and mount path of the EBS volume from which the snapshot was taken.

   Specify all EBS volumes that store data and tablespaces. Specify the same values as the script that creates snapshots placed on the primary server.

```
# Specify the mount path of the EBS storing the data.
declare -A volumes
volumes=(
    ["vol-xxxxxxxxxxxxxx"]="/dev/sdf:/data"
    ["vol-yyyyyyyyyyyyyy"]="/dev/sdg:/tablespace"
)
```

Information

You can check the ID of an EBS volume mounted to a specific instance with a command like the following.

```
$ aws ec2 describe-volumes --filters Name=attachment.instance-id,Values=<your-instance-id> --
query "Volumes[*].{ID:VolumeId}" --output tex
```

2. Editing the OS user for the instance administrator

   Specify the OS user for the instance administrator. The database will be started using the specified user.

```
export DB_OWNER=fsepuser
```

3. Editing the hostname of the standby server for replication source

   Specify the hostname of the standby server that will be the replication source and connection string for connection (primary_conninfo value in postgresql.conf).

   For an example of how to set the hostname of the standby server, refer to "11.1.1.4 Settings for Name Resolution of the Standby Server, which will be the Replica Source Server".

```
export REPLICATION_HOST=standby-server.com
ecport PRIMARY_CONNINFO="host=${REPLICATION_SOURCE_DNS}"
```

4. Editing PostgreSQL database connection information

   Specify PostgreSQL connection information to confirm database startup. If necessary, add and define environment variables related to authentication, such as passwords and SSL communication certificates. Also, define the PGDATA variable for database startup.

```
# PostgreSQL database connection information
export PGDATA=/data
export PGHOST=localhost
export PGPORT=27500
export PGDATABASE=postgres
export PGUSER=${DB_OWNER}
```

5. Editing the S3 bucket storing WAL archives

   Specify the name of the S3 bucket that stores WAL archives used for data recovery when the database starts up and the value of restore_command in postgresql.conf.

```
# S3 bucket name storing WAL archives used for data recovery
export ARCHIVE_S3_BUCKET =primary-wal-bucket
export RESTORE_COMMAND="${AWS_CLI_BIN}/aws s3 cp s3://${ARCHIVE_S3_BUCKET}/%f %p"
```

6. Editing installation path

   Specify the installation path for Fujitsu Enterprise Postgres and AWS CLI. "<*x*>" indicates the product version.

```
export FEP_INSTALL_DIR=/opt/fsepv<x>server64
export AWSCLI_BIN_DIR=/usr/local/bin
```

7. Editing postgresql.conf

   The following values are inserted into postgresql.conf when the script runs. If different values are specified for the same parameters in postgresql.auto.conf, or if you wish to add parameters, modify the values below.

```
# Recreate postgresql.conf for the replica
postgresql_conf="${PGDATA}/postgresql.conf"
cat << EOF >> "${postgresql_conf}"
# Replication Settings
hot_standby = on
primary_conninfo = '${PRIMARY_CONNINFO}'
```

```
restore_command = '${RESTORE_COMMAND}'
EOF
```

11.1.2.3 Volume Mount Definition

When EC2 instances of replica servers are deployed by scaling out, /etc/fstab is edited to mount the attached EBS volume as a data storage area.

1. Obtaining UUID

   On the primary server where the snapshot is to be taken, obtain the UUID to be defined in /etc/fstab using the lsblk or blkid command.

```
# lsblk -o NAME,UUID,MOUNTPOINTS
NAME        UUID                                 MOUNTPOINTS
nvme1n1     11111111-1111-11aa-aaaa-aaaaaaaaaaaa /database/data
nvme2n1     22222222-2222-22bb-bbbb-bbbbbbbbbbbb /database/tblspc1
```

2. Editing /etc/fstab

   On the EC2 instance where you are setting up the replica server, define the acquired UUID in /etc/fstab.

```
# vi /etc/fstab
UUID=11111111-1111-11aa-aaaa-aaaaaaaaaaaa   /database/data      xfs   defaults,nofail   0   2
UUID=22222222-2222-22bb-bbbb-bbbbbbbbbbbb   /database/tblspc1   xfs   defaults,nofail   0   2
```

3. Creating a folder to mount the volume

   Create a folder to mount the volume and change the owner of the folder to the OS user of the database instance administrator.

```
# mkdir -p /database/data
# mkdir -p /database/tblspc1
# chown fsepuser:fsepuser /database/data /database/tblspc1
```

11.1.2.4 Creation of AMI for Replica Server

Create an AMI for the replica server you set up.

In the AWS Management Console, select the EC2 instance where you set up the replica server from the EC2 instance list and create an AMI.

The AMI created here will be used when defining scale out with Auto Scaling.

11.1.3 Enable Autoscale

Create an Auto Scaling launch template and an Auto Scaling group when deploying an AMI. When creating an Auto Scaling group, integrate it with Elastic Load Balancing to distribute queries.

Creating an Auto Scaling launch template

1. From the "My AMIs" tab displayed in the EC2 console, select the AMI created with "11.1.2.4 Creation of AMI for Replica Server".
2. Under Storage and Volume, specify the EBS volume to mount to EC2. Specify a snapshot to restore data from when launching the instance.
   - Size: Specify a size equal to or larger than the primary server being replicated.
   - Device Name: Specify the device name of the volumes defined in the script that acquires the snapshot.
   - Snapshot: Specify the ID of an existing snapshot.
3. Enable the "Allow tags in metadata" option to read EC2 instance tags in the startup script and obtain the Auto Scaling Group name.
4. Define the script to be executed when the instance starts in "User data". Here, define the execution of the database startup script created in "11.1.2.2 Creation of Startup Script for Replica Server Deployment".

   The following is an example definition when the database startup script is defined under /home/fsepuser.

```
#!/bin/bash

/home/fsepuser/start-replica-database-for-autoscaling.sh
```

Creating an Auto Scaling group

1. Select a "launch template" that defines the AMI and launch script for the replica instances.
2. Select the instance launch options.
   - Select "Override launch template" for the instance type and define a mixed instances policy. This allows you to update instances by replacing only the root volume when patching replica servers, omitting the copying of data storage areas.
   - Specify the VPC and Availability Zones where the scaled-out instances will be placed as instance launch options. It is recommended to specify multiple Availability Zones.
3. Create a load balancer. Create and attach a Network Load Balancer to load balance TCP traffic.
4. Configure group size and scaling policies.
5. Add notification settings for instance launches.
6. Add tags to the group.

11.1.4 Preparation for Scale in

Describes how to define the processing to execute before instances are deleted during scale in.

The example implements processing to stop the database before instances are deleted. You can implement processing to execute before the targeted instances are deleted during scale in, such as notifying the application.

1. Create a Lambda function to stop the database on the console

   Define a Lambda function to be called by the lifecycle hook when an instance stops.

   The following is an example of the function code that stops the database of the instance to be stopped.

```
import boto3

ssm_client = boto3.client('ssm')
autoscaling = boto3.client('autoscaling')

def lambda_handler(event, context):

   # Specify the data directory as a variable
   data_directory = '/database/inst1'

   # Get EC2 instance ID
   instance_id = event['EC2InstanceId']
   # Get AutoScaling information
   hook_name = event['LifecycleHookName']
   asg_name = event['AutoScalingGroupName']
   token = event['LifecycleActionToken']

   # Execute SSM command
   ssm_client.send_command(
       InstanceIds=[instance_id],
       DocumentName='AWS-RunShellScript',
       Parameters={
           'commands': [
               f'pg_ctl stop -D {data_directory}'
           ]
       }
   )

   # Restart the termination process
```

```
    autoscaling.complete_lifecycle_action(
        LifecycleHookName=hook_name,
        AutoScalingGroupName=asg_name,
        LifecycleActionToken=token,
        LifecycleActionResult='CONTINUE'
    )

    return {
        'statusCode': 200,
        'body': 'Command sent successfully'
    }
```

2. Define Auto Scaling lifecycle hooks

   Define a lifecycle hook that invokes a Lambda function when Auto Scaling performs a scale in.

```
$ aws autoscaling put-lifecycle-hook \
    --lifecycle-hook-name <Life cycle hook name> \
    --auto-scaling-group-name <auto scaling group name> \
    --lifecycle-transition autoscaling:EC2_INSTANCE_TERMINATING \
   --notification-target-arn arn:aws:lambda:ap-northeast-1:<id>:function:<lambda function name>
\
    --default-result CONTINUE
```

3. Set the delay in load balancer deregistration time

   Set the load balancer deregistration delay as needed. The following command specifies the time until the load balancer stops connection traffic for EC2 instances targeted for scale in.

```
$ aws elbv2 modify-target-group-attributes --target-group-arn <Target group ARN> --attributes
Key=deregistration_delay.timeout_seconds,Value=300
```

11.2 Operations for Autoscale

Describes the operational procedures after auto scale out is configured.

11.2.1 Customizing Scaling Policies

Auto Scaling's scaling policy, by default, determines scale out based on CPU utilization.

Describes the steps to auto-scale out using metrics other than CPU utilization (memory utilization, number of database connections).

1. Deploy EC2 using the replica server AMI.
2. Install the CloudWatch agent on the deployed EC2.

```
$ curl "https://amazoncloudwatch-agent.s3.amazonaws.com/redhat/amd64/latest/amazon-cloudwatch-
agent.rpm" -o "amazon-cloudwatch-agent.rpm"
$ sudo rpm -Uvh amazon-cloudwatch-agent.rpm
$ rm amazon-cloudwatch-agent.rpm
```

3. Enable CloudWatch metrics collection

   Below is an example of how to get memory usage and the number of database connections.

   Example) When collecting memory usage
   Use the CloudWatch Agent to collect metrics. Below is an example of editing the Agent configuration file to enable collection of the "mem_used_percent" metric.

```
# Create a Json definition to collect memory usage
$ cat << 'EOF' > /opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.json
{
  "metrics": {
    "namespace": "Custom/FEP",
    "append_dimensions": {
```

```
      "AutoScalingGroupName": "${aws:AutoScalingGroupName}",
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "mem": {
        "measurement": [
          "mem_used_percent"
        ],
        "metrics_collection_interval": 60
      },
    }
  }
}
EOF

# Enable the Cloud Watch agent
$ systemctl enable amazon-cloudwatch-agent
```

Example) When getting the number of database connections

Use the aws command to send database connection counts to CloudWatch. Below is an example of defining database connection counts using the psql command and sending them to CloudWatch.

```
# Create a script to send the number of connections to CloudWatch
$ cat << 'EOF' > /home/fsepuser/send_fep_conn.sh
#!/bin/bash

TOKEN=$(curl -s -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-
ttl-seconds: 21600")
INSTANCE_ID=$(curl -sH "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-
data/instance-id)
ASG_NAME=$(curl -sH "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/
tags/instance/aws:autoscaling:groupName)

CONN=$(sudo -u fsepuser psql -U fsepuser -d postgres -t -c "select count(*) from
pg_stat_activity;" | xargs)
aws cloudwatch put-metric-data \
  --namespace Custom/FEP \
  --metric-name DBConnections \
  --dimensions AutoScalingGroupName="$ASG_NAME",InstanceId="$INSTANCE_ID" \
  --value "$CONN"
EOF

# Register the script with Cron for regular execution
cat <<EOF > /etc/cron.d/send_fep_conn
* * * * * root /bin/bash /home/fsepuser/send_fep_conn.sh
EOF
chmod 644 /etc/cron.d/send_fep_conn

# Enable Cron
$ systemctl enable crond
```

4. Create an AMI on the EC2 instance you set up.
5. Set up autoscale using the AMI you created.

   If you are creating a new one, refer to "11.1.3 Enable Autoscale".

   If you are updating an existing AMI that is auto scaling, refer to "11.2.4 Updating an Existing AMI".
6. Create a CloudWatch alert in the AWS console.

   Set the following to define when to scale out by issuing an alarm:

   - Metrics to monitor

- Threshold for issuing an alert
- Duration for which the threshold is exceeded

7. Modify the Auto Scaling group's scaling policy in the AWS console.

   Update the scaling policy by specifying the alert rule you created.

11.2.2 Scale in of Replica Servers

Describes the procedure for scale in a scaled out instance.

Preparation as shown in "11.1.4 Preparation for Scale in" is required in advance.

Execute scale in

Execute scale in of the replica server with the following command.

```
$ aws autoscaling update-auto-scaling-group --auto-scaling-group-name <AutoScalingGroupName> --
desired-capacity <NewDesiredCapacity>
```

11.2.3 Switching/Failback of the Cascade Replication Source for the Replica Server

Describes how to switch the replication source to continue operating the replica server, for example, when the standby server of the replication source stops abnormally.

Creation of a sample script for promoting to primary server

Prepare 2 scripts for switching the replication target of the replica server.

- Switching script to execute when the standby server is disconnected and the primary server becomes the replication source for the replica server
- Script to be executed when the standby server is restored and reintegrated, to reconfigure it as the replication source.

1. Creating the switchover script

   Sample scripts are stored in the Fujitsu Enterprise Postgres installation directory. Switching the replication destination for the replica server is achieved by modifying the Route 53 DNS server records for each script.

   - A script that is called and executed before the standby server is disconnected

     ```
     <Install directory>/share/switch-wal-source-to-primary-for-autoscaling.sh.sample
     ```

   - A script that is called and executed after the standby server is incorporated

     ```
     <Install directory>/share/return-wal-source-back-to-standby-for-autoscaling.sh.sample
     ```

2. Edit the connection information

   Edit the following connection information defined in the sample script.

```
# Specify the ID of the Route53 Private Hosted Zone used for standby server name resolution
HOSTED_ZONE_ID="YOUREHOSTEDZONEID"
# Specifies how long the DNS resolver keeps information about records
# A shorter value allows faster record updates but increases query volume and cost. A longer
value has the opposite effect
# Set this value based on the time required for replica servers to switch their connection targets
TTL=10
# Specifies the DNS server record for the standby server used as the connection target for
replica servers
WAL_SOURCE_RECORD="wal-source.sample.internal"
```

3. Specify for Mirroring Controller state transition command

   Specify the following in the server definition files for the primary and standby servers.

```
$ vi workdir/MC/server1.conf
db_instance = '/data'
pre_detach_command = '/home/fsepuser/workdir/switch-wal-source-to-primary-for-autoscaling.sh'
post_attach_command = '/home/fsepuser/workdir/return-wal-source-back-to-standby-for-
autoscaling.sh'
```

Operations during failback

After the standby server is restored, the hostname managed by ROUTE 53 is switched back by the script executed during failback. At this point, the connections already established between the primary server and replica server remain. To switch back the replication connection destination, restart the replica servers sequentially at any time.

The sample script for restarting replica servers managed by AutoScaling is stored below.

```
<Install directory>/share/rolling_restart_fep_replica-for-autoscaling.sh.sample
```

Edit the following in the sample script and run the script. "<*x*>" indicates the product version.

```
REGION="your-region"

# AutoScaling name managing replica servers
ASG_NAME="your-read-replica-asg"

# Specify the installation path of Fujitsu Enterprise Postgres and the path to the AWS CLI command
FEP_INSTALL_DIR="/opt/fsepv<x>server64"
AWS_CLI_BIN="/usr/local/bin"

# Specify the path to the data storage area
PGDATA="/data"

# Specify the OS user for the database instance administrator
DB_OWNER='fsepuser'
```

11.2.4 Updating an Existing AMI

Describes the procedure for applying Fujitsu Enterprise Postgres and OS patches to replica servers.

After changing the AMI for the replica server, edit the launch template and Auto Scaling group respectively to apply the new AMI. When performing instance updates in the Auto Scaling group, it is recommended to specify the "Replace root volume" strategy for the instance update strategy. This prevents EBS replacement from occurring and eliminates the need for snapshot restoration time.

1. Edit the replica server AMI.

   Deploy an EC2 instance using the AMI of the replica server currently in use.

   Edit the script on the deployed EC2 instance, and once modifications are complete, create a new AMI.

2. Edit the launch template.

   Create a new template or replace the AMI specified in an existing template with the new AMI. In the latter case, a new version of the launch template will be added.

3. Edit the Auto Scaling group.

   Specify the new template or new version of the launch template.

   There are two types of instance update strategies: "rolling strategy" and "root volume replacement strategy" In the former case, EBS replacement occurs and data restoration begins, so it is recommended to use the latter strategy.

11.2.5 Storage Scale up

Describes how to monitor storage utilization and scale up storage capacity when utilization exceeds a threshold.

1. Install the CloudWatch agent on each EC2 instance.
2. Create and execute a CloudWatch metric collection script on each EC2 instance.

   Example)

```
# Create a Json definition to collect disk usage in addition to memory usage
$ cat << 'EOF' > /opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.json
{
  "metrics": {
    "namespace": "Custom/FEP",
    "append_dimensions": {
      "AutoScalingGroupName": "${aws:AutoScalingGroupName}",
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "mem": {
        "measurement": [
          "mem_used_percent"
        ],
        "metrics_collection_interval": 60
      },
      "disk": {
        "measurement": [
          "used_percent"
        ],
        "resources": [
          "/database/inst1",
          "/database/tblspc1"
        ]
      }
    }
  }
}
EOF

# Enable the Cloud Watch agent
$ systemctl enable amazon-cloudwatch-agent
```

Creating a CloudWatch alert in the AWS console

Describes the following steps to automatically scale up storage when its utilization exceeds a threshold:

- Expanding the file system on the EC2 instance where EBS is mounted using SystemManager
- Invoke a Lambda function via a Simple Notification Service (SNS) topic
- Execute storage scaling using the Lambda function (create Python script, grant privileges via IAM role)
- Create a CloudWatch alert rule

The sample script here assumes the following:

- The EBS file system uses xfs or ext4
- When targeting EBS from a streaming replication cluster built with Mirroring Controller for expansion, apply the following tags. These tags identify the target EBS during storage scale up execution.
  - Target EBS:
    - Key=MountPoint, Value=<EBS mount path>
  - Primary server and Standby server EC2:
    - Key=DBRole, Value=<any value>

- Key=ASG_NAME, Value=<Auto Scaling group name that manages the replica server at the replication destination>

1. Defining EC2 file system expansion via System Manager

   In the AWS Management Console, create a System Manager Command Document. The Command Document receives the mount path of the expanded EBS volume from the Lambda function, identifies the file system, and expands it.

   The sample script for the SSM Command Document is stored below. Paste the definition example content into the Command Document editor.

   ```
   <Install directory>/share/expand-ebs-volume-for-autoscaling.yaml.sample
   ```

2. Defining notifications via an SNS topic

   In the AWS Management Console, create an SNS topic. Select Standard as the type.

3. Defining scale up using Lambda functions

   Create an IAM role to attach to the Lambda function.

Operations	Example IAM policies to assign
Expand the EBS volume	"ec2:DescribeInstances" "ec2:DescribeVolumes" "ec2:DescribeVolumesModifications" "ec2:ModifyVolume"
Execute the command in SystemManager to expand the file system	"ssm:SendCommand"

   1. Create a Lambda function with the following specifications:
      - Function creation option: Select "Create from scratch"
      - Runtime: Python 3.9 or later
      - Execution role: Select "Use another role" and specify the IAM role created for the Lambda function
   2. Configure the following in the created Lambda function:
      - Define the Python script to expand the EBS volume (using the sample script)
      - Define the environment variables used by the script
      - Define the trigger to execute the Lambda function
   3. Define the Python script to perform storage expansion in the "Code Source" editor. Paste the contents of the sample script stored below into the editor.

      ```
      <Install directory>/share/sns-triggered-lambda-template-for-autoscaling.py.sample
      ```

   4. Edit the "Environment Variables" under "Settings" and define the following environment variables.

Key	Value
ASG_NAME	Specify the autoscaling group name.
INCREASE_GIB	Specify the storage capacity increase amount numerically. Specify either this parameter or TARGET_SIZE_GIB.
TARGET_SIZE_GIB	Specify the storage capacity as a numeric value. Specify either this parameter or INCREASE_GIB.
SSM_DOCUMENT_NAME	Specify the name of the created SSM Command Document.
MOUNT_PATH	Specify the mount path of the EBS to be expanded.

Key	Value
DB_ROLE	Specify the tag names defined for the primary server and replica server.

5. Specify the trigger to execute the Lambda function from "Add trigger".
   - Select source: Choose "SNS"
   - SNS topic: Select the created SNS topic

4. Create an alert rule

   In the AWS Management Console, define thresholds and create an alert rule for the storage you want to monitor.

   Select "Create alarm" in CloudWatch.

   - Specify metrics and conditions
     - Metric: Define the expression for the metric you want to monitor
     - Threshold: Specify the threshold at which alerts will be notified for the selected metric
   - Configuring Actions

     In the Notifications section, select the following:

     - Alarm state trigger: "Alarm state"
     - Send notifications to the following SNS topic: "Select an existing SNS topic"
     - Notification destination: Select the SNS topic specified as the trigger for the Lambda function

When targeting multiple EBS volumes (e.g., tablespaces), create separate SNS topics, Lambda functions, and CloudWatch alert rules for each EBS mount path.

11.2.6 Backup/Restore

Describes how to acquire backups during auto scale out execution.

Auto scale out restores data to replica servers using EBS snapshots and WAL archives. If WAL archives after the snapshot acquisition point are insufficient, the replica server cannot catch up to the latest state of the replication source, causing the database startup to fail.

When using pgBackRest, if you acquire full backups exceeding the retention generation count, older WAL is deleted. Therefore, if the retention generation count for full backups is set to 1, WAL archives prior to the full backup are deleted. This can result in a point where WAL after the snapshot acquisition time is insufficient. Consequently, to prevent WAL archives after the snapshot used for restoration during auto scale out from being deleted, you must carefully consider the timing of snapshot and full backup acquisition.

For example, if you specify 'count' for the retention-full-type option in pgBackRest, set retention-full to a value of 2 or higher. This retains multiple generations of full backups and the WAL archives corresponding to the retention period of the full backups.

By taking an EBS snapshot immediately after acquiring a full backup, the WAL archives from the time of the previous full backup will still be retained even after the next full backup is acquired. This allows the use of WAL archives created after the latest snapshot.

This approach prevents the deletion of WAL archives created after the latest snapshot, avoiding situations where insufficient WAL during snapshot restoration prevents data recovery.

Chapter 12 Streaming Replication Using WebAdmin

This chapter describes streaming replication using WebAdmin.

A standby instance for streaming replication can be created from a standalone instance, a master instance, or another standby instance. The standby instance connects to the master instance and uses WAL records to replicate data. The standby instance can be used for read-only operations.

WebAdmin cannot back up standby instances.

Additionally, streaming replication can be set to asynchronous or synchronous mode.

Point

- If a streaming replication cluster is created using WebAdmin, the network with the host name (or IP address) specified in [Host name] will be used across sessions of WebAdmin, and also used as the log transfer network.
- To use a network other than the job network as the log transfer network, specify the host name other than the job network one in [Host name].

For characters that cannot be specified in WebAdmin, refer to "Appendix K WebAdmin Disallow User Inputs Containing Hazardous Characters".

12.1 Creating a Standby Instance

Follow the procedure below to create a standby instance.

1. In the [Instances] tab, select the instance from which a standby instance is to be created.
2. Click .
3. Enter the information for the standby instance to be created.
   - [Location]: Whether to create the instance in the server that the current user is logged in to, or in a remote server. The default is "Local", which will create the instance in the server machine where WebAdmin is currently running.
   - [Replication credential]: The user name and password required for the standby instance to connect to the master instance. The user name and password can be entered or selected from the Wallet. Refer to "Appendix J WebAdmin Wallet" for information on creating wallet entries.
   - [Instance name]: Name of the standby database instance to create.

     The name must meet the conditions below:

     - Maximum of 16 characters
     - The first character must be an ASCII alphabetic character
     - The other characters must be ASCII alphanumeric characters
   - [Instance port]: Port number of the standby database instance.
   - [Host IP address]: The IP address of the server machine where the standby instance is to be created. This information is needed to configure the standby instance to be connected to the master.
   - [Data storage path]: Directory where the database data will be stored
   - [Backup storage path]: Directory where the database backup will be stored
   - [Transaction log path]: Directory where the transaction log will be stored
   - [Encoding]: Database encoding system
   - [Replication mode]: Replication mode of the standby instance to be created ("Asynchronous" or "Synchronous")

- [Application name]: The reference name of the standby instance used to identify it to the master instance.

  The name must meet the conditions below:

  - Maximum of 16 characters
  - The first character must be an ASCII alphabetic character
  - The other characters must be ASCII alphanumeric characters

4. Click to create the standby instance.

If using WebAdmin to manage Mirroring Controller, the message below may be output to the server log or system log in the standby instance. No action is required, as the instance is running normally.

```
ERROR:  pgx_rcvall failed
ERROR:  pgx_rcvall: backup of the database has not yet been performed, or an incorrect backup storage
directory was specified
```

12.2 Promoting a Standby Instance

Streaming replication between a master and standby instance can be discontinued using WebAdmin.

Follow the procedure below to promote a standby instance to a standalone instance, thereby discontinuing the streaming replication.

1. In the [Instances] tab, select the standby instance that needs to be promoted.
2. Click .
3. Click [Yes] from the confirmation dialog box.

The standby instance will be promoted and will become a standalone instance, which is not part of a streaming replication cluster.

Once the standby instance is promoted to become a standalone instance, the backup storage status will be "Error". This is because no backups are available when the instance is newly promoted to a standalone instance. The status will be reset if a new backup is performed by clicking [Solution] or .

12.3 Converting an Asynchronous Replication to Synchronous

You can convert an asynchronous standby instance to a synchronous standby instance.

Converting an Asynchronous standby instance to Synchronous can cause the master instance to queue the incoming transactions until the standby instance is ready. For this reason, it is recommended that this operation be performed during a scheduled maintenance period.

When adding a synchronous standby instance, Fujitsu Enterprise Postgres will only keep the first entry in [Synchronous standby names] in synchronous state.

Follow the procedure below to convert an Asynchronous standby instance to Synchronous.

1. In the [Instances] tab, select the master instance of the relevant cluster.
2. Click .
3. In the [Streaming replication] section, edit the value for [Synchronous standby names].
   - Add the "Application name" of the standby instance you want to be in Synchronous mode.
4. Click .
5. Select the master instance and click .
6. Select the standby instance. [Instance type] will now show the updated status.

See

To learn more about the differences between synchronous and asynchronous standby modes and their behavior, refer to "Streaming Replication" in "High Availability, Load Balancing, and Replication" in the PostgreSQL Documentation.

12.4 Converting a Synchronous Replication to Asynchronous

Follow the procedure below to convert a Synchronous standby instance to Asynchronous.

1. In the [Instances] tab, select the master instance of the relevant cluster.
2. Click .
3. In the [Streaming replication] section, edit the value for [Synchronous standby names].
   - Remove the "Application name" of the standby instance you want to be in Asynchronous mode.
4. Click .
5. Select the master instance and click .
6. Select the standby instance. [Instance type] will now show the updated status.

See

To learn more about the differences between synchronous and asynchronous standby modes and their behavior, refer to "Streaming Replication" in "High Availability, Load Balancing, and Replication" in the PostgreSQL Documentation.

12.5 Joining a Replication Cluster

WebAdmin facilitates the joining of an old master of the cluster as a standby node.

1. In the [Instances] tab, select the remote instance (from where the new cluster node will stream WAL entries), and then click .
2. Configure the node to accept streaming requests from the new node.
3. In the [Instances] tab, select the new standby instance (which needs to be connected to the cluster), and then click .
4. Set [Replication host name] to the remote instance.
5. Enter [Replication credential].

   Specify the user name and password required for the standby instance to connect to the remote instance. The user name and password can be entered or selected from the Wallet. Refer to "Appendix J WebAdmin Wallet" for information on creating wallet entries. Replication credential (user name and password) should not contain hazardous characters. Refer to "Appendix K WebAdmin Disallow User Inputs Containing Hazardous Characters".
6. Enter [Host IP address].

   Specify the IP address of the node where the standby instance was created.
7. Click to open the [Join replication cluster] dialog box.

   For Fujitsu Enterprise Postgres 13 and earlier instances, select [Restart later] or [Restart now], and then click [Yes] to set up the standby instance.
   For Fujitsu Enterprise Postgres 14 or later, click [Yes] to set up the standby instance.
8. Upon successful completion, the confirmation dialog box will be displayed.
9. Click [Close] to return to the instance details window.

The instance will become a standby instance, and will be part of the streaming replication cluster. The replication diagram will display the relationship between the standby instance and the remote instance. The user can change the replication relationship of the remote instance from asynchronous to synchronous (and vice versa) using the [Configuration] window.

Chapter 13 Installing and Operating the In-memory Feature

The in-memory feature enables fast aggregation using Vertical Clustered Index (VCI) and memory-resident feature.

VCI has a data structure suitable for aggregation, and features parallel scan and disk compression, which enable faster aggregation through reduced disk I/O.

The memory-resident feature reduces disk I/O that occurs during aggregation. It consists of the preload feature that reads VCI data to memory in advance, and the stable buffer feature that suppresses VCI data eviction from memory. The stable buffer feature secures the proportion specified by parameter in the shared memory for VCI.

This chapter describes how to install and operate the in-memory feature.

This feature can only be used in Advanced Edition.

13.1 Installing Vertical Clustered Index (VCI)

This section describes the installation of VCI.

1. Evaluating whether to Install VCI
2. Estimating Resources
3. Setting up

13.1.1 Evaluating whether to Install VCI

VCI uses available resources within the server to increase scan performance.

It speeds up processing in many situations, and can be more effective in the following situations:

- Single table processing
- Processing that handles many rows in the table
- Processing that handles some columns in the table
- Processing that performs very heavy aggregation such as simultaneous sum and average aggregation

VCI will not be used in the following cases, so it is necessary to determine its effectiveness in advance:

- The data type of the target table or column contains VCI restrictions.
- The SQL statement does not meet the VCI operating conditions
- VCI is determined to be slower based on cost estimation

Point

If performing operations that use VCI, the full_page_writes parameter setting in postgresql.conf must be enabled (on). For this reason, if this parameter is disabled (off), operations that use VCI return an error. In addition, to perform operations for tables that do not create a VCI when the full_page_writes parameter setting is temporarily disabled (off), do not create a VCI or perform operations to tables that created a VCI during that time.

See

- Refer to "13.1.4 Data that can Use VCI" for information on VCI restrictions.
- Refer to "Scan Using a Vertical Clustered Index (VCI)" - "Operating Conditions" in the Application Development Guide for information on VCI operating conditions.

13.1.2 Estimating Resources

Estimate resources before setting up VCI.

Select the aggregation that you want to speed up and identify the required column data. The additional resources below are required according to the number of columns.

- Memory

  Secure additional capacity required for the disk space for the column for which VCI is to be created.

- Disk

  Secure additional disks based on the disk space required for the column for which VCI is to be created, as VCI stores column data as well as existing table data on the disk. It is recommended to provide a separate disk in addition to the existing one, and specify it as the tablespace to avoid impact on any other jobs caused by I/O.

Information

The operations on VCI can continue even if the memory configured for VCI is insufficient by using VCI data on the disk.

See

Refer to "Estimating Memory Requirements" and "Estimating Database Disk Space Requirements" in the Installation and Setup Guide for Server for information on how to estimate required memory and disk space.

13.1.3 Setting up

This section describes how to set up VCI.

Setup flow

1. Setting Parameters
2. Installing the Extensions
3. Creating VCI
4. Confirming that VCI has been Created

13.1.3.1 Setting Parameters

Edit postgresql.conf to set the required parameters for VCI. After that, start or restart the instance.

The following table lists the parameters that need or are recommended to be configured in advance:

Parameter name	Setting value	Description	Required
shared_preload_libraries	Literal 'vci, pg_prewarm'	VCI and shared library to be preloaded at server start.	Y
session_preload_libraries	Literal 'vci, pg_prewarm'	VCI and shared library to be preloaded at connection start.	Y
reserve_buffer_ratio	Percentage of shared memory to be used for stable buffer table	Proportion of shared memory to be used for a stable buffer table.	N
vci.control_max_workers	Number of background workers that manage VCI	Number of background workers that manage VCI. Add this value to max_worker_processes.	N

Parameter name	Setting value	Description	Required
vci.max_parallel_degree	Maximum number of background workers used for parallel scan	Maximum number of background workers used for parallel scan. Add this value to max_worker_processes.	N

Example

```
shared_preload_libraries = 'vci, pg_prewarm'
session_preload_libraries = 'vci, pg_prewarm'
reserve_buffer_ratio = 20
vci.control_max_workers = 8
vci.max_parallel_degree = 4
max_worker_processes = 18 # Example: If the initial value was 6, 6 + 8 + 4 = 18
```

Information

An error occurs if you use VCI to start instances when procfs is not mounted. Ensure that procfs is mounted before starting instances.

See

- Refer to "Appendix A Parameters" for information on all parameters for VCI. Refer also to default value for each parameter and details such as specification range in the same chapter. Refer to "Server Configuration" under "Server Administration" in the PostgreSQL documentation for information on shared_preload_libraries, session_preload_libraries, and max_worker_processes.

13.1.3.2 Installing the Extensions

Execute CREATE EXTENSION to install the VCI and pg_prewarm extensions. Both extensions need to be installed for each database. Also, extensions can only be installed on the public schema by a superuser.

- Installing VCI

```
db01=# CREATE EXTENSION vci;
```

- Installing pg_prewarm

```
db01=# CREATE EXTENSION pg_prewarm;
```

Some operations cannot be performed for VCI extensions. Refer to "13.2.1 Commands that cannot be Used for VCI" for details.

13.1.3.3 Creating a VCI

Execute the CREATE INDEX statement with the "USING vci" clause to create a VCI for the desired columns and the "WITH (stable_buffer=true)" clause to enable the stable buffer feature.

To use a separate disk for the VCI, specify the TABLESPACE clause.

```
db01=# CREATE INDEX idx_vci ON table01 USING vci (col01, col02) WITH (stable_buffer=true);
```

Point

- Some table types cannot be specified on the ON clause of CREATE INDEX. Refer to "13.1.4.1 Relation Types" for details.
- Some data types cannot be specified on the column specification of CREATE INDEX. Refer to "13.1.4.2 Data Types" for details.
- Some operations cannot be performed for VCI. Refer to "13.2.1 Commands that cannot be Used for VCI" for details.

- The same column cannot be specified more than once on the column specification of CREATE INDEX.
- VCI cannot be created for table columns that belong to the template database.
- CREATE INDEX creates multiple views named vci_*10digitRelOid_5digitRelAttr_1charRelType* alongside VCI itself. These are called VCI internal relations. Do not update or delete them as they are used for VCI aggregation.
- All data for the specified column will be replaced in columnar format when VCI is created, so executing CREATE INDEX on an existing table with data inserted takes more time compared with a general index (B-tree). Jobs can continue while CREATE INDEX is running.
- When CREATE INDEX USING VCI is invoked on a partitioned table, the default behavior is to recurse to all partitions to ensure they all have matching indexes. Each partition is first checked to determine whether an equivalent index already exists, and if so, that index will become attached as a partition index to the index being created, which will become its parent index. If no matching index exists, a new index will be created and automatically attached; the name of the new index in each partition will be determined as if no index name had been specified in the command. If the ONLY option is specified, no recursion is done, and the index is marked invalid. (ALTER INDEX ... ATTACH PARTITION marks the index valid, once all partitions acquire matching indexes.) Note, however, that any partition that is created in the future using CREATE TABLE ... PARTITION OF will automatically have a matching index, regardless of whether ONLY is specified.
- Parallel index build is not supported on VCI indexes.

13.1.3.4 Confirming that the VCI has been Created

Execute the SELECT statement to reference the pg_indexes catalog, and confirm that the VCI was created for the target columns.

Example

```
db01=# SELECT indexdef FROM pg_indexes WHERE indexdef LIKE '%vci%';
                          indexdef
-----------------------------------------------------
CREATE INDEX idx_vci ON table01 USING vci (col01, col02)
(1 row)
```

13.1.4 Data that can Use VCI

This section describes on which relation types and for which data types VCIs can be created.

13.1.4.1 Relation Types

VCIs cannot be created on some relation types.

The ON clause of CREATE INDEX described in "13.1.3.3 Creating a VCI" cannot specify relations on which VCIs cannot be created.

- Relations on which VCIs can be created
  - Normal tables
  - UNLOGGED TABLEs
- Relations on which VCIs cannot be created
  - Materialized views
  - Temporary tables
  - Views
  - Temporary views
  - Foreign tables

13.1.4.2 Data Types

VCIs cannot be created for some data types.

The column specification of CREATE INDEX described in "13.1.3.3 Creating a VCI" cannot specify a column with data type on which VCIs cannot be created.

Category	Data type	Supported by VCI?
Numeric	smallint	Y
	integer	Y
	bigint	Y
	decimal	Y
	numeric	Y
	real	Y
	double precision	Y
	serial	Y
	bigserial	Y
Monetary	money	Y
Character	varchar(*n*)	Y
	char(*n*)	Y
	nchar	Y
	nvarchar(*n*)	Y
	text	Y
Binary	bytea	Y
Date/time	timestamp	Y
	timestamp with time zone	Y
	date	Y
	time	Y
	time with time zone	Y
	interval	Y
Boolean	boolean	Y
Geometric	point	N
	line	N
	lseg	N
	box	N
	path	N
	polygon	N
	circle	N
Network address	cidr	N
	inet	N
	macaddr	N
	macaddr8	N

Category	Data type	Supported by VCI?
Bit string	bit(*n*)	Y
	bit varying(*n*)	Y
Text search	tsvector	N
	tsquery	N
UUID	uuid	Y
XML	xml	N
JSON	json	N
	jsonb	N
Range	int4range	N
	int8range	N
	numrange	N
	tsrange	N
	tstzrange	N
	daterange	N
Object identifier	oid	N
	regproc	N
	regprocedure	N
	regoper	N
	regoperator	N
	regclass	N
	regtype	N
	regconfig	N
	regdictionary	N
pg_lsn type	pg_lsn	N
Array type	-	N
User-defined type (Basic type, enumerated type, composite type, and range type)	-	N

13.2 Operating VCI

This section describes how to operate VCI.

13.2.1 Commands that cannot be Used for VCI

Some operations cannot be performed for VCI extensions and VCI itself.

This section describes SQL commands that cannot be executed for the VCI extensions and VCI itself, and client application commands.

SQL commands

- Operations that cannot be performed for the VCI extension

Command	Subcommand	Description
ALTER EXTENSION	UPDATE	The VCI extension cannot be specified. This operation is not required for VCI.
	SET SCHEMA	
	ADD	
	DROP	
CREATE EXTENSION	SCHEMA	The subcommands on the left cannot be performed if the VCI extension is specified, except when the public schema is specified. This operation is not required for VCI.

- Operations that cannot be performed on relations containing a VCI

Command	Subcommand	Description
ALTER INDEX	SET	The subcommands on the left cannot be performed if a VCI is specified. If the operation is required, delete the VCI using DROP INDEX, and re-create it using CREATE INDEX after completing the operation.
	SET TABLESPACE	
	ALL IN TABLESPACE	
ALTER OPERATOR CLASS	RENAME TO	The subcommands on the left cannot be performed if a VCI is specified. This operation is not supported in VCI.
	OWNER TO	
	SET SCHEMA	
ALTER OPERATOR FAMILY	ADD	
	DROP	
	RENAME TO	
	OWNER TO	
	SET SCHEMA	
ALTER TABLE	ALL IN TABLESPACE *name* [OWNED BY *roleName*] SET TABLESPACE *newTablespace*	A tablespace that contains a VCI cannot be specified. If the operation is required, delete the VCI using DROP INDEX, and re-create it using CREATE INDEX after completing the operation.
	DROP [COLUMN] [IF EXISTS] *colName* [RESTRICT | CASCADE]	A column that contains a VCI cannot be specified. If the operation is required, delete the VCI using DROP INDEX, and re-create it using CREATE INDEX after completing the operation.
	ALTER [COLUMN] *colName* [SET DATA] TYPE *dataType* [COLLATE *collation*] [USING *expr*]	
	CLUSTER ON *indexName*	A VCI cannot be specified. This operation is not supported in VCI.
	REPLICA IDENTITY {DEFAULT | USING INDEX *indexName* | FULL | NOTHING}	
CLUSTER	-	A table that contains a VCI and VCI cannot be specified. If the operation is required, delete the VCI using DROP INDEX, and re-create it using CREATE INDEX after completing the operation.
CREATE INDEX	UNIQUE	The subcommands on the left cannot be performed if a VCI is specified.

Command	Subcommand	Description
	CONCURRENTLY	This operation is not supported in VCI.
	[ASC | DESC]	
	[NULLS { FIRST | LAST }]	
	WITH	
	WHERE	
	INCLUDE	
CREATE OPERATOR CLASS	-	A VCI cannot be specified. This operation is not supported in VCI.
CREATE OPERATOR FAMILY	-	
CREATE TABLE	EXCLUDE	
DROP INDEX	CONCURRENTLY	The subcommands on the left cannot be performed if a VCI is specified. This operation is not supported in VCI.
REINDEX	-	A VCI cannot be specified. This command is not required as VCI uses daemon's automatic maintenance to prevent disk space from increasing.

Client application command

- Operations that cannot be performed on relations containing a VCI

Command	Description
clusterdb	Clustering cannot be performed for tables that contain a VCI.
reindexdb	VCIs cannot be specified on the --index option.

13.2.2 Data Preload Feature

The first aggregation using VCI immediately after an instance is started may take time, because the VCI data has not been loaded to buffer.

Therefore, use the preload feature to load the VCI data to buffer in advance when performing VCI aggregation after an instance is started.

When using the preload feature, execute the function pgx_prewarm_vci to each VCI created with CREATE INDEX.

```
db01=# SELECT pgx_prewarm_vci('idx_vci');
```

See

Refer to "B.5 VCI Data Load Control Function" for information on pgx_prewarm_vci.

Chapter 14 Parallel Query

Fujitsu Enterprise Postgres enhances parallel queries, by taking into consideration the aspects below:

- CPU load calculation
- Increase of workers during runtime
- Statistics view displays the action state

14.1 CPU Load Calculation

There may be a case when the user tries to execute a parallel query but there is not enough CPU available.

Adding dynamic workers at this stage will provide no benefits - instead, it may add overhead due to context switching.

Fujitsu Enterprise Postgres checks the available CPU resources when determining the number of workers for a parallel query.

When checking the available CPU resources, the system checks the CPU usage (whether there are sufficient free system resources) at the time the SQL statement is executed, and a parallel query is only planned if there is enough free CPU usage for two or more cores on the server.

For example, if a server has four cores and the total free space from core 1 to core 4 is 200% or more, a parallel query will be planned, but if it is less than 200%, a parallel query will not be planned.

14.2 Increase of Workers during Runtime

Parallel query can cause CPU overload because workers cannot be added, for example, because there are not enough workers or no workers at the start of the query.

This Fujitsu Enterprise Postgres enhancement allows systems to allocate additional workers during query execution (if there are workers available at the time). The ability to increase workers during runtime is available only with parallel query. This improves query performance.

14.3 Statistics View Displays the Action State

You can check the action state by using the existing statistics collector. Monitoring the statistics enables you to check the action state of parallel processing through, for example, changes in the system load.

The following table describes the column added to the statistics views:

pg_stat_all_tables

Column	Data type	Description
parallel_query	bigint	Number of parallel query initialized in the table.

The parallel query column has also been added to the following views:

- pg_stat_sys_tables
- pg_stat_user_tables
- pg_stat_xact_all_tables
- pg_stat_xact_sys_tables
- pg_stat_xact_user_tables

See

Refer to "The Statistics Collector" in "Server Administration" in the PostgreSQL Documentation for information on the statistics collector and views.

Values will be set for the pgx_stat_sql view in Fujitsu Enterprise Postgres if parallel query is run.

See

Refer to "D.5 pgx_stat_sql" for information on pgx_stat_sql view.

Chapter 15 High-Speed Data Load

High-speed data load uses the pgx_loader command to load data from files at high speed into Fujitsu Enterprise Postgres.

This feature is available only in the Advanced Edition.

Information

This feature is not available in single-user mode. This is because in single-user mode instances run in a single process, and it cannot start parallel workers.

15.1 Installing High-Speed Data Load

This section describes how to install high-speed data load.

Installation flow

1. Deciding whether to Install
2. Estimating Resources
3. Setup

15.1.1 Deciding whether to Install

The feature achieves high speed data load by executing the COPY FROM command in parallel. If the database system is unable to use sufficient resources due to the feature using more resources than the COPY FROM command of PostgreSQL, load performance may be inferior to that of the COPY FROM command of PostgreSQL. Therefore, determine if the feature will be effective by considering the factors below before deciding to install.

Database server memory

If the value of shared_buffers in postgresql.conf is small, fewer data pages are cached to the shared memory of the database server. This will result in multiple parallel workers more often having to wait for write exclusive locks to the same data page. Moreover, the smaller the number of data pages, the more often the table expands. During table expansion, access to the table is exclusive (standby event name: extend), so write time increases. To cater for that, increase the value of shared_buffers.

See

The standby event name is stored in the wait_event column of the pg_stat_activity view. Refer to "wait_event Description" in "The Statistics Collector" in the PostgreSQL Documentation for details.

Frequency of checkpoints

If checkpoints are issued at short intervals, write performance is reduced. If the messages below are output to the server log during data writes, increase the values of max_wal_size and checkpoint_timeout in postgresql.conf to reduce the frequency of checkpoints.

Example

```
LOG:  checkpoints are occurring too frequently (19 seconds apart)
HINT:  Consider increasing the configuration parameter "max_wal_size".
```

15.1.2 Estimating Resources

Estimate the memory requirements for high-speed data load.

Up to 128 parallel workers to perform data load can be specified for this feature. The additional resources below are required depending on the number of parallel workers.

- Dynamic shared memory created during data load

  The feature creates shared memory and shared memory message queues during data load. These are used to send external data from the back end to the parallel workers, and for error notifications.

Information

If the value of shared_buffers in postgresql.conf is small, the system will often have to wait for write exclusive locks to the same data page (as described in "Database server memory" in "15.1.1 Deciding whether to Install"). Since input data cannot be loaded from the shared memory message queues during such waits, they will often be full. In these cases, it will not be possible to write to the shared memory message queues, resulting in degraded data load performance.

See

Refer to "High-Speed Data Load Memory Requirements" in the Installation and Setup Guide for Server for information on the formula for estimating memory requirements.

15.1.3 Setup

This section describes how to set up high-speed data load.

Setup flow

1. Setting Parameters
2. Installing the Extension

15.1.3.1 Setting Parameters

Set the parameters required for high-speed data load in postgresql.conf. After that, start or restart the instance.

The table below lists the postgresql.conf parameters that must be changed, and the values that must be added to their current values. After editing postgresql.conf, start or restart the instance.

Parameter	Setting	Required
max_prepared_transactions	Add the number of transactions that can be prepared by parallel workers during data load to the parameter's current value. The resulting value must be equal to or greater than the maximum number of parallel workers used with this feature.	Mandatory
max_worker_processes	Number of parallel workers to perform data load.	Mandatory
max_parallel_workers	Add the maximum number of parallel workers to be used in a parallel query by this feature to the parameter's current value. The resulting value must be equal to or greater than the number of parallel workers used with this feature.	Mandatory

As shown in the following example, set the value of max_prepared_transactions, max_worker_processes and max_parallel_workers multiplied by the number of instances of this feature executed simultaneously.

Example

The example below shows how to configure 2 instances of high-speed data load being executed simultaneously using a degree of parallelism of 4.

```
max_prepared_transactions = 13  #Example if the initial value was 5: 5 + 2 x 4 = 13
max_worker_processes = 16        #Example if the initial value was 8: 8 + 2 x 4 = 16
max_parallel_workers = 12        #Example if the initial value was 4: 4 + 2 x 4 = 12
```

The table below lists the postgresql.conf parameters that must also be checked.

Parameter	Setting	Required
dynamic_shared_memory_type	Implementation of dynamic shared memory to be used by the instance. The default value is recommended.	Mandatory

See

Refer to "Resource Consumption" in the PostgreSQL Documentation for information on the parameters.

15.1.3.2 Installing the Extension

Execute CREATE EXTENSION to install the high-speed data load extension. The extension needs to be installed on each database. Also, extensions can only be installed on the public schema by a superuser.

Example

The example below installs the extension on the "postgres" database.

```
postgres=# CREATE EXTENSION pgx_loader;
CREATE EXTENSION
```

15.2 Using High-Speed Data Load

This section describes how to use high-speed data load.

15.2.1 Loading Data

To load data from a file into a Fujitsu Enterprise Postgres table, execute the pgx_loader command in load mode. The data inserted using this feature is dumped as a COPY command by the pg_dump command and the pg_dumpall command.

Example

The example below loads the file /path/to/data.csv (2000 records) into table tbl using a degree of parallelism of 3.

```
$ pgx_loader load -j 3 -c "COPY tbl FROM '/path/to/data.csv' WITH CSV"
LOAD 2000
```

Point

If an external file contains data that violates the format or constraints, the data load may fail partway through, resulting in delays for routine tasks such as nightly batch processing. Therefore, it is recommended to remove the invalid data before executing the data load.

See

- Refer to "pgx_loader" in the Reference for information on the command.
- Refer to "COPY" in the PostgreSQL Documentation for information on the deployment destination and access privileges for external files.

15.2.2 Checking Progress

If you are performing a data load with a large external file as input, you can verify that the process is continuing by getting progress information during the load. Progress information can be obtained from the pgx_stat_progress_loader view. This view displays the sum of the progress information of the back-end process and the number of parallel worker processes. Search the pgx_stat_progress_loader view, for example, with a SELECT statement, to locate the appropriate row. After running the pgx_loader command, look in the pg_stat_activity view and locate a row in the pgx_stat_progress_loader view with the PID obtained.

Example

1. See the pg_stat_activity view. (9311 for back-end processes, 9312, 9313, 9314 for worker processes)

```
postgres=# select pid, application_name, backend_type from pg_stat_activity
pid  | application_name |         backend_type
-----+------------------+------------------------------
6216 |                  | autovacuum launcher
6218 |                  | logical replication launcher
6271 | psql             | client backend
9311 | pgx_loader       | client backend
9312 |                  | parallel loader for PID 9311
9313 |                  | parallel loader for PID 9311
9314 |                  | parallel loader for PID 9311
6214 |                  | background writer
6213 |                  | checkpointer
6215 |                  | walwriter
```

2. Check the information in the pgx_stat_progress_loader view.

```
postgres=# SELECT * FROM pgx_stat_progress_loader
pid  | datid | datname | relid | command  | type | bytes_processed | bytes_total |
tuples_processed | tuples_excluded
-----+-------+---------+-------+----------+------+-----------------+-------------
+------------------+----------------
9311 |  222  | testdb  | 333   |COPY FROM | FILE |        192000   |    450000   |        189000
|           3000
```

Refer to "D.7 pgx_stat_progress_loader" for information on the pgx_stat_progress_loader view.

Point

When you run the pgx_loader command, the PostgreSQL pg_stat_progress_copy view prints the progress of the back-end process and the number of parallel worker processes on each line. The backend process progress information tuples_processed, tuples_excluded is 0. Also, bytes_processed and bytes_total for worker processes are 0.

```
postgres=# SELECT * FROM pg_stat_progress_copy
pid  | datid | datname | relid | command  | type | bytes_processed | bytes_total | tuples_processed |
tuples_excluded
-----+-------+---------+-------+----------+------+-----------------+-------------+------------------
+----------------
9311 |  222  | testdb  | 333   |COPY FROM | FILE |         192000  |    450000   |                0
|              0
9312 |  222  | testdb  | 333   |COPY FROM | FILE |              0  |         0   |          63000
```

```
|           1000
9313 |   222  | testdb   | 333    |COPY FROM | FILE |              0  |         0    |          63000
|           1000
9314 |   222  | testdb   | 333    |COPY FROM | FILE |              0  |         0    |          63000
|           1000
```

Refer to "pg_stat_progress_copy View" in the PostgreSQL Documentation for information on the pg_stat_progress_copy view.

15.2.3 Recovering from a Data Load that Ended Abnormally

If a system interruption such as a server failure occurs while high-speed data load is being performed, transactions prepared using this feature may be changed to the in-doubt state. At that point, resources occupied by the transaction will be locked, and access to the relevant resources from other transactions will be blocked, rendering them unusable.

In such cases, check transactions that are in an in-doubt state, and resolve them.

Checking for in-doubt transactions

This section describes how to check for in-doubt transactions.

1. Refer to the pgx_loader_state table in the pgx_loader schema.

   Retrieve the global transaction identifier (gid column) of in-doubt transactions. In-doubt transactions will contain "rollback" in the column "state".

   Example

   The example below retrieves the global transaction identifier (gid) of in-doubt transactions performed by the database role myrole and that used table tbl. The retrieved global transaction identifiers pgx_loader:9589 and pgx_loader:9590 identify in-doubt transactions.

```
postgres=# SELECT gid, state FROM pgx_loader.pgx_loader_state WHERE
postgres-# role_oid IN (SELECT oid FROM pg_roles WHERE rolname = 'myrole') AND
postgres-# relation_oid IN (SELECT relid FROM pg_stat_all_tables WHERE
postgres-# relname = 'tbl');
       gid       | state
-----------------+-------------
 pgx_loader:9590 | rollback
 pgx_loader:9591 | commit
 pgx_loader:9589 | rollback
(3 rows)
```

2. Refer to the pg_prepared_xacts system view.

   Check if the in-doubt transactions retrieved above exist.

   Example

   The example below checks if in-doubt transactions with the global transaction identifiers pgx_loader:9589 and pgx_loader:9590 exist.

```
postgres=# SELECT gid FROM pg_prepared_xacts WHERE gid IN ('pgx_loader:9589','pgx_loader:9590');
       gid
------------------
 pgx_loader:9590
 pgx_loader:9589
(2 rows)
```

See

Refer to "H.1 pgx_loader_state" for information on the pgx_loader_state table.

Resolving in-doubt transactions

Execute the pgx_loader command in recovery mode to resolve in-doubt transactions.

After executing the pgx_loader command in recovery mode, perform the procedure described in "Checking for in-doubt transactions" to check if the in-doubt transactions have been resolved.

Example

The example below completes the in-doubt transactions prepared for table tbl.

```
$ pgx_loader recovery -t tbl
```

Point

The recovery mode of the pgx_loader command only resolves transactions prepared by high-speed data load. For transactions prepared by an application using distributed transactions other than this feature, follow the procedure described in "19.13 Actions in Response to Error in a Distributed Transaction".

15.3 Removing High-Speed Data Load

This section describes how to remove high-speed data load.

15.3.1 Removing the Extension

Execute DROP EXTENSION to remove the high-speed data load extension. The information required for operation of high-speed data load is stored in the pgx_loader_state table of the pgx_loader schema. Do not remove the high-speed data load extension if the pgx_loader_state table is not empty.

The extension needs to be removed on each database. Also, extensions can only be removed on the public schema by a superuser.

Example

The example below removes the extension on the "postgres" database.

```
postgres=# DROP EXTENSION pgx_loader;
DROP EXTENSION
```

Chapter 16 Global Meta Cache

The Global Meta Cache (GMC) feature loads a meta cache into shared memory using the pgx_global_metacache parameter. This reduces the amount of memory required throughout the system.

This feature can only be used in Advanced Edition.

16.1 Usage

Describes how to use the Global Meta Cache feature.

16.1.1 Deciding Whether to Enable the Global Meta Cache Feature

Global Meta Cache is a mechanism for sharing meta caches between processes, so it works well on systems with a high number of resources accessed and SQL connections. The number of resources is primarily the number of tables accessed by a process, the number of indexes, or the total number of all columns in all tables accessed.

In particular, consider using Global Meta Cache if the total size of the meta cache for each process exceeds the amount of installed memory, or takes up a large portion of that memory, thereby squeezing memory allocations to the database cache or the Operating system file cache. Using Global Meta Cache may increase the time it takes to execute a single SQL to reference a meta cache on shared memory, but you can expect a greater benefit from being able to allocate more memory, such as for the database cache.

If performance degradation using Global Meta Cache is not acceptable, you may want to limit the number of tables accessed by a process.

16.1.2 Estimating Memory for Global Meta Cache

To enable the Global Meta Cache feature, the pgx_global_metacache parameter must specify an upper limit on the size of the shared memory (Hereinafter, the GMC area) dedicated to Global Meta Cahche. Ideally, this upper limit should be the size estimated in “Appendix A Parameters”. Values lower than this can still work, but refer to "16.1.3 How the GMC Memory Area Is Used" on using the GMC area to understand the disadvantages.

16.1.3 How the GMC Memory Area Is Used

At startup, the memory for the GMC area is not used much, but the GMC area grows as new meta caches are placed in the GMC area. If it does, it discards any meta caches that the system determines are not heavily used and places a new one in the GMC area.

Therefore, the GMC area will work even if it is smaller than the estimate, but the meta cache will be regenerated if the discarded meta cache needs to be reused. Note that if this happens frequently, it will degrade overall performance.

With this in mind, it may not be a problem if, for example, the tables to be accessed are different depending on the time zone, and the degradation of the time zone immediately after the change is acceptable.

In any case, be sure to test and tune the system thoroughly before running it.

16.1.4 Enabling the Global Meta Cache Feature

To Enable the Global Meta Cache feature edit the postgresql.conf file and set the pgx_global_metacahe parameter. Restarting the instance after editing the postgresql.conf file is required. Refer to "Appendix A Parameters" for information on the parameters.

Parameter Name	Description
pgx_global_metacache	Specify the maximum amount of memory for the GMC area on shared memory. When it’s set to 0 (default value), the Global Meta Cache feature is disabled. When enabled, the minimum value allowed is 10MB.

When the cache is created, if the total amount of meta caches on shared memory exceeds the value specified by pgx_global_metacache, the inactive, unreferenced meta caches are removed from the GMC area. Note that if all GMC are in use and the cache cannot be created in the GMC area, the cache is temporarily created in the local memory of the backend process.

Example

Here is an example postgresql.conf configuration:

```
pgx_global_metacache = 800 MB
```

Wait Events

The Global Meta Cache feature may cause wait events. Wait events are identified in the wait_event column of the pg_stat_activity view. GMC specific wait events are described below.

[GMC Feature Wait Events]

Wait Event Type	Wait Event Name	Description
LWLock	GlobalCatcache	Waiting to find, add, and remove meta caches in the GMC area.
IPC	GMCSweep	Waiting to select a meta cache that can be deleted when GMC space is low. If the GMC is fully referencing and there is no deletable meta cache, it is waiting for the reference to be removed and a deletable meta cache to be selected.

Point

If GMCSweep is happened frequently, increase the pgx_global_metacache setting.

See

Refer to "Viewing Statistics" in the PostgreSQL Documentation for information on the pg_stat_activity view.

16.1.5 Estimating Resources

Refer to "Global Meta Cache Memory Requirements" in the Installation and Setup Guide for Server for formulas to estimate the amount of memory used by the Global Meta Cache feature.

16.2 Statistics

Describes the statistics for the Global Meta Cache feature.

16.2.1 System View

You can check the cache hit ratio and size of the GMC area in the system view pgx_stat_gmc. Refer to "D.6 pgx_stat_gmc" for information on the columns.

If the cache hit ratio is low and the current memory usage is close to pgx_global_metacache, increase the pgx_global_metacache setting because performance may be degraded.

Refer to "9.6 Monitoring Database Activity" in the Operations Guide for information on the statistics.

Chapter 17 Local Meta Cache Limit

Local Meta Cache Limit feature limits the size of a Local Meta Cache by removing it if it has not been accessed for a long time.

This feature is available only in the Advanced Edition.

17.1 Usage

Describes how to use the Local Meta Cache Limit feature.

17.1.1 Deciding Whether to Enable the Local Meta Cache Limit Feature

Refer to "Appendix A Parameters", after estimating the total amount of memory to be used as the catalog cache and relation cache, when the total amount of memory exceeds the amount of installed memory or occupies a large amount of installed memory, consider using this feature.

This feature adds the action of discarding the meta cache that has been held permanently. If you attempt to refer to a destroyed meta cache again, the meta cache is recreated, so using this feature will result in poor performance compared to not using it.

Therefore, read the following to understand how to discard a meta cache.

- 17.1.3 Cache Removal when Local Meta Cache Limit is Enabled
- 17.1.4 Performance Impact and Parameter Tuning of the Local Meta Cache Limit Feature
- Parameters for the Local Meta Cache Limit feature

How to set the upper limit with these considerations is described in detail in the estimation formula in "Appendix A Parameters".

17.1.2 How to Set Parameters for the Local Meta Cache Limit Feature

To enable the Local Meta Cache Limit feature, set the pgx_catalog_cache_max_size and pgx_relation_cache_max_size parameters.

Parameter Name	Description
pgx_catalog_cache_max_size	Specify the maximum amount of memory that the backend process should use as the catalog cache. You can enable catalog cache removal by setting it to 8 KB or more. When it is set to 0 (default value), the catalog cache removal is disabled.
pgx_relation_cache_max_size	Specify the maximum amount of memory that the backend process should use as the relation cache. You can enable relation cache removal by setting it to 8 KB or more. When it is set to 0 (default value), the relation cache removal is disabled.

Example

Here is an example postgresql.conf configuration:

```
pgx_catalog_cache_max_size = 1MB
pgx_relation_cache_max_size = 1MB
```

17.1.3 Cache Removal when Local Meta Cache Limit is Enabled

When this feature is enabled, the caching strategy is to keep the cache as long as possible within the specified upper limit. If holding a new cache exceeds the limit, consider locality of reference and remove the cache from the one with the longest unreferenced time.

However, because the cache used by active transactions cannot be removed, if a transaction uses a large number of caches, the cache may be held above the limit. In this case, remove the all caches at the end of the transaction. This is necessary to free up memory.

In PostgreSQL, in order to acquire memory at high speed, a memory block of a certain size is acquired from the OS, and a small memory is cut out from the block and used. The memory for the metacache is cut out in the same way. Therefore, it is possible to return the memory block to the OS by destroying all the meta caches scattered throughout the memory block. When this happens, the next SQL execution will

be slowed down due to the re-creation of the meta cache. Therefore, upper limit of feature should be set to a value larger than the size of the meta cache used by at least one transaction.

When the size of the meta cache exceeds the upper limit, the following message is output:

```
WARNING: could not reduce Cat/RelCacheMemoryContext size to AA kilobytes, reduced to BB kilobytes
HINT: consider increasing the configuration parameter pgx_catalog/relation_cache_max_size
```

(***AA***: Upper limit, ***BB***: Amount of memory actually used)

CatCacheMemoryContext and RelCacheMemoryContext are memory areas for storing the catalog cache and relation cache, respectively. If this message is output, consider increasing the upper limit.

If the memory consumption by the backend process exceeds the allowable value by increasing the upper limit, reconsider the SQL to be executed, such as reducing the number of tables accessed in one transaction, or add memory adjust to the amount of memory used.

17.1.4 Performance Impact and Parameter Tuning of the Local Meta Cache Limit Feature

By observing how much meta cache regeneration is taking place, you can determine if the low upper limit is the cause of the failure to achieve the desired performance.

From the message below, calculate the cache hit ratio as follows:

```
Cache hit ratio = Number of cache hits ÷ Number of times the cache was searched
```

If the cache hit ratio is 80% or higher, this feature will not be the main factor that impedes performance. If not, raise the upper limit and see if performance can reach the goal. In doing so, first try to shift the focus of allocation to the relations cache. This is because when executing SQL, the relation cache generated based on the catalog cache is mainly referenced, so it is advantageous to leave a large amount of relation cache.

```
Catalog cache:catalog cache hit stats: search XX, hits YY
Relation cache:relation cache hit stats: search XX, hits YY
```

(***XX***: Number of times the cache was searched, ***YY***: Number of cache hits)

This message is printed when the transaction ends. However, if you output the message frequently, the performance will be degraded by itself, so you can adjust the output interval with the following parameters.

Parameter Name	Description
pgx_cache_hit_log_interval	When the transaction ends, if the time set in this parameter has elapsed since the previous message was output, the message is output. If set to 0, a message will be output each time the transaction ends. Setting -1 disables the output. The default value is 10min. Even if pgx_catalog_cache_max_size and pgx_relation_cache_max_size are disabled, the message output of the corresponding cache will be invalid. Immediately after connecting to the server, a small transaction occurs before the request from the user application, such as for user authentication. Since it is meaningless to know the hit ratio for these, a message is output at the end of the transaction that started after the time set in this parameter has elapsed after connecting to the server. For the same reason, setting a small value such as 0 may result in a message being printed at the end of such a small transaction. You can check which transaction the message corresponds to from the information output at the beginning. This information depends on the setting of the parameter log_line_prefix.

Example

Here is an example postgresql.conf configuration:

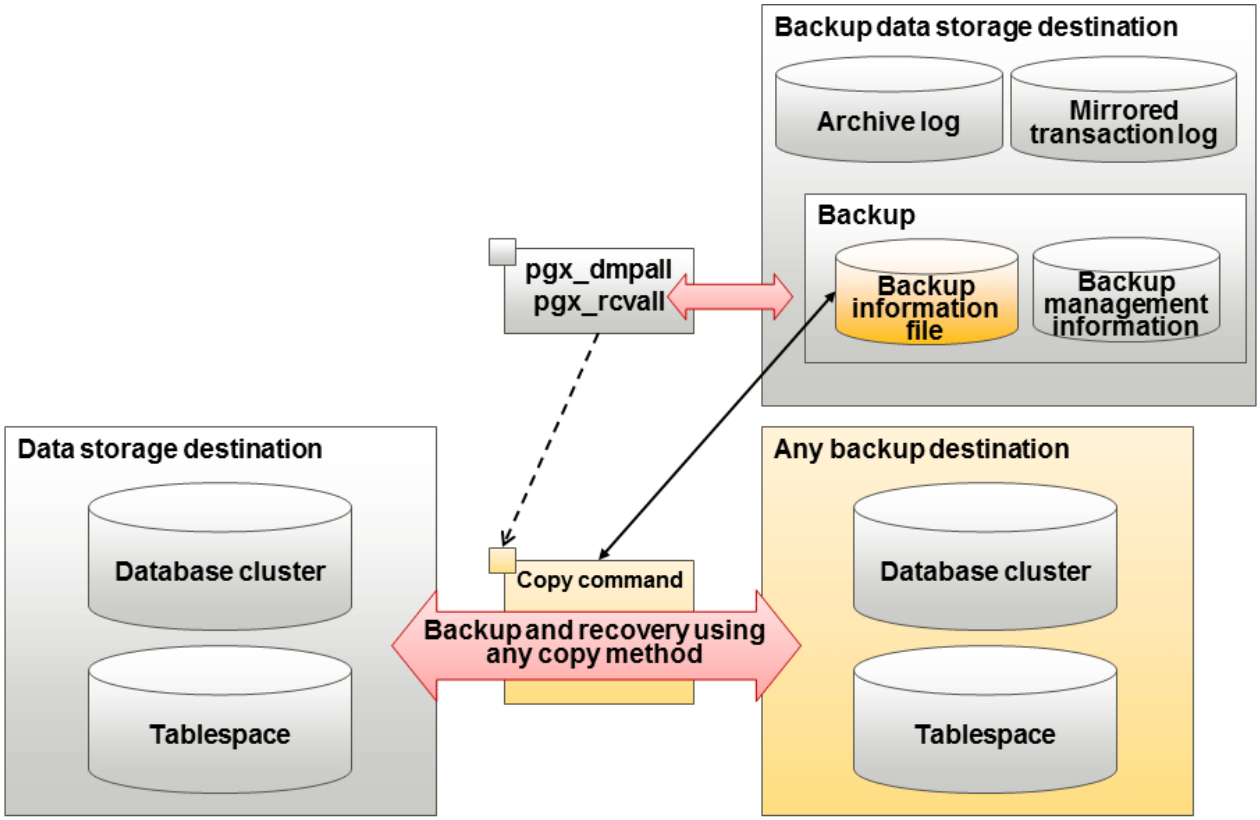
```
pgx_cache_hit_log_interval= 30min
```

Chapter 18 Backup/Recovery Using the Copy Command

By using a copy command created by the user, the pgx_dmpall command and the pgx_rcvall command can perform backup to any destination and can perform recovery from any destination using any copy method.

Copy commands must be created in advance as executable scripts for the user to implement the copy process on database clusters and tablespaces, and are called when executing the pgx_dmpall and pgx_rcvall commands.

This appendix describes backup/recovery using the copy command.



Point

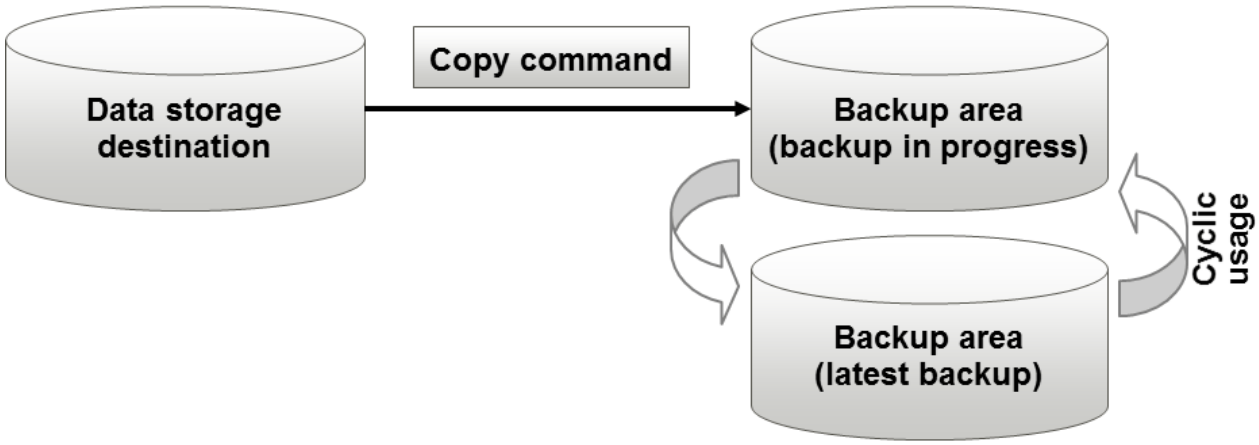
- By using the high-speed copy feature of the storage device to copy the data storage destination, the processing time for backup of large databases can be greatly reduced.
- It is also possible to back up only some tablespaces using the copy command. However, database resources not backed up using the copy command are still backed up to the backup data storage destination.
- Both the backup data storage destination and the optional backup destination are necessary for recovery - if they are located in secondary media, combined management of these is necessary.

18.1 Configuration of the Copy Command

This section describes the configuration of the copy command for backup and recovery.

Cyclic usage of the backup area

Prepare two backup areas for the copy command in case an issue affects the data storage destination during backup. The copy command performs backup while cyclically using these backup areas.

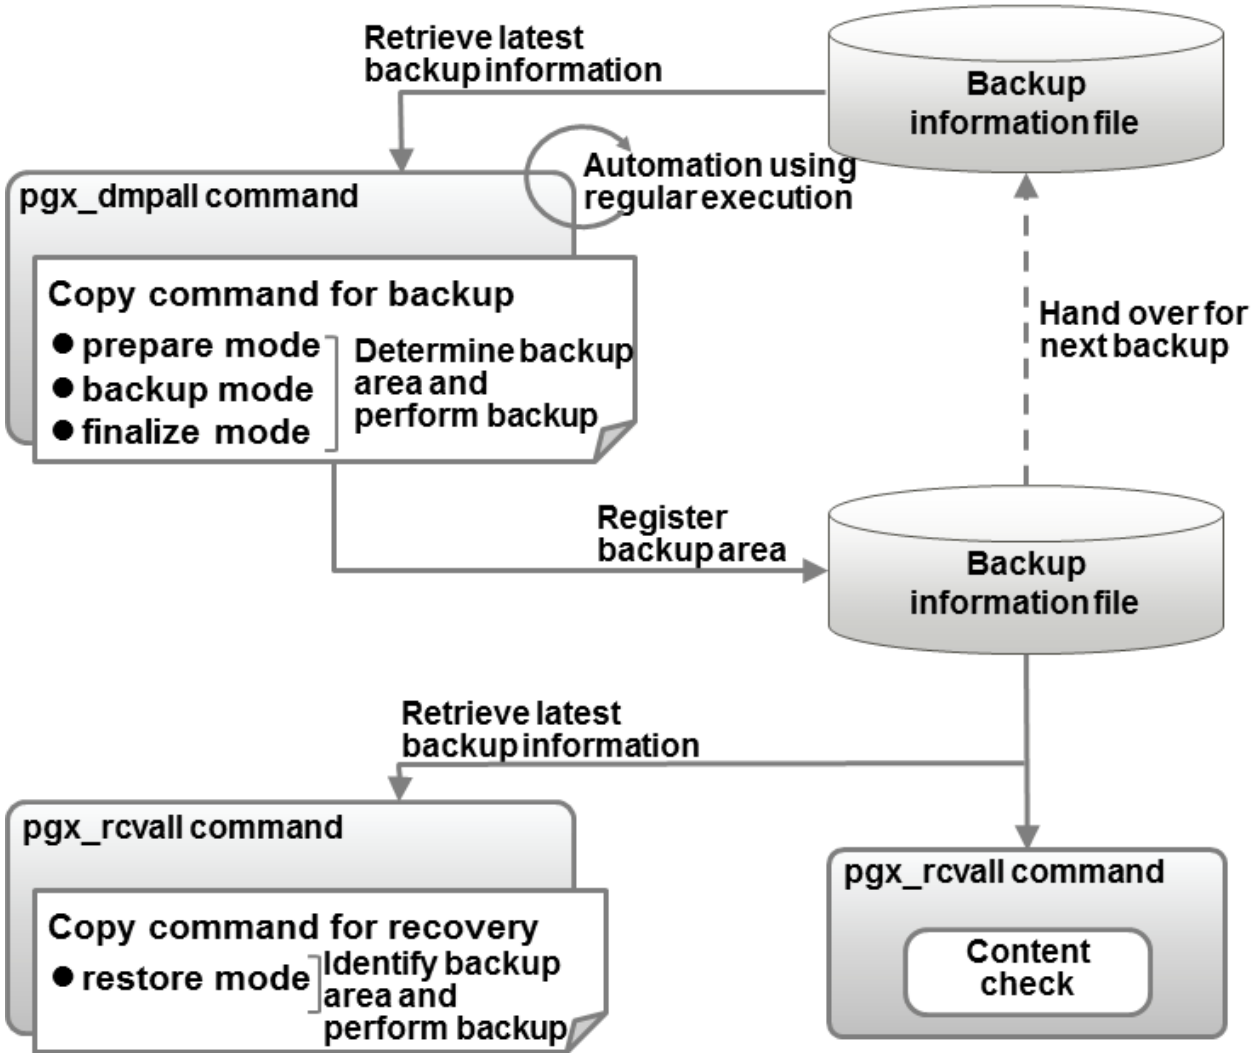


Information

The backup data storage destination cannot be used as these backup areas used by the copy command.

Backup using the backup information file

The copy command must determine the backup destination on each backup, as it is necessary to cycle through the backup areas. Backup can be automated by using the backup information file, which contains information about the backup destination.



Information

The backup information file is prepared in the backup data storage destination by the pgx_dmpall command, and contains information that can be read or updated by the copy command. This file is managed by associating it with the latest backup successfully completed by the pgx_dmpall command, so the latest backup information relating to the copy command registered by the user can be retrieved. Additionally, the content of the backup information file can be displayed using the pgx_rcvall command.

Configuration of the copy command for backup

The pgx_dmpall command calls the copy command for backup after execution for the three modes below. It is therefore necessary for the copy command for backup to implement the required processing for each of the modes. The user can use any method to hand over backup information between modes within the copy command, such as creating temporary files.

- prepare mode

  Determines which of the two backup areas will be used for the current backup.

  The backup area to be used for the current backup is determined by reading the information relating to the latest backup destination where the backup information file was written to during the previous backup.

- backup mode

  Performs backup on the backup area determined by prepare mode, using any copy method.

- finalize mode

  Writes information relating to the destination of the current backup to the backup information file.

  This enables the prepare mode to check the destination of the previous backup during the next backup.

Configuration of the copy command for recovery

The pgx_rcvall command calls the copy command for recovery for the mode below. It is therefore necessary for the copy command for recovery to implement the required processing for the mode.

- restore mode

  Any copy method can be used to implement restore from the backup destination retrieved using the copy command for backup.

Point

By referring to the mode assigned to the copy command as an argument, backup and recovery can be implemented using a single copy command.

Example

Using a bash script

```
case $1 in
    prepare)
        processingRequiredForPrepareMode
        ;;
    backup)
        processingRequiredForBackupMode
        ;;
    finalize)
         processingRequiredForFinalizeMode
        ;;
    restore)
         processingRequiredForRestoreMode
```

```
        ;;
esac
```

Point

- A sample script that backs up the database cluster and tablespace directory to a specific directory is supplied to demonstrate how to write a copy command.

  The sample is stored in the directory below:

  ```
  /installDir/share/copy_command.archive.sh.sample
  ```

- A sample script that uses OPC (an advanced copy feature of Fujitsu Storage ETERNUS disk array) is supplied. Refer to "Appendix L Copy Command Samples that Use the Advanced Copy Feature of the ETERNUS Disk Array" for details.

  The samples cannot be used on SLES 15.

18.2 Backup Using the Copy Command

To perform backup using the copy command, in addition to performing the standard backup procedure, it is also necessary to create a copy command, and then execute the pgx_dmpall command specifying it. This section describes the procedure specific to using the copy command.

Preparing for backup

You must prepare for backup before actually starting the backup process.

Perform the following procedure:

1. Determine the database resources to be backed up

   Determine the database resources to be backed up using the copy command. The copy command can back up the following resources:

   - Database cluster
   - Tablespace

   To back up only some tablespaces, create a file listing them. This file is not necessary to back up all tablespaces.

   Example

   To back up only tablespaces tblspc1 and tblspc2

   ```
   tblspc1
   tblspc2
   ```

2. Prepare a backup area

   Prepare a backup area to save the database resources to be backed up, as determined in step 1.

3. Create the copy command

   Create the copy commands for backup and recovery. Refer to "18.4 Copy Command Interface" for details.

Performing backup

Execute the pgx_dmpall command with the -Y option specifying the full path of the copy command for backup created in step 3 of preparation for backup.

The example below backs up only some tablespaces, but not the database cluster, using the copy command.

Example

```
$ pgx_dmpall -D /database/inst1 -Y '/database/command/backup.sh'
  --exclude-copy-cluster -P '/database/command/tablespace_list.txt'
```

Point

- To exclude up the database cluster from backup using the copy command, specify the --exclude-copy-cluster option.
- To back up only some tablespaces using the copy command, use the -P option specifying the full path of the file created in step 1 of preparation for backup.

See

- Refer to "pgx_dmpall" in the Reference for information on the command.

Checking backup status

Use the pgx_rcvall command to check the backup status.

Execute the pgx_rcvall command with the -l option specified to output backup data information. If backup was performed using the copy command, the resources backed up using the copy command will also be output.

Example

```
$ pgx_rcvall -l -D /database/inst1
Date                Status   Dir                                Resources backed up by the copy command
2022-03-01 13:30:40 COMPLETE /backup/inst1/2022-03-01_13-30-40 pg_data,dbspace,indexspace
```

18.3 Recovery Using the Copy Command

To perform recovery using the copy command, in addition to performing the standard recovery procedure, it is also necessary to create a copy command, and then execute the pgx_rcvall command specifying it. This section describes the procedure specific to using the copy command.

Determining the backup area of the latest backup

Check the backup information file to determine the backup area used for the latest backup, and confirm that it is in a recoverable state.

Execute the pgx_rcvall command with the --view-results-of-copying option to output the content of the backup information file.

Example

```
$ pgx_rcvall -D /database/inst1 --view-results-of-copying
```

Perform recovery

Execute the pgx_rcvall command with the -Y option specifying the full path of the copy command for recovery created in step 3 of the preparation for backup described in "18.2 Backup Using the Copy Command".

The example below recover only some tablespaces, but not the database cluster, using the copy command.

Example

```
$ pgx_rcvall -D /database/inst1 -B /backup/inst1 -Y '/database/command/recovery.sh'
```

Point

If the latest backup was performed using the copy command, the pgx_rcvall command automatically recognizes which database resources were backed up using the copy command, or whether resources were backed up to the backup data storage destination. Therefore, recovery can be performed by simply executing the pgx_rcvall command specifying the copy command for recovery.

See

Refer to "pgx_rcvall" in the Reference for information on the command.

18.4 Copy Command Interface

The following types of copy command are available:

- Copy command for backup
- Copy command for recovery

This appendix describes the interface of each copy command.

18.4.1 Copy Command for Backup

Feature

User exit (for the copy command) called from the pgx_dmpall command.

Format

The syntax for calling the copy command from the pgx_dmpall command is described below.

If the operation mode is "prepare"

```
copyCommandName prepare 'pathOfBackupInfoFile' 'pathOfBackupTargetListFile'
```

If the operation mode is "backup"

```
copyCommandName backup
```

If the operation mode is "finalize"

```
copyCommandName finalize 'pathOfBackupInfoFile'
```

Argument

- Operation mode

Mode	Description
prepare	Implements the preparation process for backing up using the copy command. Called before the PostgreSQL backup mode is started.
backup	Implements the backup process. Called during the PostgreSQL backup mode.

Mode	Description
finalize	Implements the backup completion process. Called after the PostgreSQL backup mode is completed.

Point

If using high-speed copy of the storage device (which performs high-speed retrieval of snapshots and copies data to different physical areas), it is possible to invoke the snapshot process in backup mode, and the copy process in finalize mode.

- Full path of the backup information file

  Full path of the backup information file of the latest backup, enclosed in single quotation marks. If a backup has not been performed, specify '-'.

- Full path of the backup target list file

  Full path of the file containing the resources to be backed up using the copy command, enclosed in single quotation marks. One of the following is described in each resource name.

Resource	Description
Database cluster	pg_data
Tablespace	Tablespace name

Example

To back up the database cluster and the tablespaces dbspace and indexspace using the copy command, the file should contain the following:

```
pg_data
dbspace
indexspace
```

Information

The encoding of resource names output to the backup target list file by the pgx_dmpall command is the encoding used when this command connects to the database with auto specified for the client_encoding parameter, and is dependent on the locale at the time of command execution.

The number of arguments vary depending on operation mode. The argument of each operation mode is as follows.

Operation mode	First argument	Second argument	Third argument
prepare	Operation mode	Backup information file path name	Backup target list file path name
backup		None	None
finalize		Backup information file path name	

Additionally, the access permissions for the backup information file and backup target list file are different depending on the operation mode. The access permissions of each operation mode are as follows.

Operation mode	Backup information file	Backup target list file
prepare	Can be viewed by the instance administrator only	Can be viewed by the instance administrator only
backup	-	-

Operation mode	Backup information file	Backup target list file
finalize	Can be viewed and updated by the instance administrator only	-

Return value

Return value	Description
0	Normal end The pgx_dmpall command continues processing.
Other than 0	Abnormal end The pgx_dmpall command terminates in error.

Description

- The copy command operates with the privileges of the operating system user who executed the pgx_dmpall command. Therefore, grant copy command execution privileges to users who will execute the pgx_dmpall command. Additionally, have the copy command change users as necessary.
- To write to the backup information file, use a method such as redirection from the copy command.
- Because the copy command is called for each mode, implement all processing for each one.
- To copy multiple resources simultaneously, have the copy command copy them in parallel.
- The backup information file and backup target list file cannot be deleted. Additionally, the privileges cannot be changed.
- Standard output and standard error output of the copy command are output to the terminal where the pgx_dmpall command was executed.
- If the copy command becomes unresponsive, the pgx_dmpall command will also become unresponsive. If the copy command is deemed to be unresponsive by the operating system, use an operating system command to forcibly stop it.
- Output the copy command execution trace and the result to a temporary file, so that if it terminates in error, the cause can be investigated at a later time.
- For prepare mode only, it is possible to use the PostgreSQL client application to access the database using the copy command. For all other modes, do not execute Fujitsu Enterprise Postgres commands or PostgreSQL applications.
- Enable the fsync parameter in postgresql.conf, because data on the shared memory buffer needs to have been already written to disk when backup starts.

18.4.2 Copy Command for Recovery

Feature

User exit (for the copy command) called from the pgx_rcvall command.

Format

The syntax for calling the copy command from the pgx_rcvall command is described below.

```
copyCommandName restore 'pathOfBackupInfoFile' 'pathOfBackupTargetListFile'
```

Argument

- Operation mode

Mode	Description
restore	Performs restore.

- Full path of the backup information file

  Full path of the backup information file, enclosed in single quotation marks.

- Full path of the backup target list file

  Full path of the file containing the resources to be restored using the copy command, enclosed in single quotation marks.

The access permissions for the backup information file and backup target list file are as below.

Backup information file	Backup target list file
Can be viewed by the instance administrator only	Can be viewed by the instance administrator only

Return value

Return value	Description
0	Normal end The pgx_rcvall command continues processing.
Other than 0	Abnormal end The pgx_rcvall command terminates in error.

Description

- The copy command operates with the privileges of the operating system user who executed the pgx_rcvall command. Therefore, grant copy command execution privileges to users who will execute the pgx_rcvall command. Additionally, have the copy command change users as necessary.
- The copy command is called once only in restore mode.
- To copy multiple resources simultaneously, have the copy command copy them in parallel.
- The backup information file and backup target list file cannot be deleted. Additionally, the privileges cannot be changed.
- Standard output and standard error output of the copy command are output to the terminal where the pgx_rcvall command was executed.
- If the copy command becomes unresponsive, the pgx_rcvall command will also become unresponsive. If the status of the copy command is deemed to be unresponsive by the operating system, use an operating system command to forcibly stop it.
- Output the copy command execution trace and the result to a temporary file, so that if it terminates in error, the cause can be investigated at a later time.
- Do not execute Fujitsu Enterprise Postgres commands or PostgreSQL applications in the copy command.
- There may be files and directories not required for recovery using the archive log included in the backup, such as postmaster.pid, pg_wal/*subdirectory* and pg_replslot in the database cluster. If such unnecessary files and directories exist, have the copy command delete them after the restore.

Chapter 19 Actions when an Error Occurs

This chapter describes the actions to take when an error occurs in the database or an application, while Fujitsu Enterprise Postgres is operating.

Depending on the type of error, it may be necessary to recover the database cluster. The recovery process recovers the following resources:

- Data storage destination
- Transaction log storage destination (if the transaction log is stored in a separate disk from the data storage destination)
- Backup data storage destination

Even if a disk is not defective, the same input-output error messages, as those generated when the disk is defective, may be output. The recovery actions differ for these error messages.

Check the status of the disk, and select one of the following actions:

- If the disk is defective

  Refer to "19.1 Recovering from Disk Failure (Hardware)", and take actions accordingly.

- If the disk is not defective

  Refer to "19.14 I/O Errors Other than Disk Failure", and take actions accordingly.

  A few examples of errors generated even if the disk is not defective include:

  - Network error with an external disk
  - Errors caused by power failure or mounting issues

Determining the cause of an error

If an error occurs, refer to the WebAdmin message and the server log, and determine the cause of the error.

Refer to "Configuring Parameters" in the Installation and Setup Guide for Server for information on server logs.

Approximate recovery time

The formulas for deriving the approximate recovery time of resources in each directory are given below.

If using the copy command with the pgx_rcvall command, the recovery time will depend on the implementation of the copy command.

- Data storage destination or transaction log storage destination

```
Recovery time = (usageByTheDataStorageDestination + usageByTheTransactionLogStorageDestination) /
diskWritePerformance x 1.5
```

  - *usageByTheDataStorageDestination*: Disk space used by the database cluster
  - *usageByTheTransactionLogStorageDestination*: Disk space used by the transaction log stored outside the database cluster
  - *diskWritePerformance*: Measured maximum data volume (bytes/second) that can be written per second in the system environment where the operation is performed
  - 1.5: Coefficient assuming the time excluding disk write, which is the most time-consuming step

- Backup data storage destination

```
Recovery time = usageByTheBackupDataStorageDestination / diskWritePerformance x 1.5
```

  - *usageByTheBackupDataStorageDestination*: Disk space used by the backup data

- *diskWritePerformance*: Measured maximum data volume (bytes/second) that can be written per second in the system environment where the operation is performed
- 1.5: Coefficient assuming the time excluding disk write, which is the most time-consuming step

19.1 Recovering from Disk Failure (Hardware)

This section describes how to recover database clusters to a point immediately before failure, if a hardware failure occurs in the data storage disk or the backup data storage disk.

There are two methods of recovery:

- 19.1.1 Using WebAdmin
- 19.1.2 Using Server Command

Point

Back up the database cluster after recovering it. Backup deletes obsolete archive logs (transaction logs copied to the backup data storage destination), freeing up disk space and reducing the recovery time.

19.1.1 Using WebAdmin

Recover a failed disk using WebAdmin.

In a streaming replication configuration, the master instance can be recovered, but the standby instance cannot. If disk failure occurs on a standby instance, it may be necessary to delete and re-create the instance. Also, recovering the master instance stops streaming replication to and from all standby instances. In such an event, the standby instances can be promoted to standalone instances or can be deleted and re-created

Recover the database cluster by following the appropriate recovery procedure below for the disk where the failure occurred.

If failure occurred in the data storage disk or the transaction log storage disk

Follow the procedure below to recover the data storage disk or the transaction log storage disk.

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance. Refer to "2.1.1 Using WebAdmin" for information on how to stop an instance. WebAdmin automatically stops instances if recovery of the database cluster is performed without stopping the instance.

3. Recover the failed disk

   Replace the disk, and then recover the volume configuration information.

4. Create a tablespace directory

   If a tablespace was defined after backup, create a directory for it.

5. Recover the keystore, and enable automatic opening of the keystore

   Do the following if the data in the database has been encrypted:

   - Restore the keystore to its state at the time of the database backup.
   - Enable automatic opening of the keystore.

6. Recover the database cluster

   Log in to WebAdmin, and in the [Instances] tab, click [Solution] for the error message in the lower-right corner.

7. Run recovery

   In the [Restore Instance] dialog box, click [Yes].

Instance restore is performed. An instance is automatically started when recovery is successful.

8. Resume applications

   Resume applications that are using the database.

Point

WebAdmin may be unable to detect disk errors, depending on how the error occurred.

If this happens, refer to "19.10.3 Other Errors" to perform recovery.

If failure occurred on the backup data storage disk

Follow the procedure below to recover the backup data storage disk.

1. Recover the failed disk

   Replace the disk, and then recover the volume configuration information.

2. Recover the backup data

   Log in to WebAdmin, and in the [Instances] tab, click [Solution] for the error message.

3. Run backup

   Perform backup to enable recovery of the backup data. In the [Backup] dialog box, click [Yes]. The backup is performed. An instance is automatically started when backup is performed.

Point

If you click [Recheck the status], the resources in the data storage destination and the backup data storage destination are reconfirmed. As a result, the following occurs:

- If an error is not detected

  The status of the data storage destination and the backup data storage destination returns to normal, and it is possible to perform operations as usual.

- If an error is detected

  An error message is displayed in the message list again. Click [Solution], and resolve the problem by following the resolution for the cause of the error displayed in the dialog box.

19.1.2 Using Server Command

Recover the database cluster by following the appropriate recovery procedure below for the disk where the failure occurred.

If failure occurred on the data storage disk or the transaction log storage directory

Follow the procedure below to recover the data storage disk or the transaction log storage directory.

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance, refer to "2.1.2 Using Server Commands" for details.

   If the instance fails to stop, refer to "19.11 Actions in Response to Failure to Stop an Instance".

3. Recover the failed disk

   Replace the disk, and then recover the volume configuration information.

4. Create a storage destination directory

   - If failure occurred on the data storage disk
     Create a data storage destination directory. If a tablespace was defined, also create a directory for it.
   - If failure occurred on the translation log storage disk
     Create a transaction log storage destination directory.

   Example

   To create a data storage destination directory:

   ```
   $ mkdir /database/inst1
   $ chown fsepuser:fsepuser /database/inst1
   $ chmod 700 /database/inst1
   ```

   See

   Refer to "Preparing Directories to Deploy Resources" under "Setup" in the Installation and Setup Guide for Server for information on how to create a storage directory.

5. Recover the keystore, and enable automatic opening of the keystore

   When the data in the database has been encrypted, restore the keystore to its state at the time of the database backup. Configure automatic opening of the keystore as necessary.

6. Recover the database cluster

   Recover the database cluster using the backup data.

   Specify the following in the pgx_rcvall command:

   - Specify the data storage location in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
   - Specify the backup data storage location in the -B option.

   Example

   ```
   > pgx_rcvall -D /database/inst1 -B /backup/inst1
   ```

   If recovery fails

   If recovery fails, remove the cause of the error in accordance with the displayed error message and then re-execute the pgx_rcvall command.

   If the message "pgx_rcvall: an error occurred during recovery" is displayed, then the log recorded when recovery was executed is output after this message. The cause of the error is output in around the last fifteen lines of the log, so remove the cause of the error in accordance with the message and then re-execute the pgx_rcvall command.

   Information

   The following message displayed during recovery is output as part of normal operation of pgx_rcvall command (therefore the user does not need not be concerned).

   ```
   FATAL:  the database system is starting up
   ```

7. Start the instance

   Start the instance.

   Refer to "2.1.2 Using Server Commands" for information on how to start an instance.

8. Resume applications

   Resume applications that are using the database.

If failure occurred on the backup data storage disk

The procedure for recovering the backup data storage disk is described below.

There are two methods of taking action:

- Performing recovery while the instance is active
- Stopping the instance before performing recovery

The following table shows the different steps to be performed depending on whether you stop the instance.

No	Step	Instance stopped	
		No	Yes
1	Confirm that transaction log mirroring has stopped	Y	N
2	Stop output of archive logs	Y	N
3	Stop applications	N	Y
4	Stop the instance	N	Y
5	Recover the failed disk	Y	Y
6	Create a backup data storage destination directory	Y	Y
7	Resume output of archive logs	Y	N
8	Resume transaction log mirroring	Y	N
9	Start the instance	N	Y
10	Run backup	Y	Y
11	Resume applications	N	Y

Y: Required
N: Not required

The procedure is as follows:

If an instance has not been stopped

1. Confirm that transaction log mirroring has stopped

   Use the following SQL function to confirm that transaction log mirroring has stopped.

```
 postgres=# SELECT pgx_is_wal_multiplexing_paused();
 pgx_is_wal_multiplexing_paused
-------------------
 t
(1 row)
```

   If transaction log mirroring has not stopped, then stop it using the following SQL function.

```
postgres=# SELECT pgx_pause_wal_multiplexing();
LOG:  multiplexing of transaction log files has been stopped
pgx_pause_wal_multiplexing
---------------------------

(1 row)
```

2. Stop output of archive logs

   Transaction logs may accumulate during replacement of backup storage disk, and if the data storage disk or the transaction log storage disk becomes full, there is a risk that operations may not be able to continue.

   To prevent this, use the following methods to stop output of archive logs.

   - Changing archive_command

     Specify a command that will surely complete normally, such as "echo skipped archiving WAL file %f" or "/bin/true", so that archive logs will be regarded as having been output.

     If you specify echo, a message is output to the server log, so it may be used as a reference when you conduct investigations.

   - Reload the configuration file

     Execute the pg_ctl reload command or the pg_reload_conf SQL function to reload the configuration file.

   If you simply want to stop output of errors without the risk that operations will not be able to continue, specify an empty string ('') in archive_command and reload the configuration file.

3. Recover the failed disk

   Replace the disk, and then recover the volume configuration information.

4. Create a backup data storage destination

   Create a backup data storage destination.

   Example

   ```
   $ mkdir /database/inst1
   $ chown fsepuser:fsepuser /database/inst1
   $ chmod 700 /database/inst1
   ```

   Refer to "3.2.2 Using Server Commands" for information on how to create a backup data storage destination.

5. Resume output of archive logs

   Return the archive_command setting to its original value, and reload the configuration file.

6. Resume transaction log mirroring

   Execute the pgx_resume_wal_multiplexing SQL function.

   Example

   ```
   SELECT pgx_resume_wal_multiplexing()
   ```

7. Run backup

   Use the pgx_dmpall command to back up the database cluster.

   Specify the following value in the pgx_dmpall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

   Example

   ```
   > pgx_dmpall -D /database/inst1
   ```

If an instance has been stopped

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance. Refer to "2.1.2 Using Server Commands" for details.

If the instance fails to stop, refer to "19.11 Actions in Response to Failure to Stop an Instance".

3. Recover the failed disk

   Replace the disk, and then recover the volume configuration information.

4. Create a backup data storage destination

   Create a backup data storage destination.

   Example

   ```
   # mkdir /backup/inst1
   # chown fsepuser:fsepuser /backup/inst1
   # chmod 700 /backup/inst1
   ```

   Refer to "3.2.2 Using Server Commands" for details.

5. Start the instance

   Start the instance. Refer to "2.1.2 Using Server Commands" for information on how to start an instance.

6. Run backup

   Use the pgx_dmpall command to back up the database cluster.

   Specify the following value in the pgx_dmpall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

   Example

   ```
   > pgx_dmpall -D /database/inst1
   ```

7. Resume applications

   Resume applications that are using the database.

See

- Refer to "pgx_rcvall" and "pgx_dmpall" in the Reference for information on the pgx_rcvall command and pgx_dmpall command.
- Refer to "Write Ahead Log" under "Server Administration" in the PostgreSQL Documentation for information on archive_command.
- Refer to "B.1 WAL Mirroring Control Functions" for information on pgx_resume_wal_multiplexing.

19.2 Recovering from Data Corruption

If data in a disk is logically corrupted and the database does not operate properly, you can recover the database cluster to its state at the time of backup.

There are two methods of recovery:

- 19.2.1 Using WebAdmin
- 19.2.2 Using the pgx_rcvall Command

Point

- Back up the database cluster after recovering it. Backup deletes obsolete archive logs (transaction logs copied to the backup data storage destination), freeing up disk space and reducing the recovery time.
- If you recover data to a point in the past, a new time series (database update history) will start from that recovery point. When recovery is complete, the recovery point is the latest point in the new time series. When you subsequently recover data to the latest state, the database update is re-executed on the new time series.

19.2.1 Using WebAdmin

If using WebAdmin, recover the data to the point immediately prior to data corruption by using the backup data.

Refer to "19.1.1 Using WebAdmin" for details.

19.2.2 Using the pgx_rcvall Command

Recover the database cluster by specifying in the pgx_rcvall command the date and time of the backup you want to read from. Then re-execute the transaction as required to recover the data.

Follow the procedure below to recover the data storage disk.

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance. Refer to "2.1.2 Using Server Commands" for information on how to stop an instance.

   If the instance fails to stop, refer to "19.11 Actions in Response to Failure to Stop an Instance".

3. Confirm the backup date and time

   Execute the pgx_rcvall command to confirm the backup data saved in the backup data storage destination, and determine a date and time prior to data corruption.

   Specify the following values in the pgx_rcvall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
   - Specify the backup storage directory in the -B option.
   - The -l option displays the backup data information.

   Example

   ```
   > pgx_rcvall -D /database/inst1 -B /backup/inst1 -l
   Date                    Status          Dir
   2022-03-20 10:00:00     COMPLETE        /backup/inst1/2022-03-20_10-00-00
   ```

4. Recover the keystore, and enable automatic opening of the keystore

   When the data in the database has been encrypted, restore the keystore to its state at the time of the database backup. Configure automatic opening of the keystore as necessary.

5. Recover the database cluster

   Use the pgx_rcvall command to recover the database cluster.

   Specify the following values in the pgx_rcvall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
   - Specify the backup storage directory in the -B option.
   - Specify the recovery date and time in the -e option.

   Example

   In the following examples, "March 20, 2022 10:00:00" is specified as the recovery time.

   ```
   > pgx_rcvall -D /database/inst1 -B /backup/inst1 -e '2022-03-20 10:00:00'
   ```

   If recovery fails

   If recovery fails, remove the cause of the error in accordance with the displayed error message and then re-execute the pgx_rcvall command.

If the message "pgx_rcvall: an error occurred during recovery" is displayed, then the log recorded when recovery was executed is output after this message. The cause of the error is output in around the last fifteen lines of the log, so remove the cause of the error in accordance with the message and then re-execute the pgx_rcvall command.

Information

The following message displayed during recovery is output as part of normal operation of pgx_rcvall command (therefore the user does not need not be concerned).

```
FATAL: the database system is starting up
```

6. Start the instance

   Start the instance. Refer to "2.1.2 Using Server Commands" for information on how to start an instance.

   If necessary, re-execute transaction processing from the specified recovery time, and then resume database operations.

7. Resume applications

   Resume applications that are using the database.

See

Refer to "pgx_rcvall" in the Reference for information on the pgx_rcvall command.

19.3 Recovering from an Incorrect User Operation

This section describes how to recover database clusters when data has been corrupted due to erroneous user operations.

There are two methods of recovery:

- 19.3.1 Using WebAdmin
- 19.3.2 Using the pgx_rcvall Command

Point

- Back up the database cluster after recovering it. Backup deletes obsolete archive logs (transaction logs copied to the backup data storage destination), freeing up disk space and reducing the recovery time.
- If you recover data to a point in the past, a new time series (database update history) will start from that recovery point. When recovery is complete, the recovery point is the latest point in the new time series. When you subsequently recover data to the latest state, the database update is re-executed on the new time series.
- An effective restore point is one created on a time series for which you have made a backup. That is, if you recover data to a point in the past, you cannot use any restore points set after that recovery point. Therefore, once you manage to recover your target past data, make a backup.

19.3.1 Using WebAdmin

Recover data to a backup point using WebAdmin.

In a streaming replication configuration, the master instance can be recovered, but the standby instance cannot. If disk failure occurs on a standby instance, it may be necessary to delete and re-create the instance. Also, recovering the master instance stops streaming replication to and from all standby instances. In such an event, the standby instances can be promoted to standalone instances or can be deleted and re-created

Follow the procedure below to recover the data in the data storage disk.

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance. Refer to "2.1.1 Using WebAdmin" for information on how to stop an instance.

3. Recover the keystore, and enable automatic opening of the keystore

   Do the following if the data in the database has been encrypted:

   - Restore the keystore to its state at the time of the database backup.
   - Enable automatic opening of the keystore.

4. Recover the database cluster

   Log in to WebAdmin, and in the [Instances] tab, select the instance to be recovered and click .

5. Recover to the backup point

   In the [Restore Instance] dialog box, click [Yes].

   Recovery is performed. An instance is automatically started when recovery is successful.

6. Resume database operations

   If necessary, re-execute transaction processing from the backup point to when an erroneous operation was performed, and then resume database operations.

19.3.2 Using the pgx_rcvall Command

The pgx_rcvall command recovers database clusters to the restore point created with the server command. Refer to "Setting a restore point" in "3.2.2 Using Server Commands" for information on how to create a restore point.

Follow the procedure below to recover the data in the data storage disk.

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance. Refer to "2.1.2 Using Server Commands" for information on how to stop an instance.

   If the instance fails to stop, refer to "19.11 Actions in Response to Failure to Stop an Instance".

3. Confirm the restore point

   Execute the pgx_rcvall command to confirm the backup data saved in the backup data storage destination, and use a restore point recorded in an arbitrary file, as explained in "3.2.2 Using Server Commands", to determine a restore point prior to the erroneous operation.

   Specify the following values in the pgx_rcvall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
   - Specify the backup data storage destination in the -B option.
   - The -l option displays the backup data information.

   Example

   ```
   > pgx_rcvall -D /database/inst1 -B /backup/inst1 -l
   Date                    Status          Dir
   2022-03-01 10:00:00     COMPLETE        /backup/inst1/2022-03-01_10-00-00
   ```

4. Recover the keystore, and enable automatic opening of the keystore

   When the data in the database has been encrypted, restore the keystore to its state at the time of the database backup. Configure automatic opening of the keystore as necessary.

5. Recover the database cluster

   Use the pgx_rcvall command to recover the database cluster.

   Specify the following values in the pgx_rcvall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
   - Specify the backup data storage destination in the -B option.
   - The -n option recovers the data to the specified restore point.

   Example

   The following example executes the pgx_rcvall command with the restore point "batch_20220303_1".

   ```
   > pgx_rcvall -D /database/inst1 -B /backup/inst1 -n batch_20220303_1
   ```

   If recovery fails

   If recovery fails, remove the cause of the error in accordance with the displayed error message and then re-execute the pgx_rcvall command.

   If the message "pgx_rcvall: an error occurred during recovery" is displayed, then the log recorded when recovery was executed is output after this message. The cause of the error is output in around the last fifteen lines of the log, so remove the cause of the error in accordance with the message and then re-execute the pgx_rcvall command.

   Information

   The following message displayed during recovery is output as part of normal operation of pgx_rcvall command (therefore the user does not need not be concerned).

   ```
   FATAL:  the database system is starting up
   ```

6. Start the instance

   Start the instance.

   Refer to "2.1.2 Using Server Commands" for information on how to start an instance.

7. Restart operation of the database

   If necessary, re-execute transaction processing from the specified recovery time to the point when an erroneous operation was performed, and then resume database operations.

See

Refer to "pgx_rcvall" in the Reference for information on the pgx_rcvall command.

19.4 Actions in Response to an Application Error

If there is a connection from a client that has been in the waiting state for an extended period, you can minimize performance degradation of the database by closing the problematic connection.

The following methods are available for identifying a connection to be closed:

- view(pg_stat_activity) (refer to "19.4.1 When using the view (pg_stat_activity)")
- ps command (refer to "19.4.2 Using the ps Command")
- pgAdmin (refer to "19.4.3 Using pgAdmin")

Use the system management function (pg_terminate_backend) to disconnect connections.

19.4.1 When using the view (pg_stat_activity)

When using the view (pg_stat_activity), follow the procedure below to close a connection.

1. Use psql command to connect to the postgres database.

```
> psql postgres
psql (<x>) (*1)
Type "help" for help.
```

*1: *<x>* indicates the PostgreSQL version on which this product is based.

2. Close connections from clients that have been in the waiting state for an extended period.

   Use pg_terminate_backend() to close connections that have been trying to connect for an extended period.

   However, when considering continued compatibility of applications, do not reference or use system catalogs and functions directly in SQL statements. Refer to " Notes on Application Compatibility" in the Application Development Guide for details.

   Example

   The following example closes connections where the client has been in the waiting state for at least 60 minutes.

```
select pid,usename,application_name,client_addr,pg_terminate_backend(pid) from pg_stat_activity
where backend_type = 'client backend' and state='idle in transaction' and current_timestamp >
cast(query_start + interval '60 minutes' as timestamp);
-[ RECORD 1 ]--------+---------------
pid                  | 4684
username             | fsepuser
application_name     | apl1
client_addr          | 192.11.11.1
pg_terminate_backend | t
```

See

- Refer to "System Administration Functions" under "The SQL Language" in the PostgreSQL Documentation for information on pg_terminate_backend.
- Refer to "Notes on Application Compatibility" in the Application Development Guide for information on how to maintain application compatibility.

19.4.2 Using the ps Command

Follow the procedure below to close a connection using a standard Unix tool (ps command).

1. Execute the ps command.
   Note that "*<x>*" indicates the product version.

```
> ps axwfo user,pid,ppid,tty,command | grep postgres
fsepuser 19174 18027 pts/1                \_ grep postgres
fsepuser 20517     1 ?      /opt/fsepv<x>server64/bin/postgres -D /disk01/data
fsepuser 20518 20517 ?       \_ postgres: logger
fsepuser 20520 20517 ?       \_ postgres: checkpointer
fsepuser 20521 20517 ?       \_ postgres: background writer
fsepuser 20522 20517 ?       \_ postgres: walwriter
fsepuser 20523 20517 ?       \_ postgres: autovacuum launcher
fsepuser 20524 20517 ?       \_ postgres: archiver
fsepuser 20525 20517 ?       \_ postgres: logical replication launcher
fsepuser 18673 20517 ?       \_ postgres: fsepuser postgres 192.168.100.1(49448) idle
fsepuser 16643 20517 ?       \_ postgres: fsepuser db01 192.168.100.11(49449) UPDATE waiting
fsepuser 16644 20517 ?       \_ postgres: fsepuser db01 192.168.100.12(49450) idle in transaction
```

Process ID 16643 may be a connection that was established a considerable time ago by the UPDATE statement, or a connection that has occupied resources (waiting).

2. Close connections from clients that have been in the waiting state for an extended period.

   Use pg_terminate_backend() to close the connection with the process ID identified in step 1 above.

   The example below disconnects the process with ID 16643.

   However, when considering continued compatibility of applications, do not reference or use system catalogs and functions directly in SQL statements.

```
postgres=# SELECT pg_terminate_backend (16643);
 pg_terminate_backend
----------------------
t
(1 row)
```

See

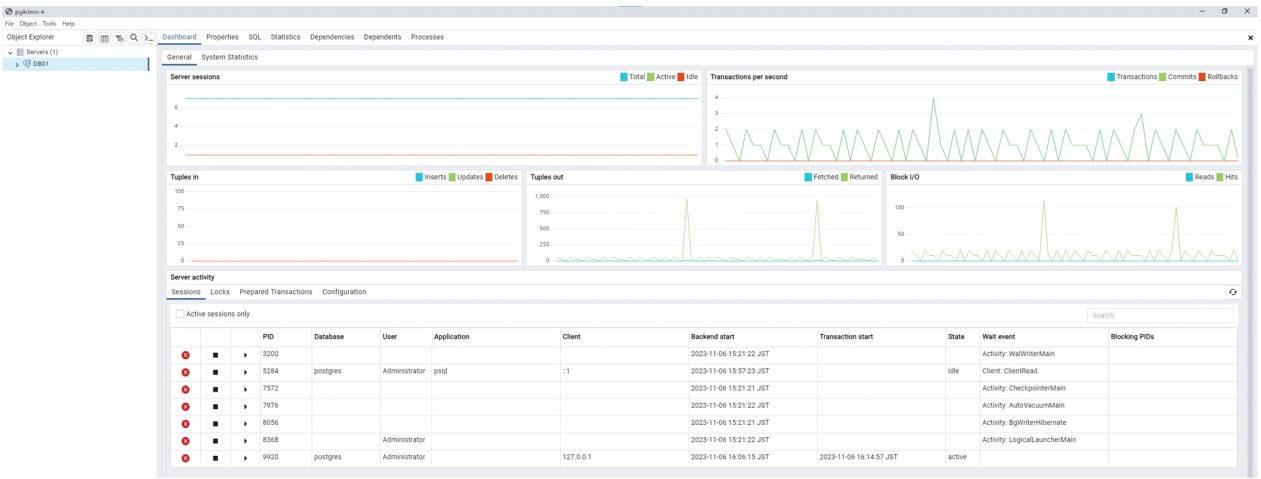
- Refer to "System Administration Functions" under "The SQL Language" in the PostgreSQL Documentation for information on pg_terminate_backend.
- Refer to "Notes on Application Compatibility" in the Application Development Guide for information on how to maintain application compatibility.

19.4.3 Using pgAdmin

If using pgAdmin, follow the procedure below to close connections.

1. In the [Browser] pane, click the relevant database server.
2. Close the client connections that have been in a wait state for an extended period.

   Click the [Dashboard] tab. In the [Server activity] section, select the connections that have been in an "idle" or "idle in transaction" state for an extended period. For each of these connections, click to close the session.



19.5 Actions in Response to an Access Error

If access is denied, grant privileges allowing the instance administrator to operate the following directories, and then re-execute the operation. Also, refer to the event log and the server log, and confirm that the file system has not been mounted as read-only due to a disk error. If the file system has been mounted as read-only, mount it properly and then re-execute the operation.

- Data storage destination

- Tablespace storage destination
- Transaction log storage destination
- Backup data storage destination

See

Refer to "Preparing Directories to Deploy Resources" under "Setup" in the Installation and Setup Guide for Server for information on the privileges required for the directory.

19.6 Actions in Response to Insufficient Space on the Data Storage Destination

If the data storage destination runs out of space, check if the disk contains any unnecessary files and delete them so that operations can continue.

If deleting unnecessary files does not solve the problem, you must migrate data to a disk with larger capacity.

There are two methods of migrating data:

- 19.6.1 Using a Tablespace
- 19.6.2 Replacing the Disk with a Larger Capacity Disk

19.6.1 Using a Tablespace

Fujitsu Enterprise Postgres enables you to use a tablespace to change the storage destination of database objects, such as tables and indexes, to a different disk.

The procedure is as follows:

1. Create a tablespace

   Use the CREATE TABLESPACE command to create a new tablespace in the prepared disk.

2. Modify the tablespace

   Use the ALTER TABLE command to modify tables for the newly defined tablespace.

See

Refer to "SQL Commands" under "Reference" in the PostgreSQL Documentation for information on the CREATE TABLESPACE command and ALTER TABLE command.

19.6.2 Replacing the Disk with a Larger Capacity Disk

Before replacing the disk with a larger capacity disk, migrate resources at the data storage destination using the backup and recovery features.

There are two methods of performing backup and recovery:

- 19.6.2.1 Using WebAdmin
- 19.6.2.2 Using Server Commands

The following sections describe procedures that use each of these methods to replace the disk and migrate resources at the data storage destination.

Point

It is recommended that you back up the database cluster following recovery. Backup deletes obsolete archive logs (transaction logs copied to the backup data storage destination), freeing up disk space and reducing the recovery time.

19.6.2.1 Using WebAdmin

Follow the procedure below to replace the disk and migrate resources at the data storage destination by using WebAdmin.

1. Back up files

   If the disk at the data storage destination contains any required files, back up the files. It is not necessary to back up the data storage destination.

2. Stop applications

   Stop applications that are using the database.

3. Back up the database cluster

   Back up the latest resources at the data storage destination. Refer to "3.2.1 Using WebAdmin" for details.

4. Stop the instance

   Stop the instance. Refer to "2.1.1 Using WebAdmin" for information on how to stop an instance.

5. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

6. Recover the database cluster

   Log in to WebAdmin, and perform recovery operations. Refer to steps 4 ("Create a tablespace directory ") to 7 ("Run recovery") under "If failure occurred in the data storage disk or the transaction log storage disk" in "19.1.1 Using WebAdmin" for information on the procedure. An instance is automatically started when recovery is successful.

7. Resume applications

   Resume applications that are using the database.

8. Restore the files

   Restore the files backed up in step 1.

19.6.2.2 Using Server Commands

Follow the procedure below to replace the disk and migrate resources at the data storage destination by using server commands.

1. Back up files

   If the disk at the data storage destination contains any required files, back up the files. It is not necessary to back up the data storage destination.

2. Stop applications

   Stop applications that are using the database.

3. Back up the database cluster

   Back up the latest resources at the data storage destination. Refer to "3.2.2 Using Server Commands" for details.

4. Stop the instance

   After backup is complete, stop the instance. Refer to "2.1.2 Using Server Commands" for information on how to stop an instance.

   If the instance fails to stop, refer to "19.11 Actions in Response to Failure to Stop an Instance".

5. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

6. Create a data storage destination

   Create a data storage destination. If a tablespace was defined, also create a directory for it.

   Example

   ```
   $ mkdir /database/inst1
   $ chown fsepuser:fsepuser /database/inst1
   $ chmod 700 /database/inst1
   ```

7. Recover the keystore, and enable automatic opening of the keystore

   When the data in the database has been encrypted, restore the keystore to its state at the time of the database backup. Configure automatic opening of the keystore as necessary.

8. Recover the database cluster

   Use the pgx_rcvall command to recover the database cluster.

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
   - Specify the backup storage directory in the -B option.

   Example

   ```
   > pgx_rcvall -D /database/inst1 -B /backup/inst1
   ```

   If recovery fails

   If recovery fails, remove the cause of the error in accordance with the displayed error message and then re-execute the pgx_rcvall command.

   If the message "pgx_rcvall: an error occurred during recovery" is displayed, then the log recorded when recovery was executed is output after this message. The cause of the error is output in around the last fifteen lines of the log, so remove the cause of the error in accordance with the message and then re-execute the pgx_rcvall command.

Information

The following message displayed during recovery is output as part of normal operation of pgx_rcvall command (therefore the user does not need not be concerned).

```
FATAL:  the database system is starting up
```

See

Refer to "pgx_rcvall" in the Reference for information on the pgx_rcvall command.

9. Start the instance

   Start the instance.

   Refer to "2.1.2 Using Server Commands" for information on how to start an instance.

10. Resume applications

    Resume applications that are using the database.

11. Restore files

    Restore the files backed up in step 1.

19.7 Actions in Response to Insufficient Space on the Backup Data Storage Destination

If space runs out on the backup data storage destination, check if the disk contains any unnecessary files and delete them, and then make a backup as required.

If deleting unnecessary files does not solve the problem, take the following action:

- 19.7.1 Temporarily Saving Backup Data
- 19.7.2 Replacing the Disk with a Larger Capacity Disk

19.7.1 Temporarily Saving Backup Data

This method involves temporarily moving backup data to a different directory, saving it there, and securing disk space on the backup data storage destination so that a backup can be made normally.

Use this method if you need time to prepare a larger capacity disk.

If space runs out on the backup data storage destination, archive logs can no longer be stored in the backup data storage destination. As a result, transaction logs continue to accumulate in the data storage destination or the transaction log storage destination.

If action is not taken soon, the transaction log storage destination will become full, and operations may not be able to continue.

To prevent this, secure space in the backup data storage destination, so that archive logs can be stored.

There are two methods of taking action:

- 19.7.1.1 Using WebAdmin
- 19.7.1.2 Using Server Commands

19.7.1.1 Using WebAdmin

Follow the procedure below to recover the backup data storage disk.

1. Temporarily save backup data

   Move backup data to a different directory and temporarily save it, and secure space in the backup data storage destination directory.

   The reason for saving the backup data is so that the data in the data storage destination can be recovered even if it is corrupted before you perform recovery. If there is no disk at the save destination and you consider that there is no risk of corruption at the data storage destination, delete the backup data.

   The following example saves backup data from the backup data storage destination directory (/backup/inst1) under /mnt/usb/backup.

   Example

   ```
   > mkdir /mnt/usb/backup/
   > mv /backup/inst1/* /mnt/usb/backup/
   ```

2. Back up the database cluster

   Back up the latest resources at the data storage destination. Refer to "3.2.1 Using WebAdmin" for details.

3. Delete temporarily saved backup data

   If backup completes normally, the temporarily saved backup data becomes unnecessary and is deleted.

   The following example deletes backup data that was temporarily saved in /mnt/usb.

   Example

   ```
   > rm -rf /mnt/usb/backup
   ```

19.7.1.2 Using Server Commands

The following describes the procedure for recovering the backup storage disk.

There are two methods of taking action:

- Performing recovery while the instance is active
- Stopping the instance before performing recovery

The following table shows the different steps to be performed depending on whether you stop the instance.

No	Step	Instance stopped	
		No	Yes
1	Stop transaction log mirroring	Y	N
2	Stop output of archive logs	Y	N
3	Stop applications	N	Y
4	Stop the instance	N	Y
5	Temporarily save backup data	Y	Y
6	Resume output of archive logs	Y	N
7	Resume transaction log mirroring	Y	N
8	Start an instance	N	Y
9	Run backup	Y	Y
10	Resume applications	N	Y
11	Delete temporarily saved backup data	Y	Y

Y: Required
N: Not required

The procedure is as follows:

Performing recovery while the instance is active

1. Stop transaction log mirroring

   Stop transaction log mirroring.

   ```
   postgres=# SELECT pgx_pause_wal_multiplexing();
   LOG:  multiplexing of transaction log files has been stopped
   pgx_pause_wal_multiplexing
   ---------------------------

   (1 row)
   ```

2. Stop output of archive logs

   Transaction logs may accumulate during replacement of backup storage disk, and if the data storage disk or the transaction log storage disk becomes full, there is a risk that operations may not be able to continue.

   To prevent this, use the following methods to stop output of archive logs.

   - Changing the archive_command parameter

     Specify a command that will surely complete normally, such as "echo skipped archiving WAL file %f" or "/bin/true", so that archive logs will be regarded as having been output.

     If you specify echo, a message is output to the server log, so it may be used as a reference when you conduct investigations.

   - Reloading the configuration file

     Run the pg_ctl reload command or the pg_reload_conf SQL function.

If you simply want to stop output of errors without the risk that operations will not be able to continue, specify an empty string ('') in archive_command and reload the configuration file.

3. Temporarily save backup data

   Move backup data to a different directory and temporarily save it, and secure space in the backup data storage destination directory.

   The reason for saving the backup data is so that the data in the data storage destination can be recovered even if it is corrupted before you perform the next step. If there is no disk at the save destination and you consider that there is no risk of corruption at the data storage destination, delete the backup data.

   The following example saves backup data from the backup data storage destination directory (/backup/inst1) under /mnt/usb/backup.

   Example

   ```
   > mkdir /mnt/usb/backup/
   > mv /backup/inst1/* /mnt/usb/backup/
   ```

4. Resume output of archive logs

   Return the archive_command setting to its original value, and reload the configuration file.

5. Resume transaction log mirroring

   Execute the pgx_resume_wal_multiplexing SQL function.

   Example

   ```
   SELECT pgx_resume_wal_multiplexing()
   ```

6. Run backup

   Use the pgx_dmpall command to back up the database cluster.

   Specify the following option in the pgx_dmpall command:

   - Specify the directory of the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

     Example

     ```
     > pgx_dmpall -D /database/inst1
     ```

7. Delete temporarily saved backup data

   If backup completes normally, the temporarily saved backup data becomes unnecessary and is deleted.

   The following example deletes backup data that was temporarily saved in /mnt/usb.

   Example

   ```
   > rm -rf /mnt/usb/backup
   ```

If an instance has been stopped

1. Stop applications

   Stop applications that are using the database.

2. Stop the instance

   Stop the instance. Refer to "2.1.2 Using Server Commands" for details.

   If the instance fails to stop, refer to "19.11 Actions in Response to Failure to Stop an Instance".

3. Temporarily save backup data

   Move backup data to a different directory and temporarily save it, and secure space in the backup data storage destination directory.

The reason for saving the backup data is so that the data in the data storage destination can be recovered even if it is corrupted before you perform recovery. If there is no disk at the save destination and you consider that there is no risk of corruption at the data storage destination, delete the backup data.

The following example saves backup data from the backup data storage destination directory (/backup/inst1) under /mnt/usb/backup.

Example

```
> mkdir /mnt/usb/backup/
> mv /backup/inst1/* /mnt/usb/backup/
```

4. Start the instance

   Start the instance. Refer to "2.1.2 Using Server Commands" for information on how to start an instance.

5. Run backup

   Use the pgx_dmpall command to back up the database cluster.

   Specify the following value in the pgx_dmpall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

     Example

     ```
     > pgx_dmpall -D /database/inst1
     ```

6. Resume applications

   Resume applications that are using the database.

7. Delete temporarily saved backup data

   If backup completes normally, the temporarily saved backup data becomes unnecessary and is deleted.

   The following example deletes backup data that was temporarily saved in /mnt/usb.

   Example

   ```
   > rm -rf /mnt/usb/backup
   ```

See

- Refer to "pgx_rcvall" and "pgx_dmpall" in the Reference for information on the pgx_rcvall command and pgx_dmpall command.
- Refer to "Write Ahead Log" under "Server Administration" in the PostgreSQL Documentation for information on archive_command.
- Refer to "B.1 WAL Mirroring Control Functions" for information on the pgx_is_wal_multiplexing_paused and pgx_resume_wal_multiplexing.

19.7.2 Replacing the Disk with a Larger Capacity Disk

This method involves replacing the disk at the backup data storage destination with a larger capacity disk, so that it does not run out of free space again. After replacing the disk, back up data to obtain a proper backup.

There are two methods of performing backup:

- 19.7.2.1 Using WebAdmin
- 19.7.2.2 Using Server Commands

19.7.2.1 Using WebAdmin

Follow the procedure below to recover the backup storage disk.

1. Back up files

   If the disk at the backup data storage destination contains any required files, back up the files. It is not necessary to back up the backup data storage destination.

2. Temporarily save backup data

   Save the backup data to a different directory.

   The reason for saving the backup data is so that the data in the data storage destination can be recovered even if it is corrupted before you perform the next step. If there is no disk at the save destination and you consider that there is no risk of corruption at the data storage destination, delete the backup data.

   The following example saves backup data from the backup data storage destination directory (/backup/inst1) under /mnt/usb/backup.

   Example

   ```
   > mkdir /mnt/usb/backup/
   > mv /backup/inst1/* /mnt/usb/backup/
   ```

3. Stop applications

   Stop applications that are using the database.

4. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

5. Run backup

   Log in to WebAdmin, and perform recovery operations. Refer to steps 2 ("Recover the backup data") and 3 ("Run backup") under "If failure occurred on the backup storage disk" in "19.1.1 Using WebAdmin".

6. Restore files

   Restore the files backed up in step 1.

7. Delete temporarily saved backup data

   If backup completes normally, the temporarily saved backup data becomes unnecessary and is deleted.

   The following example deletes backup data that was temporarily saved in /mnt/usb.

   Example

   ```
   > rm -rf /mnt/usb/backup
   ```

19.7.2.2 Using Server Commands

The procedure for recovering the backup data storage disk is described below.

There are two methods of taking action:

- Performing recovery while the instance is active
- Stopping the instance before performing recovery

The following table shows the different steps to be performed depending on whether you stop the instance.

No	Step	Instance stopped	
		No	Yes
1	Back up files	Y	Y
2	Temporarily save backup data	Y	Y
3	Confirm that transaction log mirroring has stopped	Y	N
4	Stop output of archive logs	Y	N
5	Stop applications	N	Y

No	Step	Instance stopped	
		No	Yes
6	Stop the instance	N	Y
7	Replace with a larger capacity disk	Y	Y
8	Create a backup storage directory	Y	Y
9	Resume output of archive logs	Y	N
10	Resume transaction log mirroring	Y	N
11	Start the instance	N	Y
12	Run backup	Y	Y
13	Resume applications	N	Y
14	Restore files	Y	Y
15	Delete temporarily saved backup data	Y	Y

Y: Required
N: Not required

The procedure is as follows:

If an instance has not been stopped

1. Back up files

   If the disk at the backup data storage destination contains any required files, back up the files. It is not necessary to back up the backup data storage destination.

2. Temporarily save backup data

   Save the backup data to a different directory.

   The reason for saving the backup data is so that the data in the data storage destination can be recovered even if it is corrupted before you perform the next step. If there is no disk at the save destination and you consider that there is no risk of corruption at the data storage destination, delete the backup data.

   The following example saves backup data from the backup data storage destination directory (/backup/inst1) under /mnt/usb/backup.

   #### Example

   ```
   > mkdir /mnt/usb/backup/
   > mv /backup/inst1/* /mnt/usb/backup/
   ```

3. Confirm that transaction log mirroring has stopped

   Use the following SQL function to confirm that transaction log mirroring has stopped.

   ```
    postgres=# SELECT pgx_is_wal_multiplexing_paused();
    pgx_is_wal_multiplexing_paused
   -------------------
    t
   (1 row)
   ```

   If transaction log mirroring has not stopped, then stop it using the following SQL function.

   ```
   postgres=# SELECT pgx_pause_wal_multiplexing();
   LOG:  multiplexing of transaction log files has been stopped
   pgx_pause_wal_multiplexing
   ---------------------------
   ```

```
(1 row)
```

4. Stop output of archive logs

   Transaction logs may accumulate during replacement of backup storage disk, and if the data storage destination disk or the transaction log storage destination disk becomes full, there is a risk that operations may not be able to continue.

   To prevent this, use the following methods to stop output of archive logs.

   - Changing the archive_command parameter

     Specify a command that will surely complete normally, such as "echo skipped archiving WAL file %f" or "/bin/true", so that archive logs will be regarded as having been output.

     If you specify echo, a message is output to the server log, so it may be used as a reference when you conduct investigations.

   - Reloading the configuration file

     Run the pg_ctl reload command or the pg_reload_conf SQL function.

   If you simply want to stop output of errors without the risk that operations will not be able to continue, specify an empty string ('') in archive_command and reload the configuration file.

5. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

6. Create a backup data storage destination

   Create a backup data storage destination.

   Example

   ```
   # mkdir /backup/inst1
   # chown fsepuser:fsepuser /backup/inst1
   # chmod 700 /backup/inst1
   ```

   Refer to "3.2.2 Using Server Commands" for details.

7. Resume output of archive logs

   Return the archive_command setting to its original value, and reload the configuration file.

8. Resume transaction log mirroring

   Execute the pgx_resume_wal_multiplexing SQL function.

   Example

   ```
   SELECT pgx_resume_wal_multiplexing()
   ```

9. Run backup

   Use the pgx_dmpall command to back up the database cluster.

   Specify the following value in the pgx_dmpall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

   Example

   ```
   > pgx_dmpall -D /database/inst1
   ```

10. Restore files

    Restore the files backed up in step 1.

11. Delete temporarily saved backup data

    If backup completes normally, the temporarily saved backup data becomes unnecessary and is deleted.

    The following example deletes backup data that was temporarily saved in /mnt/usb.

Example

```
> rm -rf /mnt/usb/backup
```

If an instance has been stopped

1. Back up files

   If the disk at the backup data storage destination contains any required files, back up the files. It is not necessary to back up the backup data storage destination.

2. Temporarily save backup data

   Save the backup data to a different directory.

   The reason for saving the backup data is so that the data in the data storage destination can be recovered even if it is corrupted before you perform the next step. If there is no disk at the save destination and you consider that there is no risk of corruption at the data storage destination, delete the backup data.

   The following example saves backup data from the backup data storage destination directory (/backup/inst1) under /mnt/usb/backup.

   Example

   ```
   > mkdir /mnt/usb/backup/
   > mv /backup/inst1/* /mnt/usb/backup/
   ```

3. Stop applications

   Stop applications that are using the database.

4. Stop the instance

   Stop the instance. Refer to "2.1.2 Using Server Commands" for information on how to stop an instance.

   If the instance fails to stop, refer to "19.11 Actions in Response to Failure to Stop an Instance".

5. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

6. Create a backup data storage destination

   Create a backup data storage destination.

   Example

   ```
   # mkdir /backup/inst1
   # chown fsepuser:fsepuser /backup/inst1
   # chmod 700 /backup/inst1
   ```

   Refer to "3.2.2 Using Server Commands" for details.

7. Start the instance

   Start the instance. Refer to "2.1.2 Using Server Commands" for information on how to start an instance.

8. Run backup

   Use the pgx_dmpall command to back up the database cluster.

   Specify the following value in the pgx_dmpall command:

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

   Example

   ```
   > pgx_dmpall -D /database/inst1
   ```

9. Resume applications

   Resume applications that are using the database.

10. Restore files

    Restore the files backed up in step 1.

11. Delete temporarily saved backup data

    If backup completes normally, the temporarily saved backup data becomes unnecessary and is deleted.

    The following example deletes backup data that was temporarily saved in /mnt/usb.

    Example

    ```
    > rm -rf /mnt/usb/backup
    ```

See

- Refer to "pgx_rcvall" and "pgx_dmpall" in the Reference for information on the pgx_rcvall command and pgx_dmpall command.
- Refer to "Write Ahead Log" under "Server Administration" in the PostgreSQL Documentation for information on archive_command.
- Refer to "B.1 WAL Mirroring Control Functions" for information on the pgx_is_wal_multiplexing_paused and pgx_resume_wal_multiplexing.

19.8 Actions in Response to Insufficient Space on the Transaction Log Storage Destination

If the transaction log storage destination runs out of space, check if the disk contains any unnecessary files and delete them so that operations can continue.

If deleting unnecessary files does not solve the problem, you must migrate data to a disk with larger capacity.

19.8.1 Replacing the Disk with a Larger Capacity Disk

Before replacing the disk with a larger capacity disk, migrate resources at the transaction log storage destination using the backup and recovery features.

There are two methods of performing backup and recovery:

- 19.8.1.1 Using WebAdmin
- 19.8.1.2 Using Server Commands

The following sections describe procedures that use each of these methods to replace the disk and migrate resources at the transaction log storage destination.

Point

It is recommended that you back up the database cluster following recovery. Backup deletes obsolete archive logs (transaction logs copied to the backup data storage destination), freeing up disk space and reducing the recovery time.

19.8.1.1 Using WebAdmin

Follow the procedure below to replace the disk and migrate resources at the transaction log storage destination by using WebAdmin.

1. Back up files

   If the disk at the transaction log storage destination contains any required files, back up the files. It is not necessary to back up the transaction log storage destination.

2. Back up the database cluster

   Back up the latest data storage destination resources and transaction log storage destination resources (refer to "3.2.1 Using WebAdmin" for details).

3. Stop applications

   Stop applications that are using the database.

4. Stop the instance

   Stop the instance. Refer to "2.1.1 Using WebAdmin" for information on how to stop an instance. WebAdmin automatically stops instances if recovery of the database cluster is performed without stopping the instance.

5. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

6. Create a tablespace directory

   If a tablespace was defined after backing up, create a directory for it.

7. Recover the keystore, and enable automatic opening of the keystore

   Do the following if the data in the database has been encrypted:

   - Restore the keystore to its state at the time of the database backup.
   - Enable automatic opening of the keystore.

8. Recover the database cluster

   Log in to WebAdmin, and perform recovery operations. Refer to steps 4 ("Create a tablespace directory ") to 7 ("Run Recovery") under " If failure occurred in the data storage disk or the transaction log storage disk " in "19.1.1 Using WebAdmin" for information on the procedure. An instance is automatically started when recovery is successful.

9. Resume applications

   Resume applications that are using the database.

10. Restore files

    Restore the files backed up in step 1.

19.8.1.2 Using Server Commands

Follow the procedure below to replace the disk and migrate resources at the transaction log storage destination by using server commands.

1. Back up files

   If the disk at the transaction log storage destination contains any required files, back up the files. It is not necessary to back up the transaction log storage destination.

2. Back up the database cluster

   Use server commands to back up the latest data storage destination resources and transaction log storage destination resources. Refer to "3.2.2 Using Server Commands" for information on how to perform backup.

3. Stop applications

   Stop applications that are using the database.

4. Stop the instance

   After backup is complete, stop the instance. Refer to "2.1.2 Using Server Commands" for information on how to stop an instance.

   If the instance fails to stop, refer to "19.11 Actions in Response to Failure to Stop an Instance".

5. Replace with a larger capacity disk

   Replace the disk. Then, recover the volume configuration information.

6. Create a transaction log storage destination

   Create a transaction log storage destination. If a tablespace was defined, also create a directory for it.

   Example

   ```
   # mkdir /tranlog/inst1
   # chown fsepuser:fsepuser /tranlog/inst1
   # chmod 700 /tranlog/inst1
   ```

7. Recover the keystore, and enable automatic opening of the keystore

   When the data in the database has been encrypted, restore the keystore to its state at the time of the database backup. Configure automatic opening of the keystore as necessary.

8. Recover the database cluster

   Use the pgx_rcvall command to recover the database cluster.

   - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
   - Specify the backup storage directory in the -B option.

   Example

   ```
   > pgx_rcvall -D /database/inst1 -B /backup/inst1
   ```

   If recovery fails

   If recovery fails, remove the cause of the error in accordance with the displayed error message and then re-execute the pgx_rcvall command.

   If the message "pgx_rcvall: an error occurred during recovery" is displayed, then the log recorded when recovery was executed is output after this message. The cause of the error is output in around the last fifteen lines of the log, so remove the cause of the error in accordance with the message and then re-execute the pgx_rcvall command.

Information

The following message displayed during recovery is output as part of normal operation of pgx_rcvall command (therefore the user does not need not be concerned).

```
FATAL:  the database system is starting up
```

See

Refer to "pgx_rcvall" in the Reference for information on the pgx_rcvall command.

9. Start the instance

   Start the instance.

   Refer to "2.1.2 Using Server Commands" for information on how to start an instance.

10. Resume applications

    Resume applications that are using the database.

11. Restore files

    Restore the files backed up in step 1.

19.9 Errors in More Than One Storage Disk

If an error occurs in the storage destination disks or resources are corrupted, determine the cause of the error from system logs and server logs and remove the cause.

If errors occur in either of the following combinations, you cannot recover the database.

Recreate the instance, and rebuild the runtime environment.

Data storage disk	Transaction log storage disk	Backup data storage disk
Error	-	Error
-	Error	Error

See

Refer to "Setup" in the Installation and Setup Guide for Server for information on how to create an instance and build the runtime environment.

19.10 Actions in Response to Instance Startup Failure

If an instance fails to start, refer to the system log and the server log, and determine the cause of the failure.

If using WebAdmin, remove the cause of the error. Then, click [Solution] and [Recheck the status] and confirm that the instance is in the normal state.

The following sections describe common causes of errors and the actions to take.

19.10.1 Errors in the Configuration File

If you have directly edited the configuration file using a text editor or changed the settings using WebAdmin, refer to the system log and the server log, confirm that no messages relating to the files below have been output.

- postgresql.conf
- pg_hba.conf

See

Refer to the following for information on the parameters in the configuration file:

- "Configuring Parameters" in the Installation and Setup Guide for Server
- "Appendix A Parameters"
- "Server Configuration" and "Client Authentication" under "Server Administration" in the PostgreSQL Documentation

19.10.2 Errors Caused by Power Failure or Mounting Issues

If mounting is cancelled after restarting the server, for example, because the disk device for each storage destination disk was not turned on, or because automatic mounting has not been set, then starting an instance will fail.

Refer to "19.14.2 Errors Caused by Power Failure or Mounting Issues", and take actions accordingly.

19.10.3 Other Errors

This section describes the recovery procedure to be used if you cannot take any action or the instance cannot start even after you have referred to the system log and the server log.

There are two methods of recovery:

- 19.10.3.1 Using WebAdmin
- 19.10.3.2 Using Server Commands

Note that recovery will not be possible if there is an error at the backup data storage destination. If the problem cannot be resolved, contact Fujitsu technical support.

19.10.3.1 Using WebAdmin

Follow the procedure below to perform recovery.

1. Delete the data storage destination directory and the transaction log storage destination directory

   Back up the data storage destination directory and the transaction log storage destination directory before deleting them.

2. Reconfirm the status

   Log in to WebAdmin, and in the [Instances] tab, click [Solution] for the error message.

   Click [Recheck the status] to reconfirm the storage destination resources.

3. Run recovery

   Restore the database cluster after WebAdmin detects an error.

   Refer to "19.2.1 Using WebAdmin" for details.

19.10.3.2 Using Server Commands

Follow the procedure below to recover the database.

1. Delete the data storage destination directory and the transaction log storage destination directory

   Save the data storage destination directory and the transaction log storage destination directory, and then delete them.

2. Execute recovery

   Use the pgx_rcvall command to recover the database cluster.

   Refer to "19.2.2 Using the pgx_rcvall Command" for details.

19.11 Actions in Response to Failure to Stop an Instance

If an instance fails to stop, refer to the system log and the server log, and determine the cause of the failure.

If the instance cannot stop despite taking action, perform the following operation to stop the instance.

There are two methods of recovery:

- 19.11.1 Using WebAdmin
- 19.11.2 Using Server Commands

19.11.1 Using WebAdmin

In the [Instances] tab, click and select the Fast stop mode or the Immediate stop mode to stop the instance. Forcibly terminate the server process from WebAdmin if the instance cannot be stopped.

Refer to "2.1.1 Using WebAdmin" for information on the stop modes.

19.11.2 Using Server Commands

There are three methods:

- Stopping the Instance Using the Fast Mode

  If backup is in progress, then terminate it, roll back all executing transactions, forcibly close client connections, and then stop the instance.

- Stopping the Instance Using the Immediate Mode

  Forcibly terminate the instance immediately. A crash recovery is run when the instance is restarted.

- Forcibly Stopping the Server Process

  Reliably stops the server process when the other methods are unsuccessful.

19.11.2.1 Stopping the Instance Using the Fast Mode

Specify "-m fast" in the pg_ctl command to stop the instance.

If the instance fails to stop when you use this method, stop the instance as described in "19.11.2.2 Stopping the Instance Using the Immediate Mode" or "19.11.2.3 Forcibly Stopping the Server Process".

Example

```
> pg_ctl stop -D /database/inst1 -m fast
```

19.11.2.2 Stopping the Instance Using the Immediate Mode

Specify "-m immediate " in the pg_ctl command to stop the instance.

If the instance fails to stop when you use this method, stop the instance as described in "19.11.2.3 Forcibly Stopping the Server Process".

Example

```
> pg_ctl stop -D /database/inst1 -m immediate
```

19.11.2.3 Forcibly Stopping the Server Process

If both the Fast mode and the Immediate mode fail to stop the instance, use the kill command or the kill parameter of the pg_ctl command to forcibly stop the server process.

The procedure is as follows:

1. Execute the ps command
   Note that "<*x*>" indicates the product version.

   ```
   > ps axwfo user,pid,ppid,tty,command | grep postgres
   fsepuser 19174 18027 pts/1                \_ grep postgres
   fsepuser 20517     1 ?        /opt/fsepv<x>server64/bin/postgres -D /database/inst1
   fsepuser 20518 20517 ?         \_ postgres: logger
   fsepuser 20520 20517 ?         \_ postgres: checkpointer
   fsepuser 20521 20517 ?         \_ postgres: background writer
   fsepuser 20522 20517 ?         \_ postgres: walwriter
   fsepuser 20523 20517 ?         \_ postgres: autovacuum launcher
   fsepuser 20524 20517 ?         \_ postgres: archiver
   fsepuser 20525 20517 ?         \_ postgres: logical replication launcher
   ```

   The process ID (20517) indicates the server process.

2. Forcibly stop the server process

   As instance manager, forcibly stop the server process.

Using the pg_ctl command

```
> pg_ctl kill SIGQUIT 20517
```

Using the kill command

```
> kill -s SIGQUIT 20517
```

19.12 Actions in Response to Failure to Create a Streaming Replication Standby Instance

When creating a streaming replication standby instance using WebAdmin, if the instance creation fails, refer to the system log and the server log, and determine the cause of the failure.

When an error occurs in the creation of the standby instance using WebAdmin, it is unlikely that the partially created standby instance can be resumed to complete the operation.

In such a scenario, fix the cause of the error, delete the partially created standby instance, and then create a new standby instance. This recommendation is based on the following assumptions:

- As the instance is yet to be created completely, there are no applications connecting to the database.
- The standby instance is in error state and is not running.
- There are no backups for the standby instance and as a result, it cannot be recovered.

See

Refer to "Deleting Instances" in the Installation and Setup Guide for details on how to delete an instance.

19.13 Actions in Response to Error in a Distributed Transaction

If a system failure (such as server failure) occurs in an application that uses distributed transactions (such as .NET TransactionScope), then transactions may be changed to the in-doubt state.

At that point, resources accessed by the transaction will be locked, and rendered unusable by other transactions.

The following describes how to check for in-doubt transactions, and how to resolve them.

How to check for in-doubt transactions

The following shows how to check for them:

If the server fails

1. An in-doubt transaction will have occurred if a message similar to the one below is output to the log when the server is restarted.

   Example

   ```
   LOG: Restoring prepared transaction 2103.
   ```

2. Refer to system view pg_prepared_xacts to obtain information about the prepared transaction.

   If the transaction identifier of the prepared transaction in the list (in the transaction column of pg_prepared_xacts) is the same as the identifier of the in-doubt transaction obtained from the log output when the server was restarted, then that row is the information about the in-doubt transaction.

   Example

   ```
   postgres=# select * from pg_prepared_xacts;
    transaction |   gid     |   prepared |  owner   | database
   -------------+-----------+------------+----------+----------
   ```

```
2103 | 374cc221-f6dc-4b73-9d62-d4fec9b430cd | 2022-03-06 16:28:48.471+08 | postgres |
postgres (1 row)
```

Information about the in-doubt transaction is output to the row with the transaction ID 2103 in the transaction column.

If the client fails

If there are no clients connected and there is a prepared transaction in pg_prepared_xacts, then you can determine that the transaction is in the in-doubt state.

If at least one client is connected and there is a prepared transaction in pg_prepared_xacts, you cannot determine whether there is a transaction in the in-doubt state. In this case, use the following query to determine the in-doubt transaction from the acquired database name, user name, the time PREPARE TRANSACTION was executed, and the information about the table name accessed.

```
select gid,x.database,owner,prepared,l.relation::regclass as relation from pg_prepared_xacts x
left join pg_locks l on l.virtualtransaction = '-1/'||x.transaction and l.locktype='relation';
```

If it still cannot be determined from this information, wait a few moments and then check pg_prepared_xacts again.

If there is a transaction that has continued since the last time you checked, then it is likely that it is the one in the in-doubt state.

Point

As you can see from the explanations in this section, there is no one way to definitively determine in-doubt transactions.

Consider collecting other supplementary information (for example, logging on the client) or performing other operations (for example, allocating database users per job).

How to resolve in-doubt transactions

From the system view pg_prepared_xacts mentioned above, obtain the global transaction identifier (in the gid column of pg_prepared_xacts) for the in-doubt transaction, and issue either a ROLLBACK PREPARED statement or COMMIT PREPARED statement to resolve the in-doubt transaction.

Example

- Rolling back in-doubt transactions

```
postgres=# rollback prepared '374cc221-f6dc-4b73-9d62-d4fec9b430cd';
ROLLBACK PREPARED
```

- Committing in-doubt transactions

```
postgres=# commit prepared '374cc221-f6dc-4b73-9d62-d4fec9b430cd';
COMMIT PREPARED
```

19.14 I/O Errors Other than Disk Failure

Even if a disk is not defective, the same input-output error messages, as those generated when the disk is defective, may be output.

A few examples of such errors are given below. The appropriate action for each error is explained respectively.

- 19.14.1 Network Error with an External Disk
- 19.14.2 Errors Caused by Power Failure or Mounting Issues

19.14.1 Network Error with an External Disk

This is an error that occurs in the network path to/from an external disk.

Determine the cause of the error by checking the information in the system log and the server log, the disk access LED, network wiring, and network card status. Take appropriate action to remove the cause of the error, for example, replace problematic devices.

19.14.2 Errors Caused by Power Failure or Mounting Issues

These are errors that occur when the disk device is not turned on, automatic mounting of the disk was not set, or mounting was accidentally cancelled.

In this case, check the information in the system log and the server log, the disk access LED, and whether the disk is mounted correctly. If problems are detected, take appropriate action.

If mounting has been cancelled, it is possible that mounting was accidentally cancelled, or automatic mounting at the time of starting the operating system is not set. In this case, set the mounting to be performed automatically.

19.15 Anomaly Detection and Resolution

The following operations performed via the command line interface will result in an anomaly in WebAdmin:

- Changes to the port and backup_destination parameters in postgresql.conf
- Changes to Mirroring Controller configuration of cluster replication added via WebAdmin

This section describes when WebAdmin checks for such anomalies, and what takes place when an anomaly is detected.

19.15.1 Port Number and Backup Storage Path Anomalies

An anomaly occurs when the value of [Port number] and/or [Backup storage path] in WebAdmin is different from the value of its corresponding parameter in postgresql.conf - port and backup_destination, respectively.

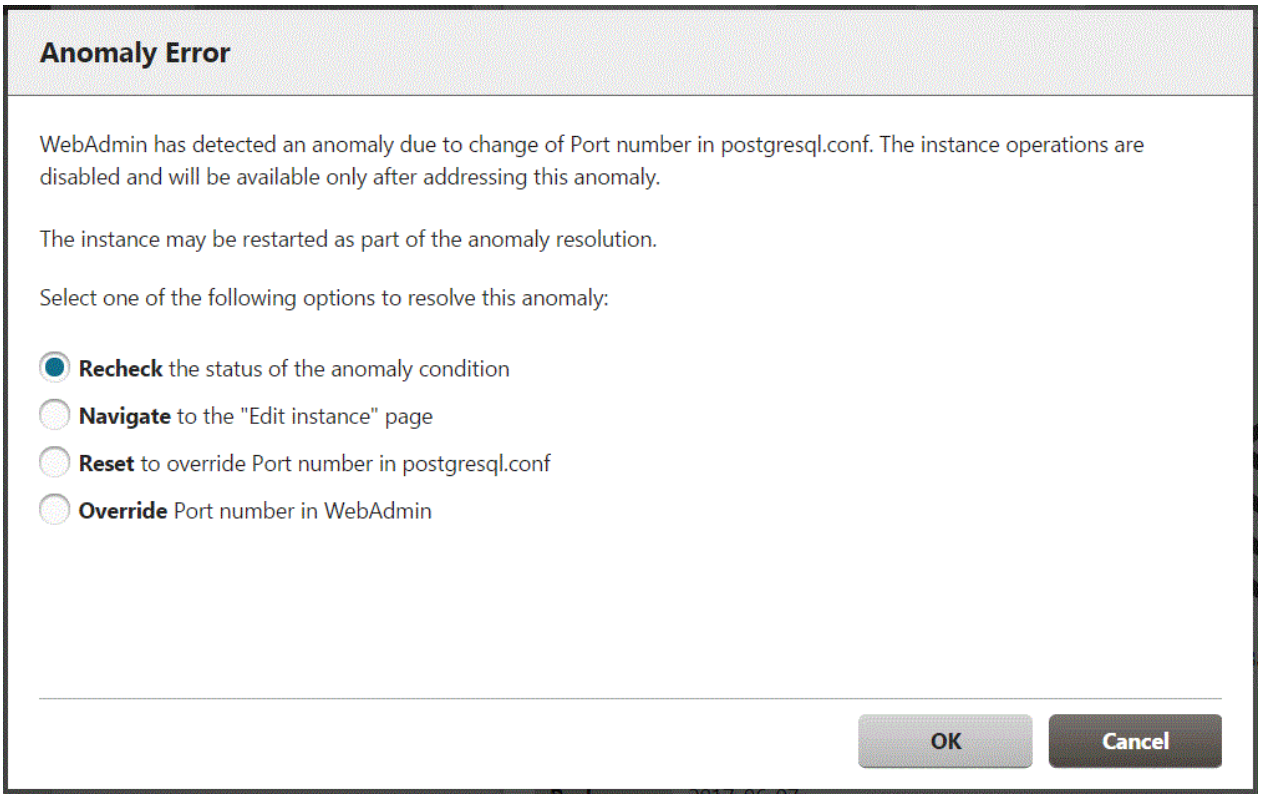
WebAdmin checks for anomalies when an instance is selected for viewing or any instance operation is performed. Anomalies will be identified for the selected instance only.

The following occurs when an anomaly is detected in port number and/or backup storage path:

- All instance operation buttons are disabled, except for "Edit instance", "Refresh instance", and "Delete Mirroring Controller"
- A red error status indicator is displayed on the instance icon
- For an anomaly specific to backup storage path, a red error status indicator is displayed on the [Backup storage] disk icon, and [Backup storage status] is set to "Error"
- The message, "WebAdmin has detected an anomaly with...", is displayed in the [Message] section along with an associated [Solution] button

Critical errors encountered during anomaly resolution will be displayed, however, rollback of the instance to its previous state is not supported.

Click [Solution]. The [Anomaly Error] dialog box is displayed.



Select the required option, click [OK], and then resolve the anomaly error.

Refer to "Editing instance information" in the Installation and Setup Guide for Server for information on the [Edit instance] page.

19.15.2 Mirroring Controller Anomalies

The following conditions will cause a Mirroring Controller anomaly:

- The Mirroring Controller management folder or configuration files have been deleted
- The permissions to the Mirroring Controller management folder or configuration files have been changed such that:
  - The instance administrator's access to Mirroring Controller configuration is denied
  - Users other than an instance administrator have access privileges to Mirroring Controller configuration files

WebAdmin checks for anomalies when Mirroring Controller status check is performed.

The following occurs when a Mirroring Controller anomaly is detected:

- All Mirroring Controller functionality is disabled for the replication cluster, except for "Delete Mirroring Controller"
- [Mirroring Controller status] is set to "Error"
- Either of the following messages is displayed in the [Message] section

  "Failed to access the Mirroring Controller management folder or configuration files '*path*'. Mirroring Controller functionality has been disabled. Consider deleting Mirroring Controller and adding it again."

  "Failed to find the Mirroring Controller management folder or configuration files '*path*'. Mirroring Controller functionality has been disabled. Consider deleting Mirroring Controller and adding it again."

Appendix A Parameters

This appendix describes the parameters to be set in the postgresql.conf file of Fujitsu Enterprise Postgres.

The postgresql.conf file is located in the data storage destination.

Information

The maximum value that can be expressed as a 4-byte signed integer changes according to the operating system. Follow the definition of the operating system in use.

- core_directory (string)

  This parameter specifies the directory where the corefile is to be output. If this parameter is omitted, the data storage destination is used by default. This parameter can only be set when specified on starting an instance. It cannot be changed dynamically, while an instance is active.

- core_contents (string)

  This parameter specifies the contents to be included in the corefile.

  - full: Outputs all contents of the server process memory to the corefile.
  - none: Does not output a corefile.
  - minimum: Outputs only non-shared memory server processes to the corefile. This reduces the size of the corefile. However, in some cases, this file may not contain sufficient information for examining the factor that caused the corefile to be output.

  If this parameter is omitted, "minimum" is used by default. This parameter can only be set when specified on starting an instance. It cannot be changed dynamically, while an instance is active.

- keystore_location (string)

  This parameter specifies the directory that stores the keystore file. Specify a different location from other database clusters. This parameter can only be set when specified on starting an instance. It cannot be changed dynamically, while an instance is active.

  Cannot be specified with the tde_kms.kms_conninfo_file parameter.

- tde_kms.plugin_path (string)

  When connecting to the key management system using a plug-in, specify the directory that stores the plug-in with an absolute path. Only database administrators should be able to store plugins in this directory. It can only be set by specifying a parameter when starting the instance.

- tde_kms.enable_shared_dek (boolean)

  Enables or disables sharing of data encryption keys between backend processes for each encrypted tablespace in transparent data encryption. Default is off. It can only be set by specifying a parameter when starting the instance.

- tde_kms.max_shared_dek (numerical value)

  Specify the maximum number of shared data encryption keys when sharing data encryption keys per tablespace in transparent data encryption. Default is 1000. It can only be set by specifying a parameter when starting the instance.

- tde_kms.kms_conninfo_file (string)

  When using the key management service as a key store, specifies the file that contains the connection information for the key management system. Cannot be specified with the keystore_location parameter.

  Create a connection information file for the key management system in one of the following format:

```
kmip    kms-name    address    port    auth-method    [auth-options]
custom  kms-name    plugin-name      [plugin-options]   [extra-args]
```

  Specify one of the following methods to connect to the key management system.

- kmip

  Access this key management system using the KMIP protocol. Take out and use the encryption key in this key management system.

- custom

  Access the key management system using a plugin module. The encryption/decryption process is done inside the plugin or inside the key management system. Fujitsu Enterprise Postgres does not use cryptographic keys directly.

For type kmip

- kms-name

  The key management system name assigned to the key management system and specified when declaring the master encryption key or opening the keystore. The name of the key management system must be unique within this file. The key management system name must be a string of no more than 63 characters beginning with a-z, consisting of a-z, a number (0 -9), and an underscore. Upper and lower case letters are the same.

- address

  Specifies the host name or IP address of the key management service.

- port

  Specifies the port number on which the key management service listens for services.

- auth-method

  Specifies the authentication method for the key management service.

- auth-options

  The auth-method is followed by the authentication method options. You can specify multiple options in a name = value field.

Authentication method when using a key management service of type kmip

cert

A certificate is used to authenticate the KMIP server and the client, Fujitsu Enterprise Postgres, to each other. The auth-options can be.

- sslcert

  Specifies the file name of the client certificate. The corresponding format is PEM format.

- sslkey

  Specifies the file name of the private key used for the client certificate. The corresponding format is PEM format. If you choose to encrypt the file with a passphrase, use a passphrase that is no more than 1023 bytes long.

- sslkeypassphrase-obf

  Specifies the file that contains the obfuscated passphrase for the private key file specified by sslkey. This option allows the keystore to be opened automatically when the server starts. The pgx _ keystore command creates obfuscated files. It can be omitted.

- sslrootcert

  Specifies the file name of the SSL Certificate Authority certificate. The corresponding format is PEM format. Used to verify the server certificate of the connection destination.

Example

```
kmip   mykmipsvr  mykmipsvr.example.com   5696   cert   sslcert=postgres.crt
sslkey=postgres.key sslrootcert=root.crt
```

Information

cert authentication does not verify that the server you are connecting to is the same server you are trying to connect to. Any server using a server certificate that is signed with the certificate of the certificate authority specified in sslrootcert is considered the correct destination. To avoid problems with this behavior, consider using your own CA or self-signed certificate for the KMIP server.

For type custom

- kms-name

  The key management system name given to the key management system, specified when declaring a master encryption key or opening a keystore. The name of the key management system must be unique within this file. The key management system name must be a string of up to 63 characters starting with a-z and consisting of a-z, digits (0-9) and underscores. Uppercase and lowercase letters are considered the same.

- plugin-name

  Specify the name of the plugin. Use the file with the same name as the plugin name in the directory specified by tde_kms.plugin_path as the plugin module. The file must have execution privilege for the OS user that starts the Fujitsu Enterprise Postgres server.

- plugin-options

  Specify other options for the plugin. Multiple options can be specified in name=value format fields. You can specify the following option names.

  - kms-secret-obf

    Specify the file containing the obfuscated KMS secret when enabling automatic opening of the keystore using transparent data encryption. The obfuscated file is created with the pgx_keystore command. The obfuscated file contents are decrypted by Fujitsu Enterprise Postgres and passed to the plugin. Can be omitted if you are not using transparent data encryption to enable automatic opening of the keystore.

- extra-args

  Specify additional arguments to pass to the specified shell command in the form arg=value. If you specify multiple extra-args, the values are passed to the shell command in that order.

Example

If you pass the plugin an additional argument: --profile user1

```
custom   mykms  mykms  arg=--profile arg=user1
```

- tablespace_encryption_algorithm (string)

  This parameter specifies the encryption algorithm for tablespaces that will be created. Valid values are "AES128", "AES256", and "none". If you specify "none", encryption is not performed. The default value is "none". To perform encryption, it is recommended that you specify "AES256". Only superusers can change this setting.

- backup_destination (string)

  This parameter specifies the absolute path of the directory where pgx_dmpall will store the backup data. Specify a different location from other database clusters. This parameter can only be set when specified on starting an instance. It cannot be changed dynamically, while an instance is active.

  Place this directory on a different disk from the data directory to be backed up and the tablespace directory. Ensure that users do not store arbitrary files in this directory, because the contents of this directory are managed by the database system.

- search_path (string)

  When using the SUBSTR function compatible with Oracle databases, set "oracle" and "pg_catalog" in the search_path parameter. You must specify "oracle" before "pg_catalog".

Example

```
search_path = '"$user", public, oracle, pg_catalog'
```

Information

- The search_path feature specifies the priority of the schema search path. The SUBSTR function in Oracle database is defined in the oracle schema.
- Refer to "Statement Behavior" under "Server Administration" in the PostgreSQL Documentation for information on search_path.

- track_waits (string)

  This parameter enables collection of statistics for pgx_stat_lwlock and pgx_stat_latch.

  - on: Enables collection of statistics.
  - off: Disables collection of statistics.

  If this parameter is omitted, "on" is assumed.

  Only superusers can change this setting.

- track_sql (string)

  This parameter enables collection of statistics for pgx_stat_sql.

  - on: Enables collection of statistics.
  - off: Disables collection of statistics.

  If this parameter is omitted, "on" is assumed.

  Only superusers can change this setting.

Parameters for the in-memory feature

- reserve_buffer_ratio (numerical value)

  This parameter specifies the proportion of shared memory to be used for a stable buffer table.

  - Minimum value: 0
  - Maximum value: 80

  If this parameter is omitted, 0 will be used.

- vci.cost_threshold (numerical value)

  This parameter specifies the lowest cost that selects an execution plan that uses a VCI. If the cost of the best execution plan that does not use a VCI is lower than this value, that execution plan will be selected.

  - Minimum value: 0
  - Maximum value: Maximum value that can be expressed as a 4-byte signed integer

  If this parameter is omitted or a value outside this range is specified, 18000 will be used.

- vci.control_max_workers (numerical value)

  This parameter specifies the number of background workers that manage VCI. The number of workers for the entire instance is limited by max_worker_processes, so add the value specified here to max_worker_processes.

  - Minimum value: 1
  - Maximum value: 8388607

  If this parameter is omitted or a value outside this range is specified, 8 will be used.

- vci.enable (string)

  This parameter enables or disables VCI.

  - on: Enables VCI.
  - off: Disables VCI.

  If this parameter is omitted, "on" will be used.

- vci.log_query (string)

  This parameter enables or disables log output when VCI is not used due to insufficient memory specified by vci.max_local_ros.

  - on: Enables log output.
  - off: Disables log output.

  If this parameter is omitted, "off" will be used.

- vci.maintenance_work_mem (numerical value)

  This parameter specifies the maximum memory size used for maintenance of VCI (when executing CREATE INDEX, for example).

  - Minimum value: 1 MB
  - Maximum value: Maximum value that can be expressed as a 4-byte signed integer

  If this parameter is omitted or a value outside this range is specified, 256 MB will be used.

- vci.max_local_ros (numerical value)

  This parameter specifies the maximum memory size used for VCI scan.

  - Minimum value: 64 MB
  - Maximum value: Maximum value that can be expressed as a 4-byte signed integer

  If this parameter is omitted or a value outside this range is specified, 64 MB will be used.

- vci.max_parallel_degree (numerical value)

  This parameter specifies the maximum number of background workers used for parallel scan. The number of workers for the entire instance is limited by max_worker_processes, so add the value specified here to max_worker_processes.

  A value from -8388607 to 8388607 can be specified.

  - Integer (1 or greater): Parallel scan is performed using the specified degree of parallelism.
  - 0: Stops the parallel scan process.
  - Negative number: The specified value minus the maximum number of CPUs obtained from the environment is used as the degree of parallelism and parallel scan is performed.

  If this parameter is omitted or a value outside this range is specified, 0 will be used.

- vci.shared_work_mem (numerical value)

  This parameter specifies the maximum memory size used for VCI parallel scan.

  - Minimum value: 32 MB
  - Maximum value: Maximum value that can be expressed as a 4-byte signed integer

  If this parameter is omitted or a value outside this range is specified, 1 GB will be used.

Parameters for the Global Meta Cache feature

- pgx_global_metacache (numerical value)

  Specifies the memory size of the GMC area.

  Specify a value calculated by the formula below.

A value lower than the calculated value will still work, but the meta cache may not be able to fit into the GMC area.

In this case, the system will discard the meta cache it thinks it is no longer needed, but if it is needed again, the meta cache will need to be expanded and will not perform well.

If the value is less than 10 MB and is set to a nonzero value that disables the feature, the database startup fails because the Global Meta Cache feature cannot operate.

A setting of 0 disables the Global Meta Cache feature. The default is 0.

Changing this setting requires restarting the database.

```
Size of GMC area
 = Max(10MB,
     (All user table x 0.4 KB
      + All user Indexes x 0.3 KB
      + All user columns x 0.8 KB) x 1.5 (*1) )

*1) Safety Factor (1.5)
This value takes into account the case where both GMC before and after the change temporarily exist
at the same time in shared memory when the table definition is changed or the row of the system
catalog is changed.
```

- track_gmc (string)

  This parameter enables collection of statistics for pgx_stat_gmc.

  - on: Enables collection of statistics.
  - off: Disables collection of statistics.

  If this parameter is omitted, "on" is used.

  Only superusers can change this setting.

Parameters for the Local Meta Cache Limit feature

- pgx_catalog_cache_max_size(numerical value)

  Specifies the maximum amount of memory that the backend process should use as the catalog cache.

  You can enable catalog cache deletion by setting it to 8 KB or more.

  A setting of 0 disables the catalog cache removal. The default is 0.

  If no units are specified, they are treated as KB.

  - Minimum value: 8KB
  - Maximum value: Maximum value that can be expressed as a 4-byte signed integer

  When calculating the parameter settings, the factors that determine the cache size are calculated as the number of tables, the number of indexes, and the number of columns. What is kept as a catalog cache or relation cache also includes objects such as databases, roles, or procedures, but these are small compared to the above factors and do not need to be factored into them. It also includes a calculation method for pgx_relacion_cache_max_size because the given memory is distributed between the catalog cache and the relation cache.

  The calculation method here assumes that all backends have similar access and that the transaction also has access to a similar number of resources. If you have a small number of singular backends or transactions, consider excluding them as errors.

  1. Determine how much memory a backend process can use. Decide by subtracting the memory size required by the entire system such as the database cache from the installed memory and dividing the rest by the number of connections.
  2. For best performance, use the following formula to calculate the total memory size of the catalog cache when the backend holds the catalog cache for all resources accessed during its lifetime.
     The amount of memory varies depending on whether Global Meta Cache is enabled or disabled. Enabling Global Meta Cache reduces the amount of memory required because most of the cache is located on shared memory.

     ```
     When Global Meta Cache is enabled:
       (Number of tables to access + Number of indexes to access + Number of columns to access)
     ```

```
      × 0.1KB × 1.5 (*1)
When Global Meta Cache is disabled:
  { Number of tables to access × 0.5KB(pg_class tuple size)
      + Number of indexes to access × 0.5KB(pg_index tuple size)
      + Number of columns to access × 1.0KB(pg_statistic tuple size)} × 1.5 (*1)

*1) Safety Factor (1.5)
The system catalog contains columns with variable-length types. For example, the tuple size in
pg_class is a constant value multiplied by the number of tables, while relname in pg_class is
variable length data.
It is not practical to calculate every definition in detail, so we added 50% to the above
formula.
```

3. In the same way as in 2., calculate the relation cache using the following formula.

```
(1.4KB × Number of tables to access + 2.4KB × Number of indexes to access) × 1.5 (*1)

*1) Safety Factor (1.5)
The relation cache is structured to facilitate the use of table and index definitions, holds
pointers to various objects, and is sized to include them. It is variable length because the
type of object allocated by the table definition and its size change. Since it is not
realistic to calculate for all definitions, 50% is added.
```

4. If the value of 1. ≥ the value of 2. + the value of 3., the backend process can keep all caches to the extent allowed, so there is no need to limit the caches. If you want to cap for safety, set the value of 2. to pgx_catalog_cache_max_size and the value of 3. to pgx_relation_cache_max_size.
5. If the value of 1. < the value of 2. + the value of 3. then you need to limit the cache. However, this parameter does not limit the size of the cache used by a transaction. Therefore, take the following steps.
6. Calculate the catalog cache used by a transaction using the formula in 2.
7. Calculate the relation cache used by a transaction using the formula in 3.
8. If the value of 1. < the value of 6. + the value of 7., then the value of 1. needs to be increased. In other words, in some cases, it may be necessary to increase the installed memory or reduce the number of connections.
9. If the value of 1. ≥ the value of 6. + the value of 7., the condition of 1. can be satisfied by limiting the cache with this parameter. Divide the value of 1. by the ratio of 2. and 3. and set it as a parameter. Set the value distributed to 2. to pgx_catalog_cache_max_size and the value distributed to 3. to pgx_relation_cache_max_size.
10. The value calculated in 9. is a provisional value. If you cannot meet your target performance, first try to shift the focus of allocation to the relation cache. This is because when executing SQL, the relation cache generated based on the catalog cache is mainly referenced, so it is advantageous to leave a large amount of relation cache. If the performance is still not satisfied, adjust the parameters by referring to "17.1.4 Performance Impact and Parameter Tuning of the Local Meta Cache Limit Feature".

For Partitioning

Be careful when partitioning the table.

The cached definition changes depending on whether the parent table is specified in the SQL statement or the child table is specified. In particular, note that if you specify a parent table, the definitions of all child tables are cached. This is because when you specify a parent table in an SQL statement, you need to know the definitions of all the child tables in order to determine which child table will contain the desired data. Note that the column information of the parent table is not cached.

When specifying the parent table:

```
Number of tables to access = Number of parent tables to access + Number of defined child tables
Number of columns = Number of defined columns x number of defined child tables
```

When specifying the child table directly:

```
Number of tables to access = Number of child tables actually accessed
Number of columns = Number of defined columns x number of child tables actually accessed
```

Example)

Suppose the parent table T (1 index, 3 columns) is split from child tables T1 to T5 (1 index, 3 columns, respectively). If the parent table T is specified in SQL, when the child tables that contain the data to be queried are limited to T1 and T2, and when accessing the data using the indexes defined by T1 and T2, calculate as follows.

```
Number of tables = 1(parent table) + 5(child table) = 6
Number of indexes = 2 (index to access)
Number of columns = 3 (number of columns) x 5 (child table) = 15
```

If you specify child tables T1 and T2 in SQL and use the indexes defined on T1 and T2 when accessing data, the calculation is as follows.

```
Number of tables = 2(child table)
Number of indexes = 2 (index to access)
Number of columns = 3 (number of columns) x 2 (child table) = 6
```

- pgx_relation_cache_max_size(numerical value)

  Specifies the maximum amount of memory that the backend process should use as the relation cache.

  You can enable catalog cache deletion by setting it to 8 KB or more.

  A setting of 0 disables the relation cache removal. The default is 0.

  If no units are specified, they are treated as KB.

  - Minimum value: 8KB
  - Maximum value: Maximum value that can be expressed as a 4-byte signed integer

  For the calculation method for parameter setting, refer to the calculation method of pgx_catalog_cache_max_size.

- pgx_cache_hit_log_interval(numerical value)

  Specifies the time interval to output a message indicating the cache reference status for each backend process.

  When the transaction ends, if the time set in this parameter has elapsed since the previous message was output, the message is output.

  If set to 0, a message will be output each time the transaction ends.

  Setting -1 disables the output. The default value is 10min.

  If no units are specified, they are treated as ms.

  Even if pgx_catalog_cache_max_size and pgx_relation_cache_max_size are disabled, the message output of the corresponding cache will be invalid.

  Immediately after connecting to the server, a small transaction occurs before the request from the user application, such as for user authentication. Since it is meaningless to know the hit rate for these, a message will be output at the end of the transaction that started after the time set in this parameter has elapsed after connecting to the server.

  For the same reason, setting a small value such as 0 may result in a message being printed at the end of such a small transaction.

  You can check which transaction the message corresponds to from the information output at the beginning.

  This information depends on the setting of the parameter log_line_prefix.

  - Minimum value: 0
  - Maximum value: 2147483647ms

See

Refer to "Server Configuration" under "Server Administration" in the PostgreSQL Documentation for information on other postgresql.conf parameters.

Parameters for the Policy-based Login Security

- userprofile_database(string)

  Specifies the name of the database to which the background worker process connects. This parameter must specify a connectable database name. If you omit this parameter, then it is assumed to be "postgres".

  The pseudo database "replication" cannot be specified for streaming replication.

  If you change this parameter, reload the configuration file.

Parameters for using OpenSSL legacy algorithms

- openssl_conf(string)

  Specifies the OpenSSL configuration file. Specifying a valid configuration file makes legacy algorithms available. Use the example below to prepare the configuration file in any directory.

  If this parameter is not specified, the empty string is assumed.

  This parameter can only be set by specifying the parameter at instance startup.

  You cannot make dynamic changes during instance startup.

  Example

  openssl_conf = '/path/to/openssl.conf'

  [OpenSSL Configuration File (openssl.conf) Example]

  ```
  ====================
  openssl_conf = openssl_init

  [openssl_init]
  providers = provider_sect

  [provider_sect]
  default = default_sect
  legacy = legacy_sect

  [default_sect]
  activate = 1

  [legacy_sect]
  activate = 1
  ====================
  ```

- openssl_modules(string)

  Specifies the directory that contains additional OpenSSL modules.

  Legacy algorithms are available by specifying 'server installation directory/lib/ossl-modules'.

  If this parameter is not specified, the empty string is assumed.

  This parameter can only be set by specifying the parameter at instance startup.

  You cannot make dynamic changes during instance startup.

  This parameter sets the OPENSSL_MODULES environment variable to be applied to the server process. Do not set the OPENSSL_MODULES environment variable in any way other than setting this parameter, as this may cause abnormal behavior.

  Example

  openssl_modules = '/opt/fsepv<*x*>server64/lib/ossl-modules'

Note that "<*x*>" indicates the product version.

Information

Legacy algorithms include the following encryption algorithms:

- BF
- CAST5
- DES-ECB
- DES-CBC
- MD4
- Whirlpool

Parameters for scheduling aggressive freeze for tuples

- pgx_stat_vacuum_freeze.track_freeze_info (boolean)

  Collects and maintains information about aggressive freeze for tuples. The default is on.

  - on: Enables information collection.
  - off: Disables information collection.

- pgx_stat_vacuum_freeze.monitoring_interval (numerical value)

  Aggregate statistics for aggressive freeze for tuples in this interval, so that statistics for each interval can be obtained in the pgx_stat_freeze_results table. Note that an aggressive freeze for tuples across this interval will still account for the overall tuple freeze at completion time. The default is 1hour.

  Set the aggressive freeze for tuples script to run at weekly intervals of days, daily intervals of hours, and hourly intervals of minutes.

  - Minimum value: 1min
  - Maximum value: 1d

  If a value out of range is specified, 1h is set.

  If this parameter is omitted, 1h is assumed.

- pgx_stat_vacuum_freeze.log_retention_period (numerical value)

  Specify how long statistics are kept. The default is 90 days.

  Set the period according to the work cycle. For example, if a monthly batch is to be processed every 1 month, set it to 90 days, which is approximately 3 times that period. to capture changes in the aggressive freeze for tuples over the duration of the cycle.

  - Minimum value: 1d
  - Maximum value: 180d

  If an out-of-range value is specified, 90d is set.

  If this parameter is omitted, 90d is assumed.

Appendix B System Administration Functions

This appendix describes the system administration functions of Fujitsu Enterprise Postgres.

See

Refer to "System Administration Functions" under "The SQL Language" in the PostgreSQL Documentation for information on other system administration functions.

B.1 WAL Mirroring Control Functions

The following table lists the functions that can be used for backup and recovery based on WAL mirroring.

Table B.1 WAL mirroring control functions

Name	Return type	Description
pgx_pause_wal_multiplexing()	void	Stops WAL multiplexing
pgx_resume_wal_multiplexing()	void	Resumes WAL multiplexing
pgx_is_wal_multiplexing_paused()	boolean	Returns true if WAL multiplexing has stopped

If WAL multiplexing has not been configured, these functions return an error. Setting the backup_destination parameter in postgresql.conf configures WAL multiplexing.

Only superusers can execute these functions.

B.2 Transparent Data Encryption Control Functions

The following table lists the functions that can be used for transparent data encryption.

Table B.2 Transparent data encryption control functions

Name	Return type	Description
pgx_open_keystore(*passphrase*) pgx_open_keystore(sslpassphrase => text)	void	Opens the keystore
pgx_set_master_key(*passphrase*)	void	Sets the master encryption key
pgx_declare_external_master_key(kms_name => text, key_id => text, sslpassphrase => text)	void	To set an encryption key existing in a key management system as a master encryption key for transparent data encryption.
pgx_set_keystore_passphrase(*oldPassphrase*, *newPassphrase*)	void	Changes the keystore passphrase

B.2.1 pgx_open_keystore

pgx_open_keystore opens the keystore.

Only superusers can execute this function. Also, this function cannot be executed within a transaction block.

File-based keystores:

The pgx_open_keystore function uses the specified passphrase to open the keystore. When the keystore is opened, the master encryption key is loaded into the database server memory. In this way, you can access the encrypted data and create encrypted tablespaces. If the keystore is already open, this function returns an error.

Using the key management system as a keystore

pgx_open_keystore makes available (opens a keystore) a master encryption key on a key management system that has already been declared for use. The keystore cannot be opened unless it has been declared to use a master encryption key.

If the keystore is already open, use the credentials you entered to reconnect to the key management system.

Specify the authentication information for connecting to the key management system. Arguments must be specified in naming notation. The information you pass in the argument depends on the key management system you use.

If the key management system information file specifies an obfuscated credentials file, the file is recreated with the new credentials.

Using the key management service of type kmip

The following arguments are specified in naming notation.

- sslpassphrase text

  Specifies the passphrase of the client certificate private key file when connecting to the KMIP server. This can be omitted if no passphrase is set in the private key file.

Using the key management service of type custom

The following arguments are specified in naming notation.

- kms_secret text

  Confidential information passed to the plugin. It can be omitted if it is not necessary for using the key management system. Whether or not it can be omitted depends on the implementation of the plugin.

Example

To specify the passphrase mykmippassphrase for the client certificate private key file in naming notation:

```
SELECT pgx_open_keystore( sslpassphrase => 'mykmippassphrase' );
```

B.2.2 pgx_set_master_key

The pgx_set_master_key function generates a master encryption key and stores it in the file-based keystore.

If the keystore does not exist, this function creates a keystore. If the keystore already exists, this function modifies the master encryption key. If the keystore has not been opened, this function opens it.

The passphrase is a string of 8 to 200 bytes.

Only superusers can execute this function. Also, this function cannot be executed within a transaction block. Processing is not affected by whether the keystore is open.

B.2.3 pgx_declare_external_master_key

pgx_declare_external_master_key declares the use of an encryption key that exists in the key management system as the master encryption key for transparent data encryption. If the master encryption key already exists, change the master encryption key. If the master encryption key already exists, the keystore must be open.

The argument specifies information that identifies the master encryption key. Arguments must be specified in naming notation. The information you pass in the argument depends on the key management system you use.

This function can only be executed by superuser. Also, you cannot execute this function within a transaction block.

This function is available if you have installed the extension 'tde_kms'.

The following arguments are specified in naming notation:

- kms_name text

  Specify the key management system name specified in the key management system connection information file. Required.

- key_id text

  Specify the key ID assigned to the encryption key. Cannot be omitted.

- sslpassphrase text

  Specify the passphrase of the client certificate private key file when connecting to the KMIP server. This can be omitted if the private key file does not have a passphrase. Ignored if the key management system type specified by kms_name is not kmip.

- kms_secret text

  Confidential information passed to the plugin. It can be omitted if it is not necessary for using the key management system. Whether or not it can be omitted depends on the implementation of the plugin. Ignored if the key management system type specified by kms_name is not custom.

Example

```
SELECT pgx_declare_external_master_key( kms_name => 'mykmipsvr', key_id =>
'a0eebc99-9c0b-0000-0000-000000000000', sslpassphrase => 'mykmippassphrase' );
```

B.2.4 pgx_set_keystore_passphrase

The pgx_set_keystore_passphrase function changes the file-based keystore passphrase.

Specify the current passphrase in *oldPassphrase*, and a new passphrase in *newPassphrase*.

The passphrase is a string of 8 to 200 bytes.

Only superusers can execute this function. Also, this function cannot be executed within a transaction block. Processing is not affected by whether the keystore is open.

B.3 Profile Management Functions and User Management Functions

The table below lists the profile management functions and user management functions used in policy-based login security.

B.3.1 Profile Management Functions

Name	Return type	Description

pgx_create_profile(profile_name name, password_parameter json)	void	Create a new profile.
		For profile_name, specify the profile name. An error will occur if an existing profile name is specified.
		For password_parameter, specify parameters and values in key-value format as follows.
		`'{`
		`"INACTIVE_USER_TIME": 15,`
		`"PASSWORD_LIFE_TIME": 30,`
		`"PASSWORD_GRACE_TIME": "UNLIMITED",`
		`"PASSWORD_REUSE_TIME": 10,`
		`"PASSWORD_REUSE_MAX": 5,`
		`"PASSWORD_LOCK_TIME": 0.5,`
		`"FAILED_LOGIN_ATTEMPTS": "DEFAULT",`
		`"PASSWORD_ALLOW_HASHED": true,`
		`"PASSWORD_ROLLOVER_TIME": 0.125`
		`}');`
		The json value accepts integer, numeric, boolean depending on the parameter, but only accepts strings "DEFAULT" and "UNLIMITED" as special values.

Name	Return type	Description
		For parameters that are omitted in json or that specify null for value, they follow the values in the default profile.Also, password_parameter can be omitted, and if omitted, a profile with all parameters conforming to the default profile will be created.

pgx_alter_profile(profile_name name, alter_parameter json)	void	Update the contents of an existing profile.
		For profile_name, specify the name of the profile to update. If you specify a profile name that does not exist, an error will occur.
		In alter_parameter, specify the variable name and value you want to change in key-value format as follows. Does not change the profile contents for parameters that are omitted or for which value is null.
		`'{`
		`"name": "new_name",`
		`"PASSWORD_LIFE_TIME": 50,`
		`"PASSWORD_GRACE_TIME": 10`
		`}');`
		name: Specify the modified profile name. null cannot be specified.
		If the default profile is specified in profile_name, the following changes cannot be made.
		- Change name
		- Change each password_parameter to "DEFAULT"

pgx_drop_profile(profile_name name, if_exists boolean, cascade boolean)	void	Delete an existing profile. Specify the profile name to be deleted in profile_name. Specifying the default profile will result in an error. if_exists specifies whether an error occurs when a nonexistent profile name is specified in profile_name. If true, no error. if_exists is optional. Default value is false. cascade specifies whether an error occurs when a profile assigned to a user is specified in profile_name. If false, an error will occur. If true, unassign all of the profiles before deleting them, and any unassigned users will be assigned the default profile instead. cascade is optional. Default value is false. [Example when specifying true] Specify arguments explicitly. (Example of named notation) `SELECT pgx_drop_profile('test_profile', cascade => true);`

B.3.2 User Management Functions

Name	Return type	Description
pgx_assign_profile_to_user(user_name name, profile_name name)	void	Assigns an existing profile to a user. Specify the assignee user in user_name. If you specify a user name that does not exist, an error will occur. Specify the profile name to be assigned in profile_name. If you specify a profile name that does not exist, an error will occur.
pgx_lock_user(user_name name)	void	Lock the user explicitly.

Name	Return type	Description
		Specify the user name in user_name. If you specify a user name that does not exist, an error will occur. If locked by this function, the lock period is indefinite. If you want to unlock it, you need to unlock it with the pgx_unlock_user function. If you lock a user that is already locked, the lock state is overwritten and becomes an indefinite lock even if it was previously a finite lock.
pgx_unlock_user(user_name name)	void	Explicitly unlock the user. The type of lock (profile reference lock or permanent lock) does not matter. Specify the user name in user_name. If you specify a user name that does not exist, an error will occur. Specifying an unlocked user does not result in an error.
pgx_make_password_expire(user_name name, expireat timestamptz)	void	Expires the specified user's password immediately. Alternatively, specify the time to expire. Specify the user name in user_name. If you specify a user name that does not exist, an error will occur. expireat can be a time that expires.expireat is optional. If omitted, execution time is specified.
pgx_make_password_rollover_expire(user_name name)	void	Expires immediately the period during which the specified user's old and new passwords can be used together so that the user cannot log in with the old password. Specify the user name in user_name. If you specify a user name that does not exist, an error will occur. If this command is executed outside the period for using the old and new passwords, it is ignored.

B.4 Data Masking Control Functions

The table below lists the functions that can be used for data masking.

Table B.3 Data masking control functions

Name	Return type	Description
pgx_alter_confidential_policy	boolean	Changes masking policies
pgx_create_confidential_policy	boolean	Creates masking policies
pgx_drop_confidential_policy	boolean	Deletes masking policies
pgx_enable_confidential_policy	boolean	Enables or disables masking policies
pgx_update_confidential_values	boolean	Changes replacement characters when full masking is specified for masking type

B.4.1 pgx_alter_confidential_policy

Description

Changes masking policies

Format

The format varies depending on the content to be changed. The format is shown below.

- Common format

```
common_arg:
[schema_name    := 'schemaName',]
table_name    := 'tableName',
policy_name     := 'policyName'
```

- Add a masking target to a masking policy

```
pgx_alter_confidential_policy(
commonArg,
[action        := 'ADD_COLUMN', ]
column_name    := 'colName'
[, function_type    := 'FULL'] |
[, function_type    := 'PARTIAL', partialOpt] |
[, function_type    := 'REGEXP', regexpOpt]
)

partialOpt:
function_parameters    := 'maskingFmt'

regexpOpt:
regexp_pattern        := 'regexpPattern',
regexp_replacement    := 'regexpReplacementChar',
[, regexp_flags        := 'regexpFlags']
```

- Delete a masking target from a masking policy

```
pgx_alter_confidential_policy(
commonArg,
action        := 'DROP_COLUMN',
column_name    := 'colName'
)
```

- Change the masking condition

```
pgx_alter_confidential_policy(
commonArg,
action        := 'MODIFY_EXPRESSION',
expression    := 'expr'
)
```

- Change the content of a masking policy set for a masking target

```
pgx_alter_confidential_policy(
commonArg,
action        := 'MODIFY_COLUMN',
column_name    := 'colName'
[, function_type    := 'FULL'] |
[, function_type    := 'PARTIAL', partialOpt] |
[, function_type    := 'REGEXP', regexpOpt]
)

partialOpt:
function_parameters    := 'maskingFmt'

regexpOpt:
regexp_pattern        := 'regexpPattern',
regexp_replacement        := 'regexpReplacementChar',
[, regexp_flags        := 'regexpFlags']
```

- Change the masking policy description

```
pgx_alter_confidential_policy(
commonArg,
action        := 'SET_POLICY_DESCRIPTION',
policy_description    := 'policyDesc'
)
```

- Change the masking target description

```
pgx_alter_confidential_policy(
commonArg,
action        := 'SET_COLUMN_DESCRIPTION',
column_name    := 'colName',
column_description    := 'colDesc'
)
```

Argument

The argument varies depending on the content to be changed. Details are as follows.

- Common arguments

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	schema_name	varchar(63)	Schema name of table for which a masking policy is applied	'public'
	table_name	varchar(63)	Name of table for which a masking policy is applied	Mandatory
	policy_name	varchar(63)	Masking policy name	Mandatory

- Add a masking target to a masking policy

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	action	varchar(63)	'ADD_COLUMN'	'ADD_COLUMN'
	column_name	varchar(63)	Masking target name	Mandatory
	function_type	varchar(63)	Masking type - 'FULL': Full masking - 'PARTIAL': Partial masking - 'REGEXP': Regular expression masking	'FULL'
Partial masking	function_parameters	varchar(1024)	Masking format for partial masking	Mandatory
Regular expression masking	regexp_pattern	varchar(1024)	Search pattern for regular expression masking	Mandatory
	regexp_replacement	varchar(1024)	Replacement character/string for regular expression masking	Mandatory
	regexp_flags	varchar(20)	Regular expression flags	NULL

- Delete a masking target from a masking policy

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	action	varchar(63)	'DROP_COLUMN'	Mandatory
	column_name	varchar(63)	Masking target name	Mandatory

- Change the masking condition

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	action	varchar(63)	'MODIFY_EXPRESSION'	Mandatory
	expression	varchar(1024)	Masking condition to be changed	Mandatory

- Change the content of a masking policy set for a masking target

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	action	varchar(63)	'MODIFY_COLUMN'	Mandatory
	column_name	varchar(63)	Masking target name	Mandatory
	function_type	varchar(63)	Masking type - 'FULL': Full masking - 'PARTIAL': Partial masking - 'REGEXP': Regular expression masking	'FULL'
Partial masking	function_parameters	varchar(1024)	Masking format for partial masking	Mandatory
Regular expression masking	regexp_pattern	varchar(1024)	Search pattern for regular expression masking	Mandatory
	regexp_replacement	varchar(1024)	Replacement character/string for regular expression masking	Mandatory
	regexp_flags	varchar(20)	Regular expression flags	NULL

- Change the masking policy description

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	action	varchar(63)	'SET_POLICY_DESCRIPTION'	Mandatory
	policy_description	varchar(1024)	Masking policy description	Mandatory

- Change the masking target description

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	action	varchar(63)	'SET_COLUMN_DESCRIPTION'	Mandatory
	column_name	varchar(63)	Masking target name	Mandatory
	column_description	varchar(1024)	Masking target description	Mandatory

Details about whether arguments can be omitted are as follows.

Argument	Mandatory or optional									
	ADD_COLUMN			DROP_COLUMN	MODIFY_EXPRESSION	MODIFY_COLUMN			SET_POLICY_DESCRIPTION	SET_COLUMN_DESCRIPTION
	Full masking	Partial masking	Regular expression masking			Full masking	Partial masking	Regular expression masking		
schema_name	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
table_name	N	N	N	N	N	N	N	N	N	N
policy_name	N	N	N	N	N	N	N	N	N	N
action	Y	Y	Y	N	N	N	N	N	N	N
column_name	N	N	N	N	-	N	N	N	-	N
function_type	Y	N	N	-	-	Y	N	N	-	-
expression	-	-	-	-	N	-	-	-	-	-
policy_description	-	-	-	-	-	-	-	-	N	-
column_description	-	-	-	-	-	-	-	-	-	N
function_parameters	-	N	-	-	-	-	N	-	-	-
regexp_pattern	-	-	N	-	-	-	-	N	-	-
regexp_replacement	-	-	N	-	-	-	-	N	-	-
regexp_flags	-	-	Y	-	-	-	-	Y	-	-

Y: Can be omitted; N: Cannot be omitted; -: Ignored when specified

Return value

Return value	Description
TRUE	Ended normally
FALSE	Ended abnormally

Execution example 1

Adding masking policy p1 to masking target c2

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1', action :=
'ADD_COLUMN', column_name := 'c2', function_type := 'PARTIAL', function_parameters := 'VVVFVVVVFVVVV,
VVV-VVVV-VVVV, *, 4, 11');
 pgx_alter_confidential_policy
-------------------------------
```

```
 t
(1 row)
```

Execution example 2

Deleting masking target c1 from masking policy p1

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1', action :=
'DROP_COLUMN', column_name := 'c1');
 pgx_alter_confidential_policy
-------------------------------
 t
(1 row)
```

Execution example 3

Changing the masking condition for masking policy p1

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1', action :=
'MODIFY_EXPRESSION', expression := 'false');
 pgx_alter_confidential_policy
-------------------------------
 t
(1 row)
```

Execution example 4

Changing the content of masking policy p1 set for masking target c2

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1', action :=
'MODIFY_COLUMN', column_name := 'c2', function_type := 'FULL');
 pgx_alter_confidential_policy
-------------------------------
 t
(1 row)
```

Execution example 5

Changing the description of masking policy p1

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1', action :=
'SET_POLICY_DESCRIPTION', policy_description := 'this policy is an example.');
 pgx_alter_confidential_policy
-------------------------------
 t
(1 row)
```

Execution example 6

Changing the description of masking target c2

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1', action :=
'SET_COLUMN_DESCRIPTION', column_name := 'c2', column_description := 'c2 column is FULL.');
 pgx_alter_confidential_policy
-------------------------------
 t
(1 row)
```

Description

- The arguments for the pgx_alter_confidential_policy system management function can be specified in any order.

- The action parameters below can be specified. When action parameters are omitted, ADD_COLUMN is applied.

Parameter	Description
ADD_COLUMN	Adds a masking target to a masking policy.
DROP_COLUMN	Deletes a masking target from a masking policy.
MODIFY_EXPRESSION	Changes expression.
MODIFY_COLUMN	Changes the content of a masking policy set for a masking target.
SET_POLICY_DESCRIPTION	Changes policy_description.
SET_COLUMN_DESCRIPTION	Changes column_description.

- The function_parameters argument is enabled when the function_type is PARTIAL. If the function_type is other than PARTIAL, it will be ignored.
- The arguments below are enabled when the function_type is REGEXP. If the function_type is other than REGEXP, these arguments will be ignored.
  - regexp_pattern
  - regexp_replacement
  - regexp_flags

- Refer to "String Constants" in the PostgreSQL Documentation for information on the strings to specify for arguments.
- Refer to "POSIX Regular Expressions" in the PostgreSQL Documentation and check pattern, replacement, and flags for information on the values that can be specified for regexp_pattern, regexp_replacement, and regexp_flags.

B.4.2 pgx_create_confidential_policy

Description

Creates masking policies

Format

The format varies depending on the masking type. The format is shown below.

```
pgx_create_confidential_policy(
[schema_name        := 'schemaName',]
table_name        := 'tableName',
policy_name         := 'policyName',
expression        := 'expr'
[, enable           := 'policyStatus']
[, policy_description    := 'policyDesc']
[, column_name        := 'colName'
     [, function_type    := 'FULL'] |
     [, function_type    := 'PARTIAL', partialOpt] |
     [, function_type    := 'REGEXP', regexpOpt]
     [, column_description    := 'colDesc']
])

partialOpt:
function_parameters    := 'maskingFmt'
```

```
regexpOpt:
regexp_pattern        := 'regexpPattern',
regexp_replacement        := 'regexpReplacementChar',
[, regexp_flags        := 'regexpFlags']
```

Argument

Details are as follows.

Masking type for which an argument can be specified	Argument	Data type	Description	Default value
All	schema_name	varchar(63)	Schema name of table for which the masking policy is created	'public'
	table_name	varchar(63)	Name of table for which the masking policy is created	Mandatory
	policy_name	varchar(63)	Masking policy name	Mandatory
	expression	varchar(1024)	Masking condition	Mandatory
	enable	boolean	Masking policy status - 't': Enabled - 'f': Disabled	't'
	policy_description	varchar(1024)	Masking policy description	NULL
	column_name	varchar(63)	Masking target name	NULL
	function_type	varchar(63)	Masking type - 'FULL': Full masking - 'PARTIAL': Partial masking - 'REGEXP': Regular expression masking	'FULL'
	column_description	varchar(1024)	Masking target description	NULL
Partial masking	function_parameters	varchar(1024)	Masking format for partial masking	Mandatory
Regular expression masking	regexp_pattern	varchar(1024)	Search pattern for regular expression masking	Mandatory
	regexp_replacement	varchar(1024)	Replacement character/string for regular expression masking	Mandatory
	regexp_flags	varchar(20)	Regular expression flags	NULL

Details about whether arguments can be omitted are as follows.

Argument	Mandatory or optional		
	Full masking	Partial masking	Regular expression masking
schema_name	Y	Y	Y
table_name	N	N	N
policy_name	N	N	N
expression	N	N	N
enable	Y	Y	Y
policy_description	Y	Y	Y

Argument	Mandatory or optional		
	Full masking	Partial masking	Regular expression masking
column_name	Y	Y	Y
function_type	Y	Y	Y
column_description	Y	Y	Y
function_parameters	-	N	-
regexp_pattern	-	-	N
regexp_replacement	-	-	N
regexp_flags	-	-	Y

Y: Can be omitted; N: Cannot be omitted; -: Ignored when specified

Return value

Return value	Description
TRUE	Ended normally
FALSE	Ended abnormally

Execution example 1

Creating masking policy p1 that does not contain a masking target

```
postgres=# select pgx_create_confidential_policy(table_name := 't1', policy_name := 'p1',
expression := '1=1');
 pgx_create_confidential_policy
--------------------------------
 t
(1 row)
```

Execution example 2

Creating masking policy p1 that contains masking target c1 of which the masking type is full masking

```
postgres=# select pgx_create_confidential_policy(schema_name := 'public', table_name := 't1',
policy_name := 'p1', expression := '1=1', enable := 't', policy_description := 'this policy is an
example.', column_name := 'c1', function_type := 'FULL', column_description := 'c1 column is FULL.');
 pgx_create_confidential_policy
--------------------------------
 t
(1 row)
```

Execution example 3

Creating masking policy p1 that contains masking target c2 of which the masking type is partial masking

```
postgres=# select pgx_create_confidential_policy( table_name := 't1', policy_name := 'p1',
expression := '1=1', column_name := 'c2', function_type := 'PARTIAL', function_parameters :=
'VVVFVVVVFVVVV, VVV-VVVV-VVVV, *, 4, 11');
 pgx_create_confidential_policy
--------------------------------
 t
(1 row)
```

Execution example 4

Creating masking policy p1 that contains masking target c3 of which the masking type is regular expression masking

```
postgres=# select pgx_create_confidential_policy( table_name := 't1', policy_name := 'p1',
expression := '1=1', column_name := 'c3', function_type := 'REGEXP', regexp_pattern := '(.*)(@.*)',
regexp_replacement := 'xxx\2', regexp_flags := 'g');
 pgx_create_confidential_policy
--------------------------------
 t
(1 row)
```

Description

- The arguments for the pgx_create_confidential_policy system management function can be specified in any order.
- If column_name is omitted, only masking policies that do not contain masking target will be created.
- One masking policy can be created for each table. Use the pgx_alter_confidential_policy system management function to add a masking target to a masking policy.
- The function_parameters argument is enabled when the function_type is PARTIAL. If the function_type is other than PARTIAL, it will be ignored.
- The arguments below are enabled when the function_type is REGEXP. If the function_type is other than REGEXP, these arguments will be ignored.
  - regexp_pattern
  - regexp_replacement
  - regexp_flags
- If a table for which a masking policy is to be applied is deleted, delete the masking policy as well.

See

- Refer to "String Constants" in the PostgreSQL Documentation for information on the strings to specify for arguments.
- Refer to "POSIX Regular Expressions" in the PostgreSQL Documentation and check pattern, replacement, and flags for information on the values that can be specified for regexp_pattern, regexp_replacement, and regexp_flags.

B.4.3 pgx_drop_confidential_policy

Description

Deletes masking policies

Format

```
pgx_drop_confidential_policy(
[schema_name    := 'schemaName', ]
table_name     := 'tableName',
policy_name    := 'policyName'
)
```

Argument

Details are as follows.

Argument	Data type	Description	Default value
schema_name	varchar(63)	Schema name of table for which a masking policy is deleted	'public'

Argument	Data type	Description	Default value
table_name	varchar(63)	Name of table for which a masking policy is deleted	Mandatory
policy_name	varchar(63)	Masking policy name	Mandatory

Details about whether arguments can be omitted are as follows.

Argument	Mandatory or optional
schema_name	Y
table_name	N
policy_name	N

Y: Can be omitted; N: Cannot be omitted

Return value

Return value	Description
TRUE	Ended normally
FALSE	Ended abnormally

Execution example

Deleting masking policy p1

```
postgres=# select pgx_drop_confidential_policy(table_name := 't1', policy_name := 'p1');
 pgx_drop_confidential_policy
------------------------------
 t
(1 row)
```

Description

- The arguments for the pgx_drop_confidential_policy system management function can be specified in any order.
- If a table for which a masking policy is to be applied is deleted, delete the masking policy as well.

Refer to "String Constants" in the PostgreSQL Documentation for information on the strings to specify for arguments.

B.4.4 pgx_enable_confidential_policy

Description

Enables or disables masking policies

Format

```
pgx_enable_confidential_policy(
[schema_name    := 'schemaName', ]
table_name     := 'tableName',
policy_name    := 'policyName',
enable        := 'policyStatus'
)
```

Argument

Details are as follows.

Argument	Data type	Description	Default value
schema_name	varchar(63)	Schema name of table for which a masking policy is enabled or disabled	'public'
table_name	varchar(63)	Name of table for which a masking policy is enabled or disabled	Mandatory
policy_name	varchar(63)	Masking policy name	Mandatory
enable	boolean	Masking policy status - 't': Enabled - 'f': Disabled	Mandatory

Details about whether arguments can be omitted are as follows.

Argument	Mandatory or optional
schema_name	Y
table_name	N
policy_name	N
enable	N

Y: Can be omitted; N: Cannot be omitted

Return value

Return value	Description
TRUE	Ended normally
FALSE	Ended abnormally

Execution example

Enabling masking policy p1

```
postgres=# select pgx_enable_confidential_policy(table_name := 't1', policy_name := 'p1', enable :=
't');
 pgx_enable_confidential_policy
--------------------------------
 t
(1 row)
```

Description

The arguments for the pgx_enable_confidential_policy system management function can be specified in any order.

See

Refer to "String Constants" in the PostgreSQL Documentation for information on the strings to specify for arguments.

B.4.5 pgx_update_confidential_values

Description

Changes replacement characters when full masking is specified for masking type

Format

```
pgx_update_confidential_values(
[number_value    := 'numberValue']
[, char_value    := 'charValue']
[, varchar_value    := 'varcharValue']
[, date_value    := 'dateValue']
[, ts_value    := 'tsValue']
)
```

Argument

Details are as follows.

Argument	Data type	Description
number_value	integer	Replacement character in numeric type
char_value	varchar(1)	Replacement character in char type
varchar_value	varchar(1)	Replacement character in varchar type
date_value	date	Replacement character in date type
ts_value	timestamp	Replacement character in timestamp type

Return value

Return value	Description
TRUE	Ended normally
FALSE	Ended abnormally

Execution example

Using '*' as a replacement character in char type and varchar type

```
postgres=# select pgx_update_confidential_values(char_value := '*', varchar_value := '*');
 pgx_update_confidential_values
--------------------------------
 t
(1 row)
```

Description

- The arguments for the pgx_update_confidential_values system management function can be specified in any order.
- Specify one or more arguments for the pgx_update_confidential_values system management function. A replacement character is not changed for an omitted argument.

Refer to "String Constants" in the PostgreSQL Documentation for information on the strings to specify for arguments.

B.5 VCI Data Load Control Function

The table below lists the function that loads VCI data to buffer cache.

Table B.4 VCI data load control function

Name	Return type	Description
pgx_prewarm_vci(vci_index regclass)	int8	Loads the VCI data to buffer cache.

pgx_prewarm_vci loads the specified VCI data to buffer cache and returns the number of blocks of the loaded VCI data.

The aggregation process using VCI may take time immediately after an instance is started, because the VCI data has not been loaded to buffer cache. Therefore, the first aggregation process can be sped up by executing pgx_prewarm_vci after an instance is started.

The amount of memory required for preloading is the number of blocks returned by pgx_prewarm_vci multiplied by the size of one block.

This function can only be executed if the user has reference privilege to the VCI index and execution privilege to the pg_prewarm function.

B.6 High-Speed Data Load Control Functions

The table below lists the functions that can be used for high-speed data load.

Table B.5 High-speed data load control functions

Name	Return type	Description
pgx_loader	bigint	Creates dynamic shared memory, starts parallel workers and loads data
pgx_loader_recovery	smallint	Resolves in-doubt transactions

The pgx_loader command executes the above functions internally.

Appendix C System Catalogs

Describes the system catalog of Fujitsu Enterprise Postgres.

See

Refer to "System Catalogs" under "Internals" in the PostgreSQL Documentation for information on other system catalogs.

C.1 pgx_profile

A system catalog for managing profile information. -1 is stored if DEFAULT is specified for each parameter in the profile, and -2 is stored if UNLIMITED is specified.

Column	Type	Description
oid	oid	Profile identifier (Primary key constraint)
prfname	name	Profile name (Unique constraint, NOT NULL constraint)
prfpasswordlifetime	integer	Value of PASSWORD_LIFE_TIME (seconds) (NOT NULL constraint)
prfpasswordgracetime	integer	Value of PASSWORD_GRACE_TIME (seconds) (NOT NULL constraint)
prfpasswordreusetime	integer	Value of PASSWORD_REUSE_TIME (seconds) (NOT NULL constraint)
prfpasswordreusemax	integer	Value of PASSWORD_REUSE_MAX (seconds) (NOT NULL constraint)
prfpasswordlocktime	integer	Value of PASSWORD_LOCK_TIME (seconds) (NOT NULL constraint)
prffailedloginattempts	integer	Value of FAILED_LOGIN_ATTEMPTS (seconds) (NOT NULL constraint)
prfpasswordallowhashed	integer	Value of PASSWORD_ALLOW_HASHED (NOT NULL constraint)
prfinactiveusertime	integer	Value of INACTIVE_USER_TIME (seconds) (NOT NULL constraint)
prfpasswordrollovertime	integer	Value of PASSWORD_ROLLOVER_TIME (seconds) (NOT NULL constraint)

C.2 pgx_user_profile

A system catalog that manages profile-related information associated with users. When DROP ROLE, the corresponding row is automatically deleted.

Column	Type	References	Description
userprfroleid	oid	pg_authid.oid	User's identifier (Primary key constraint)
userprfprfid	oid	pgx_profile.oid	Identifier of the profile assigned to the user
userprfaccountlock	smallint		User lock state (NOT NULL constraint) 0: Not locked

Column	Type	References	Description
			1: Lock (Refer to PASSWORD_LOCK_TIME in profile for duration) 2: Lock (Unlimited)
userprfpasswordstatus	char		Password status Updated if there are any changes at login (NOT NULL constraint) o: Current valid password g: In grace period e: Expired
userprflockdate	timestamp with time zone		Time the user was locked
userprfpasswordsetat	timestamp with time zone		Time you updated your current password
userprfpasswordexpire	timestamp with time zone		Password expiration time
userprflastactivetime	timestamp with time zone		Time the user's session was last checked
userprfpasswordrolloverexpire	timestamp with time zone		Time at which the period in which old and new passwords can be used ends

C.3 pgx_auth_password

The system catalog for storing user-associated password information. Used for password rollover.

Since this catalog contains passwords, it must not be readable by third parties.

Column	Type	References	Description
authpwdroleid	oid	pg_authid.oid	User's identifier (Primary key constraint)
authpwdoldpassword	text		Hashed password Used for authentication when password rollover is enabled.
authpwdoldpasswordsetat	timestamp with time zone		Time at which authpwdoldpassword was set
authpwdnewpassword	text		Hashed password Used for authentication when password rollover is enabled.
authpwdnewpasswordsetat	timestamp with time zone		Time at which authpwdnewpassword was set

C.4 pgx_password_history

A system catalog for managing password history. Used for password reuse confirmation and password rollover. When DROP ROLE is executed, the corresponding row is automatically deleted.

Since this catalog contains passwords, it must not be readable by third parties.

This system catalog is updated when the password is updated, and if the password reuse limit is finite, unnecessary history deletion is also performed. Old passwords that have been removed from the catalog are treated as having never been used.

passhistpassword is saved in the format specified by the password_encryption parameter.

Column	Type	Description
passhistroleid	oid	Identifier of the user whose password was set Set unique constraint with (passhistroleid, passhistpassword).
passhistpassword	text	Encrypted password Save rolpassword value in pg_authid as history (NOT NULL constraint)
passhistpasswordsetat	timestamp with time zone	Time when the password was updated (NOT NULL constraint)

Appendix D System Views

This appendix describes how to use the system views in Fujitsu Enterprise Postgres.

See

Refer to "System Views" under "Internals" in the PostgreSQL Documentation for information on other system views.

D.1 pgx_tablespaces

The pgx_tablespaces view provides information related to the encryption of tablespaces.

Table D.1 pgx_tablespaces view

Column	Type	References	Description
spctablespace	oid	pg_tablespace.oid	Tablespace OID
spcencalgo	text		Tablespace encryption algorithm

The spcencalgo string displays one of the following values:

- none: Tablespace is not encrypted
- AES128: AES with key length of 128 bits
- AES256: AES with key length of 256 bits

D.2 pgx_stat_lwlock

The pgx_stat_lwlock view displays statistics related to lightweight locks, with each type of content displayed on a separate line.

Table D.2 pgx_stat_lwlock view

Column	Type	Description
lwlock_name	name	Name of the lightweight lock
total_waits	bigint	Number of waits caused by the lightweight lock
total_wait_time	double precision	Number of milliseconds spent in waits caused by the lightweight lock
stats_reset	timestamp with timezone	Last time at which this statistics was reset

D.3 pgx_stat_latch

The pgx_stat_latch view displays statistics related to latches, with each type of wait information within Fujitsu Enterprise Postgres displayed on a separate line.

Table D.3 pgx_stat_latch view

Column	Type	Description
latch_name	name	Name of the latch
total_waits	bigint	Number of waits caused a wait
total_wait_time	double precision	Number of milliseconds spent in waits caused by the latch
stats_reset	timestamp with timezone	Last time at which this statistic was reset

D.4 pgx_stat_walwriter

The pgx_stat_walwriter view displays statistics related to WAL writing, in a single line.

Table D.4 pgx_stat_walwriter view

Column	Type	Description
dirty_writes	bigint	Number of times old WAL buffers were written to the disk because the WAL buffer was full when WAL records were added
writes	bigint	Number of WAL writes
write_blocks	bigint	Number of WAL write blocks
total_write_time	double precision	Number of milliseconds spent on WAL writing
stats_reset	timestamp with timezone	Last time at which this statistic was reset

D.5 pgx_stat_sql

The pgx_stat_sql view displays statistics related to SQL statement executions, with each type of SQL statement displayed on a separate line.

Table D.5 pgx_stat_sql view

Column	Type	Description
selects	bigint	Number of SELECT statements executed In database multiplexing mode, this number includes the SELECT statements executed in Mirroring Controller. Mirroring Controller executes the SELECT statement using the interval specified for the heartbeat_interval of the server definition file (milliseconds).
inserts	bigint	Number of INSERT statements executed
deletes	bigint	Number of DELETE statements executed
updates	bigint	Number of UPDATE statements executed
selects_with_parallelism	bigint	Number of times parallel scan was used in SELECT statements
inserts_with_parallelism	bigint	Not used
deletes_with_parallelism	bigint	Not used
updates_with_parallelism	bigint	Not used
copies_with_parallelism	bigint	Not used
declares	bigint	Number of DECLARE statements executed (number of cursor OPENs)
fetches	bigint	Number of FETCH statements executed
checkpoints	bigint	Number of CHECKPOINT statements executed
clusters	bigint	Number of CLUSTER statements executed
copies	bigint	Number of COPY statements executed
reindexes	bigint	Number of REINDEX statements executed
truncates	bigint	Number of TRUNCATE statements executed
locks	bigint	Number of times a lock occurred
stats_reset	timestamp with timezone	Last time at which this statistic was reset

D.6 pgx_stat_gmc

The pgx_stat_gmc view provides information about the GMC areas.

Table D.6 pgx_stat_gmc view

Column	Type	Description
searches	bigint	Number of times the cache table is searched.
hits	bigint	Number of times the cache table is hit.
size	bigint	The current amount of memory (bytes) used in the GMC area.
stats_reset	timestamp with timezone	Last time these statistics were reset.

D.7 pgx_stat_progress_loader

The pgx_stat_progress_loader view provides overall progress information for pgx_loader command.

The pgx_stat_progress_loader view displays the sum of the progress information of the back-end processes and the number of parallel worker processes when pgx_loader runs.

Table D.7 pgx_stat_progress_loader view

Column	Type	Description
pid	integer	Process ID of the backend.
datid	Oid	Oid of the database to connect to.
datname	name	Name of the database to connect to.
relid	Oid	Oid of the table to load.
command	text	Command executes the load process. (Always "COPY FROM"for pgx_loader)
type	text	Type of data source for the load operation.
bytes_processed	bigint	Size of the data at the end of the load. (Backend and worker totals)
bytes_total	bigint	Size of the data to load. (Backend and worker totals)
tuples_processed	bigint	Number of rows that have completed loading. (Backend and worker totals)
tuples_excluded	bigint	Number of rows skipped during the load process. (Backend and worker totals)

Appendix E Tables Used by Transparent Data Encryption

This appendix explains tables tables used by the transparent data encryption feature.

E.1 pgx_tde_master_key

Provides information about the master encryption key being used when using the key management system as a keystore.

Column	Type	Description
local_key_id	integer	Sequence of encryption keys used internally by Fujitsu Enterprise Postgres
kms_name	text	Key management system name
key_name	text	Not currently used
key_id	text	Key ID in key management system
start_time	timestamp	Time the key was activated
status	enum	in-use: Current master encryption key in use used: Master encryption key used in the past scheduled: A new encryption key that was requested to update the master encryption key and is to be used.

Execution example

```
postgres=# select * from pgx_tde_master_key;
local_key_id | kms_name  | key_name|              key_id                  |     start_time     | status
-------------+-----------+--------+--------------------------------------+--------------------+-----
           1  | mykmipsvr |        | a0eebc99-9c0b-0000-0000-000000000000 |2022-12-16 05:43:49| in-use
(1 row)
```

Information

Do not use queries with "*" in the selection list, as the order of the columns may change or columns may be added.

Appendix F Tables Used by Data Masking

This appendix explains tables used by the data masking feature.

Information

These tables are updated by the data masking control function, so do not use SQL statements to directly update these tables.

F.1 pgx_confidential_columns

This table provides information on masking target for which masking policies are set.

Column	Type	Description
schema_name	varchar(63)	Schema name of table for which a masking policy is applied
table_name	varchar(63)	Name of table for which a masking policy is applied
policy_name	varchar(63)	Masking policy name
column_name	varchar(63)	Masking target name
function_type	varchar(63)	Masking type - 'FULL': Full masking - 'PARTIAL': Partial masking - 'REGEXP': Regular expression masking
function_parameters	varchar(1024)	Masking format for partial masking
regexp_pattern	varchar(1024)	Search pattern for regular expression masking
regexp_replacement	varchar(1024)	Replacement character/string for regular expression masking
regexp_flags	varchar(20)	Regular expression flags
column_description	varchar(1024)	Masking target description

Execution example

```
postgres=# select * from pgx_confidential_columns;
 schema_name | table_name | policy_name | column_name | function_type |
function_parameters           | regexp_pattern | regexp_replacement | regexp_flags |
column_description
-------------+------------+-------------+-------------+---------------
+---------------------------------------+----------------+--------------------+-------------
+--------------------
 public      | t1         | p1          | c1          | FULL          |
|                |                     |             |
 public      | t1         | p1          | c2          | PARTIAL       | VVVFVVVVFVVVV, VVV-VVVV-VVVV,
*, 4, 11 |                |                     |             |
(2  row)
```

F.2 pgx_confidential_policies

This table provides information on masking policies.

Column	Type	Description
schema_name	varchar(63)	Schema name of table for which a masking policy is applied

Column	Type	Description
table_name	varchar(63)	Name of table for which a masking policy is applied
policy_name	varchar(63)	Masking policy name
expression	varchar(1024)	Masking condition
enable	boolean	Masking policy status - 't': Enabled - 'f': Disabled
policy_description	varchar(1024)	Masking policy description

Execution example

```
postgres=# select * from pgx_confidential_policies;
 schema_name | table_name | policy_name | expression | enable | policy_description
-------------+------------+-------------+------------+--------+--------------------
 public      | t1         | p1          | 1=1        | t      |
(1 row)
```

F.3 pgx_confidential_values

This table provides information on replacement characters when full masking is specified for masking type.

Column	Data type	Description	Default value
number_value	integer	Numeric	0
char_value	varchar(1)	char type	Spaces
varchar_value	varchar(1)	varchar type	Spaces
date_value	date	date type	'1970-01-01'
timestamp_value	timestamp	timestamp type	'1970-01-01 00:00:00'

Execution example

```
postgres=# select * from pgx_confidential_values;
 number_value | char_value | varchar_value | date_value |      ts_value
--------------+------------+---------------+------------+---------------------
            0 |            |               | 1970-01-01 | 1970-01-01 00:00:00

```

Appendix G Tables Used by Aggressive Freeze for Tuples

This appendix explains tables used by the aggressive freeze for tuples feature.

G.1 pgx_stat_freeze_results

The table pgx_stat_freeze_results logs statistics about aggressive freeze for tuples. If an aggressive freeze for tuples is performed, that information will be added as an accumulation. The cumulative information is summarized for the time period specified by the pgx_stat_vacuum_freeze.monitoring_interval parameter, and the information for the time period specified by the pgx_stat_vacuum_freeze.log_retention_period parameter is kept. For the information about the pgx_stat_vacuum_freeze.monitoring_interval and pgx_stat_vacuum_freeze.log_retention_period parameters, refer to "Parameters for scheduling aggressive freeze for tuples".

You can gather information to determine how long the aggressive freeze for tuples process is taking, and help estimate the aggressive freeze for tuples schedule.

Column	Type	Description
measurement_start_time	timestamp with time zone	Start time of the measurement
measurement_end_time	timestamp with time zone	End time of the measurement
vacuum_count	bigint	Number of times the freeze operation was performed
autovacuum	boolean	true for autovacuum driven vacuum
scan_pages	bigint	Accumulation of pages scanned during freezing
frozen_pages	bigint	Accumulation of frozen pages
frozen_tuples	bigint	Accumulation of frozen tuples
total_frozen_wal_records	bigint	Accumulation of the number of WAL records produced by freezing
frozen_full_page_image_wal_records	bigint	Accumulation of the number of WAL full-page images produced by freezing
wal_total_bytes	numeric	Accumulation, in bytes, of WAL generated by freezing
total_elapsed_time	double precision	Accumulation of freezing time. Units are milliseconds
sleep_times	double precision	Accumulation of time spent sleeping during freezing. Units are milliseconds

Appendix H Tables Used by High-Speed Data Load

This appendix describes the tables used by high-speed data load.

H.1 pgx_loader_state

The pgx_loader_state table provides information about transactions prepared by high-speed data load.

Column	Type	Description
id	serial	Unique identifier. This value is assigned from the pgx_loader_state_id_seq sequence.
gid	text	Global transaction identifier assigned to a transaction.
state	text	State of the transaction. The value can be one of the following: - commit: The prepared transaction has been committed. - rollback: The prepared transaction is in in-doubt state.
leader_pid	integer	Process ID of the backend process (leader process) that executed the pgx_loader control function.
role_oid	integer	Role identifier (OID). A prepared transaction can only be completed by the same user who executed the original transaction or by a superuser.
relation_oid	integer	Object identifier (OID).

Information

The pgx_loader_state table and pgx_loader_state_id_seq sequence are updated by high-speed data load. Do not update these database objects directly using SQL.

Appendix I Starting and Stopping the Web Server Feature of WebAdmin

To use WebAdmin for creating and managing a Fujitsu Enterprise Postgres instance on a server where Fujitsu Enterprise Postgres is installed, you must first start the Web server feature of WebAdmin.

- Using WebAdmin in a single-server configuration

  You must start the Web server on the server on which Fujitsu Enterprise Postgres and WebAdmin are installed.

- Using WebAdmin in a multiserver configuration

  You must start the Web server on all servers on which WebAdmin has been installed.

This appendix describes how to start and stop the Web server feature of WebAdmin.

Note that "<*x*>" in paths indicates the product version.

See

Refer to "Installing WebAdmin in a Multiserver Configuration" in the Installation and Setup Guide for Server for information on multiserver installation.

I.1 Starting the Web Server Feature of WebAdmin

Follow the procedure below to start the Web server feature of WebAdmin.

1. Change to superuser

   Acquire superuser privileges on the system.

   Example

   ```
   $ su -
   Password:******
   ```

2. Start the Web server feature of WebAdmin

   Execute the WebAdminStart command to start the Web server feature of WebAdmin.

   Example

   If WebAdmin is installed in /opt/fsepv<*x*>webadmin:

   ```
   # cd /opt/fsepv<x>webadmin/sbin
   # ./WebAdminStart
   ```

I.2 Stopping the Web Server Feature of WebAdmin

This section describes how to stop the Web server feature of WebAdmin.

Follow the procedure below to stop the Web server feature of WebAdmin.

1. Change to superuser

   Acquire superuser privileges on the system.

   Example

   ```
   $ su -
   Password:******
   ```

2. Stop the Web server feature of WebAdmin

   Execute the WebAdminStop command to stop the Web server feature of WebAdmin.

Example

If WebAdmin is installed in /opt/fsepv<*x*>webadmin:

```
# cd /opt/fsepv<x>webadmin/sbin
# ./WebAdminStop
```

Appendix J WebAdmin Wallet

This appendix describes how to use the Wallet feature of WebAdmin.

When a remote instance or a standby instance is created, it is necessary to provide user name and password for authentication with the remote machine or the database instance.

The Wallet feature in WebAdmin is a convenient way to create and store these credentials.

Once created, these credentials can be repeatedly used in one or more instances.

J.1 Creating a Credential

1. In the [My Wallet] tab, click . The [New credential] page will be displayed.
2. Enter the information for the credentials.

   Credential name, User name and Password should not contain hazardous characters. Refer to "Appendix K WebAdmin Disallow User Inputs Containing Hazardous Characters".

   - [Credential name]: Name of the credential

     The name must meet the conditions below:

     - Maximum of 16 characters
     - The first character must be an ASCII alphabetic character
     - The other characters must be ASCII alphanumeric characters

   - [User name]: The operating system user name or database instance user name that will be used later
   - [Password]: Password for the user
   - [Confirm password]: Reenter the password.
3. Click to store the credential.

J.2 Using a Credential

Once a credential is created in the Wallet, it can be used during remote instance creation or standby instance creation.

If you select the credential saved in "J.1 Creating a Credential" in [Operating system credential], the user name and password will be automatically populated.

Appendix K WebAdmin Disallow User Inputs Containing Hazardous Characters

WebAdmin considers the following as hazardous characters, which are not allowed in user inputs.

```
| (pipe sign)

& (ampersand sign)

; (semicolon sign)

$ (dollar sign)

% (percent sign)

@ (at sign)

' (single apostrophe)

" (quotation mark)

\' (backslash-escaped apostrophe)

\" (backslash-escaped quotation mark)

<> (triangular parenthesis)

() (parenthesis)

+ (plus sign)

CR (Carriage return, ASCII 0x0d)

LF (Line feed, ASCII 0x0a)

, (comma sign)

\ (backslash)
```

Appendix L Copy Command Samples that Use the Advanced Copy Feature of the ETERNUS Disk Array

Backup/recovery scripts that use OPC, an advanced copy feature of the Fujitsu Storage ETERNUS disk array (hereafter referred to as ETERNUS disk array), are supplied as copy command samples for use by the pgx_dmpall and pgx_rcvall commands.

Users can copy the samples to any file and make changes appropriate to their environment or operations.

The samples are stored in the directories below:

- Basic version

```
/installDir/share/copy_command.esf_acm1.sh.sample
```

- Advanced version

```
/installDir/share/copy_command.esf_acm2.sh.sample
```

See

The samples use the replication management command of the Fujitsu Storage ETERNUS SF AdvancedCopy Manager (hereafter referred to as ACM) for operating the advanced copy features of the ETERNUS disk array. Refer to the relevant manual for details.

Prerequisite for using the samples

To use the samples, it is necessary to configure the settings of the advanced copy features of the ETERNUS disk array in advance. The samples assume that the replication source/volume has been configured, its contents have been physically copied to the replication volume, and that the tracking process has been started.

The samples cannot be used on SLES 15. The samples use the sudo command of the operating system so that operation of the commands and file systems of ACM is performed by the superuser of the operating system. Therefore, determine if these implementations satisfy the security standards on the database server, and if necessary, perform implementations using other means.

Sample content (advanced version)

The sample uses two replication volumes as the replication source on which the database cluster and tablespace are located, alternating between them for each backup. It then registers to the backup information file the replication volume (group) used for the latest backup.

In addition, the backup information file is also used to determine the replication volume to restore during recovery.

The processing for each operation mode is described below:

prepare mode

1. The backup information file is read, and the replication volume to be used for the current backup is determined.
2. The completion status of physical copies to all replication volumes is checked using the swsrpstat command of ACM.
3. The replication volume determined in step 1 is written to a temporary file for later use by the backup mode.

backup mode

1. The temporary file is read, and the replication volume information is retrieved.
2. The file system buffer is written using the sync command of the operating system.
3. The file system targeted for backup is frozen using the fsfreeze command of the operating system.
4. Snapshot retrieval (implementation of a logical copy) is performed using the swsrpmake command of ACM.
5. The file system frozen in step 3 is unfrozen using the fsfreeze command of the operating system.

   Steps 3 to 5 are performed for all file systems targeted for backup.

finalize mode

1. The completion status of physical copies to all replication volumes is checked using the swsrpstat command of ACM.
2. Information about the replication volume used for the current backup is written to the backup information file.

restore mode

1. The backup information file is read, and the replication volume to be used for recovery is determined.
2. The file system targeted for recovery is unmounted using the umount command of the operating system.
3. Physical copy from the replication volume is performed using the swsrpmake command of ACM.
4. The file system targeted for recovery is mounted using the mount command of the operating system.
5. The completion status of physical copy from the replication volume is checked using the swsrpstat command of ACM.

   Steps 2 to 5 are performed for all file systems targeted for recovery.
6. Files and directories not needed for archive recovery are deleted.

Information

The samples temporarily freeze the file system of the data storage destination (replication source volume) to protect the file system from copy processing by advanced copy features of the ETERNUS disk array. Therefore, consider the following:

- Consider freeze time during the timeout period of an SQL statement.

  When using a feature that links with the database, such as a cluster feature that accesses the data storage destination, consider freeze time in relation to the timeout periods below.

  - When performing database multiplexing

    Misdetection may occur during abnormality monitoring, so it is necessary to consider the monitoring interval, timeout period and number of retries for abnormality monitoring, and consider temporarily stopping only the Mirroring Controller process during backup.

  - When performing failover operations using PRIMECLUSTER

    If a failure occurs while the file system is frozen, switching is triggered when PRIMECLUSTER detects an issue, but will be performed only after the system is unfrozen. In addition, if it takes time for the system to unfreeze, the active node may trigger operating system panic, resulting in a switch.

Appendix M Collecting Failure Investigation Data

For information on collecting failure investigation data, refer to "Collecting Failure Investigation Data" in the Installation and Setup Guide for Server.

FUJITSU

Fujitsu Enterprise Postgres 18SP1 for x86

Operation Guide

Windows

B1WS-1497-02ENZ0(00)

March-2026

Preface

Purpose of this document

The Fujitsu Enterprise Postgres database system extends the PostgreSQL features and runs on the Windows platform.

This document is the Fujitsu Enterprise Postgres Operation Guide.

Intended readers

This document is intended for those who install and operate Fujitsu Enterprise Postgres.

Readers of this document are assumed to have general knowledge of:

- PostgreSQL
- SQL
- Windows

Structure of this document

This document is structured as follows:

Chapter 1 Operating Fujitsu Enterprise Postgres

Describes how to operate Fujitsu Enterprise Postgres.

Chapter 2 Starting an Instance and Creating a Database

Describes how to start a Fujitsu Enterprise Postgres instance, and how to create a database.

Chapter 3 Backing Up the Database

Describes how to back up the database.

Chapter 4 Configuring Secure Communication Using Secure Sockets Layer

Describes communication data encryption between the client and the server.

Chapter 5 Protecting Storage Data Using Transparent Data Encryption

Describes how to encrypt the data to be stored in the database.

Chapter 6 Policy-based Login Security

Describes how to apply login security policies to users.

Chapter 7 Data Masking

Describes the data masking feature.

Chapter 8 Periodic Operations

Describes the periodic database operations that must be performed on Fujitsu Enterprise Postgres.

Chapter 9 Streaming Replication Using WebAdmin

Describes how to create a streaming replication cluster using WebAdmin.

Chapter 10 Installing and Operating the In-memory Feature

Describes how to install and operate the in-memory feature.

Chapter 11 Parallel Query

Describes the factors taken into consideration by Fujitsu Enterprise Postgres when performing parallel queries.

Chapter 12 High-Speed Data Load

Describes how to install and operate high-speed data load.

Chapter 13 Global Meta Cache

Describes how to use Grobal Meta Cache feature.

Chapter 14 Local Meta Cache Limit

Describes how to use Local Meta Cache Limit feature.

Chapter 15 Backup/Recovery Using the Copy Command

Describes backup and recovery using the copy command created by the user.

Chapter 16 Actions when an Error Occurs

Describes how to perform recovery when disk failure or data corruption occurs.

Appendix A Parameters

Describes the Fujitsu Enterprise Postgres parameters.

Appendix B System Administration Functions

Describes the system administration functions of Fujitsu Enterprise Postgres.

Appendix C System Catalogs

Describes the system catalog used by Fujitsu Enterprise Postgres.

Appendix D System Views

Describes the system view used by Fujitsu Enterprise Postgres.

Appendix E Tables Used by Data Masking

Describes the tables used by the data masking feature.

Appendix F Tables Used by Aggressive Freeze for Tuples

Describes the tables used by the agressive freeze for tuples.

Appendix G Tables Used by High-Speed Data Load

Describes the tables used by high-speed data load.

Appendix H Starting and Stopping the Web Server Feature of WebAdmin

Describes how to start and stop WebAdmin (Web server feature).

Appendix I WebAdmin Wallet

Describes how to use the Wallet feature of WebAdmin.

Appendix J WebAdmin Disallow User Inputs Containing Hazardous Characters

Describes characters not allowed in WebAdmin.

Appendix K Collecting Failure Investigation Data

Describes how to collect information for initial investigation.

Export restrictions

Exportation/release of this document may require necessary procedures in accordance with the regulations of your resident country and/or US export control laws.

Chapter 1 Operating Fujitsu Enterprise Postgres

This chapter describes how to operate Fujitsu Enterprise Postgres.

1.1 Operating Methods

There are two methods of managing Fujitsu Enterprise Postgres operations:

- Operation management using GUI tools
- Operation management using commands

Operation management using GUI tools

This involves managing operations using the WebAdmin and pgAdmin GUI tools.

- Management using WebAdmin

  This removes the requirement for complex environment settings and operational design for backup and recovery that is usually required for running a database. It enables you to easily and reliably monitor the state of the database, create a streaming replication cluster, back up the database, and restore it even if you do not have expert knowledge of databases.

- Management using pgAdmin

  When developing applications and maintaining the database, you can use pgAdmin to perform simple operations on database objects, such as:

  - Rebuild indexes and update statistics
  - Create, delete, and update database objects

  In addition, from pgAdmin of Fujitsu Enterprise Postgres, you can use the expanded features provided by Fujitsu Enterprise Postgres on the PostgreSQL SQL commands.

See

Refer to pgAdmin Help for information on the expanded features of pgAdmin provided by Fujitsu Enterprise Postgres.

Operation management using commands

You can use commands for configuring and operating the database and managing operations.

Points to consider when choosing an operation method

- You cannot combine WebAdmin and server commands to perform the following operations:
  - Use commands to operate an instance created using WebAdmin.
  - Use WebAdmin to recover a database backed up using commands.

  For instances created with WebAdmin, however, backup can be obtained with the pgx_dmpall command. Also, WebAdmin can perform recovery by using the backup obtained with the pgx_dmpall command.

- To operate an instance created using the initdb command in WebAdmin, the instance needs to be imported using WebAdmin.
- You can perform backup and restoration in pgAdmin, but the backup data obtained with WebAdmin and pgx_dmpall is not compatible with the backup data obtained with pgAdmin.

Features used in each phase

The following table lists the features used in each phase for GUI-based operations and command-based operations.

Operation		Operation with the GUI	Operation with commands
Setup	Creating an instance	WebAdmin is used. The server machine capacity, and the optimum parameter for operations using WebAdmin, are set automatically.	The configuration file is edited directly using the initdb command.
	Creating a standby instance	WebAdmin is used. WebAdmin performs a base backup of the source instance and creates a standby instance.	A standby instance is created using the pg_basebackup command.
	Changing the configuration files	WebAdmin is used.	The configuration file is edited directly.
Starting and stopping an instance		WebAdmin is used.	The net command or sc command of the operating system is used.
Creating a database		This is defined using pgAdmin of the GUI tool, or using the psql command or the application after specifying the DDL statement.	
Backing up the database		WebAdmin, or the pgx_dmpall command, is used.	It is recommended that the pgx_dmpall command be used. Recovery to the latest database can be performed.
Database recovery		WebAdmin is used.	To use the backup that was performed using the pgx_dmpall command, the pgx_rcvall command is used.
Monitoring	Database errors	The status in the WebAdmin window can be checked. (*1)	The messages that are output to the database server log are monitored (*1)
	Disk space	The status in the WebAdmin window can be checked. A warning will be displayed if the free space falls below 20%. (*1)	This is monitored using the fsutil command (check free space), and the dir command (check used space), of the operating system, for example. (*1)
	Connection status	This can be checked using pgAdmin of the GUI tool, or referencing pg_stat_activity of the standard statistics view from psql or the application.	

*1: This can be used together with system log monitoring using operations management middleware (Systemwalker Centric Manager, for example).

1.2 Starting WebAdmin

This section describes how to start and log in to WebAdmin.

About using WebAdmin

- It is recommended to use the following browsers with WebAdmin:
  - Microsoft Edge

    WebAdmin will work with other browsers, such as Firefox and Chrome, however, the look and feel may be slightly different.
- You must start the Web server feature of WebAdmin before using WebAdmin. Refer to "Appendix H Starting and Stopping the Web Server Feature of WebAdmin" for information on how to start the Web server feature of WebAdmin.

1.2.1 Logging in to WebAdmin

This section describes how to log in to WebAdmin.

Startup URL for WebAdmin

In the browser address bar, type the startup URL of the WebAdmin window in the following format:

```
http://hostNameOrIpAddress:portNumber/
```

- *hostNameOrIpAddress*: The host name or IP address of the server where WebAdmin is installed.
- *portNumber*: The port number of WebAdmin. The default port number is 27515.

Example

For a server with IP address "192.0.2.0" and port number "27515"

```
http://192.0.2.0:27515/
```

Display the startup windows. From this window you can log in to WebAdmin or access the product documentation.

Log in to WebAdmin

Click [Launch WebAdmin] in the startup URL window to start WebAdmin and display the login window.

To log in, specify the following values:

- [User name]: User name (OS user account) of the instance administrator
- [Password]: Password corresponding to the user name

1.3 Starting pgAdmin

This section describes how to start pgAdmin, how to add an instance required for managing a database, and how to connect to and disconnect from the instance.

You can use pgAdmin on the Windows client.

About using pgAdmin

- You must start the instance to be connected to before using pgAdmin. Refer to "2.1 Starting and Stopping an Instance" for information on how to start an instance.
- When using pgAdmin4 with Microsoft Edge, enable network access by loopback in Microsoft Edge. Also, add Microsoft Edge to the loopback exclusion list.

1.3.1 Starting pgAdmin

Click [Start] >> [All apps] >> [Fujitsu Enterprise Postgres Client(64bit) <*x*>] and start [pgAdmin 4 (64bit) (<*x*>)].

Note that "<x>" indicates the product version. Also, the shortcuts displayed in the [Start] menu may be arranged differently depending on the operating system.

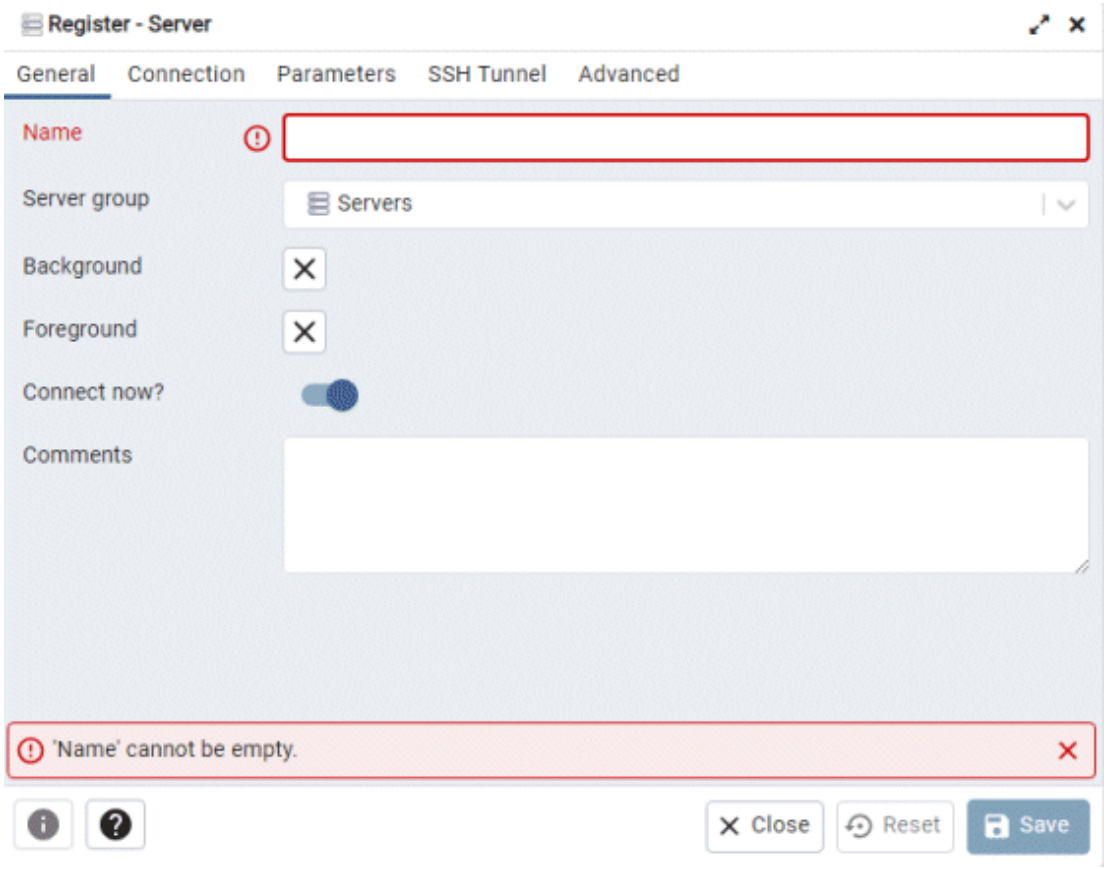
1.3.2 Adding an Instance

This section describes how to add an instance to be connected to.

If you use a link-local address with version 6 of the TCP/IP protocol, you may encounter the following error when registering the server with pgAdmin. Therefore, do not use link-local addresses.

```
unsupported format character '"' (0x22) at index 96
```

1. In the [Browser] pane, right-click [Servers], and then click [Register] >> [Server...].
2. In the [Register - Server] window, specify a value for each item.



[General] tab

- [Name]: Name of the instance to be managed

[Connection] tab

- [Host name/address]: Host name or IP address of the server where Fujitsu Enterprise Postgres is installed
- [Port]: Port number of the instance
- [Maintenance database]: Database name to which the client will connect
- [Username]: User name of the instance administrator
- [Password]: Password for the user name specified in [Username]

Point

If you select [Save password], the Fujitsu Enterprise Postgres connection password is stored in the following location. Set the appropriate access permissions for the password file to protect it from unauthorized access.

- %APPDATA%\Roaming\pgAdmin\pgadmin4.db

1.3.3 Connecting/Disconnecting an Instance

This section describes how to connect pgAdmin to an instance, and how to disconnect it.

To connect to an instance created using WebAdmin, you must first configure the settings in the [Client authentication] window of WebAdmin to permit connection from pgAdmin.

See

Refer to "Changing the settings" in the Installation and Setup Guide for Server for information on the [Client authentication] window of WebAdmin.

Connecting to an instance

Starting pgAdmin does not connect it to any instance.

To connect to an instance, in the [Browser] pane, right-click the server, and then click [Connect Server].

If a password was not saved when the instance was added, enter a password in the password entry window that is displayed.

Disconnecting from an instance

To disconnect from an instance, in the [Browser] pane, right-click the server, and then click [Disconnect from Server].

1.3.4 Changing the pgAdmin Display Language

This section describes the procedure for changing the display language of pgAdmin.

1. Start pgAdmin.
2. Click [File] >> [Preferences].
3. Click [Miscellaneous] >> [User language] in the left pane of the [Preferences] dialog.
4. Select the language you want to display from the [User language] drop-down list displayed in the right pane, and click the [Save] button.
5. Refresh page by clicking the [Refresh] button.

1.4 Operations Using Commands

You can operate and manage the database using the following commands:

- Server commands

  This group of commands includes commands for creating a database cluster and controlling the database. You can run these commands on the server where the database is operating.

  To use these commands, you must configure the environment variables.

  See

  - Refer to "PostgreSQL Server Applications" under "Reference" in the PostgreSQL Documentation, or "Reference" for information on server commands.
  - Refer to "Configure the environment variables" in the procedure to create instances in "Using the initdb Command" in the Installation and Setup Guide for Server for information on configuring the environment variables.

- Client commands

  This group of commands includes the psql command and commands for extracting the database cluster to a script file. These commands can be executed on the client that can connect to the database, or on the server on which the database is running.

  To use these commands, you must configure the environment variables.

  See

  - Refer to "PostgreSQL Client Applications" under "Reference" in the PostgreSQL Documentation, or "Reference" for information on client commands.

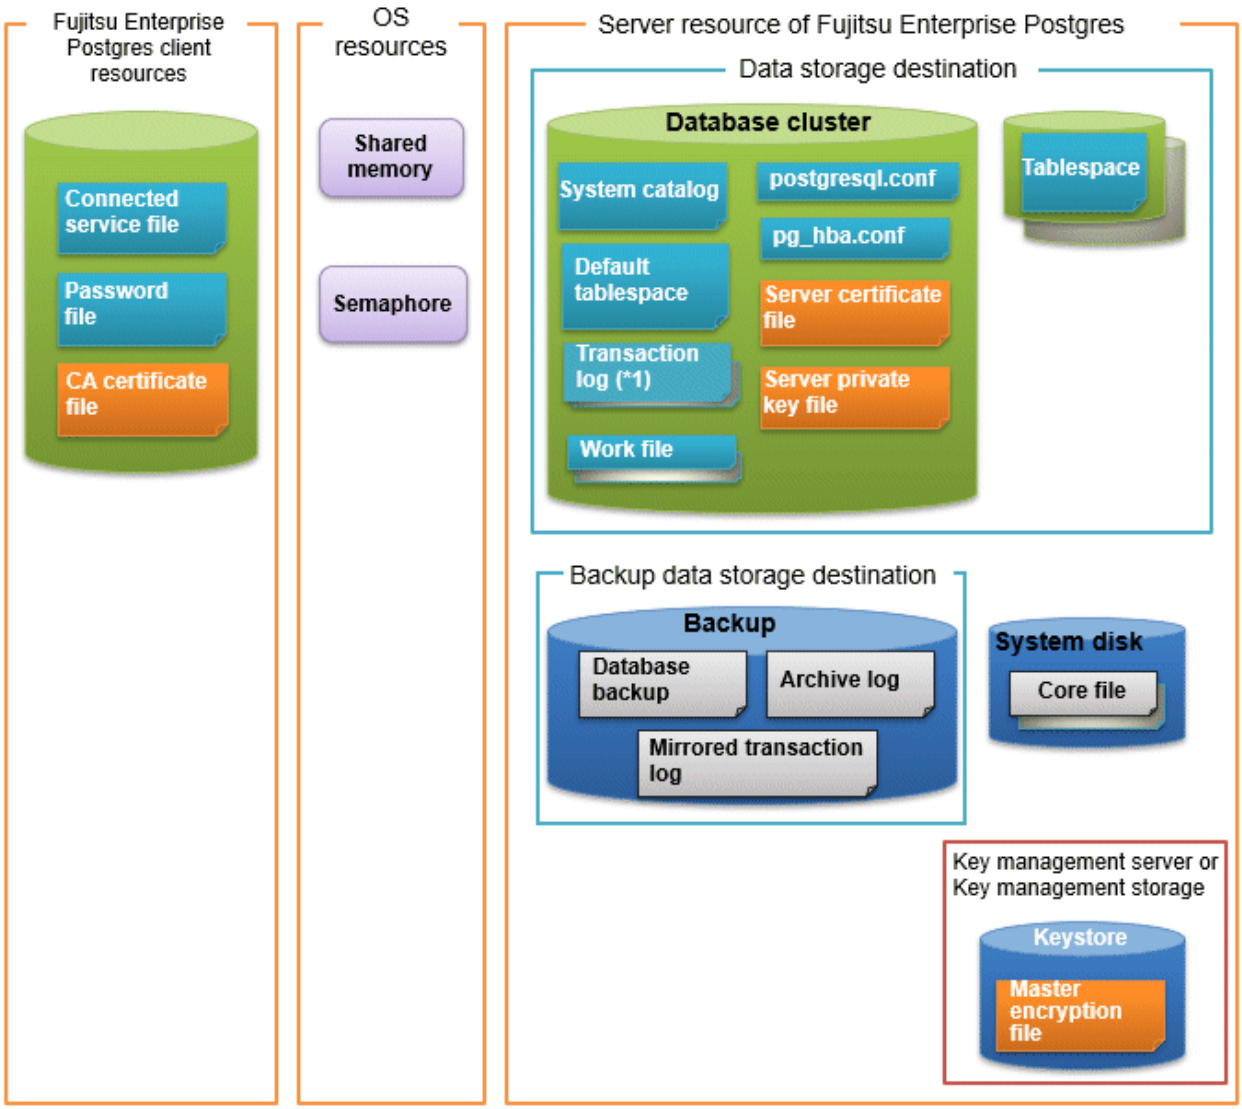
- Refer to "Configuring Environment Variables" in the Installation and Setup Guide for Client for information on the values to be set in the environment variables.

1.5 Operating Environment of Fujitsu Enterprise Postgres

This section describes the operating environment and the file composition of Fujitsu Enterprise Postgres.

1.5.1 Operating Environment

The following figure shows the configuration of the Fujitsu Enterprise Postgres operating environment. The tables given below list the roles of the OS resources and Fujitsu Enterprise Postgres resources.



*1: To distribute the I/O load, place the transaction log on a different disk from the data storage destination.

Table 1.1 OS resources

Type	Role
Shared memory	Used when a database process exchanges information with an external process.
Semaphore	

Table 1.2 Fujitsu Enterprise Postgres client resources

Type	Role
Connection service file	Specifies information, such as the host name, user name, and password, for connecting to Fujitsu Enterprise Postgres.
Password file	Securely manages the password for connecting to Fujitsu Enterprise Postgres.
CA certificate file	CA (certificate authority) certificate used for server authentication when encrypting communication data.

Table 1.3 Server resources of Fujitsu Enterprise Postgres

Type	Role
Database cluster	Database storage area on the database storage disk. It is a collection of databases managed by an instance.
System catalog	Contains information required for the system to run, including the database definition information and the operation information created by the user.
Default tablespace	Contains table files and index files stored by default.
Transaction log	Contains log information in case of a crash recovery or rollback. This is the same as the WAL (Write Ahead Log).
Work file	Work file used when executing applications or commands.
postgresql.conf	Contains information that defines the operating environment of Fujitsu Enterprise Postgres.
pg_hba.conf	Fujitsu Enterprise Postgres uses this file to authenticate individual client hosts.
Server certificate file	Contains information about the server certificate to be used when encrypting communication data and authenticating a server.
Server private key file	Contains information about the server private key to be used when encrypting communication data and authenticating a server
Tablespace	Stores table files and index files in a separate area from the database cluster. Specify a space other than that under the database cluster.
Backup	Stores the data required for recovering the database when an error, such as disk failure, occurs.
Database backup	Contains the backup data for the database.
Archive log	Contains the log information for recovery.
Mirrored transaction log (mirrored WAL)	Enables a database cluster to be restored to the state immediately before an error even if both the database cluster and transaction log fail when performing backup/recovery operations using the pgx_dmpall command or WebAdmin. Mirrored WALs can be used only for backup/recovery using the pgx_dmpall command or WebAdmin.
Core file	Fujitsu Enterprise Postgres process core file that is output when an error occurs during a Fujitsu Enterprise Postgres process.
Key management server or key management storage	Server or storage where the master encryption key file is located.
Master encryption key file	Contains the master encryption key to be used when encrypting storage data. The master encryption key file is managed on the key management server or key management storage.

1.5.2 File Composition

Fujitsu Enterprise Postgres consists of the following files for controlling and storing the database. The table below shows the relationship between the number of such files and their location within a single instance.

Table 1.4 Number of files within a single instance and how to specify their location

File type	Required	Quantity	How to specify the location
Program files	Y	Multiple	Note that "<*x*>" indicates the product version. By default, the following location is used: %Program Files%\Fujitsu\fsepv<*x*>server64
Database cluster	Y	1	Specify using WebAdmin or server commands.
Tablespace	Y	Multiple	Specify a space other than that under the database cluster, using pgAdmin or the DDL statement.
Backup	Y	Multiple	Specify using WebAdmin or server commands.
Core file	Y	Multiple	Specify using WebAdmin, server commands, or postgresql.conf.
Server certificate file (*1)	N	1	Specify using postgresql.conf.
Server private key file (*1)	N	1	Specify using postgresql.conf.
Master encryption key file (*1)	N	1	Specify the directory created as the key store using postgresql.conf.
Connection service file (*1)	N	1	Specify using environment variables.
Password file (*1)	N	1	Specify using environment variables.
CA certificate file (*1)	N	1	Specify using environment variables.

Y: Mandatory
N: Optional

*1: Set manually when using the applicable feature.

Information

If you are using antivirus software, refer to "1.5.3 Precautions when Using Antivirus Software".

1.5.3 Precautions when Using Antivirus Software

If anti-virus software is used, the instance might not start or not respond during operation, and proper operation of the database might not be guaranteed. To avoid such troubles, it is necessary to change the settings of the antivirus software so that virus scans are not executed on the active database.

Do scan exclusion for directories so that all files that comprise Fujitsu Enterprise Postgres are excluded from virus scanning. Alternatively, if the files that comprise Fujitsu Enterprise Postgres are to be scanned for viruses, stop Fujitsu Enterprise Postgres and perform the scan when tasks that use Fujitsu Enterprise Postgres are not operating.

However, setting exclusions for scans poses a risk of missing malware that should be detected by antivirus software. To meet the security requirements necessary for system operation, implement risk countermeasures against malware threats across the entire system. Consider the following measures, for example:

- Introduce WAF, IPS, and IDS to prevent unauthorized access to the database server across the entire system.

- Disable unnecessary features, services, and protocols in the OS and network you use, and always obtain and apply the latest patches to prevent malware intrusion.
- Enable access log acquisition for the OS and database to detect data tampering or leakage caused by malware.
- Perform regular backups to ensure recovery from backups in case data is tampered with.
  For backup methods of Fujitsu Enterprise Postgres, refer to "Chapter 3 Backing Up the Database".

1.6 Notes on Compatibility of Applications Used for Operations

When you upgrade Fujitsu Enterprise Postgres to a newer version, there may be some effect on applications due to improvements or enhancements in functionality.

Take this into account when creating applications so that you can maintain compatibility after upgrading to a newer version of Fujitsu Enterprise Postgres.

See

Refer to "Notes on Application Compatibility" in the Application Development Guide for details.

1.7 Notes on Upgrading Database Instances

If you are upgrading a database instance that uses the extensions, follow the procedure below to upgrade according to the source product version.

When migrating from a database instance of FUJITSU Enterprise Postgres 10 or later

If you are using pg_upgrade to upgrade a database instance from FUJITSU Enterprise Postgres 10 or later that uses the extensions, follow the procedure below to upgrade.

It is strongly recommended to back up the database using pg_dump before performing pg_upgrade.

1. Create a database cluster at the destination
2. Stop the source and destination instances
3. Run the pg_upgrade command
4. Start the destination instance
5. Update the extensions used with ALTER EXTENSION to the latest version at the destination

   ```
   ALTER EXTENSION extensionName UPDATE;
   ```

   If you are using multiple extensions, update each extension separately.

See

For information about pg_upgrade and ALTER EXTENSION, refer to "Reference" in the PostgreSQL Documentation.

When migrating from a database instance of FUJITSU Enterprise Postgres 9.x

The following describes the tasks required to upgrade a database instance of FUJITSU Enterprise Postgres 9.x using the extension with pg_upgrade.

It is strongly recommended to back up the database using pg_dump before performing pg_upgrade or using DROP EXTENSION.

Before running pg_upgrade, remove the following extensions from all databases of the instance, except for "template0". If a column was created in the user table using the following extended data types, "DROP EXTENSION" will also drop that column:. In such cases you might need to consider alternative upgrade methods rather than pg_upgrade. In that case, consider using pg_dump or pg_restore.

- pg_stat_statements

- pgx_io
- pgx_paging
- pgx_network
- pgx_network_err
- pgx_cpu
- pgx_memory
- pgx_swap
- pgx_disk
- pgx_process
- pgx_log
- oracle_compatible
- pg_dbms_stats
- pg_hint_plan

For all databases except "template0", execute the following command to remove these extensions:

```
DROP EXTENSION extensionName;
```

Once the pg_upgrade operation is complete, for all databases except "template0", execute the following command to re-create these extensions as required:

```
CREATE EXTENSION extensionName;
```

See

For information about pg_upgrade, DROP EXTENSION and CREATE EXTENSION, refer to "Reference" in the PostgreSQL Documentation.

1.7.1 Additional Steps for upgrading to Fujitsu Enterprise Postgres with Vertical Clustered Index (VCI) Enabled

When upgrading FUJITSU Enterprise Postgres 11.0 or earlier instances that are using the VCI extension to FUJITSU Enterprise Postgres 12 or later using pg_upgrade, additional steps must be performed because of the incompatibility of the VCI extension between FUJITSU Enterprise Postgres 12 or later and FUJITSU Enterprise Postgres 11 or earlier.

Follow the procedure below in all databases in the FUJITSU Enterprise Postgres 11 or earlier instance, except "template0".

Before upgrading

1. Obtain the CREATE INDEX Definitions

   Run the query below to list all the VCI indexes created in the database. Ensure that these indexes are re-created in the FUJITSU Enterprise Postgres 12 or later instance after pg_upgrade has finished.

   ```
   SELECT nspname || '.' || relname AS index_relname,* FROM pg_class, pg_namespace
     WHERE relnamespace = pg_namespace.oid AND relam IN (SELECT oid FROM pg_am WHERE amname='vci');
   ```

   For each index_relname listed above, execute the commands below to obtain the CREATE INDEX definition (to use the same SQL syntax while re-creating the indexes on the FUJITSU Enterprise Postgres 12 or later instance).

   ```
   SELECT pg_get_indexdef('indexName'::regclass);
   ```

2. Drop the VCI indexes and VCI extension along with all its dependencies.

   To remove all the VCI indexes and VCI internal objects that are created in Fujitsu Enterprise Postgres, execute the commands below. VCI internal objects will be created in FUJITSU Enterprise Postgres 12 or later automatically when CREATE EXTENSION for VCI is executed.

   ```
   DROP EXTENSION VCI CASCADE;
   ```

   Information

   To restore the VCI extension in the FUJITSU Enterprise Postgres 11 or earlier instance, execute CREATE EXTENSION.

After upgrading

Once the pg_upgrade operation is complete, for all databases except "template0", execute CREATE EXTENSION to create the VCI extension, and then execute CREATE INDEX for all the VCI indexes as required.

1.7.2 Additional Steps to upgrading to Fujitsu Enterprise Postgres with Transparent Data Encryption (TDE) Enabled

If you are using pg_upgrade to upgrade an instance of Fujitsu Enterprise Postgres that uses Transparent Data Encryption (TDE), there are steps you can take before upgrading.

If your old cluster operation was an HA cluster operation without database multiplexing operations, and you shared a single keystore file, see "Before upgrading if you shared a keystore file". For other operations, see "Before upgrading"

Before upgrading

Before upgrading, perform the following steps.

This is not necessary if you are using the old cluster keystore file location as the new cluster keystore file location. In that case, the old cluster cannot continue to be used. Enable automatic keystore opening for old and new clusters.

1. Copy Master Encryption Key

   Copy the keystore file from the old cluster to the new cluster.

   You do not need to use the pgx_set_master_key function to generate a new master encryption key on the new cluster; you must copy the keystore file from the old cluster.

   As a database superuser, do the following:

   ```
   $ mkdir <NEW-KEY-STORE>/
   $ cp -p <OLD-KEY-STORE>/keystore.ks  <NEW-KEY-STORE>/
   ```

   NEW-KEY-STORE: The directory specified by the keystore_location parameter in postgresql.conf for the new cluster

   OLD-KEY-STORE: The directory specified by the keystore_location parameter in postgresql.conf on the old cluster

Before upgrading if you shared a keystore file

If the primary and standby servers shared the same keystore file, copy the keystore file from the old environment and share it as the keystore file from the new environment.

For more secure management of keystore files, place them on a secure, isolated key management server or key management storage.

Enable automatic keystore opening for old and new clusters.

Chapter 2 Starting an Instance and Creating a Database

This chapter describes basic operations, from starting an instance to creating a database.

2.1 Starting and Stopping an Instance

This section describes how to start and stop an instance.

- 2.1.1 Using WebAdmin
- 2.1.2 Using Commands

Point

- To automatically start or stop an instance when the operating system on the database server is started or stopped, refer to "Configuring Automatic Start and Stop of an Instance" in the Installation and Setup Guide for Server and configure the settings.
- The collected statistics are initialized if an instance is stopped in the "Immediate" mode or if it is abnormally terminated. To prepare for such initialization of statistics, consider regular collection of the statistics by using the SELECT statement. Refer to "The Statistics Collector" in "Server Administration" in the PostgreSQL Documentation for information on the statistics.

2.1.1 Using WebAdmin

WebAdmin enables you to start or stop an instance and check its operating status.

Starting an instance

Start an instance by using the [Instances] tab in WebAdmin.

is displayed when an instance is stopped.

To start a stopped instance, click .

Stopping an instance

Stop an instance by using the [Instances] tab in WebAdmin.

is displayed when an instance is active.

To stop an active instance, click .

Stop mode

Select the mode in which to stop the instance. The following describes the operations of the modes:

Stop mode	Connected clients	Backup being executed using the command
Smart mode (*1)	Waits for all connected clients to be disconnected.	Waits for backups being executed using the command to finish.
Fast mode	Rolls back all transactions being executed and forcibly disconnects clients.	Terminates backups being executed using the command.
Immediate mode	All server processes are terminated immediately. Crash recovery is executed the next time the instance is started.	
Kill process mode	Send SIGKILL to the process and abort all active transactions. This will lead to a crash-recovery run at the next restart.	

*1: When the processing to stop the instance in the Smart mode has started and you want to stop immediately, use the following procedure:

1. Restart the Web server feature of WebAdmin.
2. In the [Instances] tab, click .
3. In the [Instances] tab, click , and select the Immediate mode to stop the instance.

Checking the operating status of an instance

You can check the operating status of an instance by using the [Instances] tab. The following indicators are used to show the status of a resource.

Status indicator	Explanation
	The resource is operating normally.
	The resource is stopped.
	There is an error in the resource.
	An operation is in progress on this resource or the status is being checked.
	The resource is not operating optimally and needs intervention.

If an instance stops abnormally, remove the cause of the stoppage and start the instance by using WebAdmin.

When operating WebAdmin, click to update the status. WebAdmin will reflect the latest status of the operation or the instance resources from the server.

If an error occurs while communicating with the server, there may be no response from WebAdmin. When this happens, close the browser and then log in again. If this does not resolve the issue, check the event log of the server and confirm whether a communication error has occurred.

The following message is output during startup of an instance when the startup process is operating normally, therefore, the user does not need to be aware of this message:

```
FATAL:  the database system is starting up
```

2.1.2 Using Commands

The Windows service-related commands enable you to start or stop an instance and to check its operating state.

If you are to use Windows services, you should register instances in Windows services. It is possible to start and stop an instance by executing the pg_ctl command without registering the instance in Windows services, but because the instance is started as a user process, the postgres process will be forcibly stopped if you close the command prompt window in which the command was executed. For this reason, we recommend starting and stopping an instance using Windows services.

See

Refer to "When an instance was created with WebAdmin" in "Configuring Automatic Start and Stop of an Instance" in the Installation Guide for Server for information on registering instances in Windows services.

Starting an instance

You can start an instance by specifying the service name in the net start command or sc start command.

Also, you can use the following procedure to start an instance in the Windows services window:

1. Display the [Services] window

   In the [Administrative Tools], click [Services].

2. Start a service

   Select the instance name that you wish to start from the services list, and click [Start Service].

Stopping an instance

You can stop an instance by specifying the service name in the net stop command or sc stop command.

Also, you can use the following procedure to stop an instance in the Windows services window:

1. Display the [Services] window

   In the [Administrative Tools], click [Services].

2. Stop the service

   Select the instance name that you wish to stop from the services list, and click [Stop Service]. If you stop a service while applications and commands are running, Fujitsu Enterprise Postgres will force those applications and commands to close and will stop normally.

Checking the operating state of an instance

Use the following procedure to check if an instance is operating correctly immediately after performing the operation to start an instance:

1. Display the [Services] window

   In the [Start] menu, select [Administrative Tools], and then click [Services].

2. Check the state of the service

   In the services list, check the state of the services for the applicable Fujitsu Enterprise Postgres.

To check the operating state of an instance during operation, use the pg_ctl command.

Specify the following in the pg_ctl command:

- Specify "status" as the mode.
- Specify the data storage destination directory in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

Example

When the instance is active:

```
> pg_ctl status -D D:\database\inst1
pg_ctl: server is running (PID: 1234)
```

When the instance is inactive:

```
> pg_ctl status -D D:\database\inst1
pg_ctl: no server running
```

Information

You can also use the net start command or sc query command to check the operating state of an instance.

See

Refer to "pg_ctl" in "Reference" in the PostgreSQL Documentation for information on the pg_ctl command.

2.2 Creating a Database

This section explains how to create a database.

- 2.2.1 Using pgAdmin
- 2.2.2 Using Client Commands

2.2.1 Using pgAdmin

Follow the procedure below to define a database using pgAdmin.

1. In the pgAdmin window, right-click [Databases] in the [Browser] pane, and then click [Create] >> [Database...] to display a [Create - Database] window.
2. Specify appropriate values for the following items in the [Create - Database] window.
   - [General] tab
     - [Database]: Name of the database to be managed
3. Click [Save] to create the database.

2.2.2 Using Client Commands

Follow the procedure below to define a database using client commands.

An example of operations on the server is shown below.

1. Use psql command to connect to the postgres database.
   Execute psql postgres.

```
> psql postgres
psql (<x>) (*1)
Type "help" for help.
```

   *1: *<x>* indicates the PostgreSQL version on which this product is based.

2. Create the database.
   To create the database, execute the CREATE DATABASE databaseName; statement.

```
postgres=# CREATE DATABASE db01;
CREATE DATABASE
```

3. Confirm that the database is created.
   Execute \l+, and confirm that the name of the database created in step 2 is displayed.

```
postgres=# \l+
```

4. Disconnect from the postgres database.
   Execute \q to terminate the psql command.

```
postgres=# \q
```

You can create a database using the createdb command.

See

Refer to "Creating a Database" in "Tutorial" in the PostgreSQL Documentation for information on creating a database using the createdb command.

Chapter 3 Backing Up the Database

This chapter describes how to back up the database.

Backup methods

The following backup methods enable you to recover data to a backup point or to the state immediately preceding disk physical breakdown or data logical failure.

- Backup using WebAdmin

  This method enables you to back up data through intuitive window operations using the GUI.

  WebAdmin is used for recovery.

  If performing backups with WebAdmin, the following password file is temporarily created during backup for WebAdmin to connect to the database:

  - userProfileFolder\localSettingsFolder\Fujitsu\fsep_version\instanceName\pgpass.conf

  Therefore, when you are backing up corefiles created in the core_directory parameter of postgresql.conf, or log files created in the log_directory parameter of postgresql.conf, ensure not to back up the password files located in the same directories at the same time.

- Backup using the pgx_dmpall command

  Execute the pgx_dmpall command with a script to perform automatic backup.To back up data automatically, you must register the process in the automation software of the operating system. Follow the procedure given in the documentation for your operating system.

  Additionally, you can also take backups periodically by using any external scheduler.

  The pgx_rcvall command is used for recovery.

Use the selected backup method continuously.There are several differences, such as the data format, across the backup methods. For this reason, the following restrictions apply:

- It is not possible to use one method for backup and another for recovery.
- It is not possible to convert one type of backup data to a different type of backup data.

Information

By using a copy command created by the user, the pgx_dmpall command and the pgx_rcvall command can back up database clusters and tablespaces to any destination and recover them from any destination using any copy method. Refer to "Chapter 15 Backup/Recovery Using the Copy Command" for details.

Approximate backup time

The formula for deriving the approximate backup time when you use WebAdmin or the pgx_dmpall command is as follows:

```
backupTime = dataStorageDestinationUsage / diskWritePerformance x 1.5
```

- *dataStorageDestinationUsage*: Disk usage at the data storage destination
- *diskWritePerformance*: Maximum data volume (bytes/second) that can be written per second in the system environment where operation is performed
- 1.5: Coefficient to factor in tasks other than disk write (which is the most time-consuming step)

If using the copy command with the pgx_dmpall command, the backup time will depend on the implementation of the copy command.

When defining a tablespace

If you have defined a tablespace, back it up. If you do not back it up, directories for the tablespace are not created during recovery, which may cause the recovery to fail. If the recovery fails, refer to the event log, create the tablespace, and then perform the recovery process again.

When encrypting data stored in the database

There are several considerations for the backup of the keystore and backup of the database in case the data stored in the database is encrypted. Refer to the following for details:

- 5.6.4 Backing Up and Recovering the Keystore
- 5.7 Backing Up and Restoring/Recovering the Database

Information

The following methods can also be used to perform backup. Performing a backup using these methods allows you to restore to the point when the backup was performed.

- Backup using an SQL-based dump

  Dump the data by using SQL. This backup method also enables data migration.

- File system level backup

  This backup method requires you to stop the instance and use OS commands to backup database resources as files.

- Backup by continuous archiving

  This is the standard backup method for PostgreSQL.

Refer to "Backup and Restore" in "Server Administration" in the PostgreSQL Documentation for information on these backup methods.

The following backup methods are available for the features provided by Enterprise Postgres:

Category	Backup method	Backup target	Enterprise Postgres					
			Transparent Data Encryption	Policy-based Login Security	Data Masking	Confidentiality Management	Audit Log Feature	Database Multiplexing
Physical Backup	WebAdmin	Database cluster	Y	Y	Y	Y	Y	Y
	pgx_dmpall command		Y	Y	Y	Y	Y	Y
	Backup by continuous archiving		Y	Y	Y	Y	Y	Y
	File system level backup		Y	Y	Y	Y	Y	Y
Logical backup	pg_dumpall command		N	Y	N	Y	N	Y
	pg_dump command	Database	N	N	N	Y	N	Y
	COPY command	Table	N	N	N	N	N	N

Y: Can be used

N: Cannot be used

In a logical backup, the restore process recreates the indexes. For example, if the index size is large, such as for vector data handled by pgvector, the restoration time may be long. If you want to restore quickly, use a physical backup.

To export large amounts of data from multiple tables at high speed, use multiple executions to export data in parallel.

Some features are important to keep in mind when backing up. For information about the features, see the following:

Transparent Data Encryption : "5.7 Backing Up and Restoring/Recovering the Database"

Policy-based Login Security : "6.6 Backup and Recovery"

Confidentiality Management : "Backup/Restore" in the Security Operation Guide

Database Multiplexing : "Backup Operation" in the Cluster Operation Guide(Database Multiplexing)

3.1 Periodic Backup

It is recommended that you perform backup periodically.

Backing up data periodically using WebAdmin or the pgx_dmpall command has the following advantages:

- This method reduces disk usage, because obsolete archive logs (transaction logs copied to the backup data storage destination) are deleted. It also minimizes the recovery time when an error occurs.

Backup cycle

The time interval when backup is performed periodically is called the backup cycle. For example, if backup is performed every morning, the backup cycle is 1 day.
The backup cycle depends on the jobs being run, but on Fujitsu Enterprise Postgres it is recommended that operations are run with a backup cycle of at least once per day.

3.2 Backup Methods

This section describes the methods for backing up the database.

- 3.2.1 Using WebAdmin
- 3.2.2 Using Server Commands

3.2.1 Using WebAdmin

You can use WebAdmin to perform backup and check the backup status.

Backup operation

Follow the procedure below to back up the database.

1. Select the database to back up

   In the [Instances] tab, select the instance to be backed up and click .

2. Back up the database

   The [Backup] dialog box is displayed. To perform backup, click [Yes].
   An instance is automatically started when backup is performed.

Backup status

If an error occurs and backup fails, [Error] is displayed adjacent to [Data storage status] or [Backup storage status] in the [Instances] tab. An error message is also displayed in the message list.

In this case, the backup data is not optimized. Ensure that you check the backup result whenever you perform backup. If backup fails, [Solution] appears to the right of the error message. Clicking this button displays information explaining how to resolve the cause of the error. Remove the cause of failure, and perform backup again.

When encrypting data stored in the database

If the data to be stored in the database is to be encrypted, it is necessary to enable the automatic opening of the keystore before doing so. Refer to "5.6.3 Enabling Automatic Opening of the Keystore" for details.

3.2.2 Using Server Commands

Use the pgx_dmpall command and pgx_rcvall command to perform backup and check the backup result.

Preparing for backup

You must prepare for backup before actually starting the backup process.

Follow the procedure below.

See

Refer to "Preparing Directories to Deploy Resources" in the Installation and Setup Guide for Server for information on the location of directories required for backup and for points to take into account.

1. Prepare the backup data storage disk

   For backup, prepare a separate disk unit from the database storage disk and mount it using the operating system commands.

2. Create a directory where the backup data will be stored

   Create an empty directory.

   In [Properties] in Windows(R) Explorer, set appropriate permissions so that only the instance administrator can access the directory.

   See

   Refer to [Help and Support] in Windows(R) for information on [Properties].

3. Specify the settings required for backup

   Stop the instance, and set the following parameters in the postgresql.conf file.

   Start the instance after editing the postgresql.conf file.

Parameter name	Setting	Description
backup_destination	Name of the directory where the backup data will be stored	Specify the name of the directory where the backup data will be stored. Appropriate privileges that allow only the instance administrator to access the directory must already be set. Place the backup data storage destination directory outside the data storage destination directory, the tablespace directory, and the transaction log storage destination directory.
archive_mode	on	Specify the archive log mode. Specify [on] (execute).
archive_command	'cmd /c ""*installationDirectory*\\bin\\pgx_walcopy.cmd" "%p" "*backupDataStorageDestinationDirectory*\\archived_wal\\%f"""	Specify the path name of the command that will save the transaction log and the storage destination. Note the following when specifying the path: - Specify \\ as the path delimiter. - Enclose the path in double quotes ("") if it contains spaces.
archive_library	"(default)	Specify the archive library.

Parameter name	Setting	Description
		Specify ['](default).

Refer to "Appendix A Parameters" and "Write Ahead Log" under "Server Administration" in the PostgreSQL Documentation for information on the parameters.

Backup operation (file backup)

Use the pgx_dmpall command to perform file backup. You can even embed the pgx_dmpall command in OS automation software to perform backup.

The backup data is stored in the directory specified in the backup_destination parameter of postgresql.conf.

Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

Example

```
> pgx_dmpall -D D:\database\inst1
```

Backup stores the data obtained during the backup and the backup data of the data obtained during previous backup.

If the data to be stored in the database is encrypted, refer to the following and back up the keystore:

- 5.6.4 Backing Up and Recovering the Keystore

Backup status

Use the pgx_rcvall command to check the backup status.

Specify the following values in the pgx_rcvall command:

- The -l option indicates backup data information.
- Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

```
> pgx_rcvall -l -D D:\database\inst1
Date                    Status          Dir
2022-03-01 13:30:40     COMPLETE        E:/backup/inst1/2022-03-01_13-30-40
```

If an error occurs and backup fails, a message is output to the event log.

In this case, the backup data is not optimized. Ensure that you check the backup result whenever you perform backup. If backup fails, remove the cause of failure and perform backup again.

See

Refer to "pgx_dmpall" and "pgx_rcvall" in the Reference for information on the pgx_dmpall command and pgx_rcvall command.

Setting a restore point

In case you want to recover your database to a certain point in time, you can name this particular point in time, which is referred to as the restore point, by using the psql command.

By setting a restore point before executing an application, it becomes easy to identify up to which point in time the data will be reverted.

A restore point can be set to any point in time after a backup is executed. However, if a restore point is set before a backup is executed, the database cannot be recovered to that point in time. This is because restore points are recorded in the archive logs, and the archive logs are discarded when backups are executed.

Name restore points so that they are unique within the database. Add the date and time of setting a restore point to distinguish it from other restore points, as shown below:

- YYMMDD_HHMMSS
  - YYMMDD: Indicates the date
  - HHMMSS: Indicates the time
- There is no way to check restore points you have set. Keep a record in, for example, a file.

Example

The following example uses the psql command to connect to the database and execute the SQL statement to set a restore point.

However, when considering continued compatibility of applications, do not use functions directly in SQL statements. Refer to "Notes on Application Compatibility" in the Application Development Guide for details.

```
postgres=# SELECT pg_create_restore_point('batch_20220303_1');
LOG:  restore point "batch_20220303_1" created at 0/20000E8
STATEMENT:  select pg_create_restore_point('batch_20220303_1');
 pg_create_restore_point
-------------------------
 0/20000E8
(1 row)
```

Refer to "16.3.2 Using the pgx_rcvall Command" for information on using a restore point to recover the database.

See

Refer to "System Administration Functions" under "Functions and Operators" in the PostgreSQL Documentation for information on pg_create_restore_point.

Chapter 4 Configuring Secure Communication Using Secure Sockets Layer

If communication data transferred between a client and a server contains confidential information, encrypting the communication data can protect it against threats, such as eavesdropping on the network.

4.1 Configuring Communication Data Encryption

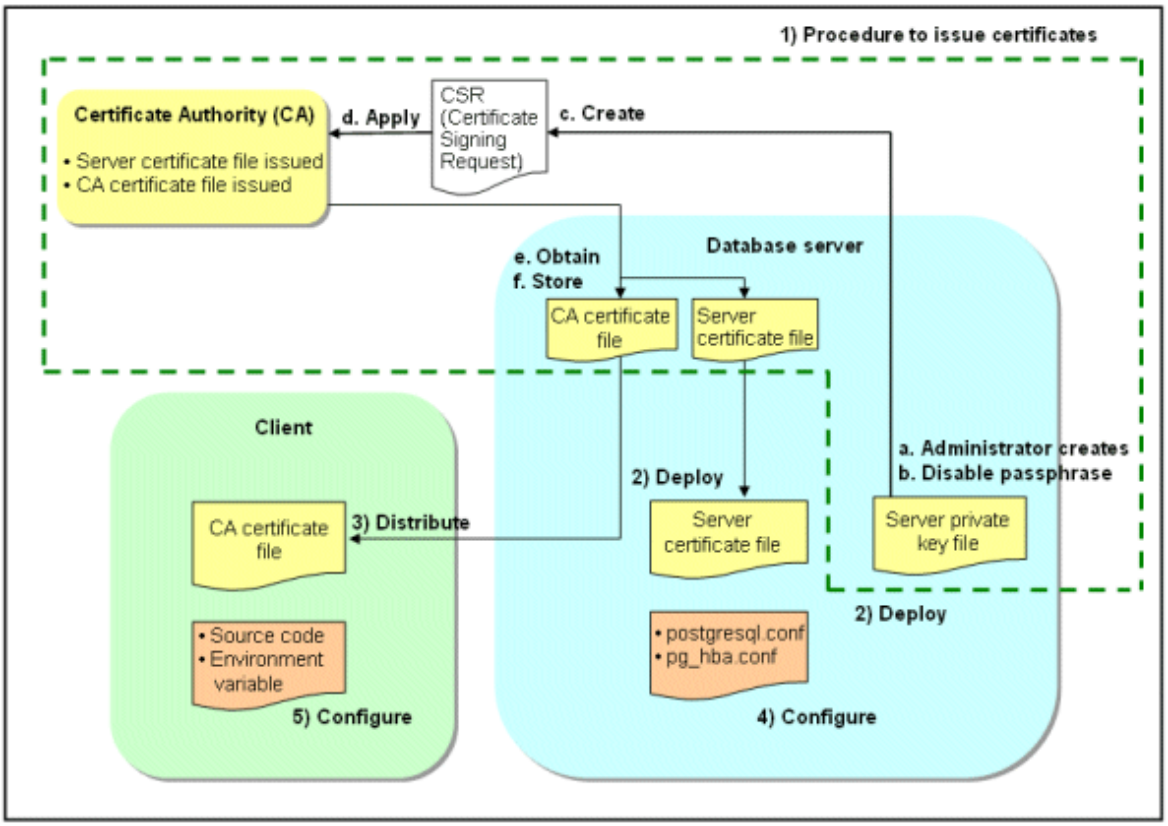
To encrypt communication data transferred between a client and a server, configure communication data encryption as described below. Communication data encryption not only protects the communication content, but it also guards against man-in-the-middle (MITM) attacks (for example, data and password theft through server impersonation).

Table 4.1 Configuration procedure

Configuration procedure
1) Issue a certificate
2) Deploy a server certificate file and a server private key file
3) Distribute a CA certificate file to the client
4) Configure the operating environment for the database server
5) Configure the operating environment for the client

The following figure illustrates the environment for communication data encryption.

Figure 4.1 Environment for communication data encryption



4.1.1 Issuing a Certificate

For authenticating servers, you must acquire a certificate issued by the certificate authority (CA).
Fujitsu Enterprise Postgres supports X.509 standard PEM format files. If the certificate authority issues a file in DER format, use a tool such as the openssl command to convert the DER format file to PEM format.

The following provides an overview of the procedure. Refer to the procedure published by the public or independent certificate authority (CA) that provides the certificate file for details.

a. Create a server private key file

b. Disable the passphrase for the server private key file

c. Create a CSR (signing request for obtaining a server certificate) from the server private key file

d. Apply to the certificate authority (CA) for a server certificate

e. Obtain a server certificate file and a CA certificate file from the certificate authority (CA)

f. Store the server certificate file and the CA certificate file
   Note: If you lose or destroy the certificates, you will need to have them re-issued.

The above procedure enables you to prepare the following files:

- Server private key file
- Server certificate file
- CA certificate file

4.1.2 Deploying a Server Certificate File and a Server Private Key File

Create a directory on the local disk of the database server and store the server certificate file and the server private key file in it.
Use the operating system features to set access privileges for the server certificate file and the server private key file so that only the database administrator has load privileges.
Back up the server certificate file and the server private key file in the event that data corruption occurs and store them securely.

4.1.3 Distributing a CA Certificate File to the Client

Create a directory on the local disk of the client and place the distributed CA certificate file there. Use the operating system features to set load privileges to protect the CA certificate file against accidental deletion.

4.1.4 Configuring the Operating Environment for the Database Server

See

Refer to "Secure TCP/IP Connections with SSL" under "Server Administration" in the PostgreSQL Documentation for details.

4.1.5 Configuring the Operating Environment for the Client

See

Refer to the following sections in the Application Development Guide for details, depending on your application development environment:

- "Settings for Encrypting Communication Data" under "Setup" in "JDBC Driver"
- "Settings for Encrypting Communication Data" under "Setup" in "C Library (libpq)"
- "Settings for Encrypting Communication Data" under "Setup" in "Embedded SQL in C"

4.1.6 Performing Database Multiplexing

When you perform communication that uses database multiplexing and a Secure Socket Layer server certificate, certificates with the same "Common Name" must be used. To ensure this, take one of the following actions:

- Create one server certificate, replicate it, and place a copy on each server used for database multiplexing.
- Create a server certificate with the same "Common Name" for each server used for database multiplexing.

See

Refer to "Using the Application Connection Switch Feature" in the Application Development Guide for information on how to specify applications on the client.

Chapter 5 Protecting Storage Data Using Transparent Data Encryption

This chapter describes how to encrypt data to be stored in the database.

5.1 Protecting Data Using Encryption

With PostgreSQL, data in a database is protected from access by unauthorized database users through the use of authentication and access controls. However, the OS file is not protected from attackers who bypass the database server's authentication and access controls.

With Fujitsu Enterprise Postgres, data inside the OS file is encrypted, so valuable information is protected even if the file or disk is stolen.

Data to be stored in a database is encrypted when it is written to the data file, and decrypted when it is read.

This is performed automatically by the instance, so the user and the application need not be aware of key management and encryption or decryption. This process is called TDE (Transparent Data Encryption).

The characteristics of TDE are described below.

Encryption mechanisms

Two-layer encryption key and the keystore

In each tablespace, there is a tablespace encryption key that encrypts and decrypts all the data within. The tablespace encryption key is encrypted by the master encryption key and saved.
Only one master encryption key exists in a database cluster. It is encrypted based on a passphrase specified by the user and stored in a keystore. Fujitsu Enterprise Postgres provides a file-based keystore. Attackers who do not know the passphrase cannot read the master encryption key from the keystore.

Strong encryption algorithms

TDE uses the Advanced Encryption Standard (AES) as its encryption algorithm. AES was adopted as a standard in 2002 by the United States Federal Government, and is used throughout the world.

Faster encryption and decryption based on hardware

TDE minimizes the overhead of encryption and decryption by using the AES-NI (Advanced Encryption Standard New Instructions) built into Intel(R) Xeon(R) processors since the 5600 series. This means that even in situations where previously the minimum encryption target was selected as a tradeoff between performance and security, it is now possible to encrypt all the data of an application.

Refer to the Intel Corporation's website for information on the list of processors equipped with AES-NI.

Zero overhead storage areas

Encryption does not change the size of data stored in tables, indexes, or WAL. There is, therefore, no need for additional estimates or disks.

Scope of encryption

All user data within the specified tablespace

The tablespace is the unit for specifying encryption. All tables, indexes, temporary tables, and temporary indexes created in the encrypted tablespace are encrypted. There is no need for the user to consider which tables and strings to encrypt.

Refer to "5.4 Encrypting a Tablespace" for details.

Backup data

The pgx_dmpall command and pg_basebackup command create backup data by copying the OS file. Backups of the encrypted data are, therefore, also encrypted. Information is protected from leakage even if the backup medium is stolen.

Refer to "5.7 Backing Up and Restoring/Recovering the Database" after enabling or reconfiguring encryption to back up the database.

WAL and temporary files

WAL, which is created by updating encrypted tables and indexes, is encrypted with the same security strength as the update target. When large merges and sorts are performed, the encrypted data is written to a temporary file in encrypted format.

Streaming replication support

You can combine streaming replication and transparent data encryption. The data and WAL encrypted on the primary server is transferred to the standby server in its encrypted format and stored.

The following are not encrypted:

- pg_dump and pg_dumpall output files
- Files output by the COPY command
- Notification event payloads that communicate using the LISTEN or NOTIFY command
- Checksum validation is not performed on encrypted tablespaces during backup and when using the pg_checksum utility.

5.2 Setting the Master Encryption Key

To use transparent data encryption, you must create a keystore and set the master encryption key.

1. In the keystore_location parameter of postgresql.conf, specify the directory to store the keystore.

   Specify a different location for each database cluster. Specify a different directory from those below as the keystore storage destination:

   - Data storage destination
   - Tablespace storage destination
   - Transaction log storage destination
   - Backup data storage destination

   ```
   keystore_location = 'C:\\key\\store\\location'
   ```

   Refer to "Appendix A Parameters" for information on postgresql.conf.

   After editing the postgresql.conf file, either start or restart the instance.

   - Using WebAdmin

     Refer to "2.1.1 Using WebAdmin", and restart the instance.

   - Using commands

     Refer to "2.1.2 Using Commands", and restart the instance.

2. Execute the pgx_set_master_key function to set the master encryption key.

   Execute it as the database superuser.

   ```
   SELECT pgx_set_master_key('passphrase');
   ```

   The value "passphrase" is the passphrase that will be used to open the keystore. The master encryption key is protected by this passphrase, so avoid specifying a short simple string that is easy to guess.

   The pgx_set_master_key function creates a file with the name keystore.ks in the keystore storage destination. It also creates a master encryption key from random bit strings, encrypts it with the specified passphrase, and stores it in keystore.ks. At this point, the keystore is open.

   Refer to "B.2 Transparent Data Encryption Control Functions" for information on the pgx_set_master_key function.

Note

Note that if you forget the passphrase, you will not be able to access the encrypted data. There is no method to retrieve a forgotten passphrase and decrypt data. Do not, under any circumstances, forget the passphrase.

5.3 Opening the Keystore

To create encrypted tablespaces and access the encrypted data, you must first open the keystore. When you open the keystore, the master encryption key is loaded into the database server memory and becomes usable for encryption and decryption.

You need to open the keystore each time you start the instance. To open the keystore, the database superuser must execute the following SQL function.

```
SELECT pgx_open_keystore('passphrase');
```

The value "passphrase" is the passphrase specified during creation of the keystore.

Refer to "B.2 Transparent Data Encryption Control Functions" for information on the pgx_open_keystore function.

Note that, in the following cases, the passphrase must be entered when starting the instance, because the encrypted WAL must be decrypted for recovery. In this case, the above-mentioned pgx_open_keystore function cannot be executed.

- If performing crash recovery at the time of starting the instance
- If performing recovery using continuous archiving

For the above cases, select one of the following methods:

- Use an automatically opening keystore

  Select this method if ease of operation has priority over enhanced security. When using an automatically opening keystore, the content of the keystore file is decrypted and a copy of the keystore file is generated. Although the content of this file is obfuscated, the level of security becomes slightly weaker.

  Select this method if performing operations using WebAdmin.

- Enter a passphrase when starting an instance

  Select this method if enhanced security has priority over ease of operation.

  Specify the --keystore-passphrase in the pg_ctl command and start the instance. This displays the prompt that asks for the passphrase to be entered.

  ```
  > pg_ctl --keystore-passphrase start
  Enter the passphrase:
  The server is currently initiating
  >
  ```

  After performing the above operation, use the pg_ctl command to stop the instance.

  Then start the instance in Windows services. Refer to "2.1.2 Using Commands" for information on how to start an instance in Windows services.

Point

When using an automatically opening keystore, you do not need to enter the passphrase and you can automatically open the keystore when the database server starts. Refer to "5.6.3 Enabling Automatic Opening of the Keystore" for details.

5.4 Encrypting a Tablespace

The keystore must be open before you can create an encrypted tablespace.

When creating a tablespace that will be encrypted, configure the encryption algorithm in the runtime parameters. For example, to create a tablespace with the name secure_tablespace using AES with a key length of 256 bits as the encryption algorithm, configure as shown below.

```
-- Specify the encryption algorithm for the tablespace to be created below
SET tablespace_encryption_algorithm = 'AES256';
CREATE TABLESPACE secure_tablespace LOCATION 'C:\My\Data\Dir';
-- Specify that the tablespace to be created below is not to be encrypted
SET tablespace_encryption_algorithm = 'none';
```

Or

```
CREATE TABLESPACE secure_tablespace LOCATION '\My\Data\Dir' WITH (tablespace_encryption_algorithm =
'AES256' );
```

When the tablespace is empty, the encryption algorithm can be modified with the command below.

```
ALTER TABLESPACE secure_tablespace SET (tablespace_encryption_algorithm=AES256);
```

Trying to set the encryption algorithm for a non-empty tablespace causes an error.

You can use AES with a key length of 128 bits or 256 bits as the encryption algorithm. It is recommended that you use 256-bit AES. Refer to "Appendix A Parameters" for information on how to specify the runtime parameters.

If user provides both GUC and command line options while creating the tablespace, the preference is given to the command line option.

The pg_default and pg_global tablespaces cannot be encrypted.

Create tables and indexes in the encrypted tablespace that you created. Relations created in the encrypted tablespace are automatically encrypted.

Example

Example 1: Specifying an encrypted tablespace when creating it

```
CREATE TABLE my_table (...)
    TABLESPACE secure_tablespace;
```

Example 2: Not explicitly specifying a tablespace when creating it and instead using the default tablespace

```
SET default_tablespace = 'secure_tablespace';
CREATE TABLE my_table (...);
```

The process is the same for encrypting temporary tables and temporary indexes. In other words, either explicitly specify the TABLESPACE clause or list encrypted tablespaces in the temp_tablespaces parameter, and then execute CREATE TEMPORARY TABLE or CREATE INDEX.

Point

If an encrypted tablespace is specified in the TABLESPACE clause of the CREATE DATABASE statement, relations created in the database without explicitly specifying a tablespace will be encrypted. Furthermore, the system catalog will also be encrypted, so the source code of user-defined functions is also protected.

Example: Specifying a tablespace in a database definition statement

```
CREATE DATABASE DB01 TABLESPACE=SP01 ... ;
```

Part of the data is also stored in the system catalog - to encrypt this data as well, specify an encrypted tablespace as above and create a database.

An encrypted tablespace cannot be created from the window used for creating the pgAdmin tablespace, or from the query tool using a multi-command string. To create an encrypted tablespace, use psql console or a single command in the query tool such as that shown in the example below.

```
CREATE TABLESPACE tspace LOCATION '/some/dir/in/the/path' WITH
(tablespace_encryption_algorithm='AES256')
```

5.5 Checking an Encrypted Tablespace

The pgx_tablespaces system view displays information about whether each tablespace has been encrypted, and about the encryption algorithm. Refer to "D.1 pgx_tablespaces" for information on strings.

You can discover which tablespaces have been encrypted by executing the following SQL statements.

However, when considering continued compatibility of applications, do not reference system catalogs (pg_tablespace) directly in SQL statements.

```
SELECT spcname, spcencalgo
FROM pg_tablespace ts, pgx_tablespaces tsx
WHERE ts.oid = tsx.spctablespace;
```

Example

```
postgres=# SELECT spcname, spcencalgo FROM pg_tablespace ts, pgx_tablespaces tsx WHERE ts.oid =
tsx.spctablespace;
      spcname      | spcencalgo
-------------------+------------
 pg_default        | none
 pg_global         | none
 secure_tablespace | AES256
(3 rows)
```

See

Refer to "Notes on Application Compatibility" in the Application Development Guide for information on how to maintain application compatibility.

5.6 Managing the Keystore

This section describes how to manage the keystore and the master encryption key to guard against the threat of theft.

5.6.1 Changing the Master Encryption Key

Using the same encryption key for an extended period gives attackers an opportunity to decipher the encrypted data. It is recommended that you change the key at regular intervals, or whenever the key is exposed to risk.

Adhere to the industry's best practices for encryption algorithms and key management when considering how often the key should be changed. For example, the NIST in the United States has published "NIST Special Publication 800-57". The PCI DSS also refers to this publication. This publication recommends changing the master encryption key once a year.

To change the master encryption key, execute the pgx_set_master_key function, which is the same function used for configuring the key. Refer to "5.2 Setting the Master Encryption Key" for details.

After changing the master encryption key, you must immediately back up the keystore.

5.6.2 Changing the Keystore Passphrase

In security policies for organizations, it is usually a requirement that the passphrase be changed whenever a security administrator who knows the passphrase is removed from duties due to transfer or retirement. It is also recommended that the passphrase be changed if it is ever exposed to risks due to deception such as social engineering.

To change the keystore passphrase, execute the following SQL function as a superuser.

```
SELECT pgx_set_keystore_passphrase('oldPassphrase', 'newPassphrase');
```

After changing the passphrase, you must immediately back up the keystore.

Refer to "B.2 Transparent Data Encryption Control Functions" for information on the pgx_set_keystore_passphrase function.

5.6.3 Enabling Automatic Opening of the Keystore

When using an automatically opening keystore, you do not need to enter the passphrase and you can automatically open the keystore when the instance starts. Execute the pgx_keystore command to enable automatic opening of the keystore.

```
> pgx_keystore --enable-auto-open C:\key\store\location\keystore.ks
Enter the passphrase:
Automatic opening of the keystore is now enabled
>
```

See

Refer to "pgx_keystore" in the Reference for information on pgx_keystore command.

When automatic opening is enabled, an automatically opening keystore is created in the same directory as the original keystore. The file name of the automatically opening keystore is keystore.aks. The file keystore.aks is an obfuscated copy of the decrypted content of the keystore.ks file. As long as this file exists, there is no need to enter the passphrase to open the keystore when starting the instance.

Do not delete the original keystore file, keystore.ks. It is required for changing the master encryption key and the passphrase. When you change the master encryption key and the passphrase, keystore.aks is recreated from the original keystore file, keystore.ks.

Protect keystore.ks, keystore.aks, and the directory that stores the keystore so that only the user who starts the instance can access them.

Configure the permission of the files so that only the user who starts the instance can access the SQL functions and commands that create these files. Accordingly, manually configure the same permission mode if the files are restored.

Set the permission mode in [Properties] in Windows(R) Explorer.

See

Refer to [Help and Support] in Windows(R) for information on [Properties].

To use WebAdmin for backup and recovery, you must enable automatic opening of the keystore.

An automatically opening keystore will only open on the computer where it was created.

To disable automatic opening of the keystore, delete keystore.aks.

5.6.4 Backing Up and Recovering the Keystore

Back up the keystore at the following times in case it is corrupted or lost. Note that you must store the database and the keystore on separate data storage media. Storing both on the same data storage medium risks the danger of the encrypted data being deciphered if the medium is stolen. A passphrase is not required to open an automatically opening keystore, so store this type of keystore in a safe location.

- When the master encryption key is first configured
- When the master encryption key is changed
- When the database is backed up
- When the keystore passphrase is changed

Point

Do not overwrite an old keystore when backing up a keystore. This is because during database recovery, you must restore the keystore to its state at the time of database backup. When the backup data of the database is no longer required, delete the corresponding keystore.

Example

- Back up the database and the keystore on March 1, 2022.

```
> pgx_dmpall -D D:\database\inst1
> copy C:\key\store\location\keystore.ks C:\keybackup\keystore_20220301.ks
```

  Specify the following in the pgx_dmpall command:

  - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

- Change the master encryption key, and back up the keystore on March 5, 2022.

```
> psql -c "SELECT pgx_set_master_key('passphrase')" postgres
> copy C:\key\store\location\keystore.ks C:\keybackup\keystore_20220305.ks
```

  Specify the following in the psql command:

  - Specify the SQL function that sets the master encryption key in the -c option.
  - Specify the name of the database to be connected to as the argument.

If the keystore is corrupted or lost, restore the keystore containing the latest master encryption key. If there is no keystore containing the latest master encryption key, restore the keystore to its state at the time of database backup, and recover the database from the database backup. This action recovers the keystore to its latest state.

Example

- Restore the keystore containing the latest master encryption key as of March 5, 2022.

```
> copy C:\keybackup\keystore_20220305.ks C:\key\store\location\keystore.ks
```

- If there is no backup of the keystore containing the latest master encryption key, recover the keystore by restoring the keystore that was backed up along with the database on 1 March 2022.

```
> copy C:\keybackup\keystore_20220301.ks C:\key\store\location\keystore.ks
> pgx_rcvall -B E:\backup\inst1 -D D:\database\inst1 --keystore-passphrase
```

  Specify the following in the pgx_rcvall command:

  - Specify the data storage directory in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.
  - Specify the backup data storage directory in the -B option.
  - The --keystore-passphrase option prompts you to enter the passphrase to open the keystore.

If you have restored the keystore, repeat the process of enabling automatic opening of the keystore. This ensures that the contents of the automatically opening keystore (keystore.aks) are identical to the contents of the restored keystore.

It is recommended that you do not back up the automatically opening keystore file, keystore.aks. If the database backup medium and the backup medium storing the automatically opening keystore are both stolen, the attacker will be able to read the data even without knowing the passphrase.

If the automatically opening keystore is corrupted or lost, you must again enable automatic opening. The keystore.aks file will be recreated from keystore.ks at this time.

See

Refer to "pgx_rcvall" and "pgx_dmpall" in the Reference for information on the pgx_rcvall and pgx_dmpall commands.

Refer to "psql" under "Reference" in the PostgreSQL Documentation for information on the psql command.

Refer to "B.2 Transparent Data Encryption Control Functions" for information on the pgx_set_master_key function.

Refer to "5.6.3 Enabling Automatic Opening of the Keystore" for information on how to enable automatic opening of the keystore.

5.7 Backing Up and Restoring/Recovering the Database

Fujitsu Enterprise Postgres enables you to use the five backup and recovery methods described below. Regardless of the method you use, you must back up the keystore at the same time.

Note that you must store the database and the keystore on separate data storage media. Storing both on the same data storage medium risks the danger of the encrypted data being deciphered if the medium is stolen.

Backup and recovery using WebAdmin

- Backup

  WebAdmin backs up encrypted data.

  Back up the key store after backing up the database.

- Recovery

  Restore the keystore to its state at the time of database backup. Refer to "5.6.4 Backing Up and Recovering the Keystore" for details.

  Enable automatic opening of the keystore in accordance with the procedure described in "5.6.3 Enabling Automatic Opening of the Keystore". Then, use WebAdmin to recover the database.

Backup and recovery using the pgx_dmpall and pgx_rcvall commands

- Backup

  The pgx_dmpall command backs up the encrypted data.

  Back up the key store after backing up the database.

- Recovery

  Restore the keystore to its state at the time of the database backup.

  Configure automatic opening of the key store as necessary.

  If automatic opening of the keystore is not enabled, execute the pgx_rcvall command with the --keystore-passphrase option specified. This will display the prompt for the passphrase to be entered.

Example

- Back up the database and the keystore on March 1, 2022.

```
> pgx_dmpall -D D:\database\inst1
> copy C:\key\store\location\keystore.ks C:\keybackup\keystore_20220301.ks
```

  Specify the following in the pgx_dmpall command:

  - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

- Recover the database and the keystore from the backup taken on March 1, 2022.

```
> copy C:\keybackup\keystore_20220301.ks C:\key\store\location\keystore.ks
> pgx_keystore --enable-auto-open C:\key\store\location\keystore.ks (Execute only when enabling
automatic opening)
> pgx_rcvall -B E:\backup\inst1 -D D:\database\inst1 --keystore-passphrase
```

  Specify the following in the pgx_rcvall command:

  - Specify the data storage destination in the -D option. If the -D option is omitted, the value of the PGDATA environment variable is used by default.

- Specify the backup data storage directory in the -B option.
- The --keystore-passphrase option prompts you to enter the passphrase to open the keystore.

Dump and restore using SQL

- Backup

  The files output by the pg_dump and pg_dumpall commands are not encrypted. You should, therefore, encrypt the files using OpenSSL commands or other means before saving them, as described in "5.8 Importing and Exporting the Database" below.

  Back up the key store after backing up the database.

- Restore

  If the backup data has been encrypted using, for example Open SSL commands, decrypt that data.

  The data generated by the pg_dumpall command includes a specification to encrypt tablespaces by default. For this reason, the psql command encrypts tablespaces during restoration.

File system level backup and restore

- Backup

  Stop the instance and backup the data directory and the tablespace directory using the file copy command of the operating system. The files of encrypted tablespaces are backed up in the encrypted state.

  Back up the key store after performing the backup.

- Restore

  Restore the keystore to its state at the time of the database backup.

  Stop the instance and restore the data directory and the tablespace directory using the file copy command of the operating system.

Continuous archiving and point-in-time recovery

- Backup

  The pg_basebackup command backs up the encrypted data as is.

  Back up the key store after performing the backup.

- Recovery

  Restore the keystore to its state at the time of the database backup.

  Configure automatic opening of the key store as necessary.

  If automatic opening of the keystore is not enabled, refer to "5.3 Opening the Keystore" for information on starting an instance by specifying pg_ctl --keystore-passphrase start.

See

- Refer to "Reference" in the PostgreSQL Documentation for information on the following commands:
  - psql
  - pg_dump
  - pg_basebackup
- Refer to the Reference for information on the following commands:
  - pgx_rcvall
  - pgx_dmpall
  - pg_dumpall

If you have restored the keystore, repeat the process of enabling automatic opening of the keystore This ensures that the contents of the automatically opening keystore (keystore.aks) are identical to the contents of the restored keystore.

Refer to "5.6.3 Enabling Automatic Opening of the Keystore" for information on how to enable automatic opening of the keystore.

5.8 Importing and Exporting the Database

The files output by the COPY TO command are not encrypted. Therefore, when transferring files to other systems, you should encrypt files using OpenSSL commands, or use file transfer software that performs encrypted communication for Windows, to encrypt the data being transferred.

Use a safe method to delete obsolete plain text files.

You can use the following methods to safely delete files:

- fsutil command

Example

```
# Export the contents of the table my_table to a CSV file.
> psql -c "COPY my_table TO 'C:\WINDOWS\Temp\my_table.csv' (FORMAT CSV)" postgres
# Encrypt the exported file.
> C:\OpenSSL-Win32\bin\openssl enc -e -aes256 -in C:\WINDOWS\Temp\my_table.csv -out my_table.csv.enc
(The user is prompted to enter the passphrase to be used for encryption)

# Check the size of plain text files, and delete them after zero padding
> dir C:\WINDOWS\Temp\my_table.csv
> fsutil file setzerodata offset=0 length=7 C:\WINDOWS\Temp\my_table.csv
> del C:\WINDOWS\Temp\my_table.csv

# Decrypt the encrypted files on other systems.
> C:\OpenSSL-Win32\bin\openssl enc -d -aes256 -in my_table.csv.enc -out my_table.csv
(The user is prompted to enter the passphrase to be used for decryption)
```

If you use COPY FROM to import data to tables and indexes in an encrypted tablespace, the imported data is automatically encrypted before being stored.

5.9 Encrypting Existing Data

You cannot encrypt existing unencrypted tablespaces. In addition, you cannot change encrypted tablespaces so that they do not encrypt.

As an alternative, transfer the tables and indexes to other tablespaces. You can use the following SQL commands for this.

```
ALTER TABLE table_name SET TABLESPACE new_tablespace;
ALTER INDEX index_name SET TABLESPACE new_tablespace;
ALTER DATABASE database_name SET TABLESPACE new_tablespace;
```

See

Refer to "SQL Commands" under "Reference" in the PostgreSQL Documentation for information on SQL commands.

5.10 Operations in Cluster Systems

This section describes how to use transparent data encryption on cluster systems such as high-availability systems, streaming replication, and database multiplexing.

5.10.1 HA Clusters that do not Use Database Multiplexing

Take the following points into account when using transparent data encryption in an HA cluster environment that does not use database multiplexing.

Placement and automatic opening of the keystore file

There are two alternatives for placing the keystore file:

- Sharing the keystore file
- Placing a copy of the keystore file

Sharing the keystore file

This involves using the same keystore file on the primary server and the standby server.

As the standby server is not active while the primary server is running, this file would not be accessed simultaneously, and therefore, it can be shared.

To manage the keystore file in a more secure manner, place it on the key management server or the key management storage isolated in a secure location.

Enable the automatic opening of the keystore on both the primary and standby servers.

Placing a copy of the keystore file

This involves placing a copy of the primary server keystore file on the standby server.

You can do this if you cannot prepare a shared server or disk device that can be accessed from both the primary and standby servers.

However, if you change the master encryption key and the passphrase on the primary server, you must copy the keystore file to the standby server again.

To manage the keystore file in a more secure manner, prepare the key management server or the key management storage isolated in a secure location for both the primary and standby servers, and place the keystore files there.

Enable the automatic opening of the keystore on both the primary and standby servers. Note that copying the automatically opening keystore file (keystore.aks) to the standby server does not enable the automatic opening of the keystore.

5.10.2 Database Multiplexing Mode

Note the following when using transparent data encryption in environments that use streaming replication, or database multiplexing with streaming replication.

Placing the keystore file

Place a copy of the primary server keystore file on the standby server.

This is required as the keystore file cannot be shared, and both servers may need to access it simultaneously.

Point

To manage the keystore file in a more secure manner, place it on the key management server or the key management storage isolated in a secure location. A keystore used by both the primary and standby servers can be managed on the same key management server or key management storage.

However, create different directories for the keystores to be used by the primary server and the standby server. Then copy the keystore for the primary server to the directory used on the standby server.

Automatically opening the keystore

You must enable automatic opening of the keystore.

To do this, enable automatic opening of the keystore in all servers that make up database multiplexing. The settings for automatic opening of the keystore include information unique to each server, so simply copying the file does not enable it.

Changing the passphrase

Changes to the passphrase are reflected in all servers that make up database multiplexing, so no special operation is required.

Building and starting a standby server

Before using the pg_basebackup command or pgx_rcvall command to build a standby server, copy the keystore file from the primary server to the standby server. When using an automatically opening keystore, use the copied keystore file to enable automatic opening on the standby server.

Open the keystore each time you start the standby server. This step is necessary for decrypting and restoring encrypted WAL received from the primary server. To open the keystore, specify the --keystore-passphrase option in the pg_ctl command or pgx_rcvall command and enter the passphrase, or use an automatically opening keystore.

If specifying --keystore-passphrase in the pg_ct command, refer to "5.3 Opening the Keystore" for details.

Changing the master encryption key and the passphrase

Change the master encryption key and the passphrase on the primary server. You need not copy the keystore from the primary server to the standby server. You need not even restart the standby server or reopen the keystore. Changes to the master encryption key and the passphrase are reflected in the keystore on the standby server.

See

Refer to "pgx_rcvall " in the Reference for information on pgx_rcvall command.

Refer to "pg_basebackup" under "Reference" in the PostgreSQL Documentation for information on pg_basebackup command.

Refer to "High Availability, Load Balancing, and Replication" under "Server Administration" in the PostgreSQL Documentation for information on how to set up streaming replication.

5.11 Security-Related Notes

- Decrypted data is cached in the database server memory (shared buffer). As a result, unencrypted data is stored in a minidump, which is the process memory dump. You should, therefore, safely delete the memory dump. You can safely delete files by using the following command:
  - fsutil command
- Unencrypted data may be written from the database server memory to the operating system's swap area. To prevent leakage of information from the swap area, consider either disabling the use of swap area or encrypting the swap area using a full-disk encryption product.
- The content of the server log file is not encrypted. Therefore, in some cases the value of a constant specified in a SQL statement is output to the server log file. To prevent this, consider setting a parameter such as log_min_error_statement.
- When executing an SQL function that opens the keystore and modifies the master encryption key, ensure that the SQL statement containing the passphrase is not output to the server log file. To prevent this, consider setting a parameter such as log_min_error_statement. If you are executing this type of SQL function on a different computer from the database server, encrypt the communication between the client and the database server with SSL.
- Starting with FEP 10, logical replication is available, which allows non-backed up clusters to subscribe to databases where transparent data encryption is enabled. Logical replication does not need to have the same encryption strategy between publisher and subscriber.

  In this scenario, if the user wants to encrypt the subscribed copy of data as well, then it is the user's responsibility to create encryption policies to the subscribed databases. By default, published encrypted tablespace data will not be encrypted in the subscriber side.

5.12 Tips for Installing Built Applications

With transparent data encryption, you can easily encrypt all the data in an application without modifying the application. Database administrators install built applications in the following manner. However, this procedure stores data to the default tablespace, so take necessary action if processing differs from the original design.

1. (Normal procedure) Create an owner and a database for the built application.

```
CREATE USER crm_admin ...;
CREATE DATABASE crm_db ...;
```

2. (Procedure for encryption) Create an encrypted tablespace to store the data for the built application.

```
SET tablespace_encryption_algorithm = 'AES256';
CREATE TABLESPACE crm_tablespace LOCATION 'C:\crm\data';
```

3. (Procedure for encryption) Configure an encrypted tablespace as the default tablespace for the owner of the built application.

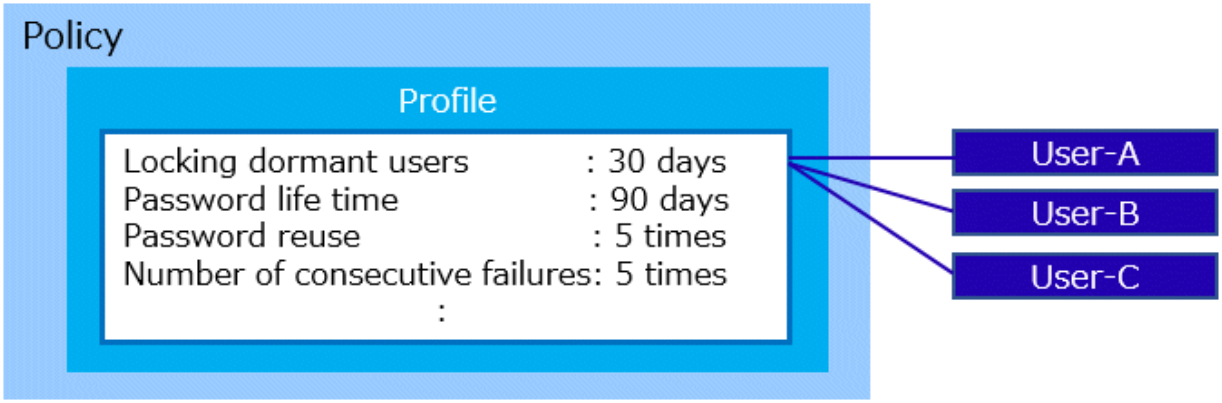
```
ALTER USER crm_admin SET default_tablespace = 'crm_tablespace';
ALTER USER crm_admin SET temp_tablespaces = 'crm_tablespace';
```

4. (Normal procedure) Install the built application. The application installer prompts you to enter the host name and the port number of the database server, the user name, and the database name. The installer uses the entered information to connect to the database server and execute the SQL script. For applications that do not have an installer, the database administrator must manually execute the SQL script.

Normally, the application's SQL script includes logic definition SQL statements, such as CREATE TABLE, CREATE INDEX, and GRANT or REVOKE, converted from the entity-relationship diagram. It does not include SQL statements that create databases, users, and tablespaces. Configuring the default tablespace of the users who will execute the SQL script deploys the objects generated by the SQL script to the tablespace.

Chapter 6 Policy-based Login Security

To apply a policy for login security to a user, define the policy as a profile and assign the profile to the user. The contents of the profile are saved as database objects.



The items that can be set for a profile are described below.

Managing Dormant Users

You can automatically lock users who have not been connected to the database for a long time.

This setting is for users with the LOGIN attribute.

Managing Policies When Using Password Authentication

You can set the following policies for users who use password authentication (password, md5, scram-sha-256).

- Set a password life time
- Restrict password reuse
- Lock accounts that have failed to login continuously
- Allow passwords to be set in encrypted form
- Set the gradual password rollover time

  Gradual password rollover is when you change a password and then keep the old password in effect for a while.
  This setting specifies the valid period.
  This is useful, for example, if it is difficult to make a new password available system-wide instantly.

6.1 Advance Preparation

Ensure that the postgres database exists and that you can connect to it.

If no connections are possible, and if using a database other than the default postgres database, specify the name of the database to which you can connect in the userprofile_database parameter in the postgresql.conf file.

Refer to "Parameters for the Policy-based Login Security" for parameters.

6.2 Changing the Contents of the default Profile

When you create a database user with CREATE ROLE, the database user is assigned the default profile. When you create the default profile, all password configuration and authentication restrictions and the gradual password rollover feature are disabled, so change the parameter values to suit your policy. Change the value with the pgx_alter_profile function.

Users with CREATEROLE privilege can modify the contents of a profile.

Refer to "B.3.1 Profile Management Functions" for functions.

Refer to "6.7 Profile parameters" for more information on parameters.

[Example]

```
SELECT pgx_alter_profile('default',
'{
    "INACTIVE_USER_TIME": 30,
    "PASSWORD_LIFE_TIME": 50,
    "PASSWORD_GRACE_TIME": 10,
    "PASSWORD_REUSE_MAX": 5,
    "PASSWORD_LOCK_TIME": 0.5,
    "PASSWORD_ALLOW_HASHED": true,
    "PASSWORD_ROLLOVER_TIME": 0.125
}');
```

6.3 Creating and Assigning Profiles

If you want to apply a different policy than the default profile, create a new profile and assign it to the user.

The pgx_create_profile function creates a profile.

To assign a profile to a user, use the pgx_assign_profile_to_user function.

Users with CREATEROLE privilege can create and assign profiles.

Refer to "B.3.1 Profile Management Functions" and "B.3.2 User Management Functions" for functions.

6.4 Actions to be Taken in the Event of Deviation from Policy

When a user is locked

Locked in the following cases:

- Restriction by INACTIVE_USER_TIME
- Restriction by FAILED_LOGIN_ATTEMPTS

If you want to allow a locked user to login again, unlock the user. Unlocking is performed using the pgx_unlock_user function. Operations can be performed by users with CREATEROLE privilege.

Refer to "B.3.2 User Management Functions" for functions.

[Example]

```
SELECT pgx_unlock_user('user1');
```

To release a lock when a database administrator is locked, users other than the locked user with CREATEROLE privilege can do so. If the user does not exist, Fujitsu Enterprise Postgres must be started in single-user mode and the lock released.

You can set PASSWORD_LOCK_TIME to automatically release locks due to FAILED_LOGIN_ATTEMPTS.

When the password expires

When a password life time is over, the password expires and cannot be used to connect to and operate on the database until the password is changed.

The password can be changed by the expired user itself, or by a user who has the CREATEROLE privilege and who is an administrator of that user (who has ADMIN privilege for that user).

6.5 Settings in Streaming Replication Configuration

For streaming replication, the policy is enabled on both the primary and standby servers.

Perform changing the contents of the profile, creating and assigning profiles, unlock, and change the password can only be done on the primary server.

This section describes how to setting streaming replication configuration.

1. Grant privilege to users for streaming replication

   The standby server connects to the primary server and propagates any state changes it detects to the primary server. The used users for streaming replication (specified in primary_conninfo) is used to connect for state change. Grant privilege to this user. Allow the user to SET ROLE directly to the group role pgx_update_profile_status.

   [Example]

   ```
   # GRANT pgx_update_profile_status TO repluser WITH SET TRUE;
   ```

   This action enables users for streaming replication to lock all other database users or unlock the lock state due to policy deviations. Also, membership in the pgx_update_profile_status group role should only be granted to users for streaming replication.

2. Add a record to pg_hba.conf

   Add a record to accept connections from the standby server. Duplicate the record for streaming replication and specify the database name in the userprofile_database parameter as the destination database name. Authentication methods other than password authentication are recommended.

   ```
   host  replication  repluser  standbyServerAddress authenticationMethod    # For Streaming
   Replication
   host  postgres     repluser  standbyServerAddress authenticationMethod    # For state change
   propagation
   ```

Information

- If the primary and standby servers are disconnected, profile-based restrictions still apply on each server. However, the standby server itself cannot change its password or unlock it explicitly. After removing the cause of the disconnect, restore the connection to the primary server and business operations, and then change the password or explicitly unlock.
- Connection information for reflecting status changes to the primary server or standby server is output as "User profile status sender" to application_name in the pg_stat_replication view. When monitoring the streaming replication status with the pg_stat_replication view, exclude the "User profile status sender" line from the monitoring target.

6.6 Backup and Recovery

Backup

Profile contents, user and profile assignment status, and password history can be backed up with physical backups and the pg_dumpall command.

When dumping with SQL statements using the pg_dumpall command, database role information is backed up at the same time it is dumped.

Information

When the pg_dumpall command is run without the --no-role-passwords option, the database user's password is included in the backup file in the form of a encrypted form. Therefore, when recovering the database user's password, temporarily set this parameter to true in the default profile of the restore destination. If the restore is successful, the contents of the default profile are restored to the contents at the time of the backup.

Recovery

If you recover using older backup data, you may be considered a dormant user at the time of recovery, or your password may have expired. In this case, unlock or change the password after recovery.

6.7 Profile parameters

Details of the parameters set in the profile are explained.

INACTIVE_USER_TIME

Number of days before auto-locking users who have not been connected to the database for a long time (users who cannot see their sessions)

[Supported values]

integer: A INTEGER value greater than or equal to 1

The unit is days. The maximum value is 24855 days.

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: No auto lock

This setting is for users with the LOGIN attribute.

If a session to the database cannot be verified for at least INACTIVE_USER_TIME, the user is locked out and cannot log in.

Sessions are checked into the database every hour and the information is saved.

If the system shuts down before the save, it is assumed that there were no logins between the last save and the shutdown. As a result, the lock period might be shorter than the value specified in this parameter.

When using streaming replication, the session confirmation to the database is performed every hour on each server. The primary server makes a locking decision while the standby server sends session confirmation information to the upstream server. This can cause a time lag of several hours before the session confirmation information from the standby server is communicated to the primary server. This lag can result in locking even when connected to a standby server.

You can determine when each user's session was last seen by the system by looking at the value of the userprlastactivetime column in the pgx_user_profile system catalog.

If the device is locked by the setting of this parameter, use the pgx_unlock_user function to unlock the device. Automatic cancellation by PASSWORD_LOCK_TIME is not performed.

When a logged-in user changes to another role with SET ROLE, the new role is not considered logged in to the database. It is assumed that the old role is still logged in to the database.

PASSWORD_LIFE_TIME

Number of days the same password can be used for authentication

[Supported values]

numeric: A NUMERIC value greater than or equal to 0

The unit is days. Hours and seconds can be specified with decimal places (e.g. 4.5 is equivalent to "4 days and 12 hours"). Precision is 1 second. The maximum value is 24855 days.

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: No life time (same password can be used indefinitely)

The password life time will be over after PASSWORD_LIFE_TIME days from the last time the password was updated for the target user. The timing of updating the profile is not the starting point. Therefore, if you specify an extremely short number of days (such as 1 day), it may already be past the life time at the time of renewal.

It is possible to specify when a password becomes invalid using the VALID UNTIL clause of CREATE ROLE or ALTER ROLE. If you specify both the VALID UNTIL clause and PASSWORD_LIFE_TIME, both values are valid. Note that in this case, you can login only if both constraints are met.

If there is no grace period, the password expires when the password life time is over. If you login using password authentication in this state, you will receive a "password expired" warning and you will not be able to execute commands other than changing your password. You can change the password to resume normal operations. Other than password authentication, you can connect to and work with the database.

For streaming replication, users will not be able to connect to the standby server after the password life time is over. There is no grace period for password expiration on standby servers. Password changes must be made on the primary server.

PASSWORD_GRACE_TIME

The number of days after a password life time is over before the password expires.

[Supported values]

numeric: A NUMERIC value greater than or equal to 0

The unit is days. Hours and seconds can be specified with decimal places (e.g. 4.5 is equivalent to "4 days and 12 hours"). Precision is 1 second. The maximum value is 24855 days.

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: Indefinite period

The password expiration grace period is PASSWORD_GRACE_TIME days from the first login time after the password life time is over. You can login with your current password during the grace period, but a warning prompts you to change your password. You can operate normally except that a warning is displayed. If specified as UNLIMITED, the grace period is infinite and you will be warned to change your password at every login. Once transitioned to the grace period, even if you change the profile value after that, you cannot go back to before the grace period, and you cannot change the life time. If 0 is specified, there is no grace period and the password expires at the first login after the password life time is over. In this case, you can perform normal operations again by changing the password.

Because the standby server does not have a grace period before the password expires, users cannot connect to the standby server after the password life time is over. Password changes must be made on the primary server.

PASSWORD_REUSE_TIME

Number of days the same password cannot be reused

The password cannot be reused by the same user for this period from the time the password is updated.

This parameter must be set in combination with PASSWORD_REUSE_MAX.

[Supported values]

numeric: A NUMERIC value greater than or equal to 0

The unit is days. Hours and seconds can be specified with decimal places (e.g. 4.5 is equivalent to "4 days and 12 hours"). Precision is 1 second. The maximum value is 24855 days.

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: Not reusable (However, if PASSWORD_REUSE_MAX is also UNLIMITED, the password can be reused without restriction)

PASSWORD_REUSE_MAX

Number of password changes required before the same password can be reused

This parameter must be set in combination with PASSWORD_REUSE_TIME.

[Supported values]

integer: An INTEGER value greater than or equal to 0

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: Not reusable (However, if PASSWORD_REUSE_TIME is also UNLIMITED, the password can be reused without restriction)

Both PASSWORD_REUSE_TIME and PASSWORD_REUSE_MAX constraints must be met to reuse passwords.

For example, if you specify PASSWORD_REUSE_TIME = 30, PASSWORD_REUSE_MAX = 10, a certain password can be reused if 30 days have passed since the update time and the password has been updated 10 times or more. When password update fails due to these parameters, the SQLSTATE will be "22023: invalid_parameter_value".

Also, if one parameter has a value and the other parameter specifies UNLIMITED, the password cannot be reused. If you want to use only one condition for reuse judgment, you need to set the value of the unused parameter to 0. However, if UNLIMITED is specified for both, these parameters are ignored and passwords can be reused without restriction.

When changing a password, if the password is specified in MD5 or SCRAM encrypted format, you cannot check that the password is being reused.

PASSWORD_ALLOW_HASHED

Whether to allow passwords to be specified in MD5 or SCRAM encrypted form when changing passwords Allow if true.

[Supported values]

boolean: true or false

DEFAULT: The value of the same parameter in the default profile

If true, there are no restrictions on how to set or change passwords.

However, note the following when changing passwords in encrypted form:

- Unable to check for password reuse (PASSWORD_REUSE_TIME, PASSWORD_REUSE_MAX)
- Password rollover disabled (PASSWORD_ROLLOVER_TIME)
- Inability to check password complexity using the extension passwordcheck

If false, the password can only be set or changed by specifying the password in clear text in the PASSWORD clause of a CREATE ROLE or ALTER ROLE statement. You cannot change the password using the psql command \password meta-command.

In this case, all password checks that cannot be performed in encrypted form are possible.

Note

Passwords specified in CREATE ROLE or ALTER ROLE statements may, depending on configuration, be logged in the psql command history and the server log.

FAILED_LOGIN_ATTEMPTS

Number of consecutive failed login attempts allowed by the user

[Supported values]

integer: An INTEGER value greater than 0

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: Indefinite period (Can fail any number of times)

If password authentication fails consecutively for the number of times specified by this parameter, the user is locked and cannot login.

The number of failed login attempts is counted separately on each server.

PASSWORD_LOCK_TIME

Number of days after a user is locked due to consecutive login failures before the user is unlocked

[Supported values]

numeric: A NUMERIC value greater than or equal to 0

The unit is days. Hours and seconds can be specified with decimal places (e.g. 4.5 is equivalent to "4 days and 12 hours"). Precision is 1 second. The maximum value is 24855 days.

DEFAULT: The value of the same parameter in the default profile

UNLIMITED: Locked indefinitely

If set to UNLIMITED, the user will be locked indefinitely and will not be automatically unlocked. Unlocking requires an explicit pgx_unlock_user function call by a user with CREATEROLE privilege.

PASSWORD_ROLLOVER_TIME

Number of days after password change before old password expires

[Supported values]

numeric: A NUMERIC value greater than or equal to 0

The unit is days. Hours and seconds can be specified with decimal places (e.g. 4.5 is equivalent to "4 days and 12 hours"). Precision is 1 second. The maximum value is 60 days. The minimum value is 0.0416 days (approximately 1 hour).

DEFAULT: The value of the same parameter in the default profile

From the time the user changes the password until PASSWORD_ROLLOVER_TIME has elapsed, the user can login using the old password.

Specify a value equal to or less than the lesser of the PASSWORD_GRACE_TIME (except when 0 is specified) or PASSWORD_LIFE_TIME. If a larger value is specified, the smaller of these parameters is used. For example, if PASSWORD_GRACE_TIME is 10 and PASSWORD_LIFE_TIME is 50, specify 10 or less for this parameter. If 15 is specified in this parameter, 10 is assumed to be specified.

If 0 is specified, the user cannot login with the old password. The default profile has an initial value of 0.

To expire the combinable period immediately before PASSWORD_ROLLOVER_TIME expires, a user or a user with CREATEROLE privilege can call the pgx_make_password_rollover_expire function.

If you execute the ALTER ROLE statement with PASSWORD NULL, password authentication is disabled. Therefore, you cannot log in with the old password.

In either of the following cases, the password rollover is disabled and the previous password expires immediately:

- When changing the password, the password is specified in MD5 or SCRAM encrypted format.
- The password method has changed since the last time the password was set.
  The relevant parameters are:
  - password_encryption
  - scram_iterations

6.8 Worker Processes

This feature allows up to two background worker processes to reside. This information is displayed in the statistics view pg_stat_activity when it needs to be processed by a worker process. The worker processes added by this feature are those with column backend_type values of "user profile status writer" and "user profile status sender".

These processes may wait on the wait event "UserProFileWorkerMain" of type "Activity".

Chapter 7 Data Masking

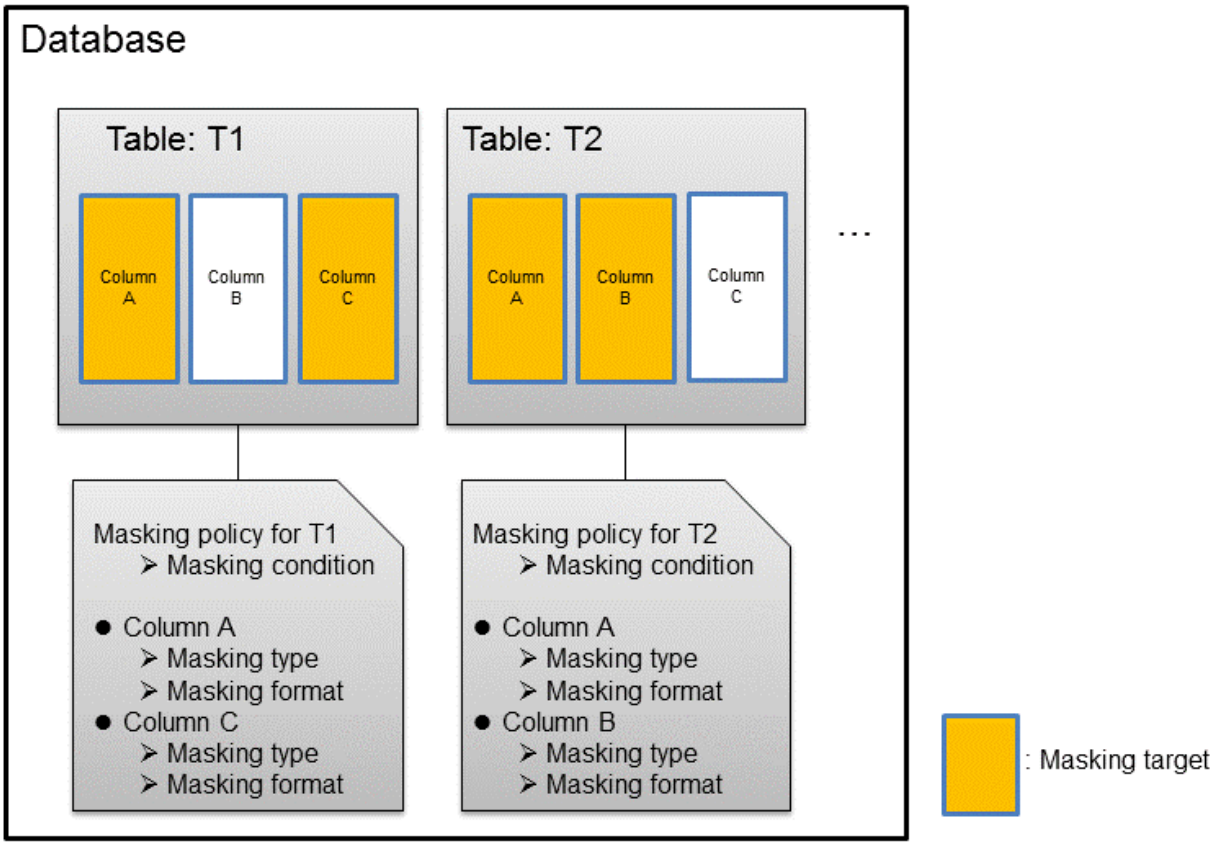
Data masking is a feature that can change the returned data for queries generated by applications, so that it can be referenced by users. For example, for a query of employee data, digits except the last four digits of an eight-digit employee number can be changed to "*" so that it can be used for reference.

When using this feature, it is recommended that the changed data be transferred to another medium for users to reference. This is because, if users directly access the database to extract the masked data, there is a possibility that they can deduce the original data by analyzing the masking policy or query result to the masking target column.

7.1 Masking Policy

Masking policy is a method of changing data under specific conditions when it is returned for a query from an application. One masking policy can be created per table. You can configure masking target, masking type, masking condition and masking format in a masking policy.

Figure 7.1 Masking policy



Information

When a masking policy is defined, the search performance for the corresponding table may deteriorate.

7.1.1 Masking Target

Masking target refers to a column to which a masking policy will be applied. When referring to a masking target or a function that includes a masking target, the execution result will be changed and obtained.

The following commands can change the execution result:

- SELECT
- COPY
- pg_dump
- pg_dumpall

Information

- If a masking target is specified to INSERT...SELECT target columns, processing will be performed using data before change.
- If a masking target other than SELECT target columns is specified, processing will be performed using data before change.
- If a masking target is specified in a function where the data type will be converted, an error will occur.

7.1.2 Masking Type

Masking type is a method to change column data that is returned from queries. Specify the masking type in the function_type parameter.

If multiple valid masking targets are specified for a function, the masking type for the left-most masking target will be applied. For example, if "SELECT GREATEST(c1, c2) FROM t1" is executed for numeric type masking target c1 and c2, the masking type for c1 will be applied.

The following masking types can be specified and selected depending on the masking target data type. When masking the data that includes multibyte characters, do not specify partial masking for masking type. The result may not be as expected.

Full masking

All the data in the specified column is changed. The changed value returned to the application that made the query varies depending on the column data type.
For example, 0 is used for a numeric type column and a space is used for a character type column.

Partial masking

The data in the specified column is partially changed.
For example, digits except the last four digits of an employee number can be changed to "*".

Regular expression masking

The data in the specified column is changed via a search that uses a regular expression.
For example, for strings such as email address that can have variable length, "*" can be used to change characters preceding "@" by using a regular expression. Regular expression masking can only be used for character type data.

7.1.3 Masking Condition

Masking condition refers to the conditions configured to perform masking. Specify the masking condition in the expression parameter. Changed or actual data can be displayed for different users by defining masking condition. An expression that returns a boolean type result needs to be specified in masking condition and masking is performed only when TRUE is returned. Refer to "Value Expressions" in the PostgreSQL Documentation for information on the expressions that can be specified. Note that expressions that include a column cannot be specified.
For example, when masking data only for "postgres" users, specify 'current_user = "postgres"' in the masking condition.

Information

Specify '1=1' so the masking condition is always evaluated to be TRUE and masking is performed all the time.

7.1.4 Masking Format

Masking format is a combination of change method and displayed characters when the masking condition is met. Masking format varies depending on the masking type. The following describes the masking format.

Full masking

With full masking, all characters are changed to values as determined by the database. Changed characters can be referenced in the pgx_confidential_values table. Also, replacement characters can be changed using the pgx_update_confidential_values system management function.

See

Refer to "7.3 Data Types for Masking" for information on the data types for which data masking can be performed.

Partial masking

With partial masking, data is changed according to the content in the function_parameters parameter. The method of specifying function_parameters varies depending on the data type.

Category	Method of specifying function_parameters
Numeric type	'*replacementCharacter*, *startPosition*, *endPosition*' - *replacementCharacter*: Specify the number to display. Specify a value from 0 to 9. - *startPosition*: Specify the start position of masking. Specify a positive integer. - *endPosition*: Specify the end position of masking. Specify a positive integer that is greater than *startPosition*. Example Specify as below to change the values from the 1st to 5th digits to 9. function_parameters := '9, 1, 5' In this example, if the original data is "123456789", it will be changed to "999996789".
Character type	*'inputFormat*, *outputFormat*, *replacementCharacter*, *startPosition*, *endPosition'* - *inputFormat*: Specify the current format of the data. Specify "V" for characters that will potentially be masked, and specify "F" for values such as spaces or hyphens that will not be masked. - *outputFormat*: Define the method to format the displayed data. Specify "V" for characters that will potentially be masked. Any character to be output can be specified for each character "F" in *inputFormat*. If you want to output a single quotation mark, specify two of them consecutively. - *replacementCharacter*: Specify any single character. If you want to output a single quotation mark, specify two of them consecutively. - *startPosition*: Specify the position of "V" as the start position of masking. For example, to specify the position of the 4th "V" from the left, specify 4. Specify a positive integer. - *endPosition*: Specify the position of "V" as an end position of masking. When working out the end position, do not include positions of "F". For example, to specify the position of the 11th "V" from the left, specify 11. Specify a positive integer that is greater than *startPosition*. Example Specify as below to mask a telephone number other than the first three digits using *. function_parameters := 'VVVFVVVVFVVVV, VVV-VVVV-VVVV, *, 4, 11' In this example, if the original data is "012-3156-7890", it will be changed to "012-****-****".
Date/timestamp type	'MDYHMS'

Category	Method of specifying function_parameters
	- M: Masks month. To mask month, enter the month from 1 to 12 after a lowercase letter m. Specify an uppercase letter M to not mask month. - D: Masks date. To mask date, enter the date from 1 to 31 after a lowercase letter d. If a value bigger than the last day of the month is entered, the last day of the month will be displayed. Specify an uppercase letter D to not mask date. - Y: Masks year. To mask year, enter the year from 1 to 9999 after a lowercase letter y. Specify an uppercase letter Y to not mask year. - H: Masks hour. To mask hour, enter the hour from 0 to 23 after a lowercase letter h. Specify an uppercase letter H to not mask hour. - M: Masks minute. To mask minute, enter the minute from 0 to 59 after a lowercase letter m. Specify an uppercase letter M to not mask minute. - S: Masks second. To mask second, enter the second from 0 to 59 after a lowercase letter s. Specify an uppercase letter S to not mask second. **Example** Specify as below to mask hour, minute, and second and display 00:00:00. function_parameters := 'MDYh0m0s0' In this example, if the original data is "2022-02-10 10:10:10", it will be changed to "2022-02-10 00:00:00".

See

- Refer to "B.4.2 pgx_create_confidential_policy" for information on function_parameters.
- Refer to "7.3 Data Types for Masking" for information on the data types for which masking can be performed.

Regular expression masking

With regular expression masking, data is changed according to the content of the regexp_pattern, regexp_replacement and regexp_flags parameters. For regexp_pattern, specify the search pattern using a regular expression. For regexp_replacement, specify the replacement character to use when data matches the search pattern. For regexp_flags, specify the regular expression flags.

When column data type is character(*n*) or char(*n*) and if the string length after change exceeds n, the extra characters will be truncated and only characters up to the nth character will be displayed.

When column data type is character varying(*n*) or varchar(*n*) and if the string length after change exceeds the length before the change, the extra characters will be truncated and only characters up to the length before change will be displayed.

Example

Specify as below to change all three characters starting from b to X.

regexp_pattern := 'b..'

regexp_replacement:= 'X'

regexp_flags := 'g'

In this example, if the original data is "foobarbaz", it will be changed to "fooXX".

See

- Refer to "POSIX Regular Expressions" in the PostgreSQL Documentation and check pattern, replacement, and flags for information on the values that can be specified for regexp_pattern, regexp_replacement, and regexp_flags.
- Refer to "7.3 Data Types for Masking" for information on the data types for which masking can be performed.

7.2 Usage Method

Preparation

The following preparation is required to use this feature.

1. Set the postgresql.conf file parameters.

   Prepend "pgx_datamasking" to the shared_preload_libraries parameter.

   Be sure to add "pgx_datamasking" to the beginning of the parameter "shared_preload_libraries".

2. Restart the instance.
3. Execute CREATE EXTENSION for the database that will use this feature.

   The target database is described as "postgres" here.

   Use the psql command to connect to the "postgres" database.

   Example

```
postgres=# CREATE EXTENSION pgx_datamasking;
CREATE EXTENSION
```

   Information

   - Specify "false" for pgx_datamasking.enable to not use this feature. Data will not be masked even if a masking policy is configured. This feature becomes available again once "true" is specified for pgx_datamasking.enable. This setting can be made by specifying a SET statement or specifying a parameter in the postgresql.conf file.
     Example

```
postgres=# SET pgx_datamasking.enable=false;
```

   - Hereafter, also perform this preparatory task for the "template1" database, so that this feature can be used by default when creating a new database.

Usage

To perform masking, a masking policy needs to be configured. Only database superusers can configure masking policies.

The masking policy setting is explained in the following steps using an example.

1. Creating a masking policy
2. Changing a masking policy
3. Confirming a masking policy
4. Enabling and disabling a masking policy
5. Deleting a masking policy

7.2.1 Creating a Masking Policy

Create a masking policy. Only one masking policy can be created per table.

All users can view the masking policy created, so do not grant the login privilege of the database where this feature is set to the users who refer to the changed data. Masking policies are defined in the "pgx_confidential_columns", "pgx_confidential_policies" and "pgx_confidential_values" tables.

An example of the operation on the server is shown below.

1. Create a masking policy
   Execute the pgx_create_confidential_policy system management function to create a masking policy.
   The following values are configured in this example.
   - Masking target: Numeric type c1
   - Masking type: FULL
   - Masking condition: '1=1'

```
postgres=# select pgx_create_confidential_policy(table_name := 't1', policy_name := 'p1',
expression := '1=1', column_name := 'c1', function_type := 'FULL');
 pgx_create_confidential_policy
--------------------------------
 t
(1 row)
```

2. Confirm the displayed data
   Confirm that the masking target data (column c1) has been correctly changed.

```
postgres=# select * from t1;
 c1 |      c2
----+--------------
  0 | 012-3456-7890
  0 | 012-3456-7891
  0 | 012-3456-7892
(3 row)
```

See

- Refer to "B.4.2 pgx_create_confidential_policy" for information on the pgx_create_confidential_policy system management function.

7.2.2 Changing a Masking Policy

An example of the operation on the server is shown below.

1. Change a masking policy
   Execute the pgx_alter_confidential_policy system management function to change a masking policy.
   The following values are changed in this example.
   - Content of change: Add a masking target
   - Masking target: Character type c2
   - Masking type: PARTIAL
   - Masking condition: 'VVVFVVVVFVVVV, VVV-VVVV-VVVV, *, 4, 11'

```
postgres=# select pgx_alter_confidential_policy(table_name := 't1', policy_name := 'p1',
action := 'ADD_COLUMN', column_name := 'c2', function_type := 'PARTIAL', function_parameters :=
'VVVFVVVVFVVVV, VVV-VVVV-VVVV, *, 4, 11');
 pgx_alter_confidential_policy
--------------------------------
 t
(1 row)
```

2. Confirm the displayed data
   Confirm that the masking target data has been correctly changed.

```
postgres=# select * from t1;
 c1 |      c2
----+--------------
  0 | 012-****-****
  0 | 012-****-****
  0 | 012-****-****
(3 row)
```

See

- Refer to "B.4.1 pgx_alter_confidential_policy" for information on the pgx_alter_confidential_policy system management function.

7.2.3 Confirming a Masking Policy

An example of the operation on the server is shown below.

1. Confirm information about a masking target where a masking policy is set
   Refer to the pgx_confidential_columns table to confirm the masking target where the masking policy is set.

```
postgres=# select * from pgx_confidential_columns;
 schema_name | table_name | policy_name | column_name | function_type |
function_parameters           | regexp_pattern | regexp_replacement | regexp_flags |
column_description
-------------+------------+-------------+-------------+---------------
+---------------------------------------+----------------+--------------------+-------------
+--------------------
 public      | t1         | p1          | c1          | FULL
|                                        |                |                    |             |
 public      | t1         | p1          | c2          | PARTIAL       | VVVFVVVVFVVVV, VVV-VVVV-
VVVV, *, 4, 11 |                |                    |             |
(2 row)
```

2. Confirm information about the masking policy content
   Refer to pgx_confidential_policies to confirm the masking policy content.

```
postgres=# select * from pgx_confidential_policies;
 schema_name | table_name | policy_name | expression | enable | policy_description
-------------+------------+-------------+------------+--------+--------------------
 public      | t1         | p1          | 1=1        | t      |
(1 row)
```

See

- Refer to "E.1 pgx_confidential_columns" for information on the pgx_confidential_columns table.
- Refer to "E.2 pgx_confidential_policies" for information on the pgx_confidential_policies table.

7.2.4 Enabling and Disabling a Masking Policy

An example of the operation on the server is shown below.

1. Disable a masking policy
   Execute the pgx_enable_confidential_policy system management function to disable a masking policy.

```
postgres=# select pgx_enable_confidential_policy(table_name := 't1', policy_name := 'p1',
enable := 'f');
```

```
 pgx_enable_confidential_policy
--------------------------------
 t
(1 row)
```

2. Confirm the displayed data
   Confirm that the original data is displayed by disabling the masking policy.

```
postgres=# select * from t1;
 c1 |      c2
----+---------------
  1 | 012-3456-7890
  2 | 012-3456-7891
  3 | 012-3456-7892
(3 row)
```

3. Enable a masking policy
   Execute the pgx_enable_confidential_policy system management function to enable a masking policy.

```
postgres=# select pgx_enable_confidential_policy(table_name := 't1', policy_name := 'p1',
enable := 't');
 pgx_enable_confidential_policy
--------------------------------
 t
(1 row)
```

4. Confirm the displayed data
   Confirm that the masking target data has been correctly changed.

```
postgres=# select * from t1;
 c1 |      c2
----+---------------
  0 | 012-****-****
  0 | 012-****-****
  0 | 012-****-****
(3 row)
```

See

- Refer to "B.4.4 pgx_enable_confidential_policy" for information on the pgx_enable_confidential_policy system management function.

7.2.5 Deleting a Masking Policy

An example of the operation on the server is shown below.

1. Delete a masking policy
   Execute the pgx_drop_confidential_policy system management function to delete a masking policy.

```
postgres=# select pgx_drop_confidential_policy(table_name := 't1', policy_name := 'p1');
 pgx_drop_confidential_policy
-------------------------------
 t
(1 row)
```

2. Confirm the displayed data
   Confirm that the original data is displayed by deleting the masking policy.

```
postgres=# select * from t1;
 c1 |      c2
----+---------------
```

```
  1 | 012-3456-7890
  2 | 012-3456-7891
  3 | 012-3456-7892
(3 row)
```

See

- Refer to "B.4.3 pgx_drop_confidential_policy" for information on the gx_drop_confidential_policy function.

7.3 Data Types for Masking

The data types for which data masking can be performed are shown below.

Even if the data type can be masking, if the data is a special value (NaN, Infinity, -Infinity), it is not.

Category	Data type	Masking type		
		Full masking	Partial masking	Regular expression masking
Numeric type	smallint	Y	Y	N
	integer	Y	Y	N
	bigint	Y	Y	N
	decimal	Y	Y	N
	numeric	Y	Y	N
	float	Y	Y	N
	real	Y	Y	N
	double precision	Y	Y	N
Character type	character varying(*n*)	Y	Y	Y
	varchar(*n*)	Y	Y	Y
	character(*n*)	Y	Y	Y
	char(*n*)	Y	Y	Y
Date/timestamp type	date	Y	Y	N
	timestamp	Y	Y	N

7.4 Security Notes

- Starting with FEP 10, logical replication is available, which allows non-backed up clusters to subscribe to databases where data masking policies are enabled. Logical replication allows publisher and subscriber databases to have their own or the same data masking policies.

  In this scenario, the user must disable data masking on the publisher database whenever a subscription is created. This ensures that subscribers are able to obtain the original data (initial copy) instead of the masked version. Then, it is the user's responsibility to set masking policies to each subscribed database.

- Take strong caution in publishing data masking's confidential tables (pgx_confidential_policies, pgx_confidential_columns, etc.) unless the user is publishing all tables of the database and wants to apply the same data masking's policies on the subscribed database for all of them.

  Otherwise, as these confidential tables contain the masking policies for all tables of the database, confidential policies of unpublished tables may be unintentionally published. Additionally, it is not possible to apply different data masking policies on the subscriber database.

Chapter 8 Periodic Operations

This chapter describes the operations that must be performed periodically when running daily database jobs.

8.1 Configuring and Monitoring the Log

Fujitsu Enterprise Postgres enables you to output database errors and warnings to a log file.

This information is useful for identifying if errors have occurred and the causes of those errors.

By default, this information is output to the event log. It is recommended that you configure Fujitsu Enterprise Postgres to collect logs from its log files (for example, log_destination) before operating Fujitsu Enterprise Postgres.

Periodically monitor the log files to check if any errors have occurred.

See

- Refer to "Error Reporting and Logging" under "Server Administration" in the PostgreSQL Documentation for information on logs.
- Refer to "Configuring Parameters" in the Installation and Setup Guide for Server for information on log settings when operating with WebAdmin.

8.2 Monitoring Disk Usage and Securing Free Space

When a database is used for an extended period, free space on the disk is continuously consumed and in some cases the disk space runs out. When this happens, database jobs may stop and no longer run.

You should, therefore, periodically monitor the usage of disk space, and delete obsolete files located in the disk.

Monitor the disk usage of the disk where the following directories are located:

- Data storage destination directory
- Transaction log storage destination (if the transaction log is stored in a different directory from the data storage destination directory)
- Backup data storage destination directory
- Tablespace storage destination directory

8.2.1 Monitoring Disk Usage

To check the disk usage, use the following operating system commands:

- fsutil volume diskfree command

You can even use SQL statements to check tables and indexes individually.

Refer to "Determining Disk Usage" under "Server Administration" in the PostgreSQL Documentation for information on this method.

Information

If you are using WebAdmin for operations, a warning is displayed when disk usage reaches 80%

8.2.2 Securing Free Disk Space

Secure free disk space by using the following operating system commands to delete unnecessary files, other than the database, from the same disk unit.

- del command

You can also secure disk space by performing the following tasks periodically:

- To secure space on the data storage destination disk:

  Execute the REINDEX statement. Refer to "8.5 Reorganizing Indexes" for details.

- To secure space on the backup data storage destination disk:

  Execute backup using WebAdmin or the pgx_dmpall command.

8.3 Automatically Closing Connections

If an application stops responding and abnormally terminates for any reason, the connection from the application may remain active on the database server. If this situation continues for an extended period, other applications attempting to connect to the database server may encounter an error, or an error indicating that the tables are unavailable may occur.

It is, therefore, recommended that idle connections be closed automatically at regular intervals.

Set the following parameters in the postgresql.conf file to indicate the time permitted to elapse before a connection is closed.

Parameter name	Setting	Description
tcp_keepalives_idle	Time until keepalive is sent (seconds) If 0, the default value of the system is used.	Sends keepalive to an idle connection at the specified interval in seconds It is recommended to specify 30 seconds.
tcp_keepalives_interval	keepalive send interval (seconds) If 0, the default value of the system is used.	Sends keepalive at the specified interval It is recommended to specify 6 seconds.

Note

The maximum number of connections allowed is 125, unless the desktop heap setting is changed.

See

Refer to "Connection Settings" under "Server Administration" in the PostgreSQL Documentation for information on the parameters.

8.4 Monitoring the Connection State of an Application

Fujitsu Enterprise Postgres does not immediately delete the updated or deleted data. If the VACUUM determines there are no transactions that reference the database, Fujitsu Enterprise Postgres collects obsolete data.

However, obsolete data is not collected if there are connections that have remained active for an extended period or connections occupying resources. In this case the database may expand, causing performance degradation.

See

Refer to "Routine Vacuuming" under "Server Administration" in the PostgreSQL Documentation for information on the VACUUM command.

In such cases, you can minimize performance degradation of the database by monitoring problematic connections.

The following methods are supported for monitoring connections that have been in the waiting status for an extended period:

- 8.4.1 Using the View (pg_stat_activity)
- 8.4.2 Using pgAdmin

8.4.1 Using the View (pg_stat_activity)

Use the view (pg_stat_activity) to identify and monitor connections where the client has been in the waiting status for an extended period.

Example

The example below shows connections where the client has been in the waiting status for at least 60 minutes.

However, when considering continued compatibility of applications, do not reference system catalogs directly in the following SQL statements.

```
postgres=# select * from pg_stat_activity where backend_type = 'client backend' and state='idle in
transaction' and current_timestamp > cast(query_start + interval '60 minutes' as timestamp);
-[ RECORD 1 ]----+------------------------------
datid            | 13003
datname          | db01
pid              | 4638
leader_pid       |
usesysid         | 10
usename          | fsep
application_name | apl01
client_addr      | 192.33.44.15
client_hostname  |
client_port      | 27500
backend_start    | 2022-02-24 09:09:21.730641+09
xact_start       | 2022-02-24 09:09:23.858727+09
query_start      | 2022-02-24 09:09:23.858727+09
state_change     | 2022-02-24 09:09:23.858834+09
wait_event_type  | Client
wait_event       | ClientRead
state            | idle in transaction
backend_xid      |
backend_xmin     |
query_id         |
query            | begin;
backend_type     | client backend
```

See

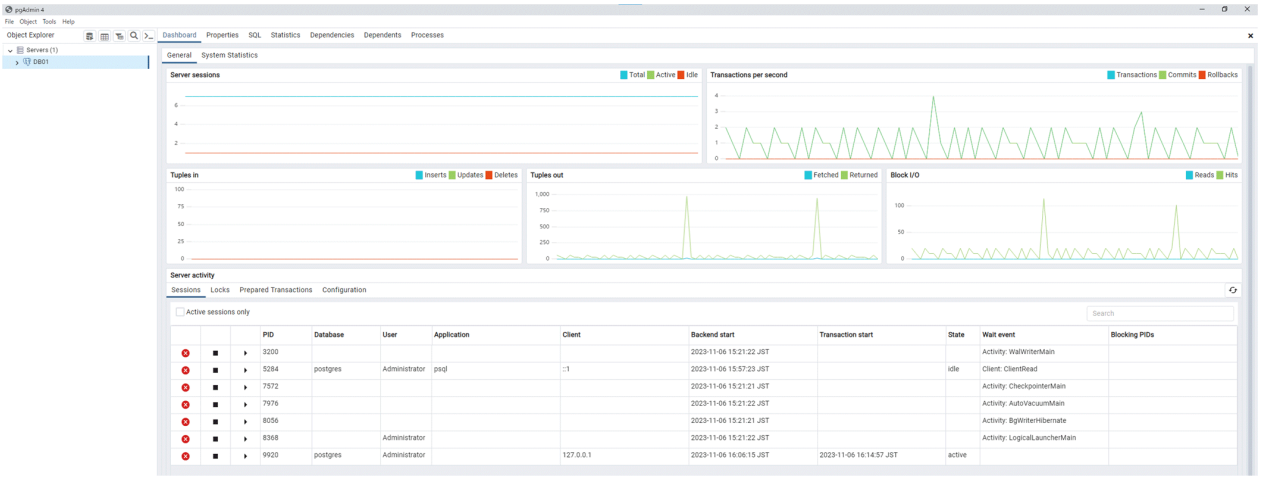
- Refer to "Notes on Application Compatibility" in the Application Development Guide for information on maintaining application compatibility.
- Refer to "The Statistics Collector" under "Server Administration" in the PostgreSQL Documentation for information on pg_stat_activity.

8.4.2 Using pgAdmin

This section describes the procedure for monitoring connections using [Server Status] in pgAdmin.

1. In the [Browser] pane, click the database server for monitoring.

2. In the [Dashboard] tab, identify client connections that have been in the waiting state for an extended period.



8.5 Reorganizing Indexes

Normally, a database defines indexes in tables, but if data is frequently updated, indexes can no longer use free space in the disk efficiently. This situation can also cause a gradual decline in database access performance.

To rearrange used space on the disk and prevent the database access performance from declining, it is recommended that you periodically execute the REINDEX command to reorganize indexes. Because the REINDEX command retrieves the exclusive lock for an index being processed and locks writing of tables that are the source of the index, other processes that access these may stop while waiting to be locked. Therefore, it is necessary to consider measures such as executing the command after the task is completed.

Check the disk usage of the data storage destination using the method described in "8.2 Monitoring Disk Usage and Securing Free Space".

See

Refer to "Routine Reindexing" under "Server Administration" in the PostgreSQL Documentation for information on reorganizing indexes by periodically executing the REINDEX command.

Point

Typically, reorganize indexes once a month at a suitable time such as when conducting database maintenance. Use SQL statements to check index usage. If this usage is increasing on a daily basis, adjust the frequency of recreating the index as compared to the free disk space.

The following example shows the SQL statements and the output.

However, when considering continued compatibility of applications, do not reference system catalogs and functions directly in the following SQL statements. Refer to "Notes on Application Compatibility" in the Application Development Guide for details.

[SQL statements]

```
SELECT
  nspname AS schema_name,
  relname AS index_name,
  round(100 * pg_relation_size(indexrelid) / pg_relation_size(indrelid)) / 100 AS index_ratio,
  pg_size_pretty(pg_relation_size(indexrelid)) AS index_size,
  pg_size_pretty(pg_relation_size(indrelid)) AS table_size
FROM pg_index I
  LEFT JOIN pg_class C ON (C.oid = I.indexrelid)
  LEFT JOIN pg_namespace N ON (N.oid = C.relnamespace)
WHERE
  C.relkind = 'i' AND
  pg_relation_size(indrelid) > 0
ORDER BY pg_relation_size(indexrelid) DESC, index_ratio DESC;
```

[Output]

```
 schema_name |            index_name             | index_ratio | index_size | table_size
-------------+-----------------------------------+-------------+------------+------------
 public      | pgbench_accounts_pkey             |        0.16 | 2208 KB    | 13 MB
 pg_catalog  | pg_depend_depender_index          |         0.6 | 224 KB     | 368 KB
 pg_catalog  | pg_depend_reference_index         |        0.58 | 216 KB     | 368 KB
...
```

See

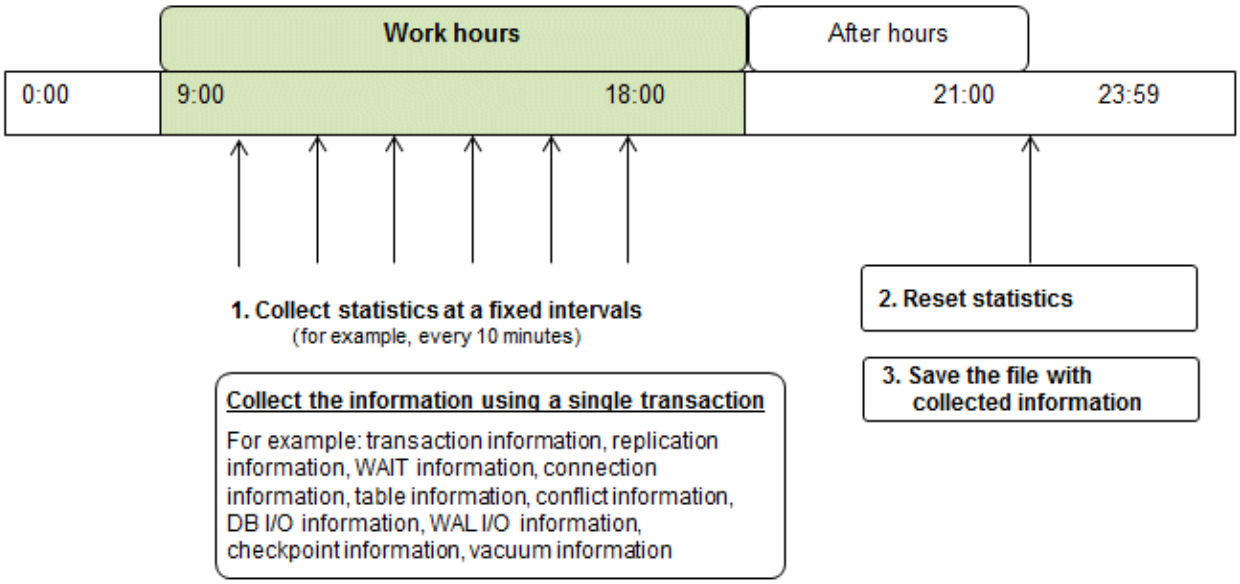
Refer to "Notes on Application Compatibility" in the Application Development Guide for information on maintaining application compatibility.

8.6 Monitoring Database Activity

Fujitsu Enterprise Postgres enables you to collect information related to database activity. By monitoring this information, you can check changes in the database status.

This information includes wait information for resources such as internal locks, and is useful for detecting performance bottlenecks. Furthermore, you should collect this information in case you need to request Fujitsu technical support for an investigation.

Figure 8.1 Overview of information collection



1. Collect statistics at fixed intervals during work hours.

   Accumulate the collected information into a file.

   Wherever possible, collect data from the various statistics views using a single transaction, because it enables you to take a snapshot of system performance at a given moment.

   Refer to "8.6.1 Information that can be Collected" for information on the system views that can be collected.

2. Reset statistics after work hours, that is, after jobs have finished.

   Refer to "8.6.3 Information Reset" for information on how to reset statistics.

3. Save the file with collected information.

   Keep the file with collected information for at least two days, in order to check daily changes in performance and to ensure that the information is not deleted until you have sent a query to Fujitsu technical support.

Where jobs run 24 hours a day, reset statistics and save the file with collected information when the workload is low, for example, at night. Statistics cumulatively add the daily database value, so if you do not reset them, the values will exceed the upper limit, and therefore will not provide accurate information.

The subsections below explain the following:

- Information that can be collected
- Collection configuration
- Information reset

8.6.1 Information that can be Collected

Information that can be collected is categorized into the following types:

- Information common to PostgreSQL
- Information added by Fujitsu Enterprise Postgres

Information common to PostgreSQL

Refer to "Monitoring Database Activity" under "Server Administration" in the PostgreSQL Documentation for information on information common to PostgreSQL.

Information added by Fujitsu Enterprise Postgres

You can collect the following information added by Fujitsu Enterprise Postgres.

Table 8.1 Information added by Fujitsu Enterprise Postgres

View name	Description
pgx_stat_lwlock	Displays statistic related to lightweight lock, with each type of content displayed on a separate line. This information helps to detect bottlenecks. Refer to "D.2 pgx_stat_lwlock" for details.
pgx_stat_latch	Displays statistics related latches, with each type of wait information within Fujitsu Enterprise Postgres displayed on a separate line. This information helps to detect bottlenecks. Refer to "D.3 pgx_stat_latch" for details.
pgx_stat_walwriter	Displays statistics related to WAL writing, in a single line. Refer to "D.4 pgx_stat_walwriter" for details.
pgx_stat_sql	Displays statistics related to SQL statement executions, with each type of SQL statement displayed on a separate line. Refer to "D.5 pgx_stat_sql" for details.
pgx_stat_gmc	Displays statistics related to Global Meta Cache hit ration and used memory size. Refer to “D.6 pgx_stat_gmc” for detail. Also refer to Chapter 13 Global Meta Cache" for information on the Global Meta Cache.

8.6.2 Collection Configuration

The procedure for configuring collection depends on the information content.

- Information common to PostgreSQL
- Information added by Fujitsu Enterprise Postgres

Information common to PostgreSQL

See

Refer to "The Statistics Collector" in "Monitoring Database Activity" under "Server Administration" in the PostgreSQL Documentation for information on information common to PostgreSQL.

Information added by Fujitsu Enterprise Postgres

Information added by Fujitsu Enterprise Postgres is collected by default.

To enable or disable information collection, change the configuration parameters in postgresql.conf. The following table lists the views for which you can enable or disable information collection, and the configuration parameters.

View name	Parameter
pgx_stat_lwlock pgx_stat_latch	track_waits (*1)
pgx_stat_sql	track_sql
pgx_stat_gmc	track_gmc

Remarks: You cannot change the collection status for pgx_stat_walwriter.

*1: When executing the SQL statement with EXPLAIN ANALYZE, processing time may increase because of this information collection. It is recommended to set this parameter to "off" when executing EXPLAIN ANALYZE to check the processing time.

Refer to "Appendix A Parameters" for information on the parameters.

8.6.3 Information Reset

This section describes how to reset information.

Information added by Fujitsu Enterprise Postgres

You can reset information added by Fujitsu Enterprise Postgres by using the pg_stat_reset_shared function in the same way as for information common to PostgreSQL.

Configure the following parameters in the pg_stat_reset_shared function:

Function	Type of return value	Description
pg_stat_reset_shared(text)	void	Reset some cluster-wide statistics counters to zero, depending on the argument (requires superuser privileges). Calling pg_stat_reset_shared('lwlock') will zero all counters shown in pgx_stat_lwlock. Similarly, in the following cases, all values of the pertinent statistics counter are reset: - If pg_stat_reset_shared('latch') is called: All values displayed in pgx_stat_latch - If pg_stat_reset_shared('walwriter') is called: All values displayed in pgx_stat_walwriter - If pg_stat_reset_shared('sql') is called: All values displayed in pgx_stat_sql

Function	Type of return value	Description
		- If pg_stat_reset_shared('gmc') is called: All values except size column in pgx_stat_gmc

See

Refer to "Statistics Functions" in "Monitoring Database Activity" under "Server Administration" in the PostgreSQL Documentation for information on other parameters of the pg_stat_reset_shared function.

8.7 Scheduling of an Aggressive Freeze for Tuples (VACUUM FREEZE)

An architectural limitation of PostgreSQL is that it requires transaction ID reclamation via tuple freezing to avoid the problem of disruptive transaction wraparound. For more information about transaction wraparound issues, refer to "Preventing Transaction ID Wraparound Failures" in the PostgreSQL Documentation.

Tuple freezing works with autovacuum and VACUUM FREEZE(aggressive freeze for tuples). However, on a system that consumes transactions quickly, autovacuum alone might be enough to run into wraparound problems. This is because autovacuum is slow to reduce frequency of collisions with applications and increase system load. Such systems must perform an aggressive tuple freeze at the appropriate time.

Fujitsu Enterprise Postgres provides scripts to perform efficient aggressive freeze for tuples.

This section describes how to monitor whether the freezing process is on time in a running system, and how to estimate the running time of the script.

Point

If you insert or update a large amount of data at once, the next freeze process will take a long time, so be sure to perform aggressive freeze for tuples after such operations.

8.7.1 Monitoring Trends in Transaction ID Usage

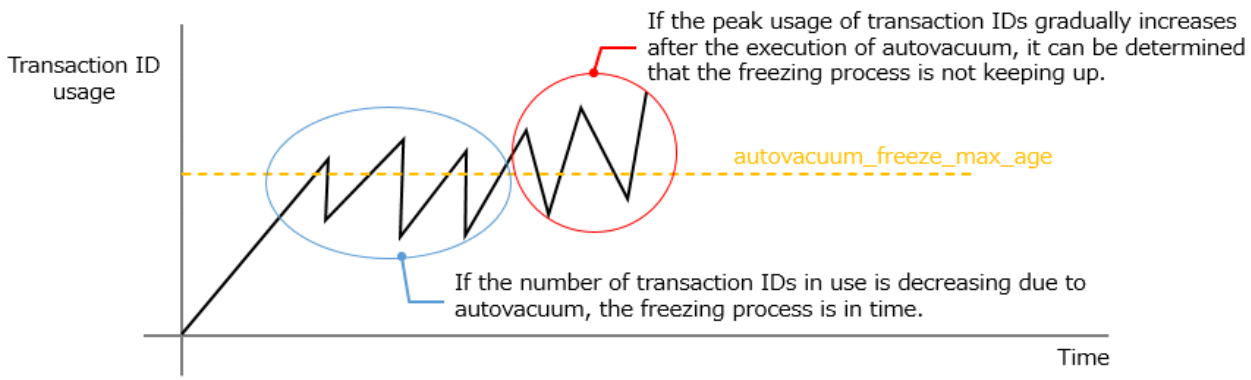
Execute the following SQL to monitor the trend in transaction ID usage.

```
# SELECT max(age(datfrozenxid)) FROM pg_database WHERE datallowconn = true;
```

If autovacuum does not sufficiently reduce transaction ID usage, schedule aggressive freeze for tuples.

Determine whether the amount of waste reduced by automatic vacuum is sufficient

Looking at the entire interval that includes several autovacuum freeze processes, the transaction ID usage will be graphed like a sawtooth, sandwiching the autovacuum_freeze_max_age setting value, depending on the start and end of the autovacuum operation. If the usage peaks are gradually getting larger, the reduction may be insufficient. In particular, if it no longer falls below autovacuum_freeze_max_age, the reduction is definitely insufficient.



8.7.2 How to Schedule Aggressive Freeze for Tuples

1. Determine a time period with low business load when aggressive freeze for tuples will have minaimal impact.
2. Copy the script that implements aggressive freeze for tuples and set the connection information, multiplicity, and timeout value parameters.

   For streaming replication configuration, specify multiple connection destinations in PGHOST and PGPORT, and specify "read-write" or "primary" in PGTARGETSESSIONATTRS to connect to the primary server.

   The scripts are stored in the following location under the Fujitsu Enterprise Postgres installation directory:

   ```
   <Install directory>\share\execute_freeze.ps1.sample
   ```

3. Register the script from step 2 in the job scheduler.
   Specify the execution timing according to the planned time period.

   Example: Use the Task Scheduler to run a script called execute_freeze.ps1 at 2:05 AM

   ```
   schtasks /create /tn "ExecuteVacuumFreeze" /tr "powershell -ExecutionPolicy Bypass -windowstyle
   hidden -File 'C:\path\to\execute_freeze.ps1'" /sc daily /st 02:05 /f
   ```

When a schedule review is required

Even after aggressive freeze for tuples is scheduled, continue to monitor the trend in transaction ID usage. If you determine that the freezing process is not keeping up, the schedule must be reviewed. To collect the statistical information required for the review, enable the extended functionality for aggressive freeze for tuples using the following procedure.

1. Modify the shared_preload_libraries parameter in postgresql.conf

   ```
   shared_preload_libraries = 'pgx_stat_vacuum_freeze'
   ```

2. Execute the following SQL

   ```
   SELECT datname FROM pg_database WHERE datallowconn = true;
   ```

   Execute the following CREATE EXTENSION for all databases to be output and define the extension.

   ```
   CREATE EXTENSION pgx_stat_vacuum_freeze;
   ```

Monitor the trends in transaction usage, and if you determine that the freezing process is not keeping up, refer to "8.7.3 Tuning the Allocation Time for Aggressive Freeze for Tuples" to calculate the time required for freezing tuples and add more allocation time.

8.7.3 Tuning the Allocation Time for Aggressive Freeze for Tuples

The interval between autovacuum runs is treated as one interval, and aggressive freeze for tuples is scheduled to be completed before the next autovacuum run. For example, if your environment is one week where freezing by autovacuum occurs, determine the required time within that interval.

Calculate the time required for aggressive freeze for tuples as follows, based on the time it took to freeze transaction IDs by past autovacuums stored in the pgx_stat_freeze_results table for each database you are using.

In this example, the interval for autovacuum freezing is set to one week. Perform this for each database you operate and calculate the total.

```
# SELECT sum(total_elapsed_time) - sum(sleep_times) as total_time FROM pgx_stat_freeze_results WHERE
measurement_start_time >= '2024/10/21 00:00:00' AND measurement_end_time < '2024/10/28 00:00:00' AND
autovacuum = true;
```

If you are unable to secure sufficient time when the workload is low, increase the degree of parallelism. You can specify the degree of parallelism in the script.

8.8 Database Monitoring with Amazon CloudWatch

Amazon CloudWatch is a monitoring tool provided by Amazon Web Services (hereinafter referred to as AWS). Fujitsu Enterprise Postgres works with Amazon CloudWatch to collect database-related metrics and logs. The collected metrics can be used to monitor the status of the database and create alert notifications when thresholds are exceeded. In addition, by analyzing the collected logs on CloudWatch, it is possible to detect abnormalities in logins and operations.

8.8.1 Metrics Collection

Metrics collection uses psql commands to retrieve metrics and the AWS CLI to forward metrics to Amazon CloudWatch.

1. Preparation

   Refer to the AWS documentation, install the AWS CLI, and configure it to transfer metrics to Amazon CloudWatch.

2. Create a metrics collection script

   Sample scripts for collecting metrics are stored in the following location under the Fujitsu Enterprise Postgres installation directory. Create a script for collecting metrics by referring to the sample script. For the metrics collected by the sample script, refer to "8.8.3 Metrics Collected by the Sample Script".

   ```
   <Install directory>\share\putting-metrics-to-monitoring-tool.ps1.sample
   ```

   Edit the following connection information defined in the sample script.

   - Amazon CloudWatch connection destination to store metrics

     Define the Amazon CloudWatch Namespace to collect metrics in “NAMESPACE”.

     ```
     $NAMESPACE="YOUR Cloud Watch NAMESPACE"
     ```

   - Database connection destination for collecting metrics

     Edit the variables below to define the PostgreSQL information for retrieving metrics.

     PGHOST: Specify the host name to connect to.

     PGPORT: Specify the port to connect to.

     PGDATABASE: Specify the database name to connect to.

     PGUSER: Specify the PostgreSQL user to use for connection. To view all statistical information for all sessions, specify a superuser or a role with the built-in role pg_read_all_stats privileges.

3. Setting environment variables

   To run the metrics collection script, you must set the path where the Fujitsu Enterprise Postgres server feature and AWS CLI are installed in the environment variable PATH.

   The PATH environment variable can be added to the environment variables of the user running the metrics collection script, or added within the script.

   The following is an example configuration when the AWS CLI is installed in C:\Program Files\Amazon\AWSCLIV2.

   ```
   set PATH = "C:\Program Files\Fujitsu\fsepv<x>server64\bin;C:\Program Files\Amazon\AWSCLIV2;%PATH
   %"
   ```

When setting environment variables within a script, make sure to write them at the beginning of the script, before the environment variable for the database connection destination.

```
$env:PATH = "C:\Program Files\Fujitsu\fsepv<x>server64\bin;C:\Program Files\Amazon\AWSCLIV2;" +
$env:PATH
```

4. Define the database connection credentials

   If necessary, define the password and the storage location of the SSL communication certificate in an environment variable or configuration file.

5. Periodically run metrics collection scripts

   Use a task scheduler or similar to periodically run the metrics collection script as the OS user who can transfer metrics using the aws cloudwatch put-metric-data command.

   Below is an example of a task scheduler definition for collecting metrics every 10 minutes.

```
# Task Scheduler screen
Right-click on "Task Scheduler Library"
-> Select Create basic task

# Definition when creating a task
1. Create a basic task
 Enter "Name" and "Description" and click "Next"
2. Trigger
 Select "Daily" and click "Next"
3. Daily
 Start: Any date
 Interval: 1 day
 Select and click "Next"
4. Operation
 Select "Start a program" and click "Next"
5. Start a program
 Enter the following and click "Next"
 Program/script: C:\Windows\System32\cmd.exe
 Add arguments: /c ""C:\Program Files\PowerShell\7\pwsh.exe" -ExecutionPolicy Bypass -File
"( Script placement location)\putting-metrics-to-monitoring-tool.ps1" >> "( Log storage location)
\put-metrics.log" 2>&1"
6. Completed
 Check "Open the Properties dialog for this task when I click Finish" and click "Finish"

# Properties screen
1. General tab
 Check "Run whether user is logged on or not"
 Define the user who will run the task with "Change User or Group"
2. Trigger tab
 Repeat every: Check the box and select 10 minutes from the dropdown
```

   In this example, the script's standard output is output to the log file "put-metrics.log", allowing you to detect whether the script is running normally or abnormally. Note that in this example, the log file continues to be output, so we recommend using a task scheduler or similar to periodically rotate and delete the logs.

   The metrics collection interval should be determined based on the purpose of collection. The following are examples of collection intervals.

   - Long intervals, such as once every 10 minutes or once an hour, are recommended when monitoring to check operational trends.
   - Short intervals, such as once a minute, are recommended when monitoring to quickly respond to increases in load, such as a sudden increase in the number of connections.

   If the collection interval is short, the load may increase because the number of queries to the database increases accordingly. Consider the business load when deciding on the execution interval and the queries to be executed for metric collection.

8.8.2 Log Collection

You can collect logs using the CloudWatch agent. For instructions on how to collect logs, see the Amazon CloudWatch manual.

8.8.3 Metrics Collected by the Sample Script

In the sample script, metrics items are created from the following perspectives to regularly check whether the database cluster is operating properly.

- Is the database capacity sufficient?
- Are your SQL performance and connections adequate?
- Are each node operating normally?

Table 8.2 List of metrics collected by the sample script

Metrics name	Metrics
pg_stat_bgwriter_*	Maps displayed in statistics collection
pg_stat_database_*	Maps displayed in statistics collection
pg_stat_database_conflicts_*	Maps displayed in statistics collection
pg_stat_archiver_*	Maps displayed in statistics collection
pg_stat_activity_*	Maps displayed in statistics collection
pg_stat_replication_*	Maps displayed in statistics collection
pg_replication_slots_*	Mapping to the pg_replication_slots system catalog
pg_locks_*	Mapping to the pg_locks system catalog
pg_capacity_connection_*	Connection metrics (e.g. txns running for 1 hour)
pg_capacity_schema_*	Schema disk space metrics
pg_capacity_tblspace_*	Tablespace disk space metrics
pg_capacity_tblvacuum_*	Metrics for tables that haven't been vacuumed in days
pg_capacity_longtx_*	Number of transactions running for more than 5 minutes
pg_capacity_datfrozenxid_*	Trends in transaction ID usage (Used for scheduling aggressive freeze for tuples (VACUUM FREEZE))
pg_performance_locking_detail_*	Blocked process details
pg_performance_locking_*	Number of blocked processes
pg_stat_user_tables_*	Vital statistics from pg_stat_user_tables
pg_statio_user_tables_*	Vital statistics from pg_statio_user_tables
pg_stat_statements_*	Statistics for SQL statements executed by the server
pg_capacity_tblbloat_*	Table fetch bloat

8.9 Monitoring Deferred SQL and Periodically Backing up statistics

After production starts, SQL execution can be delayed due to a variety of factors, including unexpected system load and data bias. You can detect delays early by monitoring for delays that affect operations. Monitoring can also reduce the time required for recovery tasks, such as determining the cause and resolving delays.

One cause of deferred SQL is a change in statistics. Some delays caused by statistics can be resolved by restoring the statistics before the delay occurred. For this reason, back up your statistics periodically to guard against delays.

Operational workflow

The workflow required to monitor delayed SQL and back up statistics is shown below.

Corresponding time	Work item	Work details
During environment construction	(1) Enabling the pg_dbms_stats extension	Enable the pg_dbms_stats extension with the Create Extension statement.
	(2) Logging settings for delayed SQL monitoring	Set the log_min_duration_statement parameter etc. in postgresql.conf.
During system development	(3) Creating and reviewing a script for backing up statistics (*1)	Provide a script to back up statistics according to the statistics and Vacuum operation.
During operation	(4) Periodic backup of statistics	Execute the script created in (3) to back up the statistics.
	(5) Monitoring delayed SQL and adjusting the allowable delay time	Monitor the occurrence of delayed SQL and adjust the allowable delay time to find the optimal settings for operation.
When delayed SQL occurs	(6) Investigating the cause of delayed SQL	If a delayed SQL occurs, we will investigate the cause of the SQL delay and consider countermeasures.
	(7) Restoring statistics (*2)	Delayed SQL is eliminated by restoring and fixing the backed up statistics.

*1: Although it is possible to perform the work during operation, please consider the impact on operation and perform the work before starting operation.

*2: If it is determined that the cause is not statistics, take appropriate measures according to the cause.

The specific work content is shown below.

(1) Enabling the pg_dbms_stats extension

To back up and restore statistics, you need the export and import functions of the pg_dbms_stats extension, so enable the pg_dbms_stats extension.

For instructions on how to enable it, refer to " Setting Up pg_dbms_stats" in the Installation and Setup Guide for Server.

(2) Logging settings for delayed SQL monitoring

Database logs are used to monitor delayed SQL.

Make the following settings in postgresql.conf. Note that the date and time are important when investigating the cause of delayed SQL, set the format and file name to include the date and time.

Parameter	Specified value
logging_collector	on
log_line_prefix	Specify the following format and add information required for investigation, such as the time and executed application. [%t]%u %d %p[%l]
log_filename	Since you will need to check past execution records, set it so that you can see the date and time. postgresql.%Y-%m-%d
log_min_duration_statement	300000

Point

If the value specified for the log_min_duration_statement parameter is small, even SQL that does not need to be considered delayed will be output to the log, and if it is too large, delayed SQL cannot be detected. Therefore, if the setting value cannot be estimated, set it small at the start of operation, and adjust it to a larger value as necessary while monitoring during operation.

(3) Creating and reviewing a script for backing up statistics

To back up statistics, use the export function of the pg_dbms_stats extension.

The backup is used not only for restoration but also for identifying the cause of delayed SQL, so the time the backup was performed is important. Therefore, be sure to create a script like the one below so that the backup time is known.

We also provide a sample script that uses the export function to export on a database basis. This allows users to respond more flexibly by making modifications themselves, such as making changes on a schema basis, so copy the script to the execution current before using it.

The sample script is stored below. Also, "<*x*>" indicates the product version.

```
c:\Program Files\Fujitsu\fsepv<x>server64\OSS\pg_dbms_stats \doc\extension\export_plain_stats-
<x>.sql.sample
```

The following is an example of a file created when it is copied to the current execution directory as "export_plain_stats-<x>.sql".

```
echo off
SET CURRENTDIR=d:\pg_dbms_stats\backup

pushd "%CURRENTDIR%"

Rem make filename
SET NOWDATE=%date:~0,4%%date:~5,2%%date:~8,2%
SET TMPTIME=%time: =0%
SET NOWTIME=%TMPTIME:~0,2%%TMPTIME:~3,2%
EXECDATE=%NOWDATE%%NOWTIME%
set FILENAME=pg_dbms_stats_back.%EXECDATE%.dmp

rem export
psql -d database1 -f export_plain_stats-<x>.sql

rem rename dump file
ren export_stats.dmp ${FILENAME}
popd
```

(4) Periodic backup of statistics

Execute the script created in "(3) Creating and reviewing a script for backing up statistics" to back up the statistics information on a regular basis.

Backup execution interval

Perform backup at the following timings according to the statistics update method.

When statistics is automatically updated (autovacuum is enabled)

Statistics are updated when autovacuum is run.

Therefore, use the OS's cron command or schedule function of the task manager to periodically execute the export function and back up the statistics to a file.

Therefore, use the OS's cron command or a scheduler such as task manager to periodically execute the script created in "(3) Creating and reviewing a script for backing up statistics" and back up the statistics information to a file.

Obtain the shortest autovacuum execution interval from the log, and back up the statistics at an interval shorter than the obtained autovacuum execution interval. autovacuum logs can be obtained by setting the log_autovacuum_min_duration parameter to 0.

When users update statistics

If the user controls the updating of statistics using the ANALYZE command, etc.,back up the statistics at the same time as updating the statistics.

Backup retention period

The backed up statistics will be used as investigation material to determine the cause of delayed SQL if a performance problem occurs. Therefore, keep it for the period of time expected to be required from the occurrence of the operational problem to its resolution.

Point

- The capacity required for backup mainly depends on the number of objects (schemas, tables, etc.) contained in the database. Estimate the required capacity from the backup file when checking the operation of the script and secure this space.
- To restore backed up statistics, the names of objects such as schemas and tables in the backup source must match. If you change the name of an object during operation, change the backup file name or storage location so that you can check whether it matches the object definition when restoring statistics.

(5) Monitoring delayed SQL and adjusting the allowable delay time

Monitors SQL that is delayed beyond the time set in the log_min_duration_statement parameter.

The settings in this section will be output in the following format.

```
[2024-04-30 10:20:11 JST]user1 postgres 3414[1]LOG: duration: 301001.541 ms  statement: SELECT
pg_sleep(301)
[2024-04-30 10:26:12 JST]user1 postgres 3414[1]LOG: duration: 302002.321 ms  statement: SELECT
pg_sleep(302)
```

When detected SQL is deemed to be delayed more than expected

Refer to "(6) Investigating the cause of delayed SQL" to determine the cause and take appropriate measures.

When SQL with execution time that does not affect operation is detected

The current setting just outputs redundant logs, so make major changes to the log_min_duration_statement parameter and then reload to enable it.

(6) Investigating the cause of delayed SQL

There are many factors that can cause SQL delays, so you must first identify the cause.

Here we will show you how to investigate SQL delays caused by changes in statistics.

Note that in the following cases, delays caused by statistics are unlikely, so recommend investigating from a different perspective (I/O, system load, etc.).

- When the SQL statement does not contain a search condition
- When the SQL statement uses the pg_hint_plan extension

1. Check the delayed SQL from the server log and identify the schema used by that SQL.
2. In a database cluster (such as a development environment) separate from the production environment, create an environment (hereafter referred to as the reproduction environment) with the same database name and table definition as the environment where the problem occurred. The reproduction environment also requires the pg_dbms_stats extension, so enable the pg_dbms_stats extension.
3. Use the pg_dump command from the production environment to obtain the target table definition.
   Since the data is not needed at this time, use the -s option of the pg_dump command from the production environment and use the extracted table definition.

   The following is an example of output to the file ddl_schema.dmp when the schema to be investigated is schema_1 in database database1.

```
pg_dump -d database1 -s schema_1 > ddl_schema.dmp
```

Using ddl_schema.dmp, create a research schema named schema_1 in the database named database1 in the reproduction environment.

```
psql -d database1 -f ddl_schema.dmp
```

4. In order to identify the cause of the SQL delay, use the backed up statistics to check whether there is a cause of the delay in the statistics. Import the statistics into the schema in the reproduction environment using the pg_dbms_stats import function (dbms_stats.import_schema_stats).
   The following is an example of restoring statistics for schema schema_1 from the backup file "pg_dbms_stats_back.20240422011223.dmp".

   ```
   psql -d database1 -c
   "SELECT dbms_stats.import_schema_stats('schema_1','pg_dbms_stats_back.20240422011223.dmp')"
   ```

   Then, execute the EXPLAIN command for the deferred SQL to obtain the execution result (query plan).

5. Restore the statistics by separately importing the statistics that were backed up during the previous time period when deferred SQL was running stably.
   For example, if the target SQL is executed daily as part of regular batch processing, use the data from the same time the previous day.
   For online processing, use the data from a previous time period when a similar business application is expected to be executed.
   The following is an example of restoring the statistics from the backup file "pg_dbms_stats_back.20240421010001.dmp" from one day ago, assuming the SQL is used in batch processing.

   ```
   psql -d database1 -c
   "SELECT dbms_stats.import_schema_stats('schema_1','pg_dbms_stats_back.20240421010001.dmp')"
   ```

   It likewise obtains the result of executing the EXPLAIN command on deferred SQL (query plan).

6. Compare the execution results (query plans) of 4. and 5., and take the following action based on the results.

   - If the query plans are the same or the expected execution time of the query plan in 5. is longer

     This may be a problem other than statistics (system load, index imbalance, I/O, etc.), so investigate from a different perspective.

   - Other than the above

     The problem is likely that the optimal query plan was not selected due to updated statistics.

     Refer to "(7) Restoring statistics" and import the statistics from the period when the system was operating stably into the production environment to restore the system.

(7) Restoring statistics

Restore the production environment statistics to the state they were in before the delay occurred. The procedure is the same as for verification, but it is as follows:

```
psql -d database1 -c
"SELECT dbms_stats.import_schema_stats('schema_1','pg_dbms_stats_back.20240422000000')"
```

8.10 Performance Tuning

8.10.1 Enhanced Query Plan Stability

Fujitsu Enterprise Postgres estimates the cost of query plans based on SQL statements and database statistics, and selects the least expensive query plan. However, like other databases, Fujitsu Enterprise Postgres does not necessarily select the most suitable query plan. For example, it may suddenly select unsuitable query plan due to changes in the data conditions.

If you know that the statistics will not change significantly, you can control the selection of the same query plan by directly specifying which query plan to select in pg_hint_plan, or by fixing the statistics referenced by the planner in pg_dbms_stats.

Also, pg_dbms_stats from Fujitsu Enterprise Postgres can fix statistics (height of Btree indexes) that OSS pg_dbms_stats cannot account for. Refer to "8.10.1.1 Fixing the Height of a Btree Index".

See

- For information about setting up pg_hint_plan and pg_dbms_stats, refer to "pg_hint_plan" and "pg_dbms_stats" in the Installation and Setup Guide for Server.
- For basic usage of pg_hint_plan and pg_dbms_stats, refer to below.
  - Control execution plans with pg_hint_plan

    https://www.postgresql.fastware.com/postgresql-insider-tun-hint-plan
  - Control execution plans by fixing statistics with pg_dbms_stats

    https://www.postgresql.fastware.com/postgresql-insider-tun-dbms-stt
- For more information about pg_hint_plan and pg_dbms_stats, refer to the OSS web page.

8.10.1.1 Fixing the Height of a Btree Index

When PostgreSQL creates a query plan, it also references the height of the Btree index to be used as part of the statistics. However, OSS pg_dbms_stats does not include the height of the Btree index in its fixed statistics. The height of a Btree index is also fixed in pg_dbms_stats for Fujitsu Enterprise Postgres.

Fixing the height of a Btree index covers Fujitsu Enterprise Postgres 16 and later, so to maintain compatibility with earlier versions, specify something like:

- PostgreSQL 9.2 and earlier compatibility

```
pg_dbms_stats.use_tree_height = off
```

- Fujitsu Enterprise Postgres 15 SP2 and earlier compatibility

```
pg_dbms_stats.lock_tree_height = off
```

See the table below for details on each parameter. If you want the parameter value to be valid for all sessions, specify it in postgresql.conf and then reload.

Parameter	Specified value	Default
pg_dbms_stats.use_tree_height	Specify whether to include the Btree index height in cost calculation and plan generation when statistics are fixed. on: Includes Btree index height in cost calculations and plan generation. off: Do not include Btree index height in cost calculation or plan generation.	on
pg_dbms_stats.lock_tree_height	Specify whether to also fix the height of the Btree index when you fix the statistics. Note that this is valid only when the specified value of pg_dbms_stats.use_tree_height is "on". on: Fixes the height of the Btree index at the height when locked. off: The height of the Btree index is not fixed and varies depending on the amount of data in the index.	on

When you want to import statistics from your legacy environment

The format of files handled by the import/export functions of this version of pg_dbms_stats is different from the format of pg_dbms_stats in OSS or Fujitsu Enterprise Postgres 15SP2 or earlier. Therefore, statistics exported from pg_dbms_stats for OSS or Fujitsu Enterprise Postgres 15SP2 or earlier should be imported using the dbms_stats.import_<obj>_stats_no_tree_height function.

How to specify the dbms_stats.import_<obj>_stats_no_tree_height function

```
dbms_stats.import_<obj>_stats_no_tree_height('Absolute path of export file')
```

<obj> indicates a database (currently connected), schema, table, or column.

Import using the dbms_stats.import_<obj>_stats function provided by OSS is not possible.

If you use the wrong import function, an error message containing the following HINT will be output. Check the combination of input file and import function type, and use the correct import function.

```
HINT:  The import function may be incorrectly combined with the format of the exported data. Please
check the documentation for the relationship between the import function and the available data.
```

Chapter 9 Streaming Replication Using WebAdmin

This chapter describes streaming replication using WebAdmin.

A standby instance for streaming replication can be created from a standalone instance, a master instance, or another standby instance. The standby instance connects to the master instance and uses WAL records to replicate data. The standby instance can be used for read-only operations.

WebAdmin cannot back up standby instances.

Additionally, streaming replication can be set to asynchronous or synchronous mode.

Point

- If a streaming replication cluster is created using WebAdmin, the network with the host name (or IP address) specified in [Host name] will be used across sessions of WebAdmin, and also used as the log transfer network.
- To use a network other than the job network as the log transfer network, specify the host name other than the job network one in [Host name].

For characters that cannot be specified in WebAdmin, refer to "Appendix J WebAdmin Disallow User Inputs Containing Hazardous Characters".

9.1 Creating a Standby Instance

Follow the procedure below to create a standby instance.

1. In the [Instances] tab, select the instance from which a standby instance is to be created.
2. Click .
3. Enter the information for the standby instance to be created.
   - [Location]: Whether to create the instance in the server that the current user is logged in to, or in a remote server. The default is "Local", which will create the instance in the server machine where WebAdmin is currently running.
   - [Replication credential]: The user name and password required for the standby instance to connect to the master instance. The user name and password can be entered or selected from the Wallet. Refer to "Appendix I WebAdmin Wallet" for information on creating wallet entries.
   - [Instance name]: Name of the standby database instance to create.

     The name must meet the conditions below:

     - Maximum of 16 characters
     - The first character must be an ASCII alphabetic character
     - The other characters must be ASCII alphanumeric characters
   - [Instance port]: Port number of the standby database instance.
   - [Host IP address]: The IP address of the server machine where the standby instance is to be created. This information is needed to configure the standby instance to be connected to the master.
   - [Data storage path]: Directory where the database data will be stored
   - [Backup storage path]: Directory where the database backup will be stored
   - [Transaction log path]: Directory where the transaction log will be stored
   - [Encoding]: Database encoding system
   - [Replication mode]: Replication mode of the standby instance to be created ("Asynchronous" or "Synchronous")

- [Application name]: The reference name of the standby instance used to identify it to the master instance.

  The name must meet the conditions below:

  - Maximum of 16 characters
  - The first character must be an ASCII alphabetic character
  - The other characters must be ASCII alphanumeric characters

4. Click to create the standby instance.

If using WebAdmin to manage Mirroring Controller, the message below may be output to the server log or system log in the standby instance. No action is required, as the instance is running normally.

```
ERROR:  pgx_rcvall failed
ERROR:  pgx_rcvall: backup of the database has not yet been performed, or an incorrect backup storage
directory was specified
```

9.2 Promoting a Standby Instance

Streaming replication between a master and standby instance can be discontinued using WebAdmin.

Follow the procedure below to promote a standby instance to a standalone instance, thereby discontinuing the streaming replication.

1. In the [Instances] tab, select the standby instance that needs to be promoted.
2. Click .
3. Click [Yes] from the confirmation dialog box.

The standby instance will be promoted and will become a standalone instance, which is not part of a streaming replication cluster.

Once the standby instance is promoted to become a standalone instance, the backup storage status will be "Error". This is because no backups are available when the instance is newly promoted to a standalone instance. The status will be reset if a new backup is performed by clicking [Solution] or .

9.3 Converting an Asynchronous Replication to Synchronous

You can convert an asynchronous standby instance to a synchronous standby instance.

Converting an Asynchronous standby instance to Synchronous can cause the master instance to queue the incoming transactions until the standby instance is ready. For this reason, it is recommended that this operation be performed during a scheduled maintenance period.

When adding a synchronous standby instance, Fujitsu Enterprise Postgres will only keep the first entry in [Synchronous standby names] in synchronous state.

Follow the procedure below to convert an Asynchronous standby instance to Synchronous.

1. In the [Instances] tab, select the master instance of the relevant cluster.
2. Click .
3. In the [Streaming replication] section, edit the value for [Synchronous standby names].
   - Add the "Application name" of the standby instance you want to be in Synchronous mode.
4. Click .
5. Select the master instance and click .
6. Select the standby instance. [Instance type] will now show the updated status.

See

To learn more about the differences between synchronous and asynchronous standby modes and their behavior, refer to "Streaming Replication" in "High Availability, Load Balancing, and Replication" in the PostgreSQL Documentation.

9.4 Converting a Synchronous Replication to Asynchronous

Follow the procedure below to convert a Synchronous standby instance to Asynchronous.

1. In the [Instances] tab, select the master instance of the relevant cluster.
2. Click .
3. In the [Streaming replication] section, edit the value for [Synchronous standby names].
   - Remove the "Application name" of the standby instance you want to be in Asynchronous mode.
4. Click .
5. Select the master instance and click .
6. Select the standby instance. [Instance type] will now show the updated status.

See

To learn more about the differences between synchronous and asynchronous standby modes and their behavior, refer to "Streaming Replication" in "High Availability, Load Balancing, and Replication" in the PostgreSQL Documentation.

9.5 Joining a Replication Cluster

WebAdmin facilitates the joining of an old master of the cluster as a standby node.

1. In the [Instances] tab, select the remote instance (from where the new cluster node will stream WAL entries), and then click .
2. Configure the node to accept streaming requests from the new node.
3. In the [Instances] tab, select the new standby instance (which needs to be connected to the cluster), and then click .
4. Set [Replication host name] to the remote instance.
5. Enter [Replication credential].

   Specify the user name and password required for the standby instance to connect to the remote instance. The user name and password can be entered or selected from the Wallet. Refer to "Appendix I WebAdmin Wallet" for information on creating wallet entries. Replication credential (user name and password) should not contain hazardous characters. Refer to "Appendix J WebAdmin Disallow User Inputs Containing Hazardous Characters".
6. Enter [Host IP address].

   Specify the IP address of the node where the standby instance was created.
7. Click to open the [Join replication cluster] dialog box.

   For Fujitsu Enterprise Postgres 13 and earlier instances, select [Restart later] or [Restart now], and then click [Yes] to set up the standby instance.
   For Fujitsu Enterprise Postgres 14 or later, click [Yes] to set up the standby instance.
8. Upon successful completion, the confirmation dialog box will be displayed.
9. Click [Close] to return to the instance details window.

The instance will become a standby instance, and will be part of the streaming replication cluster. The replication diagram will display the relationship between the standby instance and the remote instance. The user can change the replication relationship of the remote instance from asynchronous to synchronous (and vice versa) using the [Configuration] window.

Chapter 10 Installing and Operating the In-memory Feature

The in-memory feature enables fast aggregation using Vertical Clustered Index (VCI) and memory-resident feature.

VCI has a data structure suitable for aggregation, and features parallel scan and disk compression, which enable faster aggregation through reduced disk I/O.

The memory-resident feature reduces disk I/O that occurs during aggregation. It consists of the preload feature that reads VCI data to memory in advance, and the stable buffer feature that suppresses VCI data eviction from memory. The stable buffer feature secures the proportion specified by parameter in the shared memory for VCI.

This chapter describes how to install and operate the in-memory feature.

This feature can only be used in Advanced Edition.

10.1 Installing Vertical Clustered Index (VCI)

This section describes the installation of VCI.

1. Evaluating whether to Install VCI
2. Estimating Resources
3. Setting up

10.1.1 Evaluating whether to Install VCI

VCI uses available resources within the server to increase scan performance.

It speeds up processing in many situations, and can be more effective in the following situations:

- Single table processing
- Processing that handles many rows in the table
- Processing that handles some columns in the table
- Processing that performs very heavy aggregation such as simultaneous sum and average aggregation

VCI will not be used in the following cases, so it is necessary to determine its effectiveness in advance:

- The data type of the target table or column contains VCI restrictions.
- The SQL statement does not meet the VCI operating conditions
- VCI is determined to be slower based on cost estimation

Point

If performing operations that use VCI, the full_page_writes parameter setting in postgresql.conf must be enabled (on). For this reason, if this parameter is disabled (off), operations that use VCI return an error. In addition, to perform operations for tables that do not create a VCI when the full_page_writes parameter setting is temporarily disabled (off), do not create a VCI or perform operations to tables that created a VCI during that time.

See

- Refer to "10.1.4 Data that can Use VCI" for information on VCI restrictions.
- Refer to "Scan Using a Vertical Clustered Index (VCI)" - "Operating Conditions" in the Application Development Guide for information on VCI operating conditions.

10.1.2 Estimating Resources

Estimate resources before setting up VCI.

Select the aggregation that you want to speed up and identify the required column data. The additional resources below are required according to the number of columns.

- Memory

  Secure additional capacity required for the disk space for the column for which VCI is to be created.

- Disk

  Secure additional disks based on the disk space required for the column for which VCI is to be created, as VCI stores column data as well as existing table data on the disk. It is recommended to provide a separate disk in addition to the existing one, and specify it as the tablespace to avoid impact on any other jobs caused by I/O.

Information

The operations on VCI can continue even if the memory configured for VCI is insufficient by using VCI data on the disk.

See

Refer to "Estimating Memory Requirements" and "Estimating Database Disk Space Requirements" in the Installation and Setup Guide for Server for information on how to estimate required memory and disk space.

10.1.3 Setting up

This section describes how to set up VCI.

Setup flow

1. Setting Parameters
2. Installing the Extensions
3. Creating VCI
4. Confirming that VCI has been Created

10.1.3.1 Setting Parameters

Edit postgresql.conf to set the required parameters for VCI. After that, start or restart the instance.

The following table lists the parameters that need or are recommended to be configured in advance:

Parameter name	Setting value	Description	Required
shared_preload_libraries	Literal 'vci, pg_prewarm'	VCI and shared library to be preloaded at server start.	Y
session_preload_libraries	Literal 'vci, pg_prewarm'	VCI and shared library to be preloaded at connection start.	Y
reserve_buffer_ratio	Percentage of shared memory to be used for stable buffer table	Proportion of shared memory to be used for a stable buffer table.	N
vci.control_max_workers	Number of background workers that manage VCI	Number of background workers that manage VCI. Add this value to max_worker_processes.	N

Parameter name	Setting value	Description	Required
vci.max_parallel_degree	Maximum number of background workers used for parallel scan	Maximum number of background workers used for parallel scan. Add this value to max_worker_processes.	N
vci.smc_directory	Directory name in which a temporary file is created as the dynamic shared memory	Directory name in which a temporary file is created as the dynamic shared memory during a scan using a VCI.	N

Example

```
shared_preload_libraries =  'vci, pg_prewarm'
session_preload_libraries =  'vci, pg_prewarm'
reserve_buffer_ratio = 20
vci.control_max_workers = 8
vci.max_parallel_degree = 4
max_worker_processes = 18 # Example: If the initial value was 6, 6 + 8 + 4 = 18
vci.smc_directory = 'E:\\vci\\work'
```

Information

If performing operations that use VCI, do not delete the shared library names specified to "shared_preload_libraries" and "session_preload_libraries". If operations that access VCI are performed after the VCI was defined, unexpected behavior may occur.

See

- Refer to "Appendix A Parameters" for information on all parameters for VCI. Refer also to default value for each parameter and details such as specification range in the same chapter. Refer to "Server Configuration" under "Server Administration" in the PostgreSQL documentation for information on shared_preload_libraries, session_preload_libraries, and max_worker_processes.

10.1.3.2 Installing the Extensions

Execute CREATE EXTENSION to install the VCI and pg_prewarm extensions. Both extensions need to be installed for each database. Also, extensions can only be installed on the public schema by a superuser.

- Installing VCI

```
db01=# CREATE EXTENSION vci;
```

- Installing pg_prewarm

```
db01=# CREATE EXTENSION pg_prewarm;
```

Some operations cannot be performed for VCI extensions. Refer to "10.2.1 Commands that cannot be Used for VCI" for details.

10.1.3.3 Creating a VCI

Execute the CREATE INDEX statement with the "USING vci" clause to create a VCI for the desired columns and the "WITH (stable_buffer=true)" clause to enable the stable buffer feature.

To use a separate disk for the VCI, specify the TABLESPACE clause.

```
db01=# CREATE INDEX idx_vci ON table01 USING vci (col01, col02) WITH (stable_buffer=true);
```

Point

- Some table types cannot be specified on the ON clause of CREATE INDEX. Refer to "10.1.4.1 Relation Types" for details.
- Some data types cannot be specified on the column specification of CREATE INDEX. Refer to "10.1.4.2 Data Types" for details.
- Some operations cannot be performed for VCI. Refer to "10.2.1 Commands that cannot be Used for VCI" for details.
- The same column cannot be specified more than once on the column specification of CREATE INDEX.
- VCI cannot be created for table columns that belong to the template database.
- CREATE INDEX creates multiple views named vci_*10digitRelOid_5digitRelAttr_1charRelType* alongside VCI itself. These are called VCI internal relations. Do not update or delete them as they are used for VCI aggregation.
- All data for the specified column will be replaced in columnar format when VCI is created, so executing CREATE INDEX on an existing table with data inserted takes more time compared with a general index (B-tree). Jobs can continue while CREATE INDEX is running.
- When CREATE INDEX USING VCI is invoked on a partitioned table, the default behavior is to recurse to all partitions to ensure they all have matching indexes. Each partition is first checked to determine whether an equivalent index already exists, and if so, that index will become attached as a partition index to the index being created, which will become its parent index. If no matching index exists, a new index will be created and automatically attached; the name of the new index in each partition will be determined as if no index name had been specified in the command. If the ONLY option is specified, no recursion is done, and the index is marked invalid. (ALTER INDEX ... ATTACH PARTITION marks the index valid, once all partitions acquire matching indexes.) Note, however, that any partition that is created in the future using CREATE TABLE ... PARTITION OF will automatically have a matching index, regardless of whether ONLY is specified.
- Parallel index build is not supported on VCI indexes.

10.1.3.4 Confirming that the VCI has been Created

Execute the SELECT statement to reference the pg_indexes catalog, and confirm that the VCI was created for the target columns.

Example

```
db01=# SELECT indexdef FROM pg_indexes WHERE indexdef LIKE '%vci%';
                          indexdef
-------------------------------------------------------
CREATE INDEX idx_vci ON table01 USING vci (col01, col02)
(1 row)
```

10.1.4 Data that can Use VCI

This section describes on which relation types and for which data types VCIs can be created.

10.1.4.1 Relation Types

VCIs cannot be created on some relation types.

The ON clause of CREATE INDEX described in "10.1.3.3 Creating a VCI" cannot specify relations on which VCIs cannot be created.

- Relations on which VCIs can be created
  - Normal tables
  - UNLOGGED TABLEs
- Relations on which VCIs cannot be created
  - Materialized views
  - Temporary tables

- Views
- Temporary views
- Foreign tables

10.1.4.2 Data Types

VCIs cannot be created for some data types.

The column specification of CREATE INDEX described in "10.1.3.3 Creating a VCI" cannot specify a column with data type on which VCIs cannot be created.

Category	Data type	Supported by VCI?
Numeric	smallint	Y
	integer	Y
	bigint	Y
	decimal	Y
	numeric	Y
	real	Y
	double precision	Y
	serial	Y
	bigserial	Y
Monetary	money	Y
Character	varchar(*n*)	Y
	char(*n*)	Y
	nchar	Y
	nvarchar(*n*)	Y
	text	Y
Binary	bytea	Y
Date/time	timestamp	Y
	timestamp with time zone	Y
	date	Y
	time	Y
	time with time zone	Y
	interval	Y
Boolean	boolean	Y
Geometric	point	N
	line	N
	lseg	N
	box	N
	path	N
	polygon	N
	circle	N
Network address	cidr	N

Category	Data type	Supported by VCI?
	inet	N
	macaddr	N
	macaddr8	N
Bit string	bit(*n*)	Y
	bit varying(*n*)	Y
Text search	tsvector	N
	tsquery	N
UUID	uuid	Y
XML	xml	N
JSON	json	N
	jsonb	N
Range	int4range	N
	int8range	N
	numrange	N
	tsrange	N
	tstzrange	N
	daterange	N
Object identifier	oid	N
	regproc	N
	regprocedure	N
	regoper	N
	regoperator	N
	regclass	N
	regtype	N
	regconfig	N
	regdictionary	N
pg_lsn type	pg_lsn	N
Array type	-	N
User-defined type (Basic type, enumerated type, composite type, and range type)	-	N

10.2 Operating VCI

This section describes how to operate VCI.

10.2.1 Commands that cannot be Used for VCI

Some operations cannot be performed for VCI extensions and VCI itself.

This section describes SQL commands that cannot be executed for the VCI extensions and VCI itself, and client application commands.

SQL commands

- Operations that cannot be performed for the VCI extension

Command	Subcommand	Description
ALTER EXTENSION	UPDATE	The VCI extension cannot be specified. This operation is not required for VCI.
	SET SCHEMA	
	ADD	
	DROP	
CREATE EXTENSION	SCHEMA	The subcommands on the left cannot be performed if the VCI extension is specified, except when the public schema is specified. This operation is not required for VCI.

- Operations that cannot be performed on relations containing a VCI

Command	Subcommand	Description
ALTER INDEX	SET	The subcommands on the left cannot be performed if a VCI is specified. If the operation is required, delete the VCI using DROP INDEX, and re-create it using CREATE INDEX after completing the operation.
	SET TABLESPACE	
	ALL IN TABLESPACE	
ALTER OPERATOR CLASS	RENAME TO	The subcommands on the left cannot be performed if a VCI is specified. This operation is not supported in VCI.
	OWNER TO	
	SET SCHEMA	
ALTER OPERATOR FAMILY	ADD	
	DROP	
	RENAME TO	
	OWNER TO	
	SET SCHEMA	
ALTER TABLE	ALL IN TABLESPACE *name* [OWNED BY *roleName*] SET TABLESPACE *newTablespace*	A tablespace that contains a VCI cannot be specified. If the operation is required, delete the VCI using DROP INDEX, and re-create it using CREATE INDEX after completing the operation.
	DROP [COLUMN] [IF EXISTS] *colName* [RESTRICT | CASCADE]	A column that contains a VCI cannot be specified. If the operation is required, delete the VCI using DROP INDEX, and re-create it using CREATE INDEX after completing the operation.
	ALTER [COLUMN] *colName* [SET DATA] TYPE *dataType* [COLLATE *collation*] [USING *expr*]	
	CLUSTER ON *indexName*	A VCI cannot be specified. This operation is not supported in VCI.
	REPLICA IDENTITY {DEFAULT | USING INDEX *indexName* | FULL | NOTHING}	
CLUSTER	-	A table that contains a VCI and VCI cannot be specified.

Command	Subcommand	Description
		If the operation is required, delete the VCI using DROP INDEX, and re-create it using CREATE INDEX after completing the operation.
CREATE INDEX	UNIQUE	The subcommands on the left cannot be performed if a VCI is specified. This operation is not supported in VCI.
	CONCURRENTLY	
	[ASC | DESC]	
	[NULLS { FIRST | LAST }]	
	WITH	
	WHERE	
	INCLUDE	
CREATE OPERATOR CLASS	-	A VCI cannot be specified. This operation is not supported in VCI.
CREATE OPERATOR FAMILY	-	
CREATE TABLE	EXCLUDE	
DROP INDEX	CONCURRENTLY	The subcommands on the left cannot be performed if a VCI is specified. This operation is not supported in VCI.
REINDEX	-	A VCI cannot be specified. This command is not required as VCI uses daemon's automatic maintenance to prevent disk space from increasing.

Client application command

- Operations that cannot be performed on relations containing a VCI

Command	Description
clusterdb	Clustering cannot be performed for tables that contain a VCI.
reindexdb	VCIs cannot be specified on the --index option.

10.2.2 Data Preload Feature

The first aggregation using VCI immediately after an instance is started may take time, because the VCI data has not been loaded to buffer.

Therefore, use the preload feature to load the VCI data to buffer in advance when performing VCI aggregation after an instance is started.

When using the preload feature, execute the function pgx_prewarm_vci to each VCI created with CREATE INDEX.

```
db01=# SELECT pgx_prewarm_vci('idx_vci');
```

Refer to "B.5 VCI Data Load Control Function" for information on pgx_prewarm_vci.

Chapter 11 Parallel Query

Fujitsu Enterprise Postgres enhances parallel queries, by taking into consideration the aspects below:

- CPU load calculation
- Increase of workers during runtime
- Statistics view displays the action state

11.1 CPU Load Calculation

There may be a case when the user tries to execute a parallel query but there is not enough CPU available.

Adding dynamic workers at this stage will provide no benefits - instead, it may add overhead due to context switching.

Fujitsu Enterprise Postgres checks the available CPU resources when determining the number of workers for a parallel query.

When checking the available CPU resources, the system checks the CPU usage (whether there are sufficient free system resources) at the time the SQL statement is executed, and a parallel query is only planned if there is enough free CPU usage for two or more cores on the server.

For example, if a server has four cores and the total free space from core 1 to core 4 is 200% or more, a parallel query will be planned, but if it is less than 200%, a parallel query will not be planned.

11.2 Increase of Workers during Runtime

Parallel query can cause CPU overload because workers cannot be added, for example, because there are not enough workers or no workers at the start of the query.

This Fujitsu Enterprise Postgres enhancement allows systems to allocate additional workers during query execution (if there are workers available at the time). The ability to increase workers during runtime is available only with parallel query. This improves query performance.

11.3 Statistics View Displays the Action State

You can check the action state by using the existing statistics collector. Monitoring the statistics enables you to check the action state of parallel processing through, for example, changes in the system load.

The following table describes the column added to the statistics views:

pg_stat_all_tables

Column	Data type	Description
parallel_query	bigint	Number of parallel query initialized in the table.

The parallel query column has also been added to the following views:

- pg_stat_sys_tables
- pg_stat_user_tables
- pg_stat_xact_all_tables
- pg_stat_xact_sys_tables
- pg_stat_xact_user_tables

See

Refer to "The Statistics Collector" in "Server Administration" in the PostgreSQL Documentation for information on the statistics collector and views.

Values will be set for the pgx_stat_sql view in Fujitsu Enterprise Postgres if parallel query is run.

See

Refer to "D.5 pgx_stat_sql" for information on pgx_stat_sql view.

Chapter 12 High-Speed Data Load

High-speed data load uses the pgx_loader command to load data from files at high speed into Fujitsu Enterprise Postgres.

This feature is available only in the Advanced Edition.

Information

This feature is not available in single-user mode. This is because in single-user mode instances run in a single process, and it cannot start parallel workers.

12.1 Installing High-Speed Data Load

This section describes how to install high-speed data load.

Installation flow

1. Deciding whether to Install
2. Estimating Resources
3. Setup

12.1.1 Deciding whether to Install

The feature achieves high speed data load by executing the COPY FROM command in parallel. If the database system is unable to use sufficient resources due to the feature using more resources than the COPY FROM command of PostgreSQL, load performance may be inferior to that of the COPY FROM command of PostgreSQL. Therefore, determine if the feature will be effective by considering the factors below before deciding to install.

Database server memory

If the value of shared_buffers in postgresql.conf is small, fewer data pages are cached to the shared memory of the database server. This will result in multiple parallel workers more often having to wait for write exclusive locks to the same data page. Moreover, the smaller the number of data pages, the more often the table expands. During table expansion, access to the table is exclusive (standby event name: extend), so write time increases. To cater for that, increase the value of shared_buffers.

See

The standby event name is stored in the wait_event column of the pg_stat_activity view. Refer to "wait_event Description" in "The Statistics Collector" in the PostgreSQL Documentation for details.

Frequency of checkpoints

If checkpoints are issued at short intervals, write performance is reduced. If the messages below are output to the server log during data writes, increase the values of max_wal_size and checkpoint_timeout in postgresql.conf to reduce the frequency of checkpoints.

Example

```
LOG:  checkpoints are occurring too frequently (19 seconds apart)
HINT:  Consider increasing the configuration parameter "max_wal_size".
```

12.1.2 Estimating Resources

Estimate the memory requirements for high-speed data load.

Up to 128 parallel workers to perform data load can be specified for this feature. The additional resources below are required depending on the number of parallel workers.

- Dynamic shared memory created during data load
